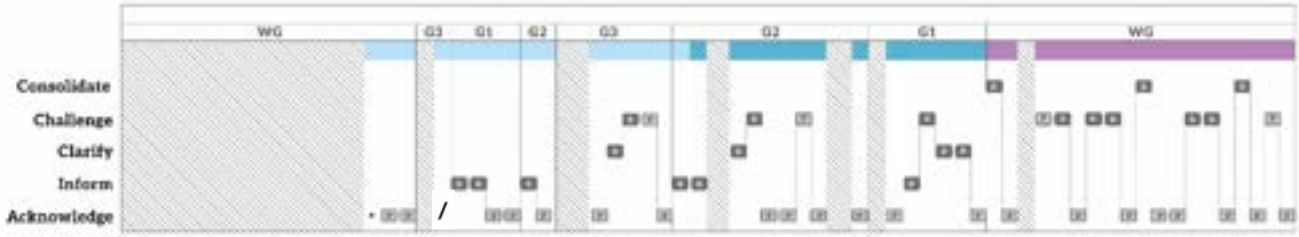
Challenge	Students to check the ideas that have been put forward or ask for an interpretation that helps to contrast ideas to elicit an idea when something doesn't fit. *i.e., ok, it melts [repeating student's answer] how so?*	A questioning of the students' ideas and rationales about the phenomenon. *i.e., Do we have the same results if we have different amounts of copper sulphate?*
Consolidate	Students to integrate the ideas discussed into a single answer. *i.e. [To end the task] Is it the same if we have two volumes of copper sulphate in the reaction?*	A synthesis of the students' ideas in a single answer. *i.e., That is also relevant because when I have a chemical change, the changes are important; besides the change in color, we also see a change in temperature.*

Findings

The analysis of teachers' discourse employs visualisations that allow us to observe how discourse and talk moves are structured in a productive conversation for a task with low modelling potential. This first finding yields a methodological tool that enables us to observe the rhythm and consistency of the dialogue in a modelling-oriented classroom. These discourse visualisations (Figure 1) show, on the left, the modelling-oriented talk moves, and, on the right, their uses by a teacher in chronological order. On top, we can examine if the conversation is between the teacher and the whole group (WC), or with a particular small group (G. number). Below the class organisation, we will find the modelling phase that the teachers promote in their discourse, colour-coded: cyan for familiarisation, blue for discussion, and purple for consensus. The descriptions of the expected conversations for each modelling phase follow the studies by Garrido



& Couso (2024) and Cortés & Marzabal (2025b). In a familiarisation phase, the teachers approach a contextualised problem situation and expect students to recognise that they need a model, express it, and, in their conversations with others, understand that there can be different versions of the model in the classroom. In the discussion phase, teachers ask questions to help students use their ideas iteratively, testing and contrasting them to revise their initial model. In the consensus phase, teachers facilitate a dialogue in which students agree on a final model that emerges from collective understanding.

In the case of the turn-of-speech boxes, we can identify whether the teacher is requesting (R) or providing (P) an idea in the modelling-oriented talk move. They have been coloured as well to facilitate the reading of the visualisation, light grey is providing, and dark grey is requesting.

Finally, every conversation that is not dialogic and interactive as a communicative act (Mortimer & Scott, 2003) is levelled with general classroom conversations and appears in the visualisation as diagonal shading. Every speech turn in a teacher's general classroom conversation has the same width as the turn-of-speech boxes with the talk moves.

In addition to the codes typified in the visualisation, two icons have been used to show how the tasks are presented to students. The asterisk (*) marks the teacher reading the task, in some tasks teachers take a time before reading the task to talk with students about something that they need to be able to complete the task, in such cases as in figure 1, we can see that the task does not start with the reading of the task, but with an explanation about how to use a balance. Another icon is a slash (/) that indicates turns of speech in which the teacher repeats the task with some alteration, providing a reformulation or simplification of the task instructions to the students.

Figure 1. Visualisation of Marina's talk moves in the task.

Science Teachers' Discursive Practices In Instructional Modelling

The analysis of the visualisation for the three chemistry teachers allows us to examine how the productive conversations unfold in instructional modelling. The findings show patterns of the dialogue that promote students' revision of their SSM.

Firstly, most of the speech turns relate to productive conversations. Although most of the modelling conversations are productive conversations, some of them are general classroom conversations that provide students with the learning opportunities they need to refine their initial model. This means that, in implementing tasks with modelling potential, an alternation between productive and general classroom conversations is required. This shift between communicative acts reflects teachers noticing and acting in accordance with the ideas expressed by their students, a key aspect of modelling conversation, as well as the responsiveness of teachers in the dialogue they mediate.

Similarly, teachers' dialogue involves extensive conversations that promote students' familiarity with the phenomena, accounting for 100% of Caroline's dialogue, 46% of Marina's turns, and 18% of Chris's dialogue. Chris's turns of speech in the familiarisation phase, unlike Marina's and Caroline's, are not grouped together, as each conversation with the small groups starts with familiarisation, shortening the amount of talk moves used in this phase. However, there is a consistency in the phase for this low modelling potential task, which relates to the request for

information each time the teachers start a familiarisation dialogue with the small groups.

Secondly, the use of talk moves oriented towards modelling shows that most of the moves have a nature of requiring (R) students' ideas in different patterns. On the one hand, teachers ask for clarification, followed by a challenge to their ideas when they are ending a familiarisation phase or starting a discussion phase. On the other hand, teachers ask them to challenge their ideas, then require clarification during the discussion phase. In the latter, teachers expect students to be clear about their ideas and how they differ from their initial model.

Lastly, there is constant use of validation moves, which are the most used talk moves. Teachers use validation moves in every phase, with every small group, and with the whole group, and they alternate them with other modelling-oriented talk moves. These moves account for 45%, 42% and 20% of the modelling-oriented talk moves used by Marina, Chris, and Caroline, respectively. The repeated use of these moves relates to teachers giving students the opportunity to see their ideas as valid, as a starting point, or as a way to explain the phenomena. They are a transitional move that teachers put in place to motivate students during the process and keep the dialogue going. Even though their use does not promote modelling practice, it allows it to unfold.

Discussion & Implications

The findings in this study lead us to believe that, when implementing the task, the teachers can maintain a productive conversation oriented toward an instructional modelling process that goes beyond the modelling potential. In this sense, Chris, Marina, and Caroline decide to facilitate the modelling process for their students by introducing a recurrent familiarisation phase into whole- and small-group conversations.

As the potential depends on the practice to be developed, in which the description (demand of the task) could lead the teacher to close the conversation in search of a particular description that teachers expect from the students, we can see in Marina's and Chris's cases that the modelling potential increases as the teacher is inviting students to reason out the observations that lead them to a representation or description of the phenomena (Park et al., 2021) instead of searching for a particular answer.

Consequently, regarding the management of modelling processes, the teachers can involve students in productive discussions. The actions of the observed science teacher are fruitful in engaging students in modelling processes. Nevertheless, the same could not be said of Caroline's productive conversations, as she closed the dialogue, ending the task before the conversation reached the discussion phase of the modelling process.

The shifts between productive and general classroom conversations are not interruptions, but rather a key discursive strategy that teachers use to respond to students' emergent needs during modelling. In the same way, each teacher exhibits common patterns but a particular style in managing classroom dialogue, demonstrating a responsive and adaptive mediation that supports transitions between phases of the modelling process, depending on the group they are talking with and the task context. The discourse decisions teachers make to manage and promote the continuation of a conversation relate to understanding when a general classroom conversation will help students in the development of the modelling phase, choosing when validation will secure students expressing their initial representations and when a particular pattern of talk moves will be more appropriate to help them review their model and negotiate the personal ideas in a group setting.

The analysis of the results suggests that mapping these interactions could serve as an analytical tool for discussing and improving teachers' discursive practices, thereby optimising students'

intellectual engagement in modelling processes.

Scientific Literacy And Socio-scientific Issues

Co-editors: *Isabel María Cruz Lorite & Eliza Rybska*

Part 8 / Strand 8 Scientific Literacy And Socio-scientific Issues

Teaching and learning about scientific literacy, socio-scientific issues and citizenship education. Topics in the strand include understanding the social aspects of science, critical media/literacy reasoning, decision making and debates on socio-scientific issues (SSI), public engagement and participation in science and understanding the relevance of science. The aforementioned topics can focus either on teachers or students.

Sub-themes:

1) Teaching and Learning about Scientific Literacy
2) Engaging Students in Socio-scientific Issues (SSI)
3) Critical Media Literacy in Science Education
4) Public Engagement and Participation in Science

Strand 8: Scientific Literacy And Socio-scientific Issues

Eliza Rybska[1] and Isabel María Cruz Lorite[2]
[1]Adam Mickiewicz University, Poland
[2]University of Zaragoza, Spain

The chapter "*Scientific Literacy and Socio-scientific Issues*" brings together contributions that tackle a significant challenge in today's science education: preparing learners and teachers to engage critically, responsibly, and thoughtfully with science in a complex and unpredictable world. Socio-scientific issues (SSI) have received more attention over the past twenty years because many problems facing modern societies—like climate change, loss of biodiversity, artificial intelligence, genetic technologies, food security, public health crises, and sustainability transitions—cannot be understood or solved with scientific knowledge alone (Sadler, 2004; Zeidler et al., 2005; Levinson, 2018). These issues involve uncertainty, different perspectives, competing values, and the necessity of making choices despite incomplete information. Citizens need to engage not only with scientific facts but also with ethical, cultural, economic, and political factors. The growing importance of SSI is especially clear in what is often called a post-truth era. Here, scientific information competes with misinformation, disinformation, ideological narratives, and content shaped by algorithms circulating in digital media (Lewandowsky et al., 2017; Erduran, 2025). As a result, scientific literacy has become both more crucial and harder to achieve. Modern scientific literacy goes beyond knowing scientific concepts and procedures. It includes the ability to evaluate evidence, assess the credibility of sources, recognize uncertainty, understand how scientific knowledge is created and shared, and engage meaningfully in public discussions and decision-making processes (OECD, 2019; National Academies of Sciences, Engineering, and Medicine, 2016). In this context, socio-scientific issues have been increasingly recognised as a powerful educational approach for preparing learners for responsible citizenship, as they engage students in considering the relevance of science in societal decision-making and encourage them to evaluate scientific, ethical, political, and cultural dimensions of contemporary problems (Evagorou & Dillon, 2020).

Developing such capacities is not only a challenge for students but also for teachers, researchers, educational institutions, policymakers, and society as a whole. A major factor driving these changes is the fast rise of artificial intelligence. AI has entered everyday life, workplaces, education, research, and public discussions at an unmatched speed. Technologies like machine learning, recommender systems, generative AI, and large language models have changed how information is produced, shared, and consumed. While these advancements provide new chances for learning and scientific communication, they also raise significant questions about transparency, ethics, data privacy, bias, accountability, and the reliability of information (Long & Magerko, 2020; Ng et al., 2021). Therefore, learners today need not just digital skills but also a critical perspective on technology, helping them understand and assess the social effects of new technologies. From an education standpoint, these fast changes call for new skills and new forms of literacy. People increasingly need to make decisions on issues with uncertain, long-term, and hard-to-predict consequences. Students, teachers, researchers, policymakers, and communities often face questions without clear or universally accepted answers. Choices about climate action, biotechnology, public health measures, sustainability, or regulating AI often have to be made before all relevant evidence is available and without certainty about future outcomes. Thus,

preparing learners to handle this uncertainty is a key goal of science education (Funtowicz & Ravetz, 1993; Levinson et al., 2017).

In this context, the contributions in this chapter provide valuable insights into fostering scientific literacy and engagement with socio-scientific issues across various educational settings. A strong theme throughout the chapter is the connection between scientific literacy and the fast-changing digital world. Several studies examine how learners understand artificial intelligence, machine learning, social media, and science communication, highlighting both the opportunities and challenges these environments present for developing critical tech and media perspectives. Issues of misinformation, source evaluation, trust in science, and the responsible use of digital technologies emerge as key concerns for science education in the twenty-first century.

Another major focus is socio-scientific reasoning and argumentation. The contributions investigate how students and future teachers think through complex and controversial topics like sustainability, climate change, resource use, biotechnology, and emerging technologies. They explore the development of argumentation, critical thinking, moral reasoning, and decision-making. They show that meaningful engagement with socio-scientific issues requires learners to connect scientific knowledge with ethical, cultural, economic, and societal factors.

The chapter also emphasizes the essential role of teacher education. Several studies analyse how future teachers gain the knowledge and skills needed to promote SSI-based learning. They pay particular attention to culturally responsive teaching, sustainability reasoning, and designing learning environments that help students relate scientific knowledge to their own experiences and cultural backgrounds. These contributions acknowledge that teachers are not just sources of knowledge but also key guides who assist students in navigating uncertainty, evaluating competing claims, and engaging in informed and responsible decision-making.

Overall, the studies in this chapter show that scientific literacy today is closely linked to the ability to engage with socio-scientific issues. They stress the need for educational approaches that encourage critical inquiry, ethical thinking, evidence-based reasoning, and active participation in democratic societies. By doing this, the chapter supports ongoing efforts to rethink science education for a world marked by rapid technological change, global connections, and increasing uncertainty.

Manipulation Of Illustrations And Graphs In Chemistry Education

Pauline Mundt and Nadja Belova
University of Bremen, Germany

Challenges like manipulation and misinformation are of particular importance in the context of modern types of media due to the absence of classical gatekeeping mechanisms. Especially illustrations and graphs with a scientific background can be manipulated in various forms. Due to the influence manipulation strategies can potentially have on society, the promotion of competencies enabling individuals to detect manipulation is needed. Therefore, a teaching unit that deals with the analysis of illustrations and graphs in chemistry education and the detection of manipulation strategies used in media content was created. In the four lessons, the students became familiar with different strategies and aims of manipulators. The media content of the teaching unit is embedded in a chemical or scientific context, and the illustrations are adapted to the design of known social media platforms. The exploratory evaluation of the unit included open-ended questions and a Likert-type questionnaire. It was investigated to which extent the students can describe the manipulation strategies used in specific illustrations and graphs at the end of the unit. The results of the evaluation show that the students are able to describe manipulation strategies used in exemplary media content by utilizing vocabularies resembling the manipulation strategies learnt in class. However, the majority is not able to identify all the different strategies. Consequently, the teaching unit seems to be able to partly promote Scientific Media Literacy, but additional practice and the acquisition of a routine is needed.

Keywords: Case Studies, Classroom Practices, Scientific Literacy

Theoretical Background

Relevance

Due to the increasing digitalization and its challenges, the promotion of media literacy became relevant as an educational and macro-social intersectional issue in Germany (KMK, 2017) and worldwide (UNESCO, 2021). Therefore, it is being integrated into different subjects. Media literacy is also important for the everyday life of young people as they regularly get confronted with media content – that often has a scientific background – and also have to deal with digital media's challenges. However, regular interaction with such content does not always mean that the interaction is reflected by users, and challenges like manipulation and misinformation occur frequently in digital media (Barzilai & Chinn, 2020; Kammerl, 2014; Tulodziecki et al., 2021). But without a deepened reflection of the content, the influence of manipulation and misinformation grows. In particular, illustrations are the aim of manipulation, because pictures taken by a camera are often associated with higher evidence (Schicha, 2005; Stein et al., 2020). Misleading graphs play a major role in advertising in order to present the product in an appealing light (Danciu, 2014).

Manipulation Strategies

Connected to manipulation, media content can be rapidly altered through strategies such as the choice of colours or changes in context created by accompanying text (Danciu, 2014; Schicha, 2005). Graphs, which are frequently used in advertisements, are also susceptible to manipulation in various ways (Danciu, 2014), for example through colour choices or by adjusting the axis range (Schaffer, 2020; Walla, 2008). This shows that manipulating media content is not particularly

complicated, which is why it is an important issue that needs to be addressed in the context of increasing digitalization. Furthermore, the media is able to influence the public perception of different issues, for example by using manipulation strategies. With regard to chemistry, the consumption of manipulated content can evoke, for instance, aversions and fears (Rollini et al., 2022). This phenomenon of creating irrational fears towards chemistry and chemicals is known as chemophobia (Rollini et al., 2022). However, the opposite can also be achieved by using manipulation strategies that suggest seriousness and scientific credibility even in areas where these are absent (Höttecke & Allchin, 2020). Additionally, the media can change the perception of scientific debates (Lewandowsky et al., 2019). Taken together, these aspects complicate interaction with digital media, particularly social media, when individuals seek to engage deeply with content. Consequently, educational contexts must foster competencies that enable learners to address these challenges effectively.

Application To Education

In order to overcome the challenges of digital media in a responsible manner, a reflected interaction with content is needed, especially when it comes to science-based information (Chang Rundgren & Rundgren, 2014). Illustrations and graphs with a scientific background are examples which can often be found in the digital media and can be manipulated in different ways, particularly on social media platforms due to the absence of traditional gatekeeping mechanisms (Höttecke & Allchin, 2020). In an educational context, a mainly preventive approach is needed, supporting students to deal with manipulated media content in the future (van der Linden, 2022). Teaching units dealing with topics like manipulation are important to promote students' critical interaction with digital media and the scientific information in it.

In the case of science-based media content, the concept of Scientific Media Literacy describes the skills and knowledge needed to deal with it (Chang Rundgren & Rundgren, 2014). The concept combines the fields of Scientific Literacy and Media Literacy and can be integrated and promoted in the science classroom (Chang Rundgren & Rundgren, 2014).

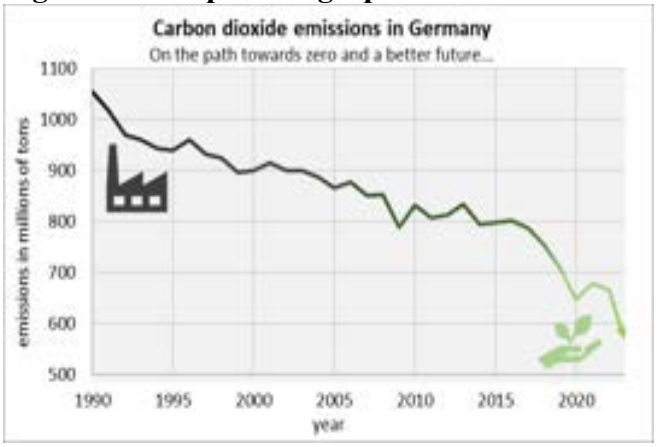
Development Of The Teaching Unit

Based on the described challenges, the aim of this exploratory study was to develop and evaluate a teaching unit of four school lessons on the topic of manipulation of illustrations and graphs in chemistry education and to (at least partly) promote Scientific Media Literacy. It has been investigated to which extent the students are able to describe the manipulation strategies used in specific illustrations and graphs at the end of the unit. The target group were German students in grades 9 to 11, and the focus of the lessons was on the analysis of different science- and chemistry-based illustrations and graphs. In addition, the students evaluated different media contents in different exercises and created their own manipulated illustrations to change their perspective. They became familiar with various manipulation strategies and how to detect them. The scientific backgrounds of the media content were chosen to be controversial. Topics like cosmetics, glyphosate, clean and natural beauty, nutritional supplements, plastics, and energy supply were part of the teaching unit. All the images were created using the software Canva based on a prior analysis of existing social media posts to allow a clear focus on the manipulation strategies and decrease distraction. An example of such manipulated media content can be seen in Figure 1.

Figure 1. Exemplary illustration of the teaching unit about glyphosate.

Detailed prior knowledge about the topics was not needed to answer the different tasks. For exercises which supposed a more comprehensive knowledge about the specific issue, information texts were created to support the students.

Methods



To investigate the impact of the unit on the students a mainly qualitative approach was used, which consisted of a participant observation and an evaluation sheet which combined open-ended and Likert-typed questions as well as two exercises in which the students had to describe the manipulation strategies used in two exemplary media contents (Figure 2, 3) and questions including feedback on the teaching unit. The unit was implemented and evaluated in a group of 53 students from grades 9 to 11. The participant observation was used to improve the identification of difficulties that occurred during the lessons, while the main part of the evaluation consisted of the evaluation sheet.

The media content used in the exercises of the evaluation sheet can be seen in Figures 2 and 3, each of them has been manipulated by applying several strategies. The students were not familiar with these specific examples and therefore had to apply the strategies they have learnt in their descriptions. Figure 2 has been manipulated by the choice of colours, added image elements such as plants and laboratory equipment, the proportions of the different parts of the figure, and the accompanying text (Schicha, 2005; Stein et al., 2020). Especially the percentage of visible moisture increase without context and information about the origin is misleading (Danciu, 2014). The manipulation strategies of Figure 3 consist of the choice of colours, unnecessary details such as the arrow at the end of the curve and the two symbols, the accompanying text, and the changed axis range (Schaffer, 2020; Schicha, 2005; Walla, 2008).

Figure 2. Manipulated illustration from the evaluation.

Figure 3. Manipulated graph from the evaluation **(source of data: Umweltbundesamt, 2023).**

The additional feedback on the teaching unit included aspects like the interest in the topic, the quality of the unit, and the self-assessment of the students' own learning gains. To obtain answers on these aspects, Likert-typed questions, open-ended questions, and a self-assessment of the individual learning gains on a scale from one to ten were used.

After the editing of the evaluation, the open-ended questions of the evaluation sheet were analysed using qualitative content analysis (Kuckartz & Rädiker, 2022) and for the Likert-typed questions we used descriptive statistics due to the exploratory nature of the study. Categories were formed based on the students' descriptions (Kuckartz & Rädiker, 2022) and afterwards compared with the manipulation strategies from the lessons described above. In addition, mean values and standard deviations of the Likert-items and the self-assessment of the individual learning gains were calculated.

Results

Description Of Manipulation Strategies

The results of the exercises show that most of the students are able to describe the manipulation strategies used in illustrations and graphs at the end of the teaching unit. Therefore, they are able to recognize manipulated media content. To describe the manipulation strategies, the students mainly used the vocabularies learnt in class. However, in most cases the students are not able to identify all the strategies from the two examples (Figure 2, 3).

Especially manipulation strategies like the choice of colours or the influence of the context, which has been changed by the text of the media content, are often detected by students. These strategies occur in both types of media and were therefore repeatedly addressed in the unit. When describing Figure 2, the majority of students refer to the text containing the percentage. The visual elements that establish a connection to nature and chemistry, such as the plants and laboratory equipment, were also often recognized. References to nature are mentioned by more than the half of participants.

It was discovered that the analysis of the graph seems to be more difficult for some students than the analysis of the illustration. The most frequently mentioned category is the choice of colours within the graph of Figure 3. The two symbols are also often described as manipulative. Manipulation strategies associated with mathematics, such as the changed axis range in Figure 3, were described less frequently and therefore seem to be more difficult for most of the students to detect. Here, the difficulty seems to be that the students have to learn how to read a graph at first (Schaffer, 2020). After that, they gain a basis to learn how to detect the manipulation of the graph

more in detail. To minimize the difficulties with graphs, general competencies for the interaction with them are needed in different subjects such as mathematics and the sciences.

The descriptions of manipulation strategies in illustrations and the results of year 11 are more comprehensive than in years 9 and 10. On average, older students describe more strategies in their descriptions, which goes in line with research findings on consumer socialization (John, 1999). Nevertheless, most students in all grades can identify at least one strategy, which means that they are aware that manipulation is present. In addition, it is noticeable that some students have begun to interpret the effects and intentions of the strategies. This was not expected in both tasks.

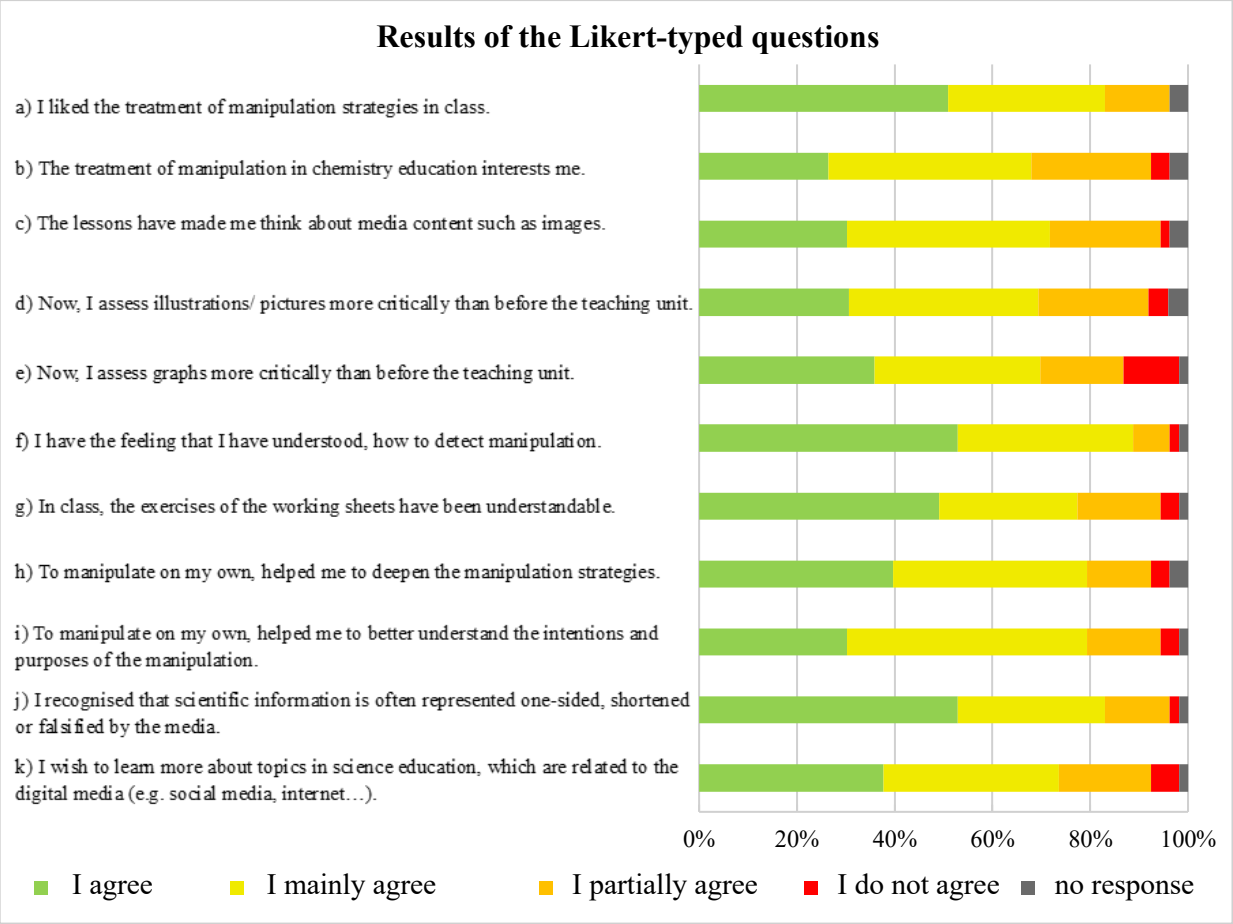
Feedback

Self-Assessment Of Learning Gains

In addition, the students rate their own learning gains as rather high than low, with an average of 6.43 out of 10. The average of year 11 is the highest with 6.76, and the average of year 9 the lowest with 6.06. The standard deviation is particularly high in the ninth grade, which shows that differences within the learning group exist. While two students even reported learning gains of 10, another student of the same class reported a gain of 1. The result of the self-assessed learning gains as a whole could relate to the self-assessment of a higher previous knowledge and the fact that the teaching unit mainly promotes skills and less factual knowledge. In the ninth grade, general differences in performance within the learning group may also have been an influencing factor.

Open-Ended Questions

Overall, the feedback concerning the interest in the topic, the learning gains and the whole unit is quite positive. Many positive aspects like the creation of an own manipulated illustration and the relevance of the topic are mentioned in the open-ended questions. In relation to the relevance of the topic, one of the students highlighted that he has never learnt to detect manipulation strategies before. This confirms the necessity for promoting comparable skills in education. The differences between the grade levels show that especially younger students need additional support for the tasks in class.



The general difficulty of the topic was also mentioned by some students, while others assessed their previous knowledge as high. The high level of previous knowledge could often not be proved by the students' performances in the exercises of the evaluation. This may be connected to the difficulties of self-assessment (Riese & Reinhold, 2014). It is also possible that some students underestimate the topic due to its close connection to everyday life, while others are more aware of the challenges associated with manipulation.

Likert-Typed Questions

Overall, the results of the Likert-type questions are positive. The results (Figure 4) show, among other aspects, that most students had the feeling to understand how to detect manipulation which is a sign of success of the unit. The majority also seem to have benefits from manipulating media content by themselves. There were major differences between the grades in terms of their perception of the comprehensibility of the tasks in class. In the eleventh grade, all students agreed or mainly agreed that the tasks were understandable. This may be because some of the younger students need additional support with the tasks. Furthermore, nobody fully disagreed that they liked the topic of manipulation strategies in class. It seems to be a motivating topic for education.

Since four students were ill during the lessons on the illustrations but took part in the evaluation, item d) was not taken into account for them (Figure 4).

Figure 4. Results of the Likert-type questions (N= 53; item d): N= 49).

Conclusions

The results demonstrate that the teaching unit seems to be able to contribute to the promotion of Scientific Media Literacy, especially concerning the media analysis (Chang Rundgren & Rundgren, 2014). The promotion is mainly designed to be preventive in order to prepare the students to deal with manipulated illustrations and graphs in the future (van der Linden, 2022). The fact that the students mainly feel secure when it comes to the detection of manipulation strategies (shown in Figure 4) is a sign that the teaching unit is able to support them.

However, the unit is not able to realize the promotion of Scientific Media Literacy on its own. Support by further units, an expansion to the other dimensions of the concept, and more practice is needed. The domain of knowledge is also integrated in the teaching unit through the scientific background of the media content and the creation of manipulated illustrations (Chang Rundgren & Rundgren, 2014), but this specific domain should also be further promoted. In addition, it would be interesting to measure students' learning process in connection with teaching units in the area of Scientific Media Literacy at different points in time following the unit. That would also reveal more about how long the effects of interventions last.

All in all, the topic of manipulation seems to be relevant for the students' daily lives, which can be supported by their answers in the evaluation. Science education plays an important role in promoting the competencies needed to address challenges related to the distortion of scientific information in the media.

ESERA 2025 Copenhagen

How Do Greek Students And Teachers Perceive Climate Change?

Katerina Paschalidou[1], Katerina Salta[1], Maria Tsetseri[1] and Dionysios Koulougliotis[2]
[1]National and Kapodistrian University of Athens, Athens, Greece
[2]Ionian University, Zakynthos, Greece

Probing people's perceptions about climate change is crucial for the design of communicational and educational practices that will motivate environmentally responsible behaviour. In this study, we explored Greek students' and teachers' perceptions about climate change. The participants (N = 166) perceive climate change to be real and primarily human caused and as a certain and present risk for them and their country. Perceptions of scientific uncertainty vary, with secondary school educators and students expressing higher levels compared to the ones of educators and students in tertiary education. Moreover, the impacts of climate change elicit moderate levels of concern among participants. A correlation was found between participants' perceptions of psychological temporal distance from climate change and their educational group (secondary/tertiary education teacher or student). Finally, participants mainly trust scientists, environmental organizations and teachers as sources of information regarding climate change. The findings contribute to the understanding of how the stakeholders of the Greek educational community perceive climate change, which should guide the design of more targeted and effective educational strategies.

Keywords: Assessment, Public Understanding of Science, Quantitative Research

Introduction

Climate change presents a significant and urgent threat to humanity (Mbah, 2024). Public perception of climate change plays a vital role for the development of effective solutions (Weber, 2010). This is because successful climate policies necessitate public support, which relies on well-informed citizens advocating for meaningful action (Pidgeon & Fischhoff, 2011).

Many studies have examined people's climate change perceptions of various types and by using diverse measurements. The current study concerns six distinguishable types of climate change perceptions, namely (a) the existence and causes of climate change, (b) concerns about the effect of climate change, (c) the personal risk of the effects of climate change, (d) the psychological temporal distance (whether people perceive the effects of climate change as occurring soon or in the distant future), (e) the perceived scientific uncertainty, and (f) the trust of information sources.

The first two types of perceptions fit with arguments of climate change sceptics, which first focus on denial of the reality of climate change, then move towards attributing it to natural causes rather than human activity and downplaying the extent to which climate change would bring about negative consequences (van Valkengoed et al., 2021).

The psychological temporal distance and uncertainty of the effects of climate change have been suggested as dimensions of people's climate change perceptions (Spence et al., 2012). Uncertainty refers to complex, encompassing scientific disagreement and the inherent unpredictability of climate systems and it is often confused with scepticism (Spence et al., 2012; Weber, 2010). Significant scientific uncertainty surrounds the potential impacts of climate change due to the immense complexity of climate systems and their interactions with human and biological systems. Our understanding of these intricate systems remains incomplete and there may be large considerable scientific disagreement and uncertainty around the potential impacts

of climate change. On the other hand, scientific disagreement and uncertainty are the sceptics' justification for the denial of climate change. Therefore, it is crucial to be precise when discussing scepticism and uncertainty related to climate change. Media often misrepresents scientific controversies and tends to focus on minimizing consensus, thus promoting the creation of confusion among the public (Pidgeon & Fischhoff, 2011). This misinformation poses a challenge for scientists and educators. People generally prefer certainty, and communicating uncertainty can hinder climate action (Weber, 2010). However, the interplay between uncertainty and other climate change perceptions remains understudied (Spence et al., 2012).

Climate change perceptions differ significantly between scientists and the public (Mbah, 2024; Myers et al., 2021). This disparity arises partly from the abstract nature of climate change, making it difficult for individuals to accurately perceive based on personal experience (Weber, 2010). Therefore, scientists, media, and educators play crucial roles in detecting and communicating climate change information. Moreover, people's trust and attention are key factors in how they perceive climate change information and individuals are more likely to pay attention to and incorporate information from trusted sources (Weber, 2010). The way climate change information is communicated and amplified by scientists, media, cultural groups, and other sources significantly shapes individuals' perceptions and actions to this critical issue (Weber, 2010).

Most research on climate change perceptions has focused on adults, while the need for effective educational strategies necessitates a holistic exploration of both student and teacher perceptions. Moreover, in Greece there has been so far no systematic research aiming at measuring the climate change perceptions of the educational community. Taking into consideration the discussion above, the present study addresses the following research question:

What are the climate change perceptions among Greek students and teachers in secondary and tertiary education?

Method

Participants

The participants are upper secondary education students (n=28, age 16–17 years) and teachers (n=34, age >25 years), as well as undergraduate students (n=89 age 18–22 years) and tertiary education teachers (n=15, age >35 years). The survey was conducted online via Google Forms.

Instrument

The instrument consists of 3 parts. The first part is composed of 25 items related to perceptions about climate change assessed by a Likert-type scale ranging from "strongly disagree" (0) to "strongly agree" (10). Moving from "strongly disagree" to "strongly agree," positive items were scored from 0 to 10, respectively, while negative items were scored in the reverse order. In the instrument the terms climate change and global warming are used interchangeably, since they are usually treated as equivalent in public discourse.

An exploratory factor analysis (EFA) followed by confirmatory factor analysis (CFA) of our data resulted in four scales corresponding: (a) Personal Risk Perceptions (5 items, Cronbach's Alpha=0.819), (b) Global Warming Beliefs (8 items, Cronbach's Alpha=0.812), (c) Scientific Uncertainty (4 items, Cronbach's Alpha=0.703), and (d) Climate Change Concerns (3 items, Cronbach's Alpha= 0.821). The values of Cronbach's Alpha exceed 0.7 for all four scales, thus indicating satisfactory internal consistency (Field, 2013). Detailed results of EFA and CFA accompanied by the reliability and validity evidence of the data gathered are reported in a submitted manuscript.

The second part consists of ten items related to trust in ten different information sources (family members, friends, scientists, the government, energy suppliers, environmental organizations, media, social media, internet, teachers). Participants' responses to each item were assessed using a Likert-type scale ranging from "no trust" (0) to "absolute trust" (10).

Finaly, the third part is an item related to the psychological temporal distance. Participants were asked to answer question "When do you think global warming will start to harm people in Greece?" choosing among (a) they are being harmed right now, (b) in 10 years, (c) in 25 years, (d) in 50 years, (e) in 100 years, (f) beyond the next 100 years, and (g) never. All the items were developed based on previous research (Özdem et al., 2014; Spence et al., 2012).

Results

Perceptions About Climate Change

The descriptive statistics (mean value, standard deviations) regarding the four scales derived from the exploratory factor analysis are shown in Table 1. Data is reported for the whole sample as well as for each of the four distinct demographic groups which comprise it.

Table 1 Descriptive statistics of four scales corresponding to perceptions about climate change

		Total (N=166)	Secondary students (N=28)	Secondary teachers (N=34)	Undergraduate students (N=89)	Tertiary teachers (N=15)
Scale		Statistics				
Personal risk perceptions	Mean	8.12	7.47	8.42	8.16	8.33
	SD	1.44	1.76	1.36	1.29	1.62
Global Warming Beliefs	Mean	8.51	8.17	8.36	8.64	8.75
	SD	1.20	1.21	1.45	1.10	1.10
Scientific Uncertainty	Mean	5.91	5.71	5.68	6.01	6.18
	SD	1.95	1.54	2.25	2.02	1.56
Climate Change Concerns	Mean	6.65	6.87	6.82	6.43	7.13
	SD	2.29	2.28	2.54	2.18	2.39

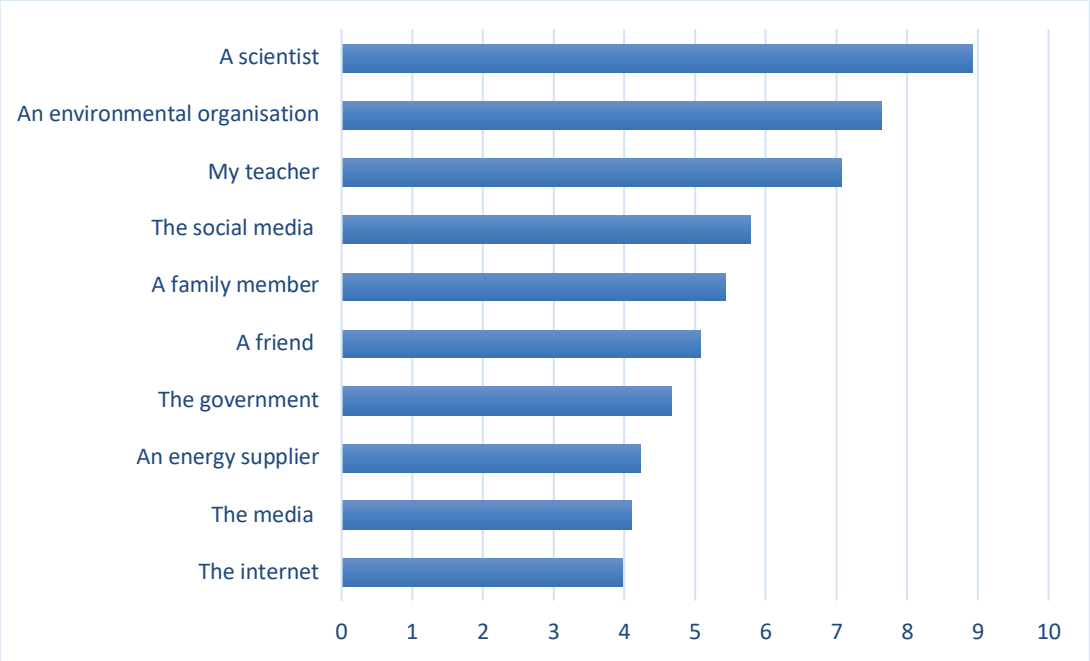
[a]*All scale values range between 0 and 10*

[b]*Higher scores correspond to lower uncertainty*

The personal risk perceptions scale reveals the subjective nature of how people perceive the risks associated with climate change. For instance, the item "Global warming will harm me personally" directly reflects an individual's perception of personal risk while the item "Global warming will harm people in Greece" reflects the participant's risk perception related to locality.

In this study, Greek students' and teachers' personal risk perceptions of climate change have mean values ranging from 7.47 to 8.42 indicating their high awareness about the effects of climate change in their country and lives.

The global warming beliefs scale is comprised of 8 items that reflect different beliefs about: (a) the causes of global warming, (b) the personal thoughts and scientific consensus about whether global warming is happening, (c) the severity of the issue, and (d) the potential consequences of global warming. As shown in Table 1, all participants responses' mean values fall in the range between 8.17 and 8.75, thus indicating that they think global warming is happening and that it is mostly anthropogenic. They do not consider the seriousness of climate change as exaggerated as they perceive that it will harm the living organisms and the future generations.



The scientific uncertainty scale consists of 4 items, which focus on the perceived or actual lack of scientific consensus, the uncertainties and the debate regarding climate change. The participants' responses reveal varying levels of perceived scientific uncertainty. Secondary teachers and students exhibited higher levels, while tertiary teachers and undergraduate students demonstrated lower levels. An analysis of participants responses to each item reveals that all of them concurred that "most scientists agree about climate change impacts" and that "there is not too much conflicting evidence about climate change." Conversely, tertiary teachers acknowledged that "there is a disagreement among scientists about whether global warming is happening" but "it is certain what the effects of climate change will be" while the other groups of participants held opposing views.

The 3 items that constitute the climate change concerns scale reflect the emotional anxiety experienced by individuals due to concerns about the consequences of climate change. The results indicate that climate change impacts elicit moderate levels of worry among Greek secondary and tertiary students and teachers, with mean scores ranging between 6.43 and 7.13.

Trust In Information Sources

Scientists (Mean=8.92, SD=1.16), followed by environmental organizations (Mean=7.63, SD=2.00) and teachers (Mean=7.63, SD=2.00) stand higher regarding the participants' trust as sources of climate change information. On the other hand, participants trust much less the internet (Mean=3.97, SD=2.40), media (Mean=4.10, SD=2.53), energy suppliers (Mean=4.22, SD=2.73), and the government (Mean=4.67, SD=2.70), as Figure 1 represents.

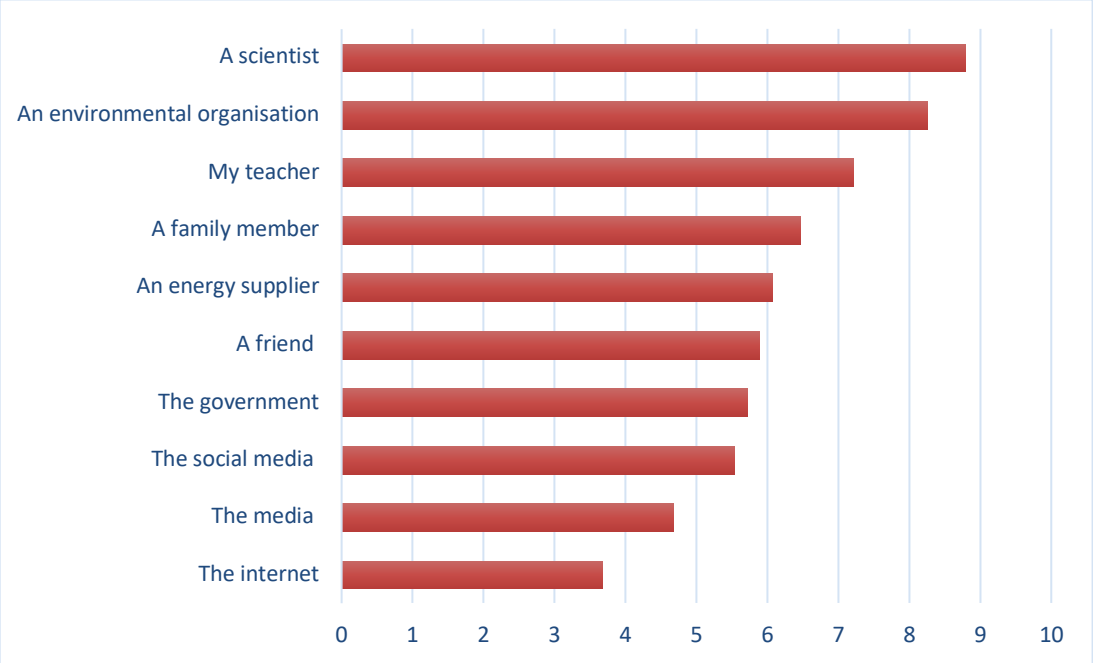


Figure 1. Mean responses on trusted sources regarding climate change

An interesting finding is that upper secondary students also trust more the scientists (Mean 8.79, SD 1.03), the environmental organizations (Mean 8.25, SD 1.38) and their teachers (Mean 7.21, SD 1.95) rather than the social media (Mean 5.54, SD 1.84) as shown in figure 2. Although, research has been shown that secondary students usually show a high level of trust in social media platforms (Haile, 2024), the upper secondary students of this study are not trusting information found on social media as much. Lower secondary Turkish students also identified scientists as a trustable source of information (Özdem et al., 2014). Zilz and Höttecke (2025) proposed that trust strategies, sources or representatives are evaluated based on the three indicators of trustworthiness: expertise, integrity, and benevolence. These indicators are indeed largely served by scientists, teachers, and environmental organizations. The academic profile, the specialized

knowledge and the transparency and effort to convey current scientific knowledge as accurately as possible without any conflicting interests, are the characteristics of these sources which contribute to trustworthiness.

Figure 2. Upper secondary students' mean responses on trusted sources regarding climate change.

Psychological Temporal Distance

With respect to the perceived psychological temporal distance, about three quarters of undergraduate students (73.0%), as well as secondary (79.4%), and tertiary teachers (73.3%), but much less upper secondary students (35.7%) think people in Greece are being harmed by global warming right now. Specifically, only 10 out of 28 upper secondary students reported that they are being harmed by global warming right now, while 5 of them reported that they will be harmed in the distant future either in 100 year (one student) or beyond the 100 years (three students), and one responded "never".

The results of a chi-square test (bootstrap with number of samples 1000 and confidence interval level 95.0%) suggest that there is a correlation between perceptions of psychological temporal distance for climate change and the four educational groups (χ^2=25929.785, df=18, p<.001).

Conclusions

Knowledge of the perceptions regarding climate change can help the design of effective strategies to promote environmentally responsible behaviour among the public. Participant responses strongly suggest a consensus that global warming is real and primarily human caused. They do not view climate change as overstated due to concerns about its impact on living organisms and future generations. Their scientific uncertainty perceptions vary with secondary teachers and students expressing higher levels of uncertainty relative to tertiary teachers and undergraduate students. Most secondary and tertiary educators, along with most undergraduate students, perceive that people in Greece are currently experiencing harm from global warming. However, this perception is significantly lower among upper secondary students. A correlation between participants' perceptions of psychological temporal distance for climate change and the four educational groups was found. The spatial and temporal disconnection of causes and effects which characterize complex systems, such as the climate, often causes major challenges in understanding the climate change effect among younger students (Roychoudhury et al., 2017).

Moreover, the time delay (temporal disconnection) may lead to personal frustration, as individuals' climate-friendly actions do not produce immediately visible impacts, which can reduce motivation to engage in such behaviours (Gifford, 2013).

Finally, participants mainly trust scientists, environmental organizations and teachers as sources of climate change information. This is a hopeful finding as previous research indicates that trust in scientists and environmental organizations is positively linked to climate-friendly actions (Cologna & Siegrist, 2020).

The results of this study indicate that it is very important to focus on secondary education. The findings highlight the need for designing risk communication techniques to reduce psychological distance and to engage secondary school students with climate change. It is very important to use trusted sources in this effort. Thus, appropriate activities could be designed at school with a cooperation of teachers, scientists and environmental organizations.

Moreover, since such studies can be used to design a roadmap aimed at raising public awareness about climate change, it seems very important to conduct them in other countries, and therefore different cultural contexts, as well.

ESERA 2025 Copenhagen

How Physics Teachers Think About Science – Physics Teachers' Views Of Science Compared To Researchers' Views

Lea Herbst and Verena Spatz
TU Darmstadt, Germany

Even though Nature of Science (NOS) and Scientific Inquiry (SI) are important aspects of the educational objectives for science lessons, as defined in the curriculum in Germany and other countries, research has shown that teachers often have insufficient professional knowledge in this area. Against this background, we have set up an outreach program in the Collaborative Research Centre 'SFB1245: Atomic Nuclei: Fundamental Interactions to Structure and Stars' at TU Darmstadt to identify and develop best practices for teaching NOS and SI at school. For this, teaching materials and handouts for teachers are being developed. In order to take into account the wishes and needs from a school perspective as well as the scientists' views, both teachers and researchers are involved in the development of these materials. The accompanying study aims to determine the extent to which this collaboration positively influences the participating teachers' ideas about NOS and SI. As a first step, we have conducted a survey about the views of secondary school physics teachers about NOS and SI and contrasted it against the researchers' views in order to shed light on the baseline condition of our sample. In this contribution we will present and interpret the results of this survey. Building on this, we argue that the most relevant aspects of NOS and SI to address within the materials include the principle of research being guided by questions, as well as the constructive role of errors and interactions between researchers.

Keywords: Nature of Science, Scientific Literacy, Teacher Education

Introduction

Knowledge about Nature of Science (NOS) and Scientific Inquiry (SI) has been an educational goal since the beginning of the 20th century (Central Association of Science and Mathematics Teachers, 1907). Even today, this knowledge has not lost its importance and is regarded as being fundamental to scientific education in the sense of scientific literacy (OECD, 2017). Nevertheless, research has shown that students' ideas about science are heterogeneous and often inadequate (Höttecke, 2012).

While knowledge about NOS and SI as educational goals should be fostered in the classroom, teachers themselves need to have the necessary knowledge about it in the first place (Kremer, 2010). However, research has revealed that teachers often have insufficient professional knowledge in this area (Billion-Kramer et al., 2020) and even if they have adequate ideas about it, this does not necessarily entail integration into their teaching (Bartos & Lederman, 2014). Reasons for this might be the complexity of the area and a lack of familiarity with the numerous aspects, as well as its inadequate consideration in teacher training, among other factors (Hößle et al., 2004).

Against this background, we conclude that there is a need for teacher training as well as teaching materials and handouts for teachers to incorporate NOS- and SI-aspects into their classrooms. We have therefore set up a project to address this, as part of the outreach program in the CRC 1245 (Collaborative Research Centre 'SFB1245: Atomic Nuclei: Fundamental Interactions to Structure and Stars') at TU Darmstadt. This is a collaboration of various research groups, who work together on overarching issues and are funded by the German Research Foundation (DFG). In this project, a group of teachers and researchers (development group) will collaborate to develop these teaching materials and handouts. The accompanying study aims to determine the extent to which this collaboration positively influences the participating teachers' ideas about NOS and SI.

In this contribution we will present and interpret the results of a preliminary study about the views of secondary school physics teachers on NOS and SI. We have conducted this study in the vicinity of our university, the sample including all teachers of the development group among others, to gain insight into the baseline conditions for our project. The aim of this study is to contrast the teachers' views against the researchers' views, and to derive the most relevant aspects of NOS and SI to address within the teaching materials and handouts.

Methods

For this purpose, we used the VOS questionnaire and the corresponding coding manual developed by Bächtold et al. (2021). It contains eleven items that cover eleven aspects (VOS 1 – 11) of NOS and SI, as shown in Table 1.

Table 1. Selected epistemological points - VOS questionnaire (Bächtold et al., 2021)

Aspect	Definition of the aspect	NOS/SI
VOS 1	Scientific knowledge is based on empirical support.	NOS
VOS 2	There is no single scientific method.	SI
VOS 3	Scientific investigations are motivated and guided by questions.	SI
VOS 4	Scientific knowledge is always tentative.	NOS
VOS 5	Science interacts with the socio-economic and cultural context.	SI
VOS 6	The empirical data on which scientific knowledge is based are always theory-laden.	NOS
VOS 7	The models built by the scientists are distinct from the empirical reality.	NOS
VOS 8	Errors may play a constructive role in the development of science.	SI
VOS 9	Interactions between scientists actively contribute to the construction and validation of scientific knowledge.	SI
VOS 10	Realism versus instrumentalism with respect to the role of models.	NOS
VOS 11	Relativism or rejection of relativism concerning the influence of the socio-economic and cultural context on the construction of scientific knowledge.	SI

These VOS-aspects are based on the NOS-aspects proposed by Lederman (Lederman et al., 2002) and the SI-aspects described by Lederman et al. (Lederman et al., 2014). Building on these frameworks, Bächtold et al. (2021) combined these NOS- and SI-aspects into an integrated set of dimensions capturing teachers' views of science and additionally introduced several new aspects, such as aspect VOS 8, which addresses the constructive role of errors, and aspect VOS 9, which focuses on interactions among scientists.

Following the coding manual by Bächtold et al. (2021), the qualitative coding of the questionnaire for each VOS-aspect is based on one to three items, whereby most items are each incorporated into the evaluation of several aspects. For VOS 1, 2, 4, 5, 7, 8 and 9 responses are assigned to one of the following categories: novice, rather novice, rather expert, expert, depending on the context or not interpretable. The aspects VOS 3 and VOS 6 are coded dichotomously as either novice or expert. For VOS 10, coding distinguishes between naïve-, balanced realism or instrumentalism, while VOS 11 is coded as strong-, rather strong-, rather moderate-, moderate relativism, rejection

of relativism or not interpretable. We translated the VOS questionnaire into German and conducted several 'think-aloud' sessions with students and researchers at our university (n=7). In addition, the questionnaire was administered to a group of university students (n=12) to pretest the translated instrument and to refine the corresponding coding manual. Additionally, the data were double-coded, followed by a coding reconciliation process.

After that, a digital version of the questionnaire was distributed via email to numerous secondary schools and teacher education institutions in the vicinity of our university between August and November 2024. In total, 58 teachers responded, of whom 42 completed the questionnaire and could therefore be included in the analysis. This group of teachers comprised 35 in-service physics teachers and seven pre-service physics teachers. Among these participants, 25 were male and 17 were female. For the analysis, only the questionnaires completed by in-service and pre-service physics teachers were considered, resulting a final sample of 42 physics teachers (17 female, 25 male). Seven in-service teachers and one pre-service teacher have a PhD.

In addition, the digital questionnaire was administered to researchers during a CRC 1245 workshop in November 2024. Due to time constraints, researchers were asked to respond only to items addressing selected aspects (VOS 1, VOS 3, VOS 4, VOS 7, VOS 8 and VOS 9) which were of particular interest for contrasting teachers' and researchers' views. In this group, 45 researchers participated, of whom 32 completed the questionnaire and were included in the analysis. The sample comprised 13 experimental physicists and 19 theoretical physicists, all specializing in nuclear and astrophysics as part of the CRC. The group included six project leaders (mostly professors), 18 PhD students, and eight researchers in other positions.

Results

Presentation Of Teachers' Results

The results of the analysis for the teachers are presented in Tables 2, 3 and 4 as rounded percentages, with absolute numbers given in brackets.

The evaluation shows that, particularly for the first aspect (VOS 1), the ideas of 43 % of the teachers are context-dependent, while 21 % are categorized as novices. This indicates that teachers hold naïve views on VOS 1, at least in certain contexts. The ratings for VOS 3 are also worrying, as 43 % of the teachers are categorized as novices, meaning that almost half of the teachers have inadequate conceptions of this aspect. Similarly, for VOS 6, nearly half of the teachers (48 %) demonstrate inadequate ideas. Aspect VOS 8 reveals that many teachers are categorized as rather novice (48 %), whereas only 41 % are classified as experts. For VOS 9, a substantial proportion of teachers (30 %) are also categorized as rather novice, indicating that many teachers lack adequate understanding of this aspect as well.

Table 2: Results VOS 10 aspect teachers in % (n=42) and the number in columns.

Naïve realism	14 (6)
Balanced realism	7 (3)
Instrumentalism	71 (30)
Others	7 (3)

Table 3. Results VOS Questionnaire teachers in % (n=42) and the number in columns.

	VOS 1	VOS 2	VOS 3	VOS 4	VOS 5	VOS 6	VOS 7	VOS 8	VOS 9
Not interpretable	12 (5)	0 (0)	2 (1)	0 (0)	0 (0)		0 (0)	12 (5)	0 (0)
Novice	21 (9)	0 (0)	43 (18)	0 (0)	7 (3)	48 (20)	14 (6)	0 (0)	0 (0)
Rather Novice	5 (2)	10 (4)		14 (6)	0 (0)		0 (0)	48 (20)	30 (16)
Depending on context	43 (18)	0 (0)		7 (3)	0 (0)		7 (3)	0 (0)	2 (1)
Rather Expert	0 (0)	29 (12)	55 (23)	52 (22)	0 (0)	52 (22)	57 (24)	0 (0)	31 (13)
Expert	15 (8)	62 (26)		26 (11)	93 (39)		21 (9)	41 (17)	29 (12)

Table 4: Results VOS 11 aspect teachers in % (n=42) and the number in columns.

Strong relativism	74 (31)
Rather moderate relativism	5 (2)
Moderate relativism	14 (6)
Rejection relativism	7 (3)
Not interpretable	0 (0)

The evaluation of the remaining aspects shows that the majority of teachers are categorized as instrumentalists for VOS 10 (71 %) and as strong relativists for VOS 11 (74 %).

A direct comparison between pre-service and in-service teachers reveals marked differences in aspects VOS 2, 3, 6, 8 and 9.

For aspect VOS 2, 43 % of the pre-service teachers are categorized as rather expert and an additional 43 % as expert, while 67 % of the in-service teachers are categorized as expert and only 24 % as rather expert. Regarding VOS 3, most pre-service teachers (71 %) are classified as

Figure 1: Results VOS 2.

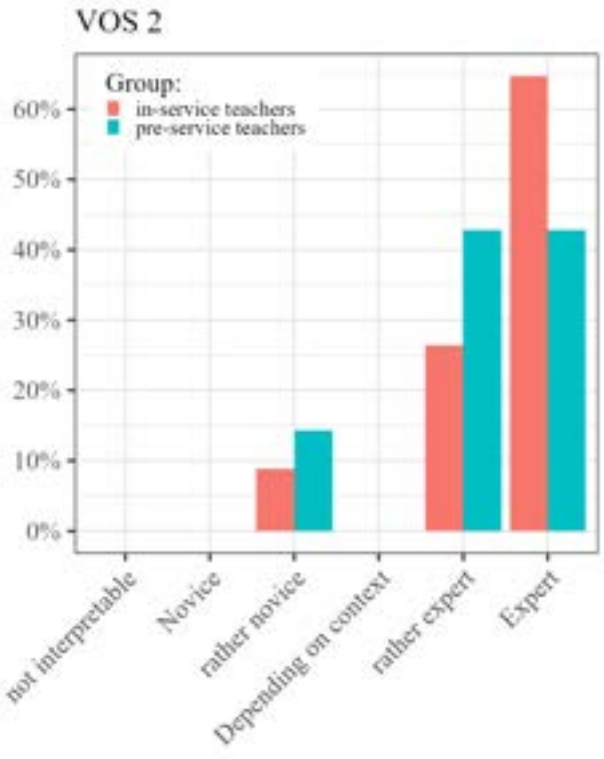

Figure 2: Results VOS 3.

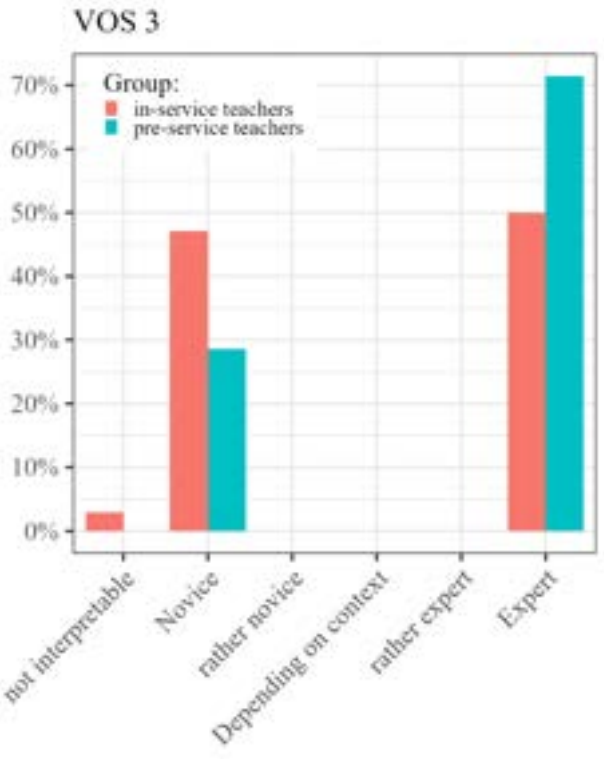

Figure 3: Results VOS 6.

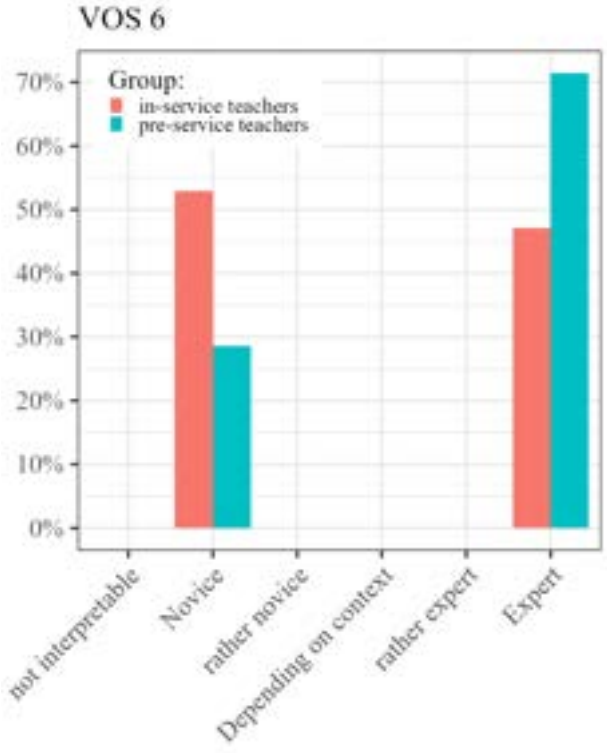

Figure 4: Results VOS 8.

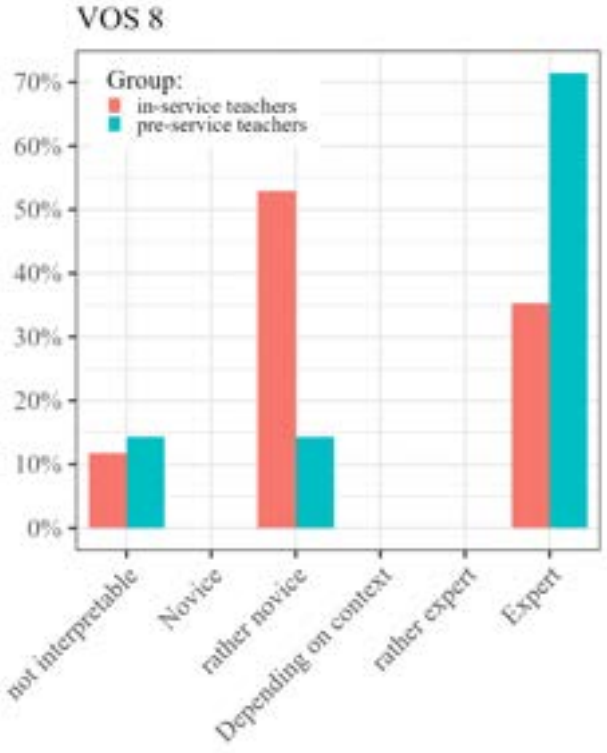

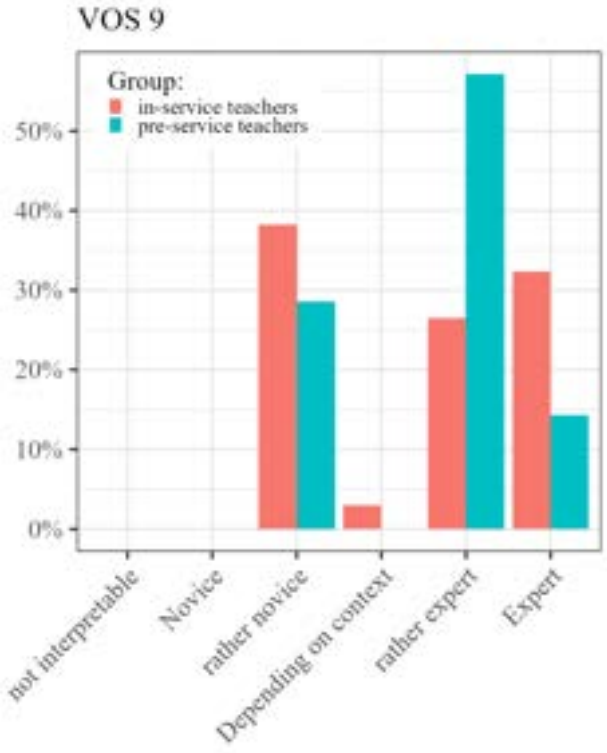

Figure 5: Results VOS 9.

experts, compared to only about half of the in-service teachers (52 %). For aspect VOS 6, again 71 % of the pre-service teachers are categorized as experts, while more than half of the in-service teachers (55 %) are categorized as novices.

A similar pattern emerges for VOS 8: 71 % of the pre-service teachers are categorized as experts and only 14 % as rather novice, while 52 % of the in-service teachers are categorized as rather novice and only 36 % as experts.

A different distribution can be observed for VOS 9. Among pre-service teachers, 29 % are categorized as rather novice, 57 % as rather expert, and only 14 % as expert. In contrast, among in-service teachers, 36 % are categorized as rather novice, 27 % as rather expert, and 33 % as expert.

Interpretation Of Teachers' Results

The analysis of the results indicates that many teachers show limited familiarity with several aspects of the VOS framework. Across multiple dimensions, a considerable proportion of teachers were categorized at lower levels, suggesting that key characteristics of scientific practice are not consistently represented in their responses. Overall, the findings point to a fragmented and context-dependent understanding rather than a comprehensive and integrated view of scientific investigations.

In general, the results suggest that many teachers have had little direct engagement with scientific research practices themselves. Their reported understanding appears to be shaped primarily by school-based experiences and formal instructional settings rather than by active involvement in research processes. Furthermore, the contact with scientific concepts during teacher education seems to have been only partially aligned with the broader epistemic aspects addressed in the framework, with a stronger focus on content knowledge and procedural routines than on overarching features of scientific inquiry.

Differences between in-service and pre-service physics teachers were observed, indicating variation in how these aspects are understood at different stages of professional development. While pre-service teachers tended to demonstrate more advanced understandings in several areas, in-service teachers also showed greater familiarity with some selected aspects, potentially reflecting professional experience. However, these differences remain descriptive, as the present data do not allow firm conclusions about their underlying causes.

Overall, the results suggest that substantial portions of both groups lack a fully developed understanding of central characteristics of scientific practice. This points to a need for further consideration of how such aspects are addressed in teacher education and professional development, particularly with respect to connecting theoretical exposure during studies more closely to the core epistemic features of scientific research.

Comparison Of Teachers' Views To Researchers' Views

To enable a more differentiated interpretation of the results, the teachers' views were compared with researchers' views of science.

The results of the analysis for the researchers are shown in Table 5.

Table 5. Results shortened VOS Questionnaire CRC-researchers in % (n=38) and the number in columns.

	VOS 1	VOS 3	VOS 4	VOS 7	VOS 8	VOS 9
Novice	38 (12)	17 (5)	0 (0)	12 (3)	0 (0)	0 (0)
Rather Novice	9 (3)		4 (1)	0 (0)	3 (1)	0(0)
Rather Expert	6 (2)		43 (12)	58 (15)	0 (0)	26 (7)
Expert	13 (4)	83 (24)	32 (9)	27 (7)	90 (26)	70 (19)
Depending on context	22 (7)		21 (6)	4(3)	0 (0)	4 (1)
Not Interpretable	13 (4)		0 (0)	0 (0)	7 (2)	0 (0)

The findings show that for aspect VOS 1, even researchers received relatively few expert ratings, while a considerable proportion (38 %) were categorized as novices. One possible explanation is, that the researchers' responses to one of the relevant items were highly specific to a particular case and therefore did not fully align with the coding scheme applied in the analysis. An analysis of the shortened VOS questionnaire completed by CRC-researchers working in experimental or theoretical physics reveals marked differences for aspect VOS 1. Theoretical physicists show a balanced distribution between notice and expert (21 % each) as well as between rather novice and rather novice (5 % each). In contrast, experimental physicists exhibit a clear tendency toward novice categorizations, with 62 % categorized as novice and no expert categorizations observed.

For aspects VOS 3 and VOS 4, researchers show a higher proportion of expert ratings compared to teachers. The result for VOS 7 is almost identical for researchers and teachers. A substantial

difference is evident for VOS 8, where the majority of researchers are categorized as experts, while about half of the teachers are categorized as rather novices. Similarly, nearly all researchers are categorized as experts or rather experts for VOS 9, while 40 % of the teachers are classified as rather novices.

Discussion

Regarding limitations, we acknowledge that the sample size of this study is relatively small. Nevertheless, the preliminary findings allow for several important conclusions relevant to the present project. The results indicate that the views of many teachers on aspects of the nature of science (NOS) and scientific inquiry (SI) are inadequate, especially for aspects VOS 1, 3, 6, 8 and 9, teachers' results showed ideas that do not reflect reality. For VOS 3, 6 and 8 pre-service teachers demonstrate more informed views than in-service teachers.

These aspects address key characteristics of scientific practice, namely that scientific knowledge is based on empirical support (VOS 1), that scientific investigations are motivated and guided by questions (VOS 3), that scientific knowledge is based on theory-laden empirical data (VOS 6), the constructive role of errors in scientific progress (VOS 8) and the importance of interactions among scientists in the development of science (VOS 9).

The results therefore suggest that pre-service teachers possess a more advanced understanding in these areas, highlighting the need for targeted interventions particularly for in-service teachers. The relevance of this is further underlined by the fact that in-service teachers have few opportunities to gain deeper insight into current research and scientific processes that they can incorporate into their teaching.

Furthermore, the views of researchers, especially those working in experimental physics, are not consistently categorized as experts in the present analysis, despite their professional expertise in NOS- and SI-aspects due to their work. The results for this question suggest some limitations in the coding manual, and interpretations based on it should be approached with caution. Revising the manual could help provide a clearer assessment of the underlying aspect.

Based on these findings, we argue that there is a clear need for further teacher training as professional development opportunities, as well as for the development of teaching materials and handouts to support teachers in addressing these topics in the classroom. Such materials should place particular emphasis on aspects VOS 3, 6, 8, and 9 by highlighting the interplay between theoretical and experimental physics, providing insights into the productive role of errors in scientific processes, and emphasizing the collaborative nature of scientific research. Within this context, the CRC provides an excellent framework for the implementation of such initiatives.

Fighting Fake News In Science Project: An Action Research Study Involving Brazilian Students, Teachers And Academics

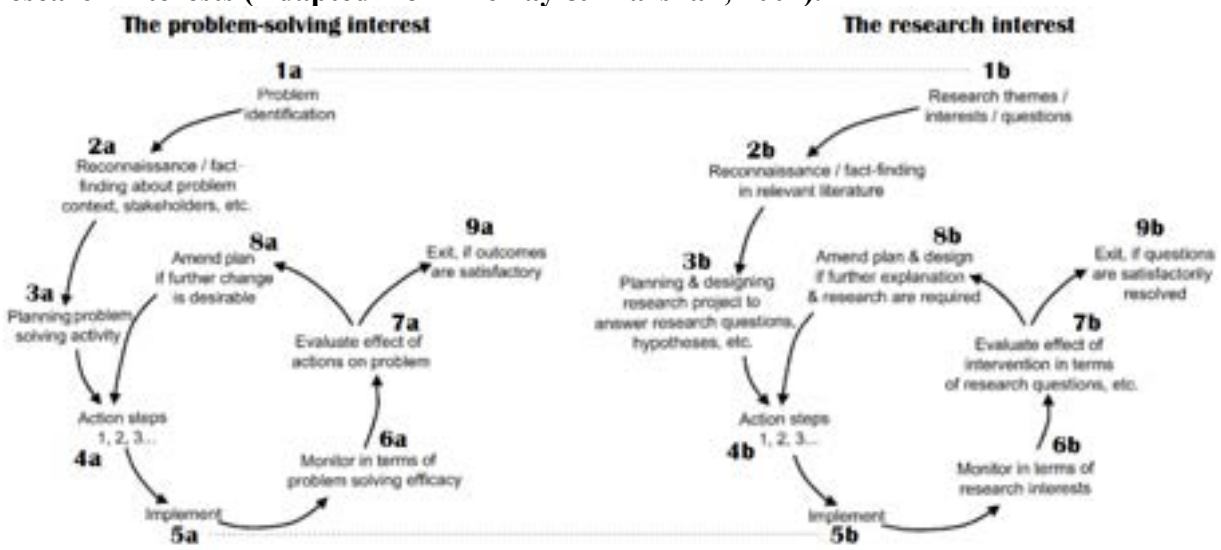
Joana Guilares de Aguiar
Universidade Federal Fluminense, Brazil

Contemporary society faces challenges in combating Fake News (FN), especially in science-related topics. During the COVID-19 pandemic, FN intensified globally, especially in Brazil, where the political misinformation, spread widely via social media, impacts collective health. The lack of media criticism and scientific literacy exacerbated the issue, highlighting the need for educational initiatives. In response, a Participatory Action Research (PAR) project titled "Fighting Fake News in Science" was launched, involving academics, teachers, and students from a public university and a school in Rio de Janeiro. Over one school year (2022), the team followed PAR's cyclical stages—Plan, Act, Reflect, Evaluate—to address misinformation about COVID-19. The methodology involved: establishing relationships and a common agenda with the team; collaboratively deciding on issues, research design, ethics, and accountability; Planning, scheduling and implementing an action plan, working together to collect and analyse data, and disseminating our findings. The action plan involved four phases where students chose, studied and analysed four FN (e.g., alkaline foods cure COVID-19) using an information disorders framework. Guided by teachers, they conduct inquiry-based activities to deconstruct FN through scientific experiments, fostering critical thinking and collaborative problem-solving. The findings were disseminated via Instagram® (@meninas_fakenews), a lecture, a workshop, and a local conference. The project achieved significant impact, engaging over 200 participants and inspiring students, particularly girls, to consider careers in Science. Testimonials highlighted the transformative experience, with students expressing gratitude for the opportunity to lead, learn, and grow. The project underscores the importance of empowering communities to combat misinformation and promote scientific understanding.

Keywords: Science Education. Misinformation. Participatory Action Research.

Introduction

Contemporary society is marked by the constant and diverse flow of information facilitated by the internet, which has democratised knowledge but also brought challenges regarding the credibility of information (Flanagin & Metzger, 2000). Fake News (FN) and manipulative reporting have gained notoriety in recent years and are often labelled as one of the biggest threats to democracy (Hinds, 2019). According to Tandoc et al. (2017), FN can be defined as false and sensationalist information disseminated as news. For Wardle and Derakhshan (2017), FN, conspiracy theories, clickbait, rumours, and hoaxes are part of a more complex framework, information disorders.



In Brazil, during the COVID-19 pandemic, the dissemination of FN intensified, representing a danger to public health, as many people accepted and shared information without critical thinking (Islam et al., 2020). The FN spread at the beginning was characterised by political content regarding misinformation about the number of cases and deaths and prevention measures and treatment, mainly disseminated through WhatsApp® and Facebook® social media (Barcelos et al., 2021).

The lack of scientific knowledge contributes to people spreading misinformation, especially regarding Natural Science disciplines, Chemistry, Physics and Biology. Scientific literacy, a polysemic term commonly used to describe an understanding of science and its societal applications (Laugksch, 2000), is crucial to empowering citizens to reckon with and combat these

untruths, promoting an adequate understanding of science and its practices. This highlighted the importance of educational initiatives. In this context, academics, high school teachers and students engaged in a project entitled Fighting Fake News in Science aimed to empower the local community to become protagonists in fighting science-based FN. This paper aims to present the Project, conducted through a Participatory Action Research (PAR) study.

Action research is an approach that integrates action and research, aiming to address practical problems while generating new knowledge (McNiff, 2013). More specifically, PAR is focused on addressing a specific local issue and attempts to empower participants or bring about social change. PAR is a cyclical process with four general phases: Plan, Act, Reflect and Evaluate. The outcomes from one cycle are used as the basis for continued exploration of practice in the following cycle. The PAR *Fighting Fake News in Science* Project was conceptualised and conducted through the dual cycle process (Figure 1) adapted from McKay and Marshall (2001), focused on both problem-solving (Steps 1a-9a) and research interests (Steps 1b-9b).

Figure 1: The dual cycle process in action research, focused on problem-solving and research interests (Adapted from McKay & Marshall, 2001).

The four stages of the PAR Project were:

- 1st Stage (PLAN) – Steps 1, 2 and 3: Examining the situation, identifying the problem, and planning the activities.
- 2nd Stage (ACT) – Steps 4 and 5: Obtaining the necessary information to answer the question, defining which sorts of data are needed and how to collect them, and developing and implementing an action plan.
- 3rd Stage (REFLECT) – Step 6: Monitoring, analysing, interpreting, and sharing the data.
- 4th Stage (EVALUATE) – Steps 7, 8 or 9: Determining improvements based on a new standard, and creating new plans to implement changes.

Results And Discussion

To select a community setting and co-researchers who agree to explore a feasible Project, we establish relationships and a common agenda to collaboratively decide on issues. The team included: two academics/full professors (Chemistry and Science Education) from the Fluminense Federal University (UFF), four high school teachers (Biology, Chemistry, Portuguese and Sociology) from a public school in Rio de Janeiro, the school's Principal, who was a Master's

student in Science Education at UFF, one undergraduate student at UFF (pre-service Chemistry teacher) and three senior high school students.

The Project was conducted through five-hour monthly meetings during one Brazilian school year (January-December 2022). The first task (*January*) was to decide on the issue the research would focus on. The students conducted an online survey with the local school community (students, parents, staff, teachers), asking them to differentiate between true and fabricated news and justify their answers. Almost 85% of the community could not distinguish between fact and false information; the COVID-19 news was the most difficult for them. Major justification relies on a lack of media criticism (e.g., not checking the information source) or science literacy (e.g., not understanding the vocabulary). Similar results were found in the recent Organization for Economic Cooperation and Development report (OECD, 2024), in which Brazil and Colombia rank lowest in identifying false content online.

Then, the team decided (*February*) to focus the problem on COVID-19 FN, involving Chemistry and Biology contents, defining the question they would like to answer: *How to improve media criticism and science literacy about COVID-19 at our school?* The academics gathered some previous research on the topic (e.g., Puig et al., 2021) and shared it with the team in a meeting (*March*). Mediated by the Sociology teacher, the students discussed the potential benefits and pitfalls of the Project and how to deal with political sensitivities around the issue (e.g., some parents disliked the theme and did not allow their children to participate in the Project).

The next meeting (*April*) was aimed at scheduling the action plan, which was organised into four phases:

- Phase 1: Choosing a COVID-19 FN to work with – one for each student.
- Phase 2: Understanding the FN according to the disorder information framework.
- Phase 3: Conducting an inquiry-based activity to deconstruct the FN, improving scientific grasp.
- Phase 4: Reporting the results to the team and creating ways to disseminate our findings to the local community.

The team gathered (*May*) to answer some critical questions (Kindon et al., 2007): *What data collection methods do we plan to use? What ethical issues may be raised by our methods? What technical skills do team members need training in? What written or visual materials must we prepare to support data gathering? How will the team incorporate reflection and iteration into our process? How do we record and store our data?* We decided to audio record the dialogues between the team, complemented by research annotations and collect all types of products the students might develop. The academic trained the science teachers to create and apply inquiry-based activities in a classroom setting. All the students and their parents signed the Informed Consent Form.

The next five meetings were used to implement the four-phase action plan. Using social media and websites, the high school students, mentored by the undergraduate student, chose the FN they wanted to study (**Phase 1**, *June*): (1) Alkaline foods, such as lemon, pineapple, garlic and dandelion, are effective in fighting coronavirus as they alter the blood pH. (2) 99% alcohol is more effective against coronavirus than 70% alcohol. (3) Alcohol gel is ineffective against coronavirus as it contains gelatine, which keeps your hand wet for longer, so we recommend

using vinegar instead. (4) Tonic water fights coronavirus because it contains quinine, which is similar to chloroquine.

Following, the students gathered with the Portuguese teacher to better understand the FN messages and their impact on our lives (**Phase 2**, *July*). Using Wardle and Derakhshan's (2017) framework, they classified the type of disorder, identified their elements (agent, message and interpreter), used source-checking and fact-checking mechanisms and proposed what technology companies, government, civil society, and education ministry could do to fight FN in our country. They made panels and essays (Figure 2) to present their results.

Figure 2: Panels and essays used by the students to present their choices and studies during Action Phase 2.

The Chemistry and Biology teachers developed inquiry-based activities (Figure 3) to engage the students in problem-solving for each FN (**Phase 3**, *August-September*). The elements of the inquiry-based activity were (Cheung, 2007): presenting a problem situation, identifying prior knowledge, proposing a question to be answered, establishing a hypothesis, conducting laboratory tests, analysing data, explaining the results based on theory and making some conclusions. They finished this phase by presenting scientific reports.

Figure 3: Inquiry-based activity created to deconstruct the first Fake News: "Alkaline foods are effective against coronavirus".

Problem Situation

The pH of the new coronavirus varies between 5.5 and 8.5. Eating foods with a pH higher than this value is enough to fight the virus. A healthy human body has a blood pH that is neither too acidic nor too alkaline – the mark varies between 7.35 and 7.45. It is necessary to eat more alkaline foods, which are above the pH level of the virus, so that it alters the blood pH and can be fought in the body. Foods such as lemon, orange, tangerine, mango, garlic and pineapple are effective against the coronavirus.

Prior Knowledge

Ask students about what they know about the concepts of acidity, basicity and the pH scale. How do you know that a food is acidic? Can a sweet or bitter food also be acidic? What measurement indicates the acidity of a substance? What does it mean for something to be alkaline? What do you understand by pH? Would you know what the pH of the blood is? Is there any substance in the blood that alters its pH?

Problem

How can you determine if a food is alkaline? Will this food be able to change the pH of your blood?

Hypotheses

Record your answers to the questions in the "Problem" in your notebook.

Laboratory

Materials: Pipette with distilled water; Glass beakers; Erlenmeyer flask; 25 test tubes on a stand; Test tube Pasteur pipettes; Graal and pistil; Glass funnel; Filter paper; Universal support and ring; Phenolphthalein solution; Ready-made solutions of pH 2, 5, 7, 10 and 13; pH indicator strip 0 to 14; Hot water; Various foods: red cabbage, lemon, avocado, garlic, mango, tangerine, pineapple, orange, egg, lemon soda, coffee, milk. Procedures

Procedure:

A) Predicting the acidity of foods

- ✓ Divide into groups with three or four students.
- ✓ Individually, predict the acidity of the foods listed: Lemon, Avocado, Garlic, Mango, Tangerine, Pineapple, Orange, Vinegar, Sparkling water, and Coffee.
- ✓ Organise your answer in a Table - write A if you think the food contains acidic substances, write B if you think it has a basic (or alkaline) character, and write N if you think the food has a neutral pH, that is, neither acidic nor basic.
- ✓ When finished, compare your predictions with your groupmates.

Laboratory (continuing)

B) Preparing the pH indicator based on red cabbage

- ✓ Chop 2 to 3 red cabbage leaves by hand.
- ✓ Add to the graal with 25 mL of hot water.
- ✓ Mash with the pestle until you obtain a dark purple extract.
- ✓ Filter using the funnel and filter paper.
- ✓ Set aside the extract.

C) Building the pH scales

- ✓ Place two rows with 5 micro test tubes each.
- ✓ Write down the pH values of 2, 5, 7, 10, 13 in each tube.
- ✓ Fill the tubes with 2 mL of each ready-made solution.
- ✓ Dip a pH indicator strip into each solution and compare it with the colour scale in the box.
- ✓ In the first row, place 2 mL of the red cabbage extract in each test tube – use the Pasteur pipette.
- ✓ In the second row, place 3 drops of the phenolphthalein pH indicator in each test tube.
- ✓ Write down all the results in a Table.

D) Testing pH test in various foods

- ✓ Separate 10 micro test tubes and label them with numbers 1 to 10 containing the foods to be tested.
- ✓ Testing should be done using any of the indicators chosen from the group along with juice or a mixture of the food with a small amount of water.
- ✓ Record the results in a Table.

Research and Conclusion

What types of pH indicators were used? Qualitative (information) or quantitative (number)?
What are the turning points (pH at which there is a colour change) of red cabbage and phenolphthalein?
Was the prediction you initially made about the pH of the food in the Fake News correct according to the results obtained?
What happened to the buffer solution when a strong base was added? Considering that blood is also a buffer solution, what would happen to the pH of our blood when we eat alkaline foods? And acidic foods?

Research which substances present in red cabbage and phenolphthalein work as pH indicators.
Research which substances present in each food tested are responsible for their acidic or basic/alkaline characteristics.

What incorrect scientific information was conveyed in the Fake News analysed? What is the impact of believing in it? How can it be combated?

The whole team planned the dissemination of the results (**Phase 4**, *October*) and evaluated the Project as a group and as individuals. The team choose three ways to communicate our findings (Figure 4): (a) to create an Instagram page (@meninas_fakenews) to post scientific information on COVID-19 and fighting FN (*November*); (b) to deliver a lecture and a workshop (*November*)

for the school community on how to identify information disorders and to use online fact-checkers; (c) to organise a local conference (*December*) to present the Project results and to conduct inquiry-based activities for other students.

We produced 22 posts on Instagram® with social media metrics: 192 followers, 1,223 likes, 235 shares and 202 comments. More than 200 people attended the lecture, workshop and conference during the Project. The students gave testimonials regarding the impact of the Project on their lives: "*The Project was wonderful, a great experience!*" (S1); "*The Project gave girls like me, who aren't very interested in Science, the opportunity to participate in such a surreal experience. It was an incredible initiative to encourage women to engage in this field. Unfortunately, opportunities like these are rare but very necessary*" (S2); "*I am extremely grateful and fulfilled because it was a wonderful and unforgettable experience. The best part was visiting UFF and meeting kind teachers. I hope you can carry out more projects like these in schools*" (S3). For the undergraduate student, "*It was a unique opportunity to take the lead in making decisions about a project and at the same time conduct teaching activities with high school students as a mentor"* (S4).

Figure 4: Students engaged in disseminating the Project findings through a lecture, a workshop, laboratory tests and a conference.

Final Remarks

The PAR "*Fighting Fake News in Science*" Project involved a multidisciplinary team of university academics and the local school community to build knowledge and insights on science-based FN about COVID-19. There is evidence of improving scientific literacy and media criticism through inquiry-based activities and social media scientific dissemination. Major limitations were found due to politically sensitive topics in a country psychologically shaken by threats to democracy and collective health. The Project ended in 2024, but its developments continue to be observed in new research, teaching and extension projects.

Pre-service Primary Teachers Evaluate Media Sources On Climate Change

Athanasia Kokolaki, Katerina Tsifetaki, Emily Michailidi and Dimitris Stavrou
University of Crete, Greece

The widespread dissemination of misinformation about climate change poses significant challenges for individuals, particularly non-experts such as pre-service primary teachers, in discerning reliable information. The present study explores the strategies employed by pre-service primary teachers to evaluate the credibility and validity of media sources related to climate change. Adopting a qualitative research design, a series of activities focusing on the recognition of deceptive tactics, the assessment of source expertise, and the understanding of media gatekeeping was developed and implemented in a form of a teaching experiment. Data was collected through audio-recorded sessions involving 14 pre-service primary teachers, working in groups of two. The findings revealed that while participants frequently emphasized source's reputation and background, they experienced difficulties in evaluating the relevance of authors' expertise and in considering the social aspects of science such as the role of scientific consensus. These findings highlight the need to integrate such aspects in initial teacher education programs in order to support the development of pre-service teachers' science media literacy.

Keywords: climate change, misinformation, science media literacy

Introduction

Climate Change Misinformation & The Need For Science Media Literacy

In recent years, there has been a growing international acceptance that climate change is one of the most urgent and challenging socioscientific issues due to its environmental, political, economic and social implications (IPCC, 2023; Leiserowitz et al., 2011). While the scientific community has reached a consensus regarding the scientific aspects of climate change and the role of anthropogenic activities in exacerbating the phenomenon, various controversial yet seemingly convincing information relating both the causes and the extent of climate change continues to be widely disseminated either through broadcast media or social media (e.g. IPCC, 2023; Leiserowitz et al., 2011). This kind of information often questions both the anthropogenic nature of climate change and the effectiveness, economic and political implications of the proposed response and adaptation measures (e.g. Whitmarsh et al., 2013).

Several interrelated factors explain why non-experts tend to believe or share such misinformation. These include cognitive dispositions that bias individuals' thinking, particularly their pre-existing beliefs, as well as social influences and online interactions that lead to isolated communities, commonly described as echo chambers or filter bubbles, which reinforce existing views and limit exposure to diverse perspectives. In addition, identity-protective thinking may lead individuals to accept misinformation that aligns with their cultural, political, or religious identities (e.g. Pimentel, 2025; Siani & Gennari, 2025). Finally, the systematic use of misinformation strategies *(deceptive tactics)* that cast doubt on well-established scientific findings, question relevant expertise and institutional credibility, emphasize scientific uncertainty, repeat false claims making them seem true *(illusory truth effect)*, and employ emotionally charged language (e.g. Lewandowsky et al., 2021) further reinforces non-experts' susceptibility to misinformation.

Within this context, tackling climate change misinformation requires a multifaceted approach. On the one hand, it involves policy initiatives and regulatory measures targeting online platforms, as well as adjustments in science communication and journalistic practices aimed at improving the quality of scientific information. On the other hand, it necessitates educational approaches that prepare individuals to critically evaluate scientific information encountered in the media. Focusing on this latter aspect, the need to equip non-experts with competencies for assessing the reliability and trustworthiness of information sources related to climate change becomes particularly relevant (e.g. Pimentel, 2025; Siani & Gennari, 2025; Osborne & Pimentel, 2023). The development of such competencies includes a. the understanding of epistemic dependance on experts and the role of empirical evidence in scientific processes; b. the interaction with media sources which involves skills and strategies for the identification of the source expertise, the identification of credible gatekeepers, the recognition of deceptive tactics; and c. the understanding of the role of personal pre-existing beliefs in the way individuals interpret information as well as the counter-balancing role of scientific consensus (e.g. Pimentel, 2025; Allchin, 2023; Osborne & Pimentel, 2023; Allchin, 2022; Höttecke & Allchin, 2020). Therefore, science education needs to emphasize the development of these competencies—commonly referred to as science media literacy—to effectively address and respond to the growing misinformation crisis related to contemporary socioscientific issues, such as climate change (e.g., Allchin, 2022; Höttecke & Allchin, 2020; Osborne & Pimentel, 2023).

Teachers' Science Media Literacy

With regard to teachers' evaluation strategies, recent research has highlighted a gap between teachers' digital skills and the depth of their information-evaluation practices. Although pre-service teachers frequently engage with online sources and demonstrate familiarity with digital tools, their evaluation of scientific information often remains superficial, focusing on surface-level indicators rather than epistemic or social - institutional features of science (e.g., Bellocchi et al., 2025). At the same time, there is limited empirical evidence on the specific strategies teachers employ when evaluating media sources related to socioscientific issues. The literature therefore underscores the need to enrich initial teacher education with science media literacy–oriented approaches, so that teachers can develop robust evaluation practices and gradually transfer these competencies to science classrooms (e.g., Fernández-Carro et al., 2024).

Based on the above, the purpose of the present study is to explore the way pre-service primary teachers interact with and evaluate media sources regarding contemporary socioscientific issues such as climate change. Hence, the research question that leads the present study is *"What strategies do pre-service primary teachers employ in order to evaluate media sources regarding climate change?"*.

Methods

Participants

The participants of the study were 14 pre-service primary teachers (PPTs) who were in the second year of a 4-year bachelor degree in primary education. The participants had attended a compulsory course on fundamental concepts of physics as well as a course on fundamental principles of science education. The participants were divided into seven groups.

The Teaching Experiment

In the present study, the teaching experiment method was employed, which is an interview organized as a learning situation (Komorek & Duit, 2004). This method is particularly appropriate

for exploratory studies, as it allows researchers to examine participants' reasoning processes as they unfold during engagement with the learning activities. The teaching experiment was structured in five phases. Initially, pre-service primary teachers (PPTs) engaged in an introductory activity designed to elicit their prior criteria for evaluating media sources. The subsequent phases emphasized (i) the recognition of deceptive tactics, (ii) the evaluation of credibility across different media gatekeeping mechanisms, and (iii) the assessment of source expertise (Allchin, 2022; Allchin, 2023; Höttecke & Allchin, 2020). In the final phase, participants applied these competencies to support evidence-based reasoning and decision-making in a new authentic situation.

The teaching experiment was implemented through the development of five learning activities. The instructional context involved a renewable energy source company accused of providing deceptive data regarding the level of carbon dioxide emissions associated with its products. Within this scenario, the company's lawyer had access to a variety of information sources and was required to decide which sources could be used to build company's defense strategy. PPTs were asked to assume the role of the lawyer's assistants and were responsible for evaluating the credibility and validity of the available sources. The content of each activity is described below:

Activity 1. PPTs Orientation & Engagement

PPTs are presented with four snapshots of media sources (a scientific report, an online newspaper, a blog post, and an Instagram post) (Figure 1) addressing climate change and are asked to rank the sources in order of increasing validity, explicitly mentioning the criteria used.

Figure 1. Snapshots of media sources.

(a) Scientific report

(b) Online newspaper

(c) Blog post

(d) Instagram post

Activity 2. PPTs Familiarization With Common Deceptive Tactics

PPTs are provided with an article and a rubric outlining five common deceptive tactics and are asked to identify whether these tactics are present in the text. The aim for PPTs is to categorize the article as a high or low quality source and to justify whether it should be considered credible evidence in the case.

Activity 3. PPTs Familiarization With Review Mechanisms

PPTs are initially presented with three different media sources (an academic paper, an online newspaper, and an Instagram post) communicating the same information by the same author and are asked to comment on the validity of each source. Subsequently, PPTs discuss the mediation of professional gatekeepers across different media types and rank the sources in order of increasing validity to determine which source should be provided to the court.

Activity 4. Ppts Familiarization With Criteria For Assessing Source Expertise.

PPTs are presented with five cards describing different source profiles based on educational background, professional and academic experience, participation in organizations and institutions, and other relevant responsibilities. PPTs are asked to select the most suitable profile to trust in relation to a renewable energy source dilemma and to justify whether this source should be presented to the court. Additionally, PPTs are asked to reflect on what further information they would require in order to finalize their decision.

Activity 5. Application Of Knowledge And Skills To A New Context.

PPTs are provided with an authentic TikTok video featuring a scientist expressing views on renewable energy sources. PPTs are asked to decide whether the source should be trusted and used as evidence in court, providing justification for their decision.

Data Collection And Analysis

The teaching experiment was conducted during one 90 – minute session for each group of participants and data was collected accordingly through audio recordings of each session.

Due to the exploratory nature of the study, qualitative methods of content analysis were used (Bryman, 2017). The category system developed to analyse the criteria employed by PPTs when evaluating media sources is presented in Table 1 and includes six broad categories: (i) source expertise, (ii) source features, (iii) source motivations, (iv) source attitude towards science, (v) source communication strategies, and (vi) source interface.

Table 1. Categorization of evaluation criteria.

Categories	**Subcategories**
Source expertise	Status
	Background & expertise
	Credentials & reputation
Source features	Review mechanisms
	References
	Authenticity
Source motivations	Conflicts of interests
	Purpose of the source
Source attitude towards science	Questioning of scientists & formal institutions
	Alignment with scientific consensus
	Scientific uncertainty
	Illustration of empirical data
Source communication strategies	Use of emotional language
	Illusory truth effect
Source interface	Web domain
	Layout

Results

With regard to the results of the study, data analysis revealed that PPTs predominantly refer to source expertise when evaluating a media source related to climate change as well as to the source

features and attitude towards science. In contrast, references to source motivations such as conflicts of interests or communication strategies including the use of emotional language, were less often. Finally, it seems that the technical characteristics of online sources do not constitute a primary criterion in PPTs' source evaluation strategies. The following table (Table 2) presents the absolute frequencies of PPTs' references to the different evaluation criteria.

Table 2. Results regarding PPTs evaluation criteria.

Categories	Subcategories	References	Total
Source expertise	Status	35	123
	Background & expertise	43	
	Credentials & reputation	45	
Source features	Review mechanisms	48	78
	References	23	
	Authenticity	7	
Source motivations	Conflicts of interests	13	44
	Purpose of the source	31	
Source attitude towards science	Questioning of scientists & formal institutions	24	76
	Alignment with scientific consensus	10	
	Scientific uncertainty	10	
	Illustration of empirical data	32	
Source communication strategies	Use of emotional language	24	30
	Illusory truth effect	6	
Source interface	Web domain	7	12
	Layout	5	

By focusing on source expertise, PPTs tended to emphasize the source's credentials, such as their collaborations, the reputation of their home institutions, and the source's educational background or professional experience. For instance, one PPT noted: *"He {the source} has a PhD and he is now working at a well-known institution while he has recently published three papers. So, I think that this profile is the most reliable one"*. Interestingly, source status alone was sometimes considered sufficient for establishing validity, even without mentioning specific background or experience. For example, one pre-service teacher mentioned: *"She is a researcher, and we unquestioningly trust researchers and scientists"*. Thus, although PPTs frequently referred to source expertise, closer examination of their reasoning suggests that such references often relied on indicators of scientific status or authority rather than on the relevance of expertise to the issue under examination.

Concerning source features, PPTs mainly highlight the review mechanisms employed in different media sources, such as peer review or editorial review. For instance, one PPT explained: *"In scientific reports or academic papers, there is a scientific committee responsible for checking the research process, whereas on platforms like Instagram or TikTok, no one verifies what is published—anyone can share their views and beliefs"*.

Regarding sources' attitude toward science, PPTs often emphasized that the illustration of empirical data - such as diagrams or data visualizations - enhances a source's perceived validity. Less frequently, they recognized that questioning scientists or the broader scientific consensus is an indicator of reduced credibility. For instance, one PPT noted: *"Here, I think that he casts doubt on something that nine out of ten scientists have agreed on. So, I think that I won't take this source into account"*.

The findings reported here illustrate the ways in which PPTs evaluated media sources related to climate change.

Discussion And Conclusions

Based on the study findings, PPTs seem to apply credibility criteria that have been identified in the literature when evaluating media sources on climate change and they are generally able to distinguish between high- and low-quality sources (e.g. Pimentel, 2025; Allchin, 2023; Osborne & Pimentel, 2023). In particular, PPTs tend to rely heavily on source expertise - a finding consistent with recent empirical research involving pre-service science teachers in Australia (e.g. Bellochi et al., 2025) - as well as on the presence of review mechanisms and the use of empirical data representations. However, relying solely on diagrams, numerical data and tables may be misleading for PPTs, since such elements can mirror the structure of professional scientific reports without necessarily reflecting robust scientific practices (e.g. Allchin, 2022; Pimentel, 2025). From a science media literacy perspective, this fact highlights the importance of moving beyond surface indicators of credibility toward evaluation strategies that take into account how scientific knowledge is produced and validated. Additionally, the emphasis placed on a source's status indicates that PPTs tend to accept scientific authority, without considering whether a scientist's expertise is directly relevant to the issue under examination – an aspect widely recognized as crucial in the evaluation of scientific information. Finally, PPTs rarely identified or even tried to identify potential source conflicts of interests, and they paid limited attention to the role of scientific consensus when assessing the credibility of information. These findings suggest limited familiarity with the social-institutional aspects of science, which are central to informed evaluation of socioscientific information (e.g., Pimentel, 2025; Erduran & Dagher, 2014) and suggest that PPTs approach source evaluation primarily through indicators that are associated with scientific authority and credibility of an individual source rather than broader scientific processes.

In conclusion, the present findings highlight key areas for supporting PPTs' development of science media literacy competencies. In particular, teacher education programs could place greater emphasis on the social and institutional dimensions of science, such as the role of scientific consensus, conflicts of interest, and the relevance of expertise to a specific scientific or socioscientific issues, in order to strengthen PPTs' science media literacy. Accordingly, future work may focus on the design, development, and evaluation of teaching resources informed by these insights, as well as on further examination of how to support the development of more robust evaluation strategies among PPTs and how such competencies are transferred to classroom practice.

ESERA 2025 Copenhagen

The Deep Structure For Teaching And Learning Socioscientific Issues

Antonio Rueda and Andreas Borowski
Potsdam University, Germany

The present theoretical contribution proposes a comprehensible framework for teachers who wish to integrate socioscientific issues (SSI) into their science classes. To this end, we conduct a theoretical argumentation that demonstrates a relationship between visions of scientific literacy and competencies for teaching and learning science through SSI. Following this, we discuss possible approaches to teaching SSI and emphasize the need for a theoretical foundation in collective pedagogical content knowledge for SSI. Our approach involves combining learning objectives and teaching structures to promote moral development in students working with SSI, based on existing theoretical models. The connection between learning and teaching is facilitated by the combination of so-called 'basis-models', which aim to foster communication and assessment competencies. By structuring science classes in this way, teachers can be empowered to effectively manage a scaffolding of lessons. This enables teachers to clarify their role in enabling argumentations and promoting students' moral development within SSI.

Keywords: SSI, moral-development, basis-models

Introduction

The modern world is undergoing a transformative era marked by profound changes in sociopolitical, economic, and environmental spheres, as well as in the established social order. These aspects are interrelated, often controversial, and require complex analysis for comprehensive understanding. When included in science classes, topics such as climate change are referred to a socioscientific issues (SSI). SSI are defined as "the deliberate use of scientific topics that require students to engage in dialogue, discussion, and debate" (Zeidler & Nichols, 2009, p. 49). Engaging in argumentation and discourse on SSI should promote the development of critical assessment competencies, as decision-making is heavily influenced by the abundance of both accurate and misleading information. As a result, the significance of SSI in education has grown (Chen & Xiao, 2021). Some national curriculum standards have already incorporated explicit topics, such as climate change (Guerrero & Sjöström, 2024). Given these contemporary and essential demands, it is crucial to focus on the role of teachers, who must guide students in navigating and engaging in complex argumentation and discourse. Although there is a considerable amount of research and educational materials on SSI, a comprehensive theoretical pedagogical framework is still lacking (Viehmann et al., 2024). To address this gap, we propose integrating an established learning-teaching model into the discussion — the basis-model-theory (Oser & Baeriswyl, 2001) — and applying it to SSI. Building on this model, we develop a theoretical framework that is grounded in the deep structures of learning and teaching processes aimed at fostering students' moral development while addressing SSI.

Aim: Developing A Theoretical Approach

In this contribution, we aim to address the following question: Which deep structures underpin the learning and teaching of socioscientific issues? To explore this question, we implement a theoretical approach by using an accessible syllogism:

- First premise: Learning about SSI involves recognizing a dilemma, using criteria to argumentatively address the dilemma, and perceiving the resulting moral development.

- Second premise: Moral development requires teaching SSI, where planning includes learning objectives, appropriate content that can be acquired through self-regulation, and well-guided interactions.
- Conclusion: Teaching SSI should encourage learners to develop their moral understanding in relation to a dilemma. Through moderation and self-regulation, learners are able to formulate arguments. Development is perceived through teacher-learner interactions. The combination of two so-called basis models (Oser & Baeriswyl, 2001) provides the scaffolding for teaching and subsequently learning SSI.

First Premise: Learning Through SSI Promotes Moral Development

There is an apparent consensus regarding the main learning goal of science education in school, which is defined by the term '*scientific literacy*'. This refers to the knowledge of science that should empower individuals to solve problems within scientific domains, facilitate critical thinking, and enable participation in complex discussions about technology and sustainability. The definitions provided by Roberts for scientific literacy form a basis of these widely accepted understandings (Roberts, 2007, p. 766). Chen and Xiao noted that despite this consensus, the concept of scientific literacy has been interpreted differently within the national curriculum standards of various countries (Chen & Xiao, 2021, p. 11).

In their examination of the connection between scientific literacy and SSI, Valladares and Sjöström reviewed the interpretations and visions of scientific literacy, emphasizing the need for developing learning objectives. These range from "Vision I," which relates to traditional content-based teaching, through "Vision II," which involves applying science to SSI contexts, to "Vision III," where science facilitates engagement in action and transformation (Sjöström, 2024; Valladares, 2021). Such engagement could be understood as an externalization of acquired argumentation and evaluation competencies. In summary, learners should become competent outsiders, especially in today's era of misinformation (Osborne & Pimentel, 2023).

Recently, the concept of '*science identity*' has been developed from the previous construct of scientific literacy, as a parallel dimension to ‘scientific knowledge’ and the ‘competencies’ (OECD, 2023). This relatively new concept aims to evaluate young people's connection to science. Within this dimension, one sub-dimension explicitly considers environmental awareness and the integration of personal and scientific values applicable to SSI contexts, as defined in the PISA framework (ibid.). These concerns should be incorporated into critical decision-making processes and sustainable practices.

In addition, Kashyap (2026) recognizes the relationship between science identity and scientific literacy, proposing a pathway that links the two. According to Kashyap, science identity can grow into scientific literacy through the “capacity to adopt meta-positions” and the “awareness of the dialogical self” (ibid., p. 12). His approach involves developing the concept of literacy as the coordination of “value-laden and socially consequential” concepts within a dialogical competence (ibid., p. 18).

In our case, in Germany, the discourse on science literacy does not play a predominant role, but rather the competencies that show similarities, such us the ability of using scientific knowledge for decision making (Kauertz et al., 2012). The term ‘*competencies*’ refers to Weinert’s definition, which involves long-term learning processes that address “cognitive and (in many cases) motivational, ethical, volitional, and/or social components” (Weinert, 2001, p. 62). Over the past decade, science competencies have been operationalized into standards divided into four competency areas: content knowledge, scientific enquiry, communication and assessment (i.e. evaluation) (Neumann et al., 2010).

The new national educational standards explicitly include interdisciplinary objectives in communication and assessment areas, which can be contextualized with reference to SSI (*KMK*, 2024). In these contexts, students must navigate various criteria based on scientific and personal perspectives to formulate well-grounded arguments that lead to decisions and subsequent reflections on consequences (ibid.). Such argumentations are shown to play a central role as a vehicle for reasoned claims, a view accepted internationally (Dawson & Carson, 2017). For this aim, students must learn how to construct an argument, identify and select criteria, and apply them accurately in language. The abilities involved are part of communication competence. Beyond those skills, students must also evaluate dilemmas and develop well-reasoned personal viewpoints on interdisciplinary topics. Furthermore, when making decisions, they connect their competence with their performance (Blömeke et al., 2015). This process is closely linked to assessment competence and is similar to a form of "functional scientific literacy" (Zeidler & Sadler, 2023, p. 920).

As they evolve their personal beliefs through these evaluation processes, it can be assumed they undergo moral development (Oser & Baeriswyl, 2001), as defined by the theory of moral development (Kohlberg & Hersh, 1977). Zeidler adds, in this context, the term of moral inquiry, as "an activity aimed at advancing virtue when confronted with conflicting or unclear moral judgements" (Zeidler, 2024, p. 41). Moral inquiry can be addressed through controversial SSI after creating an ethical disequilibrium that awakens "empathy, sympathy, and compassion" (ibid., p. 40). Furthermore, an "empathetic dissonance" is necessary to trigger a motivational response (ibid., p. 47). In this way, learners can develop their morality by engaging in dilemma discussions that facilitate the realization of context-related moral reasoning through both cognitive and motivational dimensions (Nunner-Winkler, 2007). Immersive experiences, such as place-based SSI instruction, promote conceptual and moral development in students (Herman et al., 2021).

Second Premise: Teaching SSI Requires The Involvement Of Morality

Regarding pedagogical structures for dealing with SSI, Saunders and Rennie developed a model for ethical inquiry, which they investigated qualitatively with a small sample of teachers (Saunders & Rennie, 2013). The model proposes nine sequential stages: "(1) teacher preparation, (2) students engaging with the broad issue, (3) students understanding the science behind the issue, (4) individual reflection on the issue/values exploration, (5) group discussion of specific issues, (6) deciding on specific questions or controversial statements, (7) ethical thinking about the questions or statements from various ethical frameworks, (8) ethical decision-making and justification, (9) action/evaluation/decision" (ibid., p. 270). Teachers highlighted that the model demonstrates cohesiveness and flexibility and aids students in critical thinking. The study emphasized the need to develop pedagogies that move away from transmissive approaches, advocating for teachers to guide students' self-regulated research and debates. To achieve this, "teachers may require assistance in developing criteria that support them in assessing issues where there are no right or wrong answers" (cf. ibid., p. 269). In this noteworthy approach, the need for argumentative moral development is also recognized.

Macalalag et al. (Macalalag et al., 2020; Johnson et al., 2020; Minken et al., 2021) developed, implemented, and investigated a professional development course for teaching SSI in STEM classes, which considers the following steps: "(A) Identifying the issue, (B) Scientific phenomenon, (C) Engage in STEM modeling, (D) Consider issue system dynamics, (E) Employ reflective scientific scepticism , (F) Compare and contrast multiple perspectives, (G) Elucidate own position / solution" (Minken et al., 2021, p. 123). The study showed that the participant teachers increased their knowledge and instructional skills regarding SSI. However, they

demonstrated lower levels of content knowledge related to the SSI and of scientific scepticism (ibid.).

The results of Macalalag et al.'s study are consistent with Bayram-Jacobs et al. (2019). In Bayram-Jacobs et al.'s research, teachers learned to adapt SSI materials in a professional development course. In that study, all materials used the same scaffolding: "Presenting a dilemma, recap or learn scientific knowledge needed for the task, and a student's SSI task which is a simple, structured activity to resolve the dilemma" (ibid., p. 1213).

Both Macalalag and Bayram's theoretical background resides in PCK. Building on the theoretical approach of Magnusson et al. (1999), the presented studies qualitatively illuminate some interactions between the components of PCK for teaching SSI: "Knowledge of Instructional Strategies for Teaching SSI, Knowledge of assessment of SSI, Knowledge of curriculum, Knowledge of learning context, and Knowledge of students' SSI learning" (Chang & Park, 2020, p. 425).

A final model, called Values and Knowledge Education, combines the mentioned perspectives in a very complete approach that aimed at solving dilemma situations: "(0) Preparation of the students and pupils, (1) Introduce dilemma, (2) First decision, (3) First arguments, (4) Exchange experience and asking about missing information, (5) Looking for evidence, (6) Exchange information, (7) Second arguments (dilemma discussion), (8) Synthesis of information, (9) Repeat 4 through 8 if necessary, (10) General synthesis, (11) Generalization" (Patry & Weyringer, 2022, p. 29). Studies conducted using this framework demonstrate positive development of transformative processes by participants (ibid.).

In Germany, a group of science educators from different science education disciplines with a focus on assessment competence, has presented a model comprising six stages: (1) Perceiving, (2) Analysing, (3) Arguing, (4) Weighing, (5) Deciding, (6) Reflecting (Langlet et al., 2022). Each stage is further divided into several substages, except for the last one. The publication also provides useful exercises and tips, such as separating steps into three types of implementations: to perceive and analyse; to argue; and to weigh, decide and reflect. Once again, the progression of arguments, decisions, and reflections occurs in clearly defined steps, supporting the moral development of students.

Finally, research has shown that interdisciplinary collaboration among teachers in schools is an effective way to develop interdisciplinary content and establish pedagogical knowledge of SSI, thereby promoting the intended moral development through argumentation (Kutluca, 2021; Viehmann et al., 2024).

Conclusion: Bringing Teaching And Learning Together Through Deep Structures

A Selection Of 'Basis-Models' For Designing The Deep Structure

As highlighted in the previous paragraphs, moral development can be identified as the fundamental learning objective for students engaging with SSI. Moreover, fostering moral development in science classes demands teaching plans that ensure effective communication and assessment, particularly in the context of SSI. Both, assertions and recognized needs require a theoretical approach that depicts the deep structures of learning and teaching SSI, with a clear emphasis on promoting moral development.

Oser and Baeriswyl proposed a theory of 12 so-called basis-models for the deep structure design of teaching processes, drawing on psychological and educational theories (Oser & Baeriswyl, 2001). These basis-models are derived from diverse learning objective types and consist of

various steps of teaching and learning that form chains. The theory does not allow any steps to be skipped or omitted. In addition, basis-models can be combined sequentially or interwoven. Research has shown that planning lessons using a selection of three basis-models ('Concept Building', 'Learning Through Discovery', and 'Problem Solving') can enhance students' learning outcomes in science classrooms (Geller et al., 2014). However, basis-models for the competency areas of communication and assessment have not been sufficiently investigated and are not included in this selection, as they target developmental processes beyond content-based or inquiry learning (Hümbert-Schnurr et al., 2022). Instead, they aim to foster multi-perspective, valid arguments, as discussed in the previous paragraphs.

An analysis of the remaining nine basis-models reveals that competencies concerning assessment and communication can be enhanced through different learning objective types and corresponding choreographies. Two of these models are particularly well-suited because their learning goal types are similar to those of SSI (Oser & Baeriswyl, 2001, p. 1046):

- "Development as the Aim of Education" (DAE), with the learning goal type "deep structure transformation, such as moral judgment" in five steps.
- "Hypertext Learning" (HL), with the learning goal type "reordering and revaluing information bits" in six steps.

The basis-models DAE and HL can be combined as follows to achieve the learning objectives described in the right column of Table 1b. Starting from the corresponding steps, the resulting learning processes foster engagement with conflicts (DAE1) and exploration of positions in complex contexts (DAE2). During the self-regulated phase (DAE3), students search for information independently or in groups to support arguments. Oser predicted moral development in this step (ibid.). Subsequently, with teacher moderation, students analyse and weigh these arguments (DAE4). The process culminates in reflection on personal development (DAE5), which contributes to moral development. The HL basis-model can be introduced in the step (DAE3) if the lesson also focuses on critical thinking, for example. In that case, students must first select the topic (HL1), then structure the information (HL2), define the objectives (HL3) and determine their learning approach (HL4). After that, they execute the self-determined path (HL5) and, finally, they manage the results (HL6).

Comparison Of Models

The presented combination of basis-models reflects the fundamental characteristic of our approach, which underscores the deep structure. The following tables illustrate this characteristic by comparing the stages outlined by Saunders & Rennie, Macalalag et al., Patry & Weyringer and Langlet et al. (as presented above) with those of our own approach.

Table 1a. Comparison of first two approaches presented in this contribution.

	Saunders & Rennie	Macalalag et al.
(-)	(1) Teacher preparation	
(I)	(2) Students engaging with the issue	(A) Identifying the issue
(II)	(3) students understanding the science behind the issue	
(III)	(4) individual reflection on the issue/values exploration (5) group discussion of specific issues (6) deciding on specific questions or controversial statements	(B) Scientific phenomenon (C) Engage in STEM modeling (D) Consider issue system dynamics
(IV)	(7) ethical thinking about the questions or statements from various ethical frameworks (8) ethical decision-making and justification	(E) Employ reflective scientific skepticism (F) Compare and contrast multiple perspectives
(V)	(9) action/evaluation/decision	(G) Elucidate own position / solution

Table 1b. Comparison of following two approaches and our own.

	Patry & Weyringer	Langlet et al.	Our Approach
(-)	(0) Preparation of students		
(I)	(1) Introduce dilemma	(1) Perceiving	1. Dilemma presentation (DAE1)
(II)	(2) First decision	(2) Analizing	2. Exploring controversial positions (DAE2)
(III)	(3) First arguments (4) Exchange experience and asking about missing information (5) Looking for evidence (6) Exchange information	(3) Arguing	3. Exposure to advance arguments (DAE3) 1. Topic selection (HL 1) 2. Structuring information (HL2) 3. Defining objectives (HL3) 4. Learning approach (HL4) 5. Path execution (HL5) 6. Result management (HL6)
(IV)	(7) Second arguments (dilemma discussion) (8) Synthesis of information (9) Repeat (4)-(8) if necessary	(4) Weighing	4. Argument Analysis (DAE4)
(V)	(10) General synthesis (11) Generalization	(5) Deciding (6) Reflecting	5. Reflection (DAE5)

The selection and combination of basis models reveal an underlying structure for planning and analysing teaching sequences for SSI. Additionally, this approach's coherence with others has been emphasized. One strength of the present approach is its simple, user-friendly structure, which supports learning processes. Furthermore, rather than providing a solution to a dilemma, these learning processes encourage investigation and debate surrounding it. Therefore, fostering communication and assessment competence should be a long-term process that incorporates similar strategies and deep structures in several SSI lessons on different topics. Furthermore, the selected basis models focus on the self-regulated development of students' science identities and beliefs, which teachers moderate. As shown above, this is a starting point for moral inquiry. In conclusion, this approach explicitly fosters interactions between at least three components of SSI-PCK: knowledge of instructional strategies for teaching SSI, knowledge of the learning context, and knowledge of students' SSI learning.

Limitations, Future Direction, And Conclusion

One difficulty when working with the basis-models is that the functions of the different steps may be misunderstood (Krabbe et al., 2015). In this case, it is important to explicitly define the stages of the deep structure applied to SSI and develop materials based on the proposed guidelines. This would allow for the extrapolation of the SSI framework to a smaller order of magnitude.

Additionally, when considering the practical implementation of controversial debates, developing teaching strategies for scaffolding in the last two steps presented in Table 1b (right column) seems necessary. In this context, the basis-model 'Learning Through Realistic Discourses' could be considered for the deep structure of these learning and teaching processes.

Understanding the underlying deep structures of teaching and learning, as proposed in our approach, is essential for identifying better future research directions in the field of SSI. The selected basis-models are based on psychological and pedagogical research and consider the development of students' knowledge and morality. They are also more process-oriented than product-oriented, making them more coherent with the desired competencies and activities.

The present approach could make SSI more practical for teachers due to its simple structure, which makes planning single science lessons easier, for example. However, future empirical analyses of existing SSI materials, as well as the development of new materials, are necessary. These materials could then be used in professional development programs for pre-service and in-service teachers. The effectiveness of these training courses should be studied.

For science teachers, this knowledge could provide with insight into managing SSI processes, enabling them to motivate students to move away from transmissive pedagogies and facilitate personal growth.

Acknowledgement

I would like to thank my colleagues for their continuous support and for the interesting discussions we've had regarding this work.

ESERA 2025 Copenhagen

Socioscientific Issues And Laboratory Work In Lower Secondary School - Some Challenges

Niels Matti Søndergaard and Nana Quistgaard
The LIFE Foundation, Denmark

Previous research suggests socioscientific issues (SSI) can improve student interest in science, increase learning of content and strengthen scientific literacy. Most of this research, however, is focused on the level of the teaching unit. There is relatively less on how different activities within the teaching units suit an SSI approach. In this study we investigate the teaching and impacts of a module focused on food production and population growth in lower secondary school (age 15). We employ a mixed-methods design, combining classroom observation and interview with a pre-post difference-in-differences design. Quantitative results (n=3876) are promising with medium-sized effects on situational interest and content specific self-efficacy. Qualitative results based on 90 hours of observation and interviews with students and teachers, however, indicate that socio scientific issues work well with non-experimental activities, but less so with experimental lab activities. The laboratory parts of the module tend to be more focused on proving the usefulness of suggested solutions than on allowing students to investigate their own hypotheses. This has consequences for the depth of discussions and limits the types of evidence it is possible to bring forward by students. We suggest that this reflects not only limitations in the design of the module but also points to broader challenges in integrating student laboratory work within SSI-based teaching, particularly for younger students.

Keywords: Socioscientific Issues, Laboratory Work in Science, Secondary School

Introduction

Socioscientific issues (SSI) are ill-structured problems with no simple solutions that involve political, ethical, social aspects as well as scientific knowledge. They are often controversial and contentious issues for society, requiring the use of evidence from science as well as other disciplines, and often include a debate between students about possible ways of action, moral reasoning and judgement (Evagorou & Nielsen, 2019; Evagorou & Dillon, 2020; Tidemand & Nielsen, 2017). SSIs can be based on dilemmas from many domains such as environmental sustainability (e.g. ecological systems, food production), resources and energy (e.g. clean energy development), technology (e.g. artificial intelligence and large language models), medicine and neurosciences (e.g. gene therapy) (Evagorou & Nielsen, 2019; Wan & Bi, 2018).

Previous research has suggested the use of socioscientific issues in science education can promote student interest in science, increase learning of content, as well as their scientific literacy. On this basis, many scholars have argued for the integration of SSI into science teaching (Sadler & Dawson, 2012; Çalik & Wiyarsi, 2024). At the same time, the literature highlights a number of challenges associated with SSI-based teaching, including resistance to pedagogical innovation, the inherent complexity of the topics, and the demand for specialized teacher training (Tidemand & Nielsen, 2017; Zeidler & Sadler 2023; Ke, Sangori, Sadler & Friedrichsen 2020).

In recent years, empirical research on socioscientific issues (SSI) has expanded considerably. However, much of this literature has focused on analysing the effectiveness of complete teaching units or instructional sequences, rather than examining the role of individual activities within those units. As a result, comparatively little research has addressed how specific classroom

activities are designed and how well they align with the principles of SSI-based teaching, particularly at educational levels below upper secondary or tertiary education (see e.g. Sadler, 2004; Sadler & Dawson, 2012; Çalik & Wiyarsi, 2024; Zeidler & Sadler, 2023; Nolan & Zeidler, 2025; Karisan et al., 2018; Sá-Pinto et al., 2022). Moreover, relatively few studies have investigated how younger students engage with the SSI approach and different types of activities, such as experimental laboratory work, within such a framework (Evagorou & Nielsen, 2019).

To address these gaps, the present study examines how fifteen-year-old students in lower secondary school engage with and make sense of classroom activities within an SSI-based teaching module. By focusing on classroom processes during implementation, the study provides a more fine-grained understanding of how SSI-oriented activities function for younger students across different activity types. The following research questions guided the study:

- In what ways do lower secondary students participate in an SSI-based teaching module?
- How do experimental laboratory activities and non-experimental activities function within an SSI-based teaching approach?

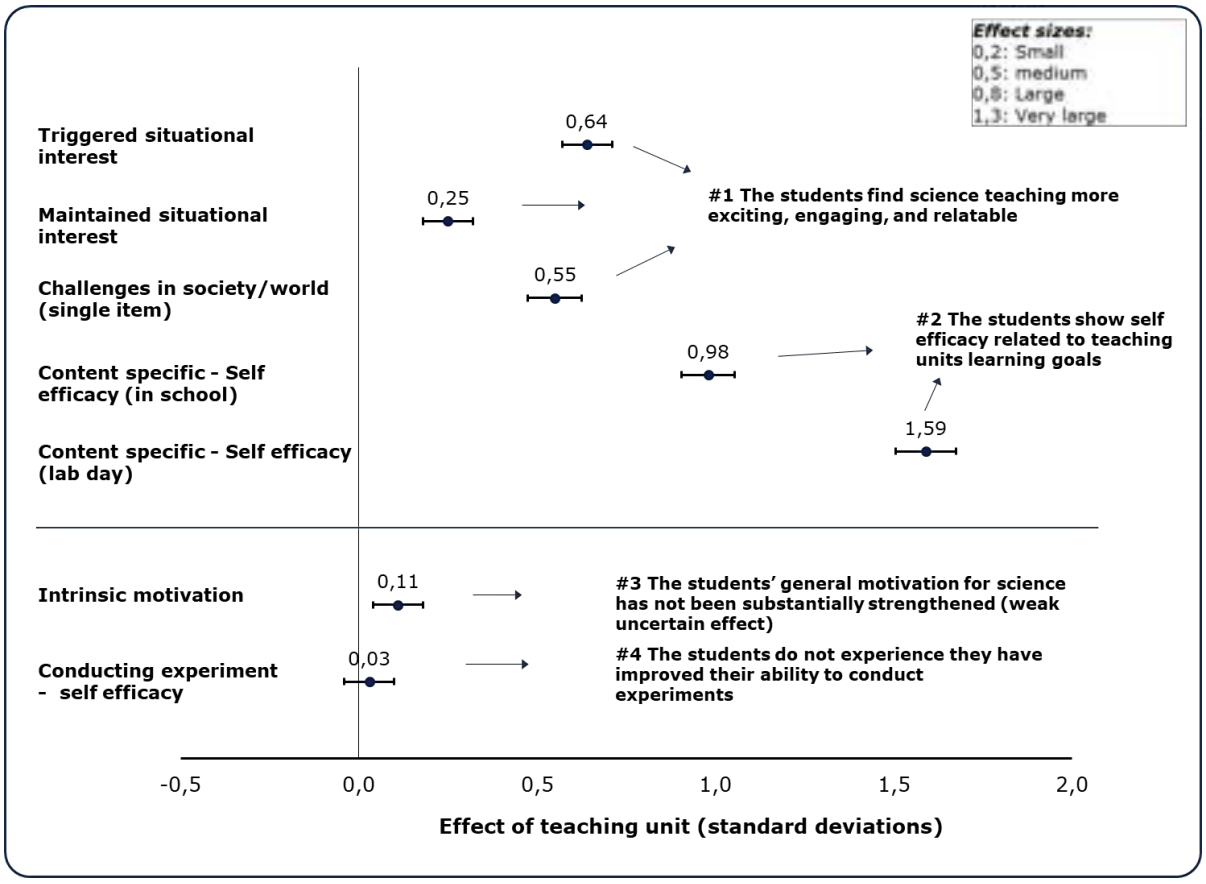
Research Method And Data

The study is based on a mixed-methods approach combining classroom observation and interviews with a pre-post difference-in-differences design based on survey data from students. Although this paper draws on the quantitative part of the study for necessary context and background, this paper primarily is concerned with data from the qualitative component.

The module under study consists of a five-week in-school activity followed by a one-day out-of-school activity for some classes. The module integrates content from physics/chemistry, geography, and biology.

The approach in the quantitative component of the study is reported elsewhere (Bergquist & Osmundsen, in press). The qualitative component is based on case studies of eight lower secondary school classes in which the module was implemented. Cases were selected using a maximum-variation sampling strategy to support analytical transferability, based on criteria such as teacher experience and school socio-economic context. Qualitative data collection took place during the first part of the 2023/24 school year (August–December 2023).

The SSI framework served as an explicit analytical lens throughout the qualitative study. Prior to classroom data collection, a desk study of the module's learning materials was conducted, during which all activities were analysed against key characteristics of SSI-based teaching, including the extent to which activities foregrounded socioscientific problems, supported student deliberation, and facilitated discussion of the possibilities and limitations of scientific and technological solutions. This analysis informed both the observation focus and the subsequent interpretation of classroom practices.



The main body of qualitative data consists of approximately 90 hours of naturalistic classroom observation across the eight cases. During observations, detailed field notes were taken and subsequently transcribed. In addition, focus group interviews were conducted with 3–5 students in each class at selected points during the course and with one focus group per class at the conclusion of the module. Students were selected to capture a range of perspectives, including variation in engagement with the module.

Finally, semi-structured interviews were conducted with each of the eight participating teachers at the end of the course to elicit their reflections on implementing the SSI-based module. All interviews were audio-recorded and transcribed verbatim.

Findings

Figure 1 shows the results of the quantitative part of the study.

Figure 1. Impacts on student interest, motivation and self-efficacy.

Note: Standardized effect estimates from regression models, with cluster-robust standard errors at the class level. Lines indicate 95% confidence intervals around point estimates (n=3,876 observations).
Source: Bergquist and Osmundsen (in press)

Results showed improved student interest and self-efficacy. Students who were taught the module were more interested in and showed a greater desire to participate, compared to students in the control group (Triggered situational interest, medium effect: 0.64 SD) (see Figure 1). Additionally, students found that the teaching unit could be related to daily lives to a high degree. (Sustained situational interest, small effect: 0.25 SD) With regards societal or global challenges, there was a medium effect (0.55 SD).

However, the results also showed that there was only a weak uncertain effect on intrinsic motivation for science (0,11 SD) and that it didn't improve their ability to conduct experiments (se Figure 1).

These largely positive results are supported by the qualitative results; however, they also show a more nuanced picture. The module consists of many different teaching activities that can roughly be divided into two groups: non-experimental and experimental activities. All of the latter take place in a laboratory setting. We observe a marked difference in student engagement in the non-experimental and experimental activities.

A non-experimental activity that figures prominently in the module is a turn-based game, where the students develop a fictitious country. In each round, they invest within four categories: agriculture, fertilizer, education and behaviour. As they have limited resources, they must prioritize their investments. After each turn, they can see the consequences of their choices for the country's food needs, food production, CO2 emissions and school attendance. In their

prioritization, they must use knowledge about the country's demography, climate and soil conditions, which they know from a previous activity. The game gives the students a lot of autonomy as there is no 'right answer' and students truly get the opportunity to investigate and select solutions to deal with the socioscientific issue.

We see that students participate in the game with an exploratory approach, for example by studying data about the population and climate of the country while discussing investments. We also see students trying to figure out which real country their fictional country most likely resembles and then research everything about that country to strengthen their actions in the game. Furthermore, we see that students engage in arguments with each other for and against different investments from each other. For example, they relate to scientific evidence when they discuss possibilities and limitations of investments and to their consequences for the economy, climate, environment and people. This behaviour shows that the students at the same time have an exploratory, independent and creative approach and can relate to the socioscientific issue. A teacher describes the link between the game and the socio-scientific issue like this: *"The game is clearly the one activity who make the students aware of factors that you have to take into account: Why can't you just make sure that now we make investments that give lots of food? That won't solve the problem. It just results in more population growth and even greater food needs".* In addition to working competently with the problem, students work with commitment. Even if the game is very simple in design, the students identify with the country they are playing. As one student puts it: "*It's a great responsibility to be responsible for the development of a whole country. And we're only 15 years old!".*

The module also includes several experimental lab activities. In these activities the students show less engagement and less competence compared with the gaming activity. Examples of experimental lab activities include when students examine properties of catalytic reactions, as catalysis is part of the production of artificial fertilizers, which is one of the possible solutions to increase food production. They investigate, via hypothesis formation and variable control, how much nutrient is leached from the soil of their fictitious country when crops are exposed to chemical fertilizers. Both these activities are closed-ended with a fixed protocol that the students must follow.

We see that the students in the experimental lab activities participate in a results-oriented way, with a focus on solving the task 'correctly' and finding 'the right answer'. We also see uncertainty among students, as they often seek the teacher's confirmation as to whether they are on the right path. We don't see indications of the students connecting their work in the experimental lab activities with the problems or the challenges of their fictional country. The students' commitment and participation are directed towards the lab work itself, and reflection on results is not linked to the problem or to what they can use their results for in relation to the development of their countries. Nor do they reflect on how what they have investigated relates to the production or use of chemical fertilizers. As one teacher puts it: "*It is quite demanding for the students to succeed with the lab activities, and this puts the socioscientific issue in the background".* At the same time, we also noticed that the teachers rarely made explicit connections between the experimental laboratory activities and the socioscientific issue or the students' fictional countries.

Discussion

In conclusion, we find that non-experimental activities generally support the intentions of SSI-based teaching, whereas experimental laboratory activities appear less successful in this regard, suggesting a possible challenge in SSI-based teaching. We argue that this is not only due to limitations in the design of the module under study but also points to broader challenges in integrating student laboratory work within SSI-based teaching, particularly for younger students.

These challenges may be related to safety considerations and students' limited laboratory competencies, which are often associated with age and maturity in lower secondary school. As a result, meaningful laboratory activities can be difficult to design in ways that allow students sufficient autonomy to explore and evaluate different solutions. Consequently, experimental laboratory activities tend to be relatively close-ended, with fixed protocols for students to follow, which may conflict with key principles of socioscientific issues. Rather than enabling students to explore alternative solutions experimentally, laboratory work often focuses on confirming the solution proposed in the module or by the teacher. This finding has broader implications for the integration of SSI-based teaching alongside traditional science education, as many curricula emphasise not only data collection and analysis but also students' engagement with laboratory work.

Acknowledgement

We would like to acknowledge Mia Lange, Nanna Friche, Viggo Lehrmann Hansen and Pernille Vils for their help with data collection and Robert Harry Evans for helpful feedback on an earlier version of the manuscript.

Argument Development Through Socioscientific Issue-Based Teaching: Asteroid Mining With Gifted Students

Gül İrem Özen[1] and Gamze Babaoğlu[2]
[1]The author is an independent researcher, Turkey
[2]Ministry of National Education, Turkey

This study examines how socioscientific issue-based instruction supports the argument development processes of gifted secondary school students. The research was conducted within the context of asteroid mining, a contemporary socioscientific topic that encompasses scientific, ethical, and societal dimensions. The teaching process was structured based on the Socioscientific Issues Teaching Framework developed by Friedrichsen et al. (2016). The activities were enriched in line with Renzulli's (2014) Triple Enrichment Model to support the cognitive and affective characteristics of gifted students. Furthermore, socioscientific dilemma cards, developed based on Yacoubian's (2015) Critical Thinking and Nature of Science Framework, were used to deepen students' critical thinking and awareness of the nature of science. The research was conducted using a case study design, adopting a qualitative research approach. The study group consisted of 30 gifted secondary school students studying at a Science and Art Centre in Turkey. The implementation process lasted six weeks and consisted of four main activities. The data sources were written arguments developed by the students; the data were examined through descriptive analysis, taking into account the structural characteristics of the arguments. The findings show that the arguments developed by the students can be grouped into three levels: simple, advanced, and complex. It was determined that a significant proportion of the students demonstrated reasoned thinking skills, but the number of students developing complex arguments was limited. The results reveal that socioscientific issue-based instruction supports gifted students in developing arguments by evaluating scientific, ethical, and social dimensions together; however, it also highlights the need for explicit and structured argumentation instruction to develop more complex argumentation skills.

Keywords: argumentation, asteroid mining, gifted students

Introduction

Today, rapid, complex and often unpredictable developments in science and technology mean that it is no longer sufficient for individuals to simply possess knowledge of scientific concepts (Hodson, 2011). Instead, it is becoming increasingly critical for individuals to be able to evaluate this knowledge within social, ethical, political, and economic contexts (Jasanoff, 2004; OECD, 2018). The increasing visibility of the social consequences of scientific knowledge production necessitates a rethinking of the aims of science education (Sadler, 2004). In this context, one of the fundamental goals of science education is to ensure that students are not merely consumers of knowledge but grow into individuals who can make reasoned and informed decisions about complex, controversial, and uncertain scientific issues (Sadler, 2011; Zeidler, 2014).

Socioscientific issues, which lie at the intersection of scientific knowledge and social values and inherently involve uncertainty, ethical dilemmas, and multiple perspectives, provide a strong pedagogical context for this goal (Sadler & Zeidler, 2005; Zeidler et al., 2009). These topics reveal that scientific knowledge is not a fixed, unchanging and indisputable structure, but rather a value-laden process negotiated within social contexts (Kolstø, 2001; Sadler, 2004). In this respect, socioscientific issues enable students to develop a more critical and realistic understanding of the nature of science (Lederman, 2007; Yacoubian, 2015).

Socioscientific issue-based teaching is an approach that aims to holistically develop students' critical thinking, scientific reasoning, and argumentation skills, and it is gaining increasing attention in the field of science education (Evagorou & Osborne, 2013; Zeidler et al., 2009). This approach seeks to transform students from passive recipients of information into active participants who evaluate scientific evidence, consider opposing views, and develop reasoned arguments (Sadler et al., 2007). Research shows that teaching processes conducted in socioscientific contexts strengthen students' ability to relate scientific knowledge to everyday problems and increase their motivation to learn (Aikenhead, 2006; Ratcliffe & Grace, 2003).

Argumentation is a fundamental scientific practice that involves individuals defending their claims with evidence, evaluating alternative views, and reaching reasoned conclusions (Kuhn, 1991; Toulmin, 1958). In the context of science education, argumentation is recognised as a central learning practice that makes students' scientific thinking processes visible and encourages critical evaluation (Erduran et al., 2004; Sampson & Clark, 2008). Numerous studies have demonstrated that argumentation-based learning environments deepen students' conceptual understanding and support their scientific reasoning skills (Berland & Reiser, 2009; Osborne et al., 2004).

Argumentation-based learning environments, particularly for gifted students, offer significant opportunities for supporting higher-order cognitive skills and deep thinking (VanTassel-Baska, 2013; Zohar & Dori, 2003). These students have the potential to evaluate multiple perspectives, think abstractly, and engage in critical inquiry when faced with complex problems (Renzulli, 2014; VanTassel-Baska, 2013). However, for this potential to emerge, learning environments must be consciously structured and students must be guided towards active intellectual production (Subotnik et al., 2011).

Space mining, and asteroid mining in particular, has emerged as a contemporary socioscientific topic in recent years, drawing attention for its scientific, economic, and political dimensions (Cockell, 2011; Sonter, 1997). Asteroid mining encompasses numerous controversial elements, such as the sustainable use of natural resources, space law, technological limitations, global economic inequalities, and ethical responsibilities (Elvis, 2014; Milligan & Schwartz, 2020). This multidimensional structure makes addressing the topic in the context of science education pedagogically meaningful (Sadler, 2011; Zeidler et al., 2005).

With these characteristics, asteroid mining provides a rich learning context that enables students to discuss not only the question of ‘what is possible?’ but also ‘what should be done?’ (Sadler, 2011; Zeidler & Nichols, 2009). This context supports students in questioning the limits of scientific knowledge, the societal consequences of scientific progress, and value-based decision-making processes (Osborne et al., 2004).

The main aim of this study is to examine how socioscientific issue-based teaching conducted in the context of asteroid mining reflects on the argument development processes of gifted students. In this regard, the main research question is formulated as follows:

RQ1. How do gifted students participating in a socioscientific issue-based learning environment develop arguments regarding a controversial socioscientific issue such as asteroid mining?

Within the scope of this question, the structural characteristics, levels of complexity, and perspectives contained in the arguments developed by the students are examined.

Theoretical Framework

This study is built upon three fundamental theoretical pillars: the teaching approach to socioscientific topics, argumentation, and the education of gifted students. These three theoretical

areas provide a holistic teaching approach that supports students' reasoned thinking about controversial scientific issues, evaluation of multiple perspectives, and scientific decision-making processes (Erduran et al., 2004; Sadler, 2004; Zeidler et al., 2011).

The socioscientific issues teaching approach argues that scientific knowledge cannot be considered independently of its social, ethical, and political contexts and aims to engage students in active reasoning processes within these contexts (Sadler, 2004; Zeidler et al., 2011). Due to their inherent uncertainty, value conflicts, and multiple perspectives, socioscientific issues require students not only to learn scientific concepts but also to evaluate this knowledge alongside its societal consequences (Kolstø, 2001; Sadler & Zeidler, 2005). With these characteristics, socioscientific issues contribute to the development of a more critical and realistic understanding of the nature of science (Lederman, 2007; Yacoubian, 2015).

The Socioscientific Issues Teaching Framework developed by Friedrichsen et al. (2016) proposes that teaching such topics should holistically address context creation, scientific content, ethical and social dimensions, and students' reasoning processes. This framework enables students to position scientific knowledge not merely as content to be conveyed, but as a type of knowledge that is discussed and negotiated in social contexts (Friedrichsen et al., 2016; Sadler et al., 2007). Based on this theoretical framework, socioscientific dilemma cards were developed using Yacoubian's (2015) framework of Critical Thinking and Nature of Science Framework. These cards are designed to clearly highlight epistemological uncertainty, value-laden decision-making processes, and the evaluation of evidence in socioscientific contexts. Through structured dilemmas that encourage students to reason, compare alternative perspectives, and reflect on the nature and limitations of scientific knowledge, the aim is to support students' participation in informed and critical reasoning processes.

Argumentation is defined as a fundamental scientific practice that involves individuals defending their claims with evidence, evaluating alternative views, and reaching reasoned conclusions (Kuhn, 1991; Toulmin, 1958). Toulmin's argument model, with its structure consisting of claim, evidence, reason, supporting evidence, qualifier, and counterclaim components, is widely used in science education research to make students' thinking processes visible (Erduran et al., 2004; Sampson & Clark, 2008). Numerous empirical studies have demonstrated that argumentation-based learning environments support students' conceptual understanding, scientific reasoning, and critical thinking skills (Berland & Reiser, 2009; Osborne et al., 2004).

Argumentation processes conducted in sociological contexts enable students to reason not only based on scientific evidence but also by considering ethical, economic, and social values (Sadler & Zeidler, 2005; Zeidler & Nichols, 2009). In this respect, argumentation stands out as a thinking and learning practice suited to the multidimensional nature of socioscientific issues (Sadler, 2011).

The education of gifted students requires enriched, cognitively demanding, and flexible learning environments that support these students' high levels of curiosity, creativity, and problem solving potential (Renzulli, 2014; VanTassel-Baska, 2013). In this study, the teaching process was structured in line with the Triple Enrichment Model developed by Renzulli (2014). This model aims to deepen students' areas of interest, encourage higher-order thinking skills, and support them in producing original work (Renzulli, 2014; Subotnik et al., 2011).

The integration of socioscientific topics and argumentation-based activities with the Triple Enrichment Model provides a powerful learning environment that activates gifted students' cognitive depth, creativity, and task awareness (VanTassel-Baska, 2013; Zohar & Dori, 2003). This integrated structure supports students not only in producing knowledge but also in critically

questioning it and reconstructing it from different perspectives (Sadler, 2011; Subotnik et al., 2011).

Methodology

This research was conducted using a qualitative research approach with a case study design (Merriam, 2009; Yin, 2018). The case study provides a method suitable for the purpose of this research, as it allows for an in-depth examination of teaching practices conducted within a specific context (Yin, 2018).

The study group consists of gifted secondary school students enrolled at the Science and Art Centre. These Centres are supportive educational institutions affiliated with the Ministry of National Education in Turkey. They aim to identify the individual talents of gifted students continuing their formal education at an early age and to develop their scientific, artistic, and cognitive potential through enriched programmes (Ministry of National Education [MoNE], 2016). The implementation process lasted six weeks and consisted of four main activities, spanning a total of six class hours. The activities were structured in line with socioscientific subject-based teaching principles and designed to encourage students to engage in active discussion and argumentation (Friedrichsen et al., 2016). In the final activity, discussions were held on ethical, economic, and social dimensions using socioscientific dilemma cards based on Yacoubian's (2015) framework of critical thinking and the nature of science.

The activities carried out during the implementation process were structured to support students in gradually developing arguments within the context of socioscientific issues and are described in Table 1.

Table 1. Activities Implemented During the Instructional Process.

Activity	Description of the Activity	Pedagogical Purpose
Activity 1: Asteroid Modeling	Students created physical models to elicit their prior knowledge about the concept of asteroids.	To activate students' prior knowledge and foster affective engagement with the topic
Activity 2: Concept introduction of asteroid mining	The scientific and technological aspects of asteroid mining were explored.	To promote engagement with scientific content and awareness of diverse perspectives
Activity 3: Modeling of Metal Composition	The metals potentially found in asteroids and their possible uses were modeled.	To support the use of scientific evidence and reasoned thinking
Activity 4: Socioscientific Dilemma Cards	Discussions were conducted using dilemmas addressing ethical, economic, and societal dimensions.	To enable students to develop arguments by considering multiple perspectives

The data were examined through descriptive analysis, taking into account the structural characteristics of the arguments (Erduran et al., 2004).

Findings

In this study, the arguments developed by gifted students in the context of asteroid mining were analysed, taking into account their structural characteristics and levels of complexity. During the

analysis process, the students' arguments were classified into three levels: simple, advanced, and complex, using the Toulmin-based argumentation approach (Erduran et al., 2004; Toulmin, 1958).

The findings reveal that a significant proportion of students demonstrated reasoned thinking skills in a socioscientific context. However, these skills varied in terms of argumentation complexity. This classification of arguments into levels is consistent with the developmental progression proposed in the argumentation literature (Erduran et al., 2004; Kuhn, 1991). The distribution of argument types developed by students is presented in Table 2.

Table 2. Types of Arguments Developed by Students.

Argument Level	Frequency	General Characteristics of the Arguments
Simple Arguments	12	Arguments based on a single claim, containing limited justification, and primarily focusing on the potential benefits of asteroid mining
Advanced Arguments	11	Arguments incorporating scientific concepts and concrete examples, but including counterarguments to a limited extent
Complex Arguments	7	Arguments that integrate multiple perspectives, acknowledge potential limitations, and address ethical dimensions, demonstrating a high level of justification

Table 2 shows that students developed arguments most frequently at the basic and advanced levels. The fact that arguments at the basic level were mostly structured around a single claim and contained limited justification suggests that students initially approached the socioscientific topic superficially. This situation is consistent with previous studies showing that students initially evaluate socioscientific issues in a benefit-consequence-oriented manner (Sadler & Zeidler, 2005; Zeidler et al., 2009).

In advanced-level arguments, it was observed that students used scientific concepts more consciously and attempted to support their claims with specific examples and explanations. These findings parallel research showing that socioscientific issue-based learning environments support students' deeper engagement with scientific content (Evagorou & Osborne, 2013; Osborne et al., 2004).

Although complex-level arguments were developed by a more limited number of students, it was determined that these arguments addressed multiple perspectives, ethical concerns, and possible limitations together. Such arguments demonstrate that students incorporate not only scientific knowledge but also value-based reasoning into the process. This points to the potential of socioscientific issues to develop students' reasoning skills that take into account ethical and social dimensions (Sadler, 2011; Zeidler et al., 2011).

Discussion And Conclusion

The findings of this study reveal that socioscientific issue-based teaching meaningfully supports gifted students' argument development skills. The fact that a significant proportion of students moved from simple claim-based explanations to more structured and reasoned arguments confirm the role of socioscientific contexts in promoting scientific reasoning (Sadler, 2004; Zeidler et al.,

2009). This finding is consistent with studies arguing that socioscientific topics move students away from being passive recipients of information and towards active intellectual engagement (Aikenhead, 2006; Ratcliffe & Grace, 2003).

However, the relatively limited number of students developing arguments at a complex level indicates that some components of argumentation require more explicit and structured instruction. In particular, the limited use of higher-level argumentation elements such as refutation, the use of qualifying statements, and the systematic handling of counterarguments is a situation that has also been emphasised in previous argumentation studies (Erduran et al., 2004; Kuhn, 1991; Sampson & Clark, 2008).

From a pedagogical perspective, it can be said that socioscientific issue-based teaching has the potential to activate gifted students' multidimensional thinking skills. The use of a current and controversial topic such as asteroid mining has facilitated students' ability to relate scientific knowledge to ethical and social contexts. This aligns with studies arguing that socioscientific topics bridge learning with real-world problems (Sadler, 2011; Zeidler & Nichols, 2009).

Consequently, this study demonstrates that socioscientific issue-based instruction supports gifted students' argument development processes. Future research should examine how instructional designs that include longer-term applications, explicit argumentation instruction, and structured peer interaction affect students' ability to develop complex and multidimensional arguments (Mercer, 2000; Sampson & Clark, 2008).

Acknowledgement

The authors would like to thank the participating students and the staff of the Science and Art Center for their cooperation and support during the implementation of this study.

ESERA 2025 Copenhagen

Connecting The Dots: Quassr Scores And S^{3}R Profiles In Preservice Teachers' Socio-Scientific Scenarios

Ece Yılmaz Kalemci and Meltem Irmak
Gazi University, Turkey

This study is aimed to explore the relationship between preservice science teachers' (PSTs) socio-scientific reasoning (SSR) levels, evaluated through the Quantitative Assessment of Socio-scientific Reasoning (QuASSR), and their Socio-scientific Sustainability Reasoning (S^{3}R) profiles through self-generated socio-scientific scenarios. A sample of eight PSTs created scenarios addressing a variety of complex socio-scientific issues. The research included qualitative analysis based on the S^{3}R model framework to examine these scenarios. Quantitative results indicated that PSTs showed medium SSR levels, with notable strengths in the perspective-taking dimension and limitations in scepticism . However, scenarios produced by PSTs with lower inquiry scores demonstrated strong S^{3}R profiles, excelling in components such as problematization and values. However, these lower inquiry participants showed deficiencies in the knowledge and governance dimensions compared to their higher inquiry. These findings illustrate a qualitative correlation between SSR and S^{3}R profiles, accompanied by a quantitative discrepancy, particularly in the inquiry dimension. This discrepancy highlights the need for further exploration of measurement methodologies pertaining to the inquiry dimension within SSR assessments. The study contributes to the expanding literature on SSR by illuminating the complex interplay between quantitative and qualitative evaluations. It also offers crucial insights that may inform the development of effective pedagogical strategies aimed at enhancing the SSR skills of future science educators, thereby supporting their capacity to engage with contemporary societal issues critically and thoughtfully. Through this research, it is aimed to advance understanding of how different dimensions of reasoning can coexist and develop within preservice teacher education.

Keywords: Pre-Service Teacher Education, Qualitative Research, Science Education

Introduction

Socio-scientific issues (SSIs) are complex, controversial topics that require individuals to integrate scientific knowledge with social, ethical, and personal values to make informed decisions (Zeidler et al., 2005). SSR is usually viewed as a multidimensional construct, comprised of complexity, inquiry, perspective-taking and scepticism dimensions (Romine et al., 2017). Complexity reveals that SSIs cannot be addressed with singular and simple solutions due to the multi-layered structure of issues. Perspective-taking indicates that different stakeholders involved in SSI topics can develop different but contextually valid solution proposals in line with their individual priorities, beliefs, and prejudices. Inquiry emphasizes that SSIs involve numerous questions awaiting answers in both scientific and social contexts and therefore require a continuous process of research and debate. Scepticism requires careful selection of information sources related to these issues; it necessitates questioning whether sources are biased and whether the data presented is reliable (Sadler et al., 2007) Together, these dimensions indicate how well individuals can apply scientific understanding and reasoning within the context of SSIs while integrating relevant social and ethical considerations. It is especially important for preservice science teachers to develop strong SSR skills, because their reasoning practices will influence the framing, discussion, and negotiation of socio-scientific issues in future classrooms.

Developing socio-scientific reasoning (SSR) skills is crucial for citizens to effectively engage in contemporary societal challenges such as climate change, genetic engineering, and energy production (Sadler et al., 2007). Assessing PSTs' SSR through self-generated SSI scenarios

provides a valuable window into their understanding and application of these complex concepts (Ekborg et al., 2009). By creating their own scenarios, PSTs demonstrate their ability to identify and analyse key issues, consider different perspectives, and integrate scientific knowledge with ethical and social considerations.

The Quantitative Assessment of Socio-Scientific Reasoning (QuASSR) is a well-established instrument for measuring scientific reasoning skills (Romine et al., 2017). However, it primarily focuses on assessing SSR based on given cases. It is limited in its capacity to analyse discourse or other student-generated artifacts like SSI scenarios. In contrast, the Socio-scientific Sustainability Reasoning (S^3R) model offers a structured rubric for examining reasoning across multiple dimensions in student-generated artifacts, including collectively produced texts and self-generated socio-scientific scenarios (Morin et al., 2014). Focusing on student-generated artifacts through qualitative analysis makes it possible to examine how individuals define socio-scientific problems, develop and justify arguments, draw on scientific and contextual knowledge, and deal with uncertainty within these issues. The S^3R framework includes six interrelated components: problematization, interactions, knowledges, uncertainties and risks, values, and governance. Problematization focuses on recognizing the multidimensional structure inherent in the process of addressing an issue and understanding that the problem cannot be confined to a simple framework. Interactions emphasize awareness of the mutual relationships between components within dynamic systems and the complexity created by these relationships. Knowledges focus on how different sources of knowledge (experiential, social, local, etc.) are brought together and related to academic knowledge. Uncertainties and risks involve approaching claims of knowledge with caution, accepting that knowledge is contextual, and expressing scepticism at the epistemological level. Values focus on the explicit articulation of value-based attitudes and the justification of these attitudes. Governance addresses how regulatory mechanisms offer opportunities for citizen participation in the process of balancing different interests. S^3R model provides a valuable rubric for assessing various levels of reasoning in different dimensions in student-generated artifacts (collective text on wikis) (Morin et al., 2014).

This study investigates the relationship between QuASSR-assessed SSR levels and S^3R profiles in PSTs' scenario development. By analysing the scenarios developed by preservice teachers, we examined how their socio-scientific SSR skills, as measured by QuASSR, relate to their S^3R profiles. This research will contribute to a deeper understanding of the multifaceted nature of SSR and provides valuable insights into developing practical pedagogical approaches that foster SSR skills in future science educators. Our research question is as follows:

> What is the relationship between QuASSR-assessed SSR levels and S^3R profiles in pre-service science teachers' socioscientific scenario development?

This study will contribute to a growing body of research on SSR by exploring the interplay between quantitative and qualitative assessments. By examining the relationship between QuASSR scores and S^3R profiles, we can better understand the factors that contribute to effective SSR in future science educators.

Methods

The participants of the study consisted of 8 pre-service science teachers (PSTs) (1 male, 7 female). There were 12 participants at the beginning; however, 4 of them was removed from the study as their scenarios did not have characteristics of SSI. They did either not have any conflict or not include science. Within the scope of the 'Socio-scientific Issues in Science Teaching' elective course, quantitative data were obtained from the PSTs using the QUASSR (Quantitative Assessment of Socio-scientific Reasoning) scale, and qualitative data were obtained by asking

them to create a socio-scientific scenario. In the scope of the course, the nature of SSI were discussed in the first week. In the second week the PSTs were asked to fill in the QUASSR test. Then based on what they learned about the nature of SSI and the example scenarios they read in QUASSR test, they were asked to create their own scenarios. They were allowed to select any topic they were interested, either any topic they are experiencing or witnessing or any hypothetical topic they were expecting to be an issue in the future. Then, they were given time to make research to create their scenarios. The limited number of participants was suitable for the qualitative approach of this study, since the goal was to conduct a detailed examination centered on the reasoning patterns demonstrated through self-generated socio-scientific scenarios.

The QUASSR scale developed by Romine, Sadler, and Kinslow (2017) includes two socio-scientific cases (Hydraulic Fracking at Pavilion Wyoming and Branville Bay) with 11 two-stage questions each. These are related to the four sub-dimensions of socio-scientific reasoning (SSR): complexity (4 questions), inquiry (6 questions), perspective-taking (4 questions), and scepticism (6 questions). The Cronbach alpha reliability coefficient of the scale was calculated as 0.79 by Romine et al. (2017) and 0.82 by Irmak (2020), who adapted it into Turkish. The data from the QUASSR scale was analysed in line with the framework proposed by Romine et al. (2017). According to this framework, 0 represents low-level, 1 represents medium-level, and 2 represents high-level SSR. The average score for each SSR dimension for each PSTs were calculated using IBM SPSS software. Then, the PSTs were grouped as low-level and high-level SSR based on their QUASSR scores. PSTs having less than the mean score of the group were categorized as low-level SSR while the rest were categorized as high-level SSR group.

The scenarios were analysed according to the S^3R (socio-scientific sustainability reasoning) model consisting of 6 components (problematization, interactions, knowledges, uncertainties and risks, values and governance) with the help of the rubric developed by Morin et al. (2014). Radar charts were drawn for S^3R profiles of two SSR level groups. Radar charts were applied as a visual analytic to describe the relative distribution of S^3R components between groups, and to compare the overall reasoning profiles. To ensure the trustworthiness of the study, different data collection methods were used, and the findings were interpreted together (triangulation). In addition, 35% of the scenarios created by the PSTs were analysed by both researchers, and the inter-coder reliability was calculated 0.83 (acceptable value) using the consensus/(agreement+disagreement) formula proposed by Miles and Huberman (1994).

Results

Table 1. SSR Scores of PSTs.

Participants	Complexity	Inquiry	Scepticism	Perspective-Taking	Total SSR
PST_1	1,25	1,17	0,33	1	0,9
PST_2	0,75	1,33	1,5	1	1,2
PST_3	1,5	0.83	1,67	1,25	1,3
PST_4	1,5	1,17	1,83	2	1,6
PST_5	0,5	1.67	0	1	0,8
PST_6	1,25	1,25	0,17	1,5	1
PST_7	1,5	1,5	1,33	1,5	1,25
PST_8	1,5	1,5	1	2	1,6
Mean	1,22	1,29	0.98	1,41	1,21

PSTs SSR scores ranged from 0.98 to 1.41 with a mean of 1.21 indicating medium SSR. The lowest mean score was found in scepticism dimension (M=0.98) and highest in perspective taking dimension (M=1.41), which is similar to the result of Irmak (2020). These findings suggest that PSTs generally demonstrate moderate level of SSR, which varies across different dimensions. SSR and S^3R scores of the PSTs are provided in Table 1 and Table 2.

When PSTs scenarios were inspected, it was realized that their selected topics were about various topics: climate change (2), gene therapy (2), pharmacology, space research, genetically modified foods, and cosmetics. An example scenario (PST_4) about food capsules (GMF) can be given as follows:

> "In the future, as humanity's resources decrease, scientists have developed a hunger-relieving capsule. This capsule provides the nutrients that a person needs, leading to a change in food production. Not feeling hungry all-day results in increased productivity and resource savings, which are among the advantages of this capsule.
>
> However, just as any scientific development has advantages, it also has disadvantages. The effects of this capsule will be of the nature of a medicine, and like any medicine, they will have negative side effects that will affect people. Furthermore, this capsule may be addictive. Uncontrolled use will harm human health. Lastly, it reduces socialization because eating food is a social activity. People who use the capsule in just one sip will become more dependent on the easily accessible hunger-relieving capsule."

PSTs' scenario texts were analysed based on S^3R model. Their highest values were found in problematization dimension (M=2,63) while the lowest dimensions were knowledge (M=1) and uncertainties and risks (M=1,13).

Table 2. S^3R Scores of PSTs.

Participants	Problematization	Interactions	Knowledges	Uncertainties and Risks	Values	Governance
PST_1	3	3	1	1	2	3
PST_2	2	2	1	1	2	3
PST_3	3	2	1	2	3	2
PST_4	4	2	1	1	3	1
PST_5	1	1	1	1	2	1
PST_6	2	1	1	1	2	1
PST_7	3	2	1	1	3	2
PST_8	3	3	1	1	3	3
Mean	2,63	2	1	1,13	2,5	2

Based on S^3R scores radar charts were generated to illustrate the profiles of PSTs with different SSR levels. Each axis of the radar chart represents a component of the S^3R framework: Problematization, Interactions, Knowledges, Uncertainties, Values, and Governance. The distance of each line from the centre indicates the level of each component within the S^3R profile.

As in Figure 1, participants with higher SSR total scores (average of all dimensions together) tend to demonstrate stronger S^3R capabilities across all dimensions. This suggests that a strong foundation in SSR is crucial for developing a holistic understanding of complex SSI.

In Figure 2, each radar chart represents the S3R profiles of the PSTs grouped by their performance on a specific dimension of the QuASSR instrument (Complexity, Perspective Taking, Inquiry, and Scepticism). When the radar chats created for four dimensions of SSR differently, some

inconsistencies with the one drawn based on SSR total scores are seen. While the overall trend was evident, notable inconsistencies emerged when examining the specific dimension of inquiry. Low-inquiry group's scenarios were assessed to be better in terms of most of the aspects of S^3R except for interactions and knowledges.

Figure 1. S^3R Profile of PSTs based on SSR Total Scores.

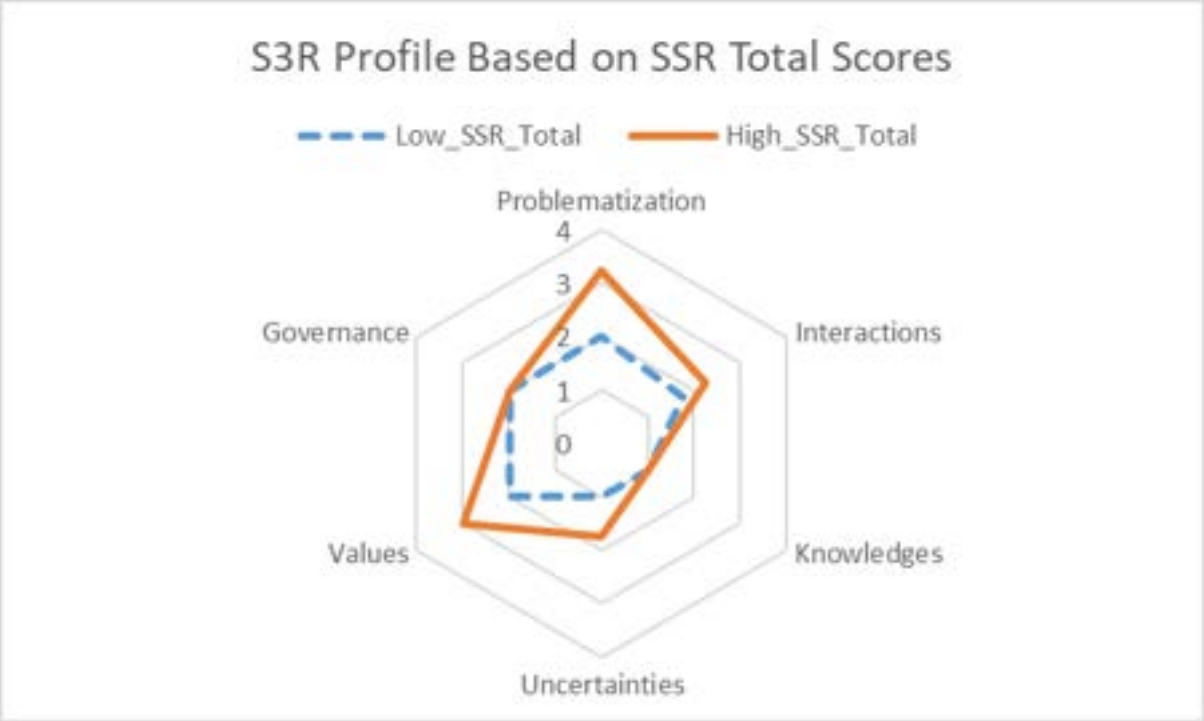

Figure 2. S^3R Profile of PSTs based on Different Dimensions of SSR.

The inquiry dimension of SSR refers to understanding that there are many questions that need to be answered scientifically and socially in SSIs and that SSIs are open to continuous research in the scientific and social field, feeling the need to ask more questions and research more new information in the discussion of SSIs (Romine et al., 2017). Therefore, the radar charts indicated

that contrary to other SSR skills, inquiry is not an indicator of high-quality scenarios in terms of reasoning.

Discussion

This study investigated the relationship between QuASSR-assessed SSR levels and S^3R profiles in preservice science teachers. While the findings suggest a positive correlation between higher QuASSR scores and stronger S3R profiles, the study also highlights the limitations of relying solely on quantitative measures like the QuASSR to fully capture the multifaceted nature of SSR In particular, the results for the inquiry dimension suggest that quantitatively assessed SSR skills do not always align with the quality of reasoning evident in self-generated socio-scientific scenarios. Quantitative methods often fail to adequately capture the social, institutional, and relational contexts that shape values and reasoning (Morris, 1991). The QuASSR, for example, may not fully account for the diverse social and cultural backgrounds of the PSTs, which can significantly influence their perspectives on SSI. Conducting a qualified reasoning and interpretation process regarding SSI requires individuals to have a certain level of mastery over the relevant topics. In this context, selecting topics that individuals are familiar with in terms of knowledge and experience in studies addressing SSI will yield more reliable results (Tüzüngüç, Doğan & Han Tosunoğlu, 2021). However, in scenario-based and quantitative measurement tools such as QuASSR, differences in PSTs' prior knowledge of the scenario under consideration may cause the measured levels of SSR to be affected by scenario-specific knowledge gaps. This situation carries the risk that findings obtained with QuASSR may reflect PSTs' mastery of the scenario topic rather than their actual reasoning abilities, limiting the scale's use as a context independent assessment tool. Additionally, the focus on standardized questions may have overlooked the richness of qualitative data, such as personal experiences, interpretations, and emotional responses, which are crucial for understanding the complexities of SSR. Self-generated scenarios analysed through the S^3R framework help make these implicit aspects of reasoning more appearent. As noted in the QuASSR validation process, inconsistencies across different scenarios highlight the potential for biases and limitations in quantitative assessments (Romine et al., 2017). Conversely, while qualitative methods can provide deeper insights into SSR, they may lack the generalizability and precision that quantitative approaches offer. A balanced integration of both methodologies could enhance the assessment of SSR, allowing for a more comprehensive understanding of this complex construct. In addition, these findings indicate that quantitative and qualitative approaches address different aspects of SSR.

ESERA 2025 Copenhagen

Unlocking Perspectives: Exploring Initial Design Principles Of Culture-Based Socio-Scientific Issues Training For Indonesian Pre-Service Biology Teachers

Aprillyana Utami[1,2], Andri Christodoulou[1] and Marcus Grace[1]
[1]University of Southampton, United Kingdom
[2]Sunan Kalijaga State Islamic University Yogyakarta, Indonesia

In the last two decades, socio-scientific issues (SSIs) have been crucial in advancing scientific literacy. Students' socio-cultural backgrounds need to be considered in SSI-based education because cultural beliefs might influence their initial knowledge and guide their decision-making. SSIs require competent teachers, so it is important to introduce SSI-based education to pre-service biology teachers (PBTs), especially in Indonesia, which is known for its diverse subcultures and has limited research on SSIs. Currently, limited research examines how PBTs incorporate students' socio-cultural backgrounds when designing their CBSSIs classes. A deeper understanding of Indonesian lecturers and PBTs' perspectives is needed to understand how to develop a CBSSIs training programme for Indonesian PBTs to strengthen their skills in helping students navigate the complexity of science and culture. In developing the training programme, understanding the current landscape in teaching and learning SSIs and CBSSIs in the Indonesian context and the needs and aspirations of the CBSSIs training programme from lecturers' and PBTs' perspectives is needed. Semi-structured interviews were used to explore these perspectives. The results showed that teaching and learning SSIs is not done explicitly. Lecturers and PBTs shared their needs and aspirations for the training programme. Based on the results, five initial design principles (IDPs) were extracted to develop the training programme, which are (a) Understanding SSIs/CBSSIs, (b) Experiential Learning, (c) Collaboration and Reflection, (d) Accommodating Third Space, and (e) Theory and Practice. This work provides a basis for science educators on what principles to use when introducing CBSSIs to pre-service teachers.

Keywords: pre-service teacher education; teacher preparation; sociocultural perspectives; cultural diversity; socio-scientific issues

Introduction

In the last two decades, socio-scientific issues (SSIs) have been crucial in advancing scientific literacy. Ratcliffe and Grace (2003, p. 1) defined SSIs as "any issue which has a basis in science and has a potentially large impact on society". In SSI-based education, students' socio-cultural backgrounds need to be considered (Zeidler & Kahn, 2014) because cultural beliefs might influence their initial knowledge and guide their decision-making (Wahono et al., 2021). However, Ladachart and Ladachart (2021) argue that teaching SSIs using cultural contexts, also known as Culture-Based Socio-Scientific Issues (CBSSIs), is mainly uncommon. Nelson and Braff (2020, p. 6) define culture as "a set of beliefs, practices, and symbols that are learned and shared". Since teaching SSIs requires competent teachers (Subiantoro et al., 2021), and the success of navigating from everyday life to science classrooms and vice versa depends on the teachers (Aikenhead & Jegede, 1999), it is important to introduce SSI-based education to pre-service biology teachers (PBTs).

Currently, limited research, if any, examines how PBTs incorporate students' socio-cultural backgrounds when designing their CBSSIs classes; but doing so is important for fostering meaningful learning. Researchers have attempted to introduce SSIs to pre-service teachers (PSTs), such as Evagorou et al. (2014), focusing on how PSTs integrate content and pedagogical knowledge simultaneously; Espeja and Lagarón (2015) examined how PSTs conceptualise SSIs

using four categories: SSIs topics, controversy, uncertainty, and argument, and exploring PSTs' appreciation to teach SSIs; and Espeja and Couso (2020) emphasised that in preparing PSTs to teach SSIs, the lecturers should facilitate them to experience SSIs lessons themselves while also guiding them to design, implement and reflect on SSIs lessons. However, the efforts to introduce SSIs to PSTs in teacher training have not yet drawn on students' socio-cultural backgrounds despite the importance of providing meaningful and personally relevant science teaching. A deeper understanding of Indonesian lecturers and PBTs' perspectives is needed to understand how to develop a CBSSIs training programme for Indonesian PBTs to strengthen their skills in helping students navigate the complexity of science and culture. The research uses the Indonesian context because Indonesia is known for its diverse subcultures (Forshee, 2006). Also, there is still limited study of Indonesia's science education related to SSIs (Subiantoro et al., 2021). The research question is *What initial design principles can be used to develop a CBSSIs training programme for Indonesian PBTs*?

Methods

The study used a qualitative methodology. In answering the research question, a literature review and interviews were employed. Semi-structured online interviews were conducted with two Indonesian lecturers and three PBTs from one Indonesian public university. The selection criteria for the lecturers were those who had published a paper about SSIs, and the PBTs were based on their mixed abilities and coming from different parts of Indonesia. The consent forms were collected before the interviews. The interview protocols were adopted from the need analysis questions from McKenney and Reeves (2012) and questions from Subiantoro (2017) to explore the current landscape in teaching and learning SSIs and CBSSIs in the Indonesian context and ask lecturers and PBTs' needs and aspirations of the training programme. The interviews took around 1 hour each, mainly using the Indonesian language. However, some participants also spoke some English and Javanese (local language). After the five interviews were conducted, the interviews were transcribed for analysis. Then, the research participants were asked for approval to use the transcript. All of them agreed that the transcripts could be used in this study. The analysis was conducted in the original language spoken to maintain the nuance of the languages (Taber, 2018). The transcribed data were analysed using thematic analysis with the help of NVivo to extract initial design principles (IDPs) for a CBSSI-based training programme.

Results

The analysis reveals that the lecturers do not explicitly teach SSIs, as exemplified:

> "I basically do not structure it or do not, in the quote, "explicitly" like... "Let's prepare Biology education students to master SSI so that they can then implement the SSI learning model in schools". No. It's not explicitly structured the lesson like that" – Lecturer 2.

However, in the interview with the PBTs, PBT3 emphasised that they want to be explicitly taught SSIs. This preference can be incorporated as one of the IDPs, specifically focusing on *Understanding SSIs/CBSSIs,* as this is important in developing the training programme. It aligns with Anagün and Özden's (2010) statement that to be confident in teaching SSIs, understanding SSIs serves as a basis for introducing SSIs to PBTs, enabling them to teach CBSSIs.

In addition, Kolb's (1984) experiential learning theory highlights the importance of learning through experience. This theoretical perspective informed the training programme, equipping PBTs with authentic practice in designing and teaching CBSSIs. This idea also emerged from the interview, as the lecturers mentioned that PBTs should experience CBSSIs first-hand to help them understand the concept of SSIs/CBSSIs, suggesting that *Experiential learning* can be another IDP, where lecturers involve PBTs with direct experiences, as stated by Lecturer 1:

> "We, as lecturers, apply SSI-based education in the class. Then, we told PBTs that what is being applied is SSI-based education. Or we can do it the conventional way: PBTs are told or asked to look for it [SSI-based education] and then discuss it in class. But I think I'm more interested in the first one. By implementing it ourselves, the PBTs will experience it [SSI-based education] themselves." – Lecturer 1.

Furthermore, PBTs' understanding of SSIs/CBSSIs can be promoted through collaboration, such as a co-design and co-teaching scheme (Foulk et al., 2020; Huang & He, 2023), followed by a reflection session to enhance their understanding (Loughran, 2002). PBTs also explained that they need guidance in selecting and understanding appropriate issues for CBSSIs and analysing SSIs from diverse perspectives. PBTs also want their lecturers to support them in discussing and working collaboratively with peers in designing CBSSIs lesson plans, which leads to IDP *Collaboration and Reflection,* as PBT3 stated, "Maybe I only understand reproduction issues from my ethnicity. Maybe issues related to the circulatory or respiratory systems can be learned from other ethnicities." – PBT3.

The statement above from PBT3 also implied that the training should leverage PBTs' cultural background to introduce SSIs/CBSSIs. This also aligns with Lecturer 2's concern that teachers need to address SSIs in culturally different settings when designing CBSSIs lessons. The third space concept, arising from the literature review, will accommodate how science, culture, and society intersect in CBSSIs. In teaching SSIs/CBSSIs, PBTs need to address students' different cultural backgrounds (Tatham-Fashanu, 2023), facilitate the negotiation process between their everyday world and science class (Bhabha, 1990, 1994; Glasson et al., 2010), and navigate the tensions in SSI classrooms (Lee et al., 2020). These lead to the IDP of *Accommodating Third Space*.

Both lecturers and PBTs expressed that PBTs should be guided by lecturers in designing and implementing CBSSI lesson plans, which leads to IDP *Theory and Practice*, as stated by Lecturer 1, "I think it [the CBSSI lesson plans] would be more meaningful if implemented … Hopefully, everything will be implemented from the concept to the implementation. But if not, at least until the implementation." – Lecturer 1. It implies that, in addition to understanding the theory, PBTs need to practice what they have learned about teaching SSIs/CBSSIs to minimise the gap between theory and practice (Korthagen, 2010).

All five IDPs were extracted from the data analysis presented in Figure 1. These IDPs can be used to develop a CBSSIs training programme.

Figure 1. Initial Design Principles of CBSSIs Training Programme

Discussion and Conclusions

The study revealed lecturers' and PBTs' perspectives on the current teaching and learning of SSIs and CBSSIs and their needs and aspirations regarding developing the CBSSIs training programme. Enabling PBTs to understand SSIs and CBSSIs can be done through direct experiences as extracted to IDPs Understanding SSIs/CBSSIs and Experiential Learning. These findings align with research from Espeja and Couso (2020), who emphasised using the Experience-Design-Implement-Reflect pattern in preparing PSTs to teach SSIs. Espeja and Couso's (2020) work also aligns with the other IDPs: Collaboration and Reflection and Theory and Practice. PBTs collaborate with their peers in designing the CBSSIs lesson plan and reflect on their teaching skills. PBTs will also engage with theory and practice by implementing the CBSSIs lesson plan directly. This research found that Accommodating Third Space as an initial design principle is needed in developing the training. The third space theory provides a valuable framework to bridge students' background knowledge and science concepts in CBSSIs class. In the 'third space', students negotiate between their existing knowledge from everyday experiences and the novel concepts they encounter in science (Glasson et al., 2010). The third space can be used to explore and understand how science, culture, and society intersect to identify productive and culturally sensitive ways of negotiating science-society-culture in science education classrooms. In summary, five initial design principles (IDPs) were extracted in this study to develop the training programme, which are (a) Understanding SSIs/CBSSIs, (b) Experiential Learning, (c) Collaboration and Reflection, (d) Accommodating Third Space, and (e) Theory and Practice. This study provides a basis for science educators on what principles to use when introducing CBSSIs to pre-service teachers.

Science Education And Communication: Innovative Methods To Promote Scientific Literacy

Susanna Puecher and Roberta Silva
University of Verona

The paper presents my Ph.D. research project, which aims to understand how to connect Science Communication (SC) and Science Education (SE) through edutainment, in order to develop Scientific Literacy (SL), which is necessary to cope with contemporary scientific and technological development (EC, 2015). To achieve this goal, we need innovative SE curricula that develop critical thinking (Akcay, 2018) and consider informal and non-formal educational contexts, such as SC on social media. The presented research is structured in two phases: an integrative review to identify the connecting elements of SC and SE through edutainment, and an educational research study aiming to exploit the educational benefits of SC in primary and middle schools. The results of the review allowed the creation of a teaching project based on active and cooperative learning methodologies, involving students as active users of SC and promoting SL. The research follows a phenomenological approach to explore students' and teachers' experiences and their meanings (Mortari, 2007) through different data collection methods. The final aim is to explore the benefits and challenges of SC in SE and to generate guidelines for STEM education to optimise and innovate the teaching experience.

Keywords: Science Education, Science Communication, Scientific Literacy

Introduction

This project addresses the need to enhance Scientific Literacy (SL) among 21st-century citizens (Serpa et al., 2021) in response to rapid scientific and technological development (EC, 2015). SL integrates knowledge and critical thinking (Ah-Namand & Osman, 2018), facilitates informed decision-making and responsible citizenship (EC, 2015) and develops through both formal setting with Science Education (SE) and non-formal setting with Science Communication (SC) (EC, 2020a). To be effective, SE should adhere to a multidisciplinary, reflective approach that fosters both disciplinary expertise and critical thinking (Akcay, 2018). As regards the SC, it raises awareness of STEM issues, fosters public trust in science (EREA, 2022), and conveys messages through accessible language, interaction and engagement, creating edutainment, an entertaining form of education (EC, 2020b). Moreover, digital technologies (which often play an essential role in conveying SC) facilitate interactive relationships between disseminators and audiences, promoting critical perspectives and responsible behaviour (López-Goñi & Sánchez-Angulo, 2018).

It is clear that SE and SC have areas of fruitful interaction, but despite their shared aims, their connection remains absent in educational practice (Everhart, 2009), due to a lack of research-based guidelines (Lewenstein & Baram-Tsabari, 2022). However, science communicators on social media contribute to public education, revealing a latent synergy between SE and SC. This dynamic became particularly evident during the COVID-19 pandemic, which underscored the need for education to address the infodemic through SC (WHO, 2020). As this occurs without explicit pedagogical frameworks, it can lead to an underestimation of the educational and formative potential of this tool, or its ineffective use.

This illustrates the urgency of innovation in STEM education, which requires a theoretical and practical bridge between SE and SC on social media through edutainment. This research aims to highlight its benefits and risks, offering insights, instruments and guidelines for STEM education,

shaped for teachers and shareable within different contexts, to innovate the teaching experience (Jorde & Dillon, 2012; Akkerman et al., 2021).

Research Design And Methods

Starting from the element that emerged from the initial literature review, the research is based on two research questions:

What are the most effective prompts offered by science communicators on social media, connected with edutainment, that it is possible to use to connect SC e SE positively?

How can be designed and realized teaching and learning project in the STEM area for different school levels (primary and middle school) which exploit the potential of SC in terms of engagement and use it as a stimulus to the development of SL?

The research design is structured into two phases to answer the two research questions. The first is an integrative review, which aims to identify the relevant theory and effective practices. The second is an educational research study, designed according to the results of the literature review, and implemented in primary and middle schools to foster SL development and assess its effectiveness.

Integrative Review

The first phase aimed to investigate, through a literature analysis conducted by an integrative review method, the relationships and implementation lines between SC on social media and SE through edutainment. The integrative review encourages complex phenomena investigation by connecting theoretical and empirical literature and focusing on the context, processes and subjective elements of the phenomenon, revealing different perspectives (Whittemore & Knafl, 2005). The databases consulted were JStore, Eric, Scopus, while the search strings contained the terms: “science education”, “science communication”, “edutainment” and “social media”. The search period covered twenty years, from January 2004 (the year Facebook appeared) to January 2024. Thirty-two papers were selected, and their analysis offered a theoretical background and practical-operational suggestions useful for the subsequent teaching project. They present teaching activities that link SC and SE through edutainment, employing different social media to propose a scientific mindset and content (Makarius, 2017) and facilitating learning (Swensen et al., 2014). Such tools are relevant for young people (Danielsson et al., 2023), as they share information and interests creating discussing networks (Bigelow & Kaminski, 2016). In the education context, they can promote peer-to-peer knowledge (Karahan & Roehrig, 2015), debate lesson-related content, and foster a process of knowledge co-construction (Dubovi & Tabak, 2020). This facilitates students' involvement both inside and outside the classroom, increases collaboration and creates a sense of community, leading to enthusiasm, motivation and engagement (Caratozzolo et al., 2022). Furthermore, they encourage content acquisition, creative thinking, problem-solving, and a reflective and searching perspective on scientific content (Bigelow & Kaminski, 2016). Such skills are needed as people increasingly search for information, including scientific information, online (Karahan & Roehrig, 2015). Individuals follow scientific content online for personal and educational interests (Rosenthal, 2018), but there is a risk that they assimilate information without critical thinking (Szu et al., 2017). Indeed, social media are nowadays, together with the school, among the educational contexts in which the scientific learning process takes place (Reid & Norris, 2016). In order to maximize the transformative potential presents in the relationship between SE and SC, it is necessary to design and promote innovative teaching methods that consciously integrate them. They should be linked with a specific effort aimed at educating young people to use all the tools at their disposal as a

stimulus to inform themselves and stimulate their curiosity, such as social media, which today represent a priority vehicle for the SC.

Teaching Project

The integrative review provided essential insights for the design of a teaching project that integrates SE and SC on social media through an edutainment approach. These findings served as the basis for the creation of two different teaching programs, which were adapted to the specific educational stages, one for fifth-grade primary and one for third-grade middle school students, and consisting of four/five sessions, lasting one to two hours each. The learning objective is to foster SL by promoting the development of scientific knowledge, as well as critical thinking and digital and information skills. To achieve this, the project employs Active Learning and Cooperative Learning methodologies. It emphasizes interactive activities that encourage students in active participation and engage them in both practice and reflective analysis moments. The project is structured into four phases, each of which is presented through practical activities related to the participants' personal experiences to facilitate understanding of the topics:

1. *Critical analysis of SC content*: students identify key indicators of effective SC (e.g. clarity, accuracy, engagement, etc.) reflecting alone and in pairs. This phase is useful for assessing the content reliability.
2. *Research on a scientific content*: after viewing a SC content video, in small groups, students define their topic and search sources and online information about it. During this phase, they assess the reliability and quality of the sources.
3. *Production of SC content*: students work in small groups to design communication plans and create videos using digital tools. The activities enhance and consolidate their learning.
4. *Sharing and discussing:* students present their content both in class and on dedicated social media platforms (created with appropriate ethical considerations of their use in an educational context), trying to be science communicators.

These steps are aimed at developing SC skills, from the search for information to the effective presentation of content, promoting teamwork and critical evaluation of sources and social media content. The goal is to shift students from passive to active consumers, enhancing their awareness of SC mechanisms through its implementation and fostering their role as student researchers and communicators, integrating scientific knowledge within a broader framework of knowledge and experience. Moreover, teaching programs were refined in collaboration with classroom teachers to ensure effective integration into existing curricula, addressing both content and pedagogical needs in different contexts. Meanwhile, an educational research study was conducted to assess the program's effectiveness, adopting a phenomenological approach to examine students' experiences and the meanings they attributed to them (Mortari, 2007).

Data Collection

The project was implemented in six schools located in different areas: the city centre, the suburbs and outside the town. Throughout the implementation phase (before, during and after), data were collected using various methods to capture different dimensions of the project.

Firstly, field notes and eye-guides completed during participant observation, together with pre-intervention teacher interviews, were used to understand the contexts and their specific needs, so that the educational project could be adapted accordingly. Pre- and post-intervention teacher interviews also provided insights into teachers' perspectives on the project, helping to identify its effectiveness and weaknesses from the viewpoint of key participants. Alongside the teachers' thoughts, students' opinions were gathered through self-assessment activities and audio

recordings of classroom discussions. Further data were collected to evaluate the project's two key objectives. The first aim focused on the development of critical abilities in evaluating sources and videos, and was examined through pre- and post-tasks, along with analysis, reflections and discussions on two videos, classroom audio recordings of dialogues and students' online searches. The second goal concerned the ability to produce a video, and was investigated using data on communication designs, student-created videos, and audio-recorded discussions.

Data Analysis

The data analysis is ongoing and follows a phenomenological approach, which requires conducting research in the field and observing phenomena as they occur, with the aim of understanding the lived experiences of participants (Mortari, 2007). The data are analysed using inductive content analysis (Elo & Kyngäs, 2008) and crystallisation technique (Ellingson, 2009).

Inductive content analysis is useful as often used to manage large volumes of textual data from diverse sources (Prasad, 2008), as in this research. It requires to transform the data into content-related labels and categories, creating a coding system (Elo & Kyngäs, 2008). Specifically, labels emerge directly from the text data becoming a coherent description of the studied phenomena (Elo & Kyngäs, 2008; White & Marsh, 2006). Different coding systems can be compared, allowing to create logical inferences between them. Moreover, the crystallisation technique facilitates the integration of these diverse forms of analysis into a coherent narrative. The aim is to gain a deep understanding of the phenomena by examining them from various perspectives using different types of data in order to reveal their nuances (Ellingson, 2009).

All the collected data cannot be analysed using the same method. Particularly, the videos produced by children require the development of a specific framework and an evaluation grid. This framework was developed through a literature review conducted using content analysis, which identified key elements to consider when producing SC videos for social media. Based on these elements, a supporting instructional tool was developed and proposed to the children, and an evaluation grid was derived from it and used to analyse the video data.

First Results

As seen, data collected allow to investigate different dimensions of the project, the results will describe these elements. Specifically, the educational research study investigates SC's educational potential by observing and analysing the setting, people interactions, their experiences, thoughts and learning objectives, allowing to investigate the effectiveness and areas for improvement of the project. Firstly, a preliminary context analysis was conducted using participant observation, eye guides and semi-structured interviews with teachers. Based on the data collected, the teaching project was refined according to the characteristics of each classroom, ensuring both research relevance and pedagogical applicability. For instance, the online information search activity was implemented in different ways based on dialogue with teachers regarding students' abilities. In particular, in some primary school classes, students could not find information online alone due to lack of digital skills, which is understandable given their age. For this reason, we decided to provide them with pre-selected online materials, including the necessary information for a reflection, such as source links, text and pictures. In these cases, the aim of the activity was not to find information online on their own, but rather to encourage critical reflection on the provided materials with the guidance of adults. Therefore, the program was designed and implemented in collaboration with teachers, recognising and respecting their professional expertise and class knowledge.

The remaining data are currently under analysis, with a particular focus on the perspectives of the main actors (students and teachers), as well as the two central themes. The first concerns the

development of critical thinking skills in the evaluation of online sources and videos. The second relates to students' ability to produce SC videos for social media, an activity that enables students to internalise the effective elements of such videos. Through this process, they become more aware of, and more critical of, the potential risks and benefits of online SC videos in their daily lives. Both abilities are necessary for developing students' SL, as they encourage critical thinking about scientific content and the development of an informed and conscious awareness of them in relation to everyday situations.

Conclusion

In conclusion, the project included an integrative review phase to identify the theoretical foundations and practical-operational insights present in the literature on the integration of SE and SC through edutainment on social media. The results of this review guided the design of an educational project aimed at promoting this integration in order to effectively fostering SE through an interactive and engaging approach that encourages students' critical thinking and SL, transforming them from passive to active users of SC. This process is part of an educational research study that examines the effectiveness of the teaching program by identifying both its strengths and limitations. To achieve this, various types of data were collected throughout the project's implementation, such as participants' perspectives and data on educational goals, that are currently being analysed.

Finally, the project aims to develop guidelines for STEM education innovation that align with technological advancements while bridging formal and informal learning environments and promoting informed decision-making and responsible citizenship among students. The research wants to contribute to the development of more effective and engaging STEM education strategies addressing the current social context.

ESERA 2025 Copenhagen

Understanding AI In Secondary School Education: How Technical Knowledge Affects Students' Technology-Critical Understanding

Sine Zambach[1], Cecilie Svane Pedersen[2], Elisa Nadire Caeli[3], Morten Misfeldt[4] and Jeppe Bundsgaard[5]
[1]Copenhagen Business School, Denmark,
[2]Danish School of Education, Aarhus University, Denmark,
[3]Danish School of Education, Aarhus University, Denmark,
[4]University of Copenhagen, Denmark
[5]Danish School of Education, Aarhus University, Denmark

Machine learning is widely used in society today. It is therefore crucial that children and young people develop insights into how machine learning works, as well as technology-critical skills to discuss and impact how AI and machine learning are used today. In this study, we present a first analysis to understand the interplay between technical and technology-critical skills, focusing on the reflections of lower secondary school students from interviews. Preliminary findings indicate that while some students developed an understanding of machine learning mechanisms, others struggled to relate machine learning to the real world. We discuss which relevant technical aspects of machine learning are needed for students to become able to develop technology-critical skills. Future research should explore how focusing on technical aspects in a deeper and more specific way affects students' technology-critical understanding.

Keywords: AI Literacy, Critical Thinking, Secondary Education

Introduction

In educational research there is an awareness of the importance of preparing students for a society that extensively uses AI. Curricula about AI and machine learning have been developed (Chiu, et al., 2022; Touretzky et al., 2023), and studies on societal impacts of AI have been conducted in relation to AI literacy (Lee & Kwon., 2024; Demir & Güraksın., 2022; Zambach, 2025). Those works are of importance for future generations' understanding of this domain in regard to taking a critical stance on the use and development of AI in society (Elicer et al., forthcoming).

The increased use and acknowledgement of machine learning and AI in society calls for more development and integration of curricula about AI and how it affects everyday life as well as teaching and learning (Yue et al., 2022; Smith et al., 2023). In that context, the purpose of this study is to explore secondary school students' understanding of machine learning. We present interview data as well as a work in progress analysis that maps the participating students' ability to critically understand the use and development of machine learning in society, based on their experiences with developing and discussing a machine learning model.

In this work-in-progress study we address the question:

How do lower secondary school students understand machine learning, and how do they reflect on technology-critical aspects of it based on their experiences in the classroom?

We investigate this using design methods and data consisting of six focus group interviews with students from 7th, 8th and 9th grade in a Danish school.

Case

This analysis is part of a research project based on developing a teaching sequence designed for lower secondary school in the context of biology as a school subject and using a scenario-didactic teaching approach (Fougt et al., 2022). The purpose of the research project is to examine students' understanding of machine learning models in the world, and to be able to critically evaluate the use of and responsibly develop such models in a STEM-context. In this context, technology-critical aspects refer to students' ability to critically reflect on topics such as ethical dilemmas and data usage in relation to society.

The course consists of a scenario where students act as employees in a fictional company that develops apps for health-tracking. In its current form, it has a duration of nine lectures of 45 minutes. By using Machine Learning for Kids (https://machinelearningforkids.co.uk/) to classify different images of food into different health related categories, the purpose is for students to learn the fundamental principles of machine learning models. After playing out different scenarios where the company enters a partnership with a fictional recruitment company, the students are to critically reflect on responsible usage of data and the influence on data-based algorithms in society. Afterwards the students discuss societal and ethical issues regarding the scenario. See an overview of the teaching lessons in the table below (Caeli et al., 2025).

Table 1. Overview of the teaching lessons.

Part 1: Preparation/Onboarding (3 x 45 minutes lessons)
Lesson 1: ***Welcome***
Brief, phones, teams and welcome folder.
Lessons 2 and 3: ***Onboarding***
The students work through an onboarding process as part of the newly started development department (an introduction and initial course in the program Machine Learning for Kids). The onboarding process is available as a step-by-step guide on a fictional intranet.

Part 2: Development (6 x 45 minutes lessons)
Lessons 4 and 5: ***Developing the food app***
Video 1: The CEO of the fictional company explains the task. The students discuss how to categorize food into healthy and unhealthy and assign a score. Students are then told to categorize their images into healthy, medium and unhealthy. They work on their model in Machine Learning for Kids, i.e. categorize the images and train the model.
Lessons 6, 7 and 8: ***Developing the health app***
Video 2: The CEO of the company announces the partnership with a fictional recruitment company. Students discuss and make notes on what data to collect about health, create a scoring system, test their solutions, create wireframes of the app, and see a dashboard for the recruitment company.
Lesson 9: ***Discussing responsible development***
Department meeting: Discussion of the categorization, reaction to the deception of users (discussion on ethics and responsible development). Half of the teams must argue *for* and half must argue *against* profiling and selling data. Department meeting: The groups present pros and cons. They discuss whether their company should continue down this path and consider ethical principles for responsible development.

A pilot study was conducted in the spring of 2023 (see Caeli et al. 2024), the first full design cycle was conducted in April 2024, and the last iteration was conducted in November/December 2024.

Methods And Data

The following presents the methodological basis for interviews and the collected data.

Method

The research project was developed as a design study in collaboration between researchers and teachers. Data was collected through face-to-face qualitative focus group interviews, using semi-structured interview guides on specific themes. Open-ended questions elicited students' opinions, thoughts, and experiences to enable further course development and iterations (Creswell & Creswell, 2018).

The focus groups were interviewed prior to the development of the teaching sequence (August 2023) and follow-up interviews were conducted after the teaching sequence (December 2024, different students). The purpose of the interviews was to gain insight into the participating students' technical and technology-critical understanding before and after being taught a teaching sequence in machine learning in order to develop more relevant and appropriate teaching.

The preliminary interviews covered three themes: 1) Machine learning understanding, 2) Critical stance on machine learning and 3) Interaction between biology and machine learning. Follow-up interviews included questions on scenario didactics and teaching.

To answer the research question, we focused on: 1) Understanding machine learning and 2) Critical stance on machine learning in a biology context. In addition, we had a specific view on the relationship between technical skills and technology-critical skills in the classroom, based on experiences from our pilot. Additionally, we chose to use the term AI instead of machine learning because we expected students to be more familiar with this term. All interviews were coded in Nvivo.

Data

The data consists of interviews with students from lower secondary school as illustrated in the table below.

Name	**Period**	**Type**	**No of participants**	**Level**
Pre1, Pre2	Preliminary	Focus group interview	2 groups of 4 each	9th grade
FO1, FO2, FO3, FO4	Follow-up	Focus group interview	4 groups of 4 each	2 classes from 7th grade and 2 from 8th grade

Findings

In the following we present our findings based on the two areas mentioned above.

Understanding Machine Learning

In the preliminary interviews, some of the participating students expressed that they lack, and would like to have, an understanding of how AI works, how it is used, and exactly what data is being collected by, for instance, social media. It also appeared that most of the participating students did not have any immediate thoughts about how machine learning works. However, one

student (Pre2), stated that AI can be used to create images, indicating an awareness of AI's capabilities.

From the interviews, some of the participating students seemed to have a broad understanding of the fact that the computer/machine is not intelligent in itself. A student expressed that it is humans who make the machine intelligent (FO1). Another student stated that it is not the machine that is intelligent, but that it is programmed and coded (FO3). In another interview, the students agreed that the machine is not intelligent like a human, partly because it does not know who the user of it is (FO4). From another interview a student expressed that it is the data that the computer uses that is intelligent, not the computer in itself (Pre2).

In one interview, a student presented an interesting opinion when answering yes to ChatGPT being intelligent because it is an artificial intelligence, putting emphasis on the word intelligence. Another student then emphasized that the intelligence is artificial and thus has a different understanding of why it is not intelligent (FO4).

In the follow-up interviews, we observed an overall understanding that the machine can learn (FO1-FO4), but, interestingly, not an overall understanding of how it works or what it actually is, which was one of the learning objectives in the project.

Critical Stance On Machine Learning

All students in Pre2 are aware that apps like TikTok, Netflix, and Instagram use data about them to target content. They seem to have an awareness and understanding that machine learning is used in many areas, although they seem to have a general understanding of AI.

In general, the students participating in the follow-up interviews are reflective about how organizations monitor data. One student reflected that the benefit of targeting ads lies with those who make money from them, but the student does not think it is okay that they know so much about the user (FO1). This attitude is echoed by another student who added that it is scary and weird that someone can know so much about you but also expressed that it is smart because it personalizes your experience (FO1). Another student agreed and is happy not to be shown useless videos (FO3) instead of (useful) user targeted content, and another said that machine learning is smart because you do not have to watch content you do not like (FO4).

Thus, a variation of what appears to be informed use seems to be present among the participating students, who take positions both for and against user targeted content (recommender systems) in, for example, social media. However, in another interview (FO3), the students expressed that they would like to know more about what AI does and how data is used by the company. In contrast to this, a student from another interview expressed that it is not necessary to learn about AI in their opinion (FO4).

Discussion

One observation was that while the students were taught how machine learning works, what data is, and critical aspects of data use, some students expressed they did not know what AI does and how data is used. As our teaching material focuses on the machine learning mechanism of image classification as part of a “health-app”, perhaps the machine learning method related to the critical discussion about the use of data should be supplemented with deeper technical understanding, in this case of recommender systems. Recommender systems are another type of machine learning than classification methods, and they create the basis of the recommendations of social media. Likewise, the discussion was also affected by opinions on ChatGPT which is based on generative AI - yet another type of machine learning.

A practical implication of this finding is that when teaching machine learning, it is important to distinguish between these different types of machine learning methods and focus on the ones important for the project. Additionally, one could discuss the taxonomy of these in class for students to have a better chance of understanding different technical aspects of machine learning - and thus possibly also technology-critical aspects on a higher level.

Interestingly, we saw a similar pattern in a pilot study (Caeli et al., 2024), in which we had included block code programming for introducing deeper computational thinking (MIT App Inventor, https://appinventor.mit.edu/). This seemed to be time-consuming and distracting for students' technical understanding of machine learning, so we removed the block programming content in subsequent iterations.

Future research could consider exploring how deeper and more specific focus on technical aspects affects students' technology-critical understanding, i.e. the balance between the two aspects.

There are inherent limitations to this study, which is a work-in-progress study and thus focuses on a relatively narrow scope. Additionally, the study's reliance on a specific educational context in one school may not capture the full diversity of student experiences and understandings.

Strand 9: Science Education for Sustainability, Agency and Futures Literacy

Laura Colucci-Gray[1] and Olivia Levrini[2]
[1]University of Edinburgh, UK
[2]University of Bologna, Italy

Strand 9 brings together research concerned with the role of science education in addressing sustainability challenges, socio-scientific complexity, civic participation and futures-oriented science education. The strand focuses on how learners, teachers and educational communities can engage with environmental, technological and social issues that are uncertain, contested and ethically charged. Across the contributions, science education is not framed simply as the transmission of scientific knowledge, but as a space for developing responsibility, agency, critical reflection, communicative rationality, future literacy and democratic participation.

The papers included in this section cover a wide range of sustainability-related themes. Scientific literacy continues to be a strong theme particularly in relation to political and structural issues associated with the energy transitions. Several contributions go in depth about the significance and necessity of bringing together disciplines across the natural sciences to address social and environmental challenges, including biodiversity loss, green infrastructures, ecosystem services, wind energy, critical raw materials, bio-based plastics, vegan diets and green and sustainable chemistry. These papers explore how science education can make complex environmental issues meaningful for students and teachers by connecting scientific concepts with ethical, emotional, political and everyday dimensions of sustainability. In this sense, the strand strongly reflects the conference theme of sustainability, showing how environmental issues are increasingly approached through interdisciplinary, participatory and action-oriented pedagogies.

A second important group of contributions focuses on Education for Sustainable Development, Global Citizenship Education. These papers examine teachers' competences, willingness and pedagogical preparation for integrating ESD into school and university contexts, including technical and higher education. Ongoing attention is given to the importance of teacher preparation learning through professional development courses, exploratory seminars, interdisciplinary teaching and design-based approaches which supports students in assessing sustainability controversies from environmental, economic and social perspectives. Together, these contributions highlight that sustainability-oriented science education requires not only new topics, but also new forms of curriculum design, teacher learning and institutional support.

A third set of papers foregrounds responsibility, agency and civic engagement. Contributions examine a wide range of assessment tools for measuring students' sense of responsibility in chemistry-related STSE contexts, which emphasise wider civic competencies with practical applications in climate assemblies, opportunities for youth participation, placemaking, and collective and political agency in the Anthropocene. These studies point to a shared concern: students need opportunities to participate in decision-making, imagine alternative futures, engage with uncertainty and act in relation to complex global challenges such as climate change, biodiversity loss and social inequalities. Approaches such as serious games, imagining futures are offerings which are multi-modal and participatory. These contributions also resonate with the conference theme of digital advances suggesting that digital and game-based environments can support imagination, systems thinking, collaboration and engagement with complex sustainability issues when they are embedded in critical and pedagogically meaningful designs.

Positioned within the wider field of science education research, Strand 9 contributes to ongoing debates on scientific literacy, STSE education, socio-scientific inquiry, ESD, climate change education, and democratic approaches to science education. The contributions collectively challenge narrow technocratic views of science education and call for pedagogies that are more relational, critical, participatory and future-oriented. They portray science education as a key site for preparing learners and educators to understand complexity, to deliberate about values, to imagine desirable futures and participate responsibly in the transformation of society towards more just and sustainable worlds.

ESERA 2025 Copenhagen

Trade-Offs In ESD Related To Using Wind Energy – A Study Conception

Helen Fischer and Markus Prechtl
Technical University of Darmstadt, Germany

The use of wind energy is highlighted in the interests of sustainability. At the same time, wind turbines harm the environment due to their demand for raw materials and their purification processes. A trade-off is required. For education for sustainable development (ESD), this expresses the need to promote evaluation skills in addition to the transfer of knowledge about raw materials. Research is already being carried out on the contents of raw materials, evaluation skills, and dealing with trade-offs within ESD. This project aims to expand the discussion of raw materials in the context of wind turbines while incorporating new evaluation perspectives, including emotional interaction. This is considered particularly relevant in the emotionalised context of ESD trade-offs. Therefore, an intervention study monitors the interaction of school students with different presentations of the trade-offs related to wind turbines. The article shows the structure of the project, the methodological approach as well as initial findings from the first study.

Keywords: Education for Sustainable Development, Raw Materials, Emotion

Introduction

Global warming increasingly poses a threat to the environment. To reduce the impact of energy supply on the climate, efforts are being made to expand renewable energies such as wind energy, as set out in SDG 7.2. No greenhouse gases are released when wind energy is converted into electrical energy. Nevertheless, the energy supply with wind energy is not ‘neutral’ in terms of climate and environment. Raw materials such as iron, copper, rare earth elements, aluminium and carbon fibre are required for the construction of wind turbines (Rueda-Bayona et al., 2022).

With its demand for raw materials and the associated purification processes, the technology declared sustainable in SDG 7.2 counteracts the efforts of SDG 15 to a certain extent; making a trade-off necessary. Such trade-offs over raw materials are represented more transparent in the media, most recently concerning lithium mining (e.g. Santos, 2024). This can be overwhelming for school students. ESD aims to support students develop the skills they need to help shape sustainable development despite trade-offs. The ability to allow ambiguity and to learn balancing different goals are central to these skills (UNESCO, 2020). Therefore, when dealing with trade-offs in ESD, it is necessary to analyse the content of raw materials but also train evaluation skills and create a framework that allows for ambiguity. In doing so, the emotional impact of the content needs to be considered in addition to the content itself.

In the following, the context of wind turbines presents the content level. While fossil-fuelled energy plants place a heavy burden on the environment during the operational phase, wind energy has almost no impact on these factors during operation. But what about the phases before and after operation? Life cycle assessments include these steps in their endpoint categories of ecosystem, human health, and resource depletion (Rueda-Bayona et al., 2022). They show that wind energy plants have the greatest impact on the environment in their production including the mining, beneficiation and purification of raw materials (Xu et al., 2018). These processes require energy and chemicals and release emissions into soil, water, and air. This can be exemplified by the purification of the rare earth element neodymium. Neodymium is used in permanent magnets in the generators of some wind turbine types. Usually, concentrated sulphuric acid is used for leaching of neodymium-containing ores, e.g. fluorocarbonates. This produces harmful by-

products such as hydrogen fluoride. In addition, radioactive thorium is released, and acidic wastewater remains due to incomplete reactions (Schreiber et al., 2021).

Even though life cycle assessments identify different environmental impacts of wind turbines, the primarily impact is the abiotic resource depletion potential of chemical elements (Atilgan & Azapagic, 2016). The impacts can be varied depending on decisions in three areas: the energy plant itself (Atilgan & Azapagic, 2016), the raw materials used (Schreiber et al., 2019), and the processing of the raw materials (Li et al., 2019).

Although the trade-off is dealt with, scientifically, in life cycle assessments, it is hardly ever recognised in society and schools. So far, school students have made an undifferentiated distinction between renewable and non-renewable energy use with the descriptions clean and dirty (Hüfner, 2020). A differentiated evaluation allowing ambiguity must be aimed, for example with the process-oriented framework PAAWD^{R} (Langlet et al., 2022). It allows to focus on ambiguity, criteria determination, and balancing more closely, which are of particular interest in these complex trade-offs in ESD. PAAWD^{R} divides the process into the steps of perceiving, analysing, arguing, weighting, deciding, and reflecting (Langlet et al., 2022).

Regarding the perception, it requires an openness to engage with the trade-off and to allow nuances between the clean-dirty distinction. In ESD contexts, the emotional preload and reaction should not be overlooked, especially due to the nature of the challenge in trade-offs. Studies show that learning in the context of climate change can evoke worries, hopelessness, and helplessness. Half of young people are very worried about climate change (Hickman et al., 2021) and disillusioned about a sustainable future (Grund & Brock, 2019). The sometimes resulting helplessness (Kuthe et al., 2020) runs counter to the aim of ESD to promote the ability to shape the future.

In addition to their impact on society, emotions such as fear and hopelessness can be harmful to the learning success. In achievement emotions, positive activating emotions such as joy were found out to be the most promising, and negative deactivating emotions such as hopelessness the least promising (Pekrun et al., 2007). The feeling of hope can counteract paralysing fear or hopelessness (Kleres & Wettergren, 2017). Grund and Brock (2019) therefore encourage emotionally sensitive ESD with the promotion of constructive hope. This in mind, solution-oriented approaches are developed along the sustainability strategies of sufficiency, efficiency, and consistency (e.g. Applis et al., 2022). In this research project, aspects of these solution-oriented approaches will serve as inspiration for the design of the intervention and learning content.

Aim And Research Questions

The aim of the whole project is to design a learning unit for chemistry. Using the example of the raw material demand for wind turbines, the unit should introduce school students to an emotionally charged ESD trade-off in a sensitive manner and support them in making differentiated evaluations.

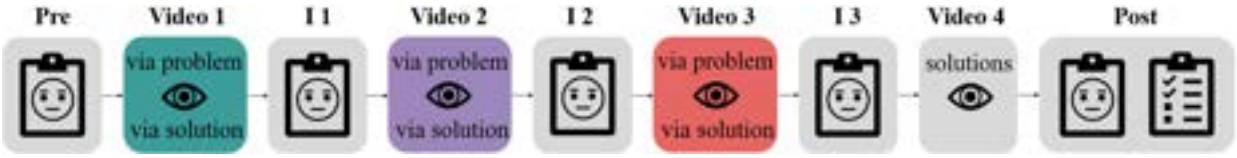
To this end, two key questions with sub questions will be investigated and categorised according to the PAAWD^{R} model. The first question focusses on perception. The second question covers weighting, deciding, and reflecting.

1. How do school students perceive different facets of the trade-offs on wind turbines?
   1.1 Which area would they like to deepen?
   1.2 Which emotions occur while being confronted by the trade-offs?

2 What information is relevant for school students in their decision-making process of the trade-offs regarding wind turbines?
  2.1 Which criteria are important to them?
  2.2 How does their evaluation change?
  2.3 Why does their evaluation (not) change?

Method

Within this project, the research questions are investigated through two studies using a mixed-methods design. The study presented here focuses quantitively on students' perception of the trade-offs (RQ1, $N = 129$). It was conducted in 2025 with 10th and 11th grade students. The second research question (RQ2) will be addressed qualitatively in a separate forthcoming study.



The trade-offs addressed in the study cover the three areas mentioned: energy plants (contrasting wind energy and natural gas plants), raw materials (contrasting the use of a higher amount of copper to rare earth elements in the generator of an energy plant), processing (contrasting pyrometallurgical and hydrometallurgical methods). The trade-off interventions are presented as videos with a duration of two to three minutes. Moreover, the subject of solution perspectives is addressed, using examples from the sustainability strategies sufficiency, efficiency and consistency (see table 1).

Table 1. Content of the intervention.

	Energy plant	**Raw materials**	**Processing**
Problem-oriented trade-off	Wind energy vs. natural gas	Copper vs. rare earth elements	Pyrometallurgical vs. hydrometallurgical
Added solution approach	Sufficiency	Efficiency	Consistency

The study was conducted with an online questionnaire (duration: 30 min) including a pre-test, video interventions on the trade-offs, a post test, and a video on solution approaches. In addition, there were brief intermediate measurements after each video (see Figure 1). The trade-off interventions were carried out in two groups. Group A was introduced to the trade-off directly via the problem. Group B was introduced to the trade-off via a solution approach that reduces the extent of the trade-off beforehand.

Figure 1. Structure of intervention (I: intermediate measurement, face: emotion measurement, eye: video intervention, list: selection of topics).

The intermediate measurements assess the emotions dimensionally using the Self-Assessment Manikin (Bradley & Lang, 1994). The emotions were further assessed categorically pre and post using a 5-point Likert-scale (adapted from Duffy et al., 2020). Moreover, students' attitudes towards wind turbines were assessed, and in the post-test, they selected the trade-off topic and solution approach they would like to explore further as well as whether they would like to study one of the two selected topics in greater depth than the other.

Data with more than 30% missing values or unusually fast processing times (RSI > 2; < 25 s on intervention pages) were excluded, leaving $n = 99$. Analyses were conducted in *IBM SPSS*

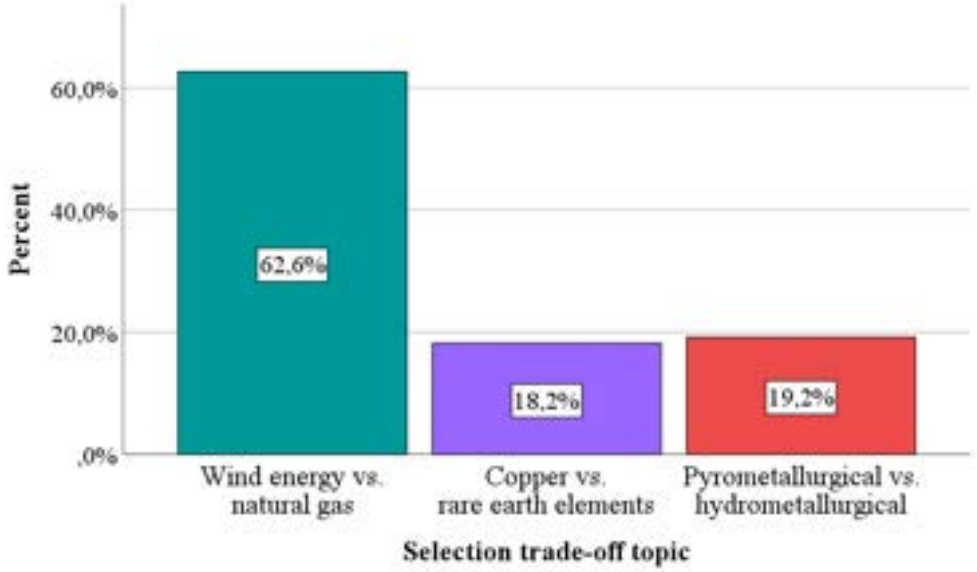
Statistics 29.0.0.0. The topic selection is described via frequency distributions (RQ1.1). Since the emotion variables are not normally distributed (Shapiro-Wilk-test: $p < 0.001$), Wilcoxon test will be applied for the categorical emotions and Friedman test for the dimensional emotion assessment (RQ1.2).

Initial Results And Discussion

The analysis for RQ1 is still ongoing. However, the initial results of the analysis of the frequency distribution of the topic selection (RQ1.2) have already been obtained. These results show a clear tendency within the trade-off-topics to deepen the trade-off concerning energy plants, as well as a desire for solution approaches to be discussed.

The majority of students (62,6%) want to expand the trade-off between wind energy vs. natural gas use. The trade-offs in the areas of raw materials and processing are similarly chosen (see figure 2).

Figure 2. Initial results of the selection of a problem-oriented trade-off topic.



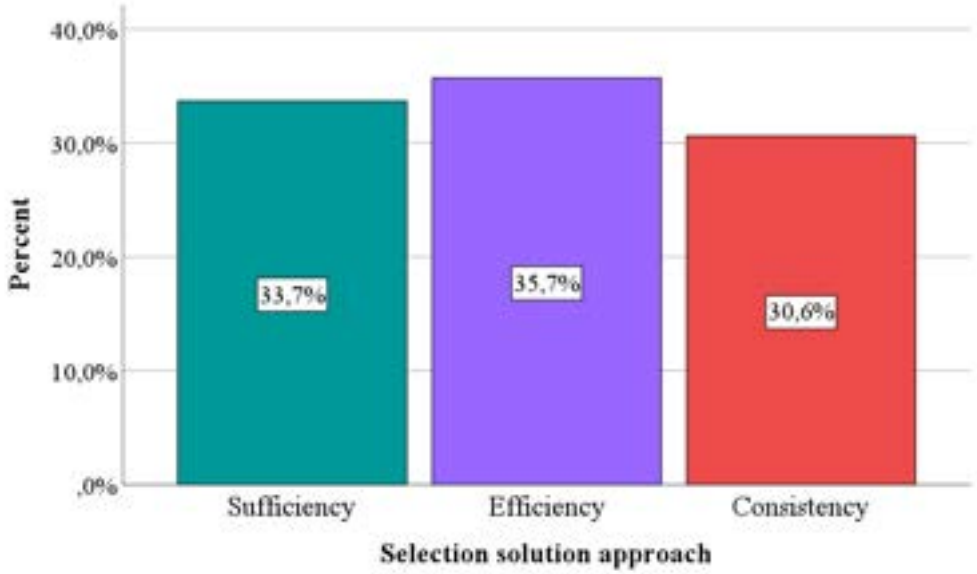


Figure 3. Initial results of the selection of a solution approach

The solution choice is more evenly balanced with a slight preference for the efficient use of raw materials (35,7%, see Figure 3). Comparing the selected trade-off topic and solution approach, only nearly a fourth of the students want to focus on their problem-oriented choice (24,2%) in

further lessons. More students want to concentrate on the solution approach (35,4%) or equally both (39,4%).

Based on the results of life cycle assessments and the objectives of ESD, this article emphasises the importance of addressing trade-offs related to the use of raw materials. It presents potential topics in three areas as well as school students' preferences within these topics. Both trade-off topics and corresponding solution approaches were considered. The surveyed preferences for the areas are topic-specific and cannot be generalised. Nevertheless, for the chosen topics the initial results of this study show that the implementation of solution approaches to promote constructive hope, as proposed by Grund and Brock (2019) and Ojala (2012), is also demanded by the students.

The analysis on the topic emotions and their changes alongside the (different) interventions still needs to be carried out. Furthermore, in order to answer RQ2, data from a second study will be obtained and analysed.

ESERA 2025 Copenhagen

Exploring Students' Conceptions Of Critical Raw Materials And Their Availability

Yannick L. Legscha and Markus Prechtl
Technical University of Darmstadt, Germany

Critical Raw Materials (CRMs) are essential for clean-energy technologies, yet their supply is often vulnerable due to import dependencies, geopolitical conflicts, and socio-environmental constraints. Although policy initiatives such as the EU Critical Raw Materials Act address these challenges, public awareness remains limited, highlighting the need for education. While existing science education projects provide valuable learning environments addressing CRMs, less is known about how students conceptualize the availability of CRMs prior to instruction. This study is embedded in the educational research of the Collaborative Research Center (CRC) "Iron, upgraded!" and follows the Model of Educational Reconstruction (MER). Focusing solely on the learner perspective in this article, we investigate students' conceptions of the availability of CRMs. A preliminary survey (N = 295) on associations with the term "critical raw material" indicated that students primarily approach the topic in a problem-oriented way, while also referencing dimensions of criticality such as scarcity and importance. Subsequently, guideline-supported interviews with 12 upper secondary school students were conducted and analysed using qualitative content analysis. Five conceptions regarding the availability of CRMs emerged: supply constraints due to (i) low geological availability, (ii) geopolitical instability, (iii) low ecological and social acceptance, (iv) demand growth, and (v) limited technological accessibility. Results suggest that students predominantly interpret availability through a finite-stock mental model, while geopolitical, socio-ecological, technological, and demand-related dimensions are less spontaneously integrated and may require contextual prompts. These insights provide starting points for MER-based instructional design and point to opportunities for linking criticality to mitigation strategies such as substitution.

Keywords: Conceptual Understanding, Sustainability, Critical Raw Materials

Introduction

Critical Raw Materials In The Energy Transition

In response to the global climate crisis, a shift towards a post-fossil society with a sustainable energy system is essential. However, this transition requires substantial amounts of raw materials needed for deploying clean energy technologies. For instance, EU demand for lithium is expected to increase twelve-fold by 2030 and twenty-fold by 2050 (European Commission, 2024). Yet, many of these raw materials are either not found in Europe or are not mined in sufficient quantities. Consequently, the EU relies heavily on imports, often from geopolitically unstable regions or single-source suppliers (European Commission, 2023). Without coordinated action, the European climate goals are at risk (European Commission, 2024).

To address these challenges, the concept of Critical Raw Materials (CRMs) has gained prominence (European Commission, 2011; Graedel et al., 2012; NRC, 2008). CRMs lack a universally agreed definition because criticality varies by time, country, and context. However, it is broadly understood as the likelihood and potential consequences of a supply disruption (Schrijvers et al., 2020). Accordingly, the EU describes CRMs as materials of high economic importance while also being highly vulnerable to supply disruptions (European Commission, 2011). Initiatives such as the EU's Critical Raw Materials Act aim to secure these materials to meet the 2030 climate and digitalization targets (European Commission, 2024). Nevertheless,

public awareness of CRMs and their role in the energy transition remains limited, making education and communication essential (Kot-Niewiadomska, 2022).

Critical Raw Materials In Science Education

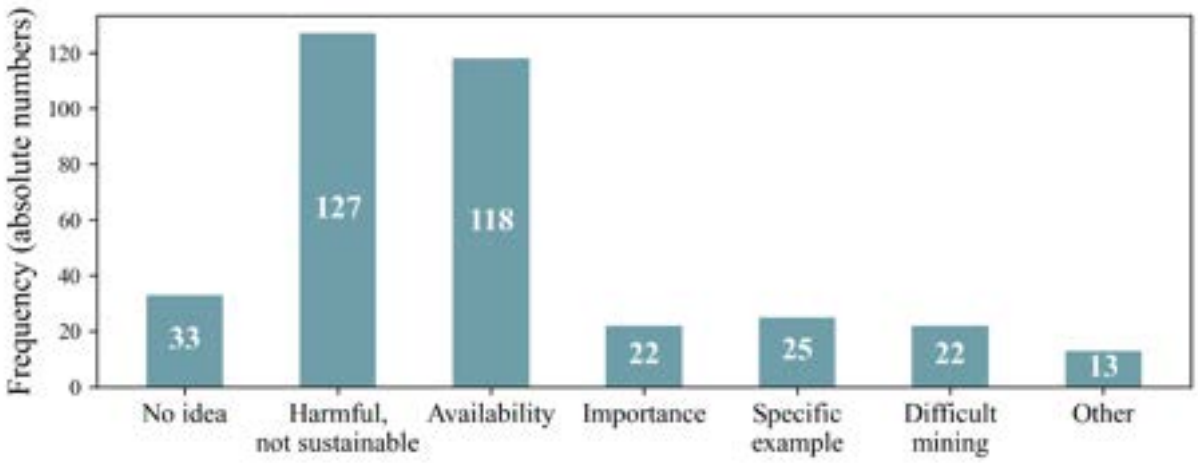
Several EU-funded projects address the educational gap around raw materials and sustainability. For example, the "Young Raw Material Ambassadors" program equips students aged 10 to 18 with knowledge about raw materials through interactive tools such as digital serious games (Torreggiani et al., 2021). Gullón Corral et al. (2023) developed the "Briefcase Project", a hands-on teaching kit highlighting mineral properties, societal impacts, and the role of raw materials in everyday life. Beyond these EU projects, Huwer et al. (2022) created digital learning environments for chemistry education incorporating augmented reality to explore elements in everyday devices and their recyclability. Bütow and Eilks (2023) developed a digital learning environment designed to integrate CRMs into chemistry curricula and subsequently evaluated its implementation by comparing German high school students with U.S. undergraduate chemistry students (Bütow et al., 2025).

While these projects provide valuable resources, a research gap remains concerning students' conceptions of critical raw materials, especially regarding what "availability" means and what learners intuitively consider as causes of scarcity. Such insights could be beneficial for designing learning environments that connect to learners' existing ideas and support conceptual development.

Motivation And Theoretical Framework

This study is embedded in the educational research subproject WIKO (German abbreviation for *Wissenschaftskommunikation*, i.e., science communication) of the Collaborative Research Center (CRC) "Iron, upgraded!" (www.chemie.tu-darmstadt.de/iron-upgraded/index.en.jsp), which investigates how iron's reactivity and selectivity can be controlled so that iron-based compounds can substitute rare, toxic, expensive, or critical metals in key technological applications, such as fuel cells and magnets. A key aim of the WIKO project is to support learners in understanding the relevance of CRMs and the idea of material substitution (e.g., iron-based solutions as potential alternatives to scarce or geopolitically sensitive materials in specific applications).

The study follows the theoretical framework of the Model of Educational Reconstruction (MER), which emphasizes the interconnection of reconstructed scientific content and students' pre-instructional conceptions to foster meaningful learning (Bliesmer & Komorek, 2023; Duit et al., 2012). MER highlights the importance of acknowledging students' perspectives and aligning them with scientifically accurate concepts (Komorek & Kattmann, 2008). This approach, rooted in conceptual change theory, is particularly effective when students' fragmented and context-dependent knowledge is incorporated into instructional design (diSessa & Sherin, 1998; Treagust & Duit, 2008).



MER comprises three perspectives: (i) the investigation of scientists' conceptions, including the analysis and structuring of scientific content, (ii) the investigation of learners' conceptions, and (iii) the design or evaluation of a learning environment. **The present contribution focuses only on the learner perspective.** It therefore provides a targeted overview of how learners think about the availability of critical raw materials, rather than reporting a complete MER cycle. We address the following research question: What conceptions do upper secondary school students hold about the availability of critical raw materials?

Preliminary Study: Students' Associations

Starting the investigation into learners' perspectives, we first explored whether the term "critical

raw material" is sufficiently present in students' thinking to justify in-depth qualitative exploration. Accordingly, we conducted a preliminary quantitative survey asking: "What do you associate with the term 'critical raw material'?" (Prechtl et al., 2025). To ensure data quality, we excluded responses that were incomplete or showed signs of insufficient engagement, specifically those where the processing time fell below the threshold of 10 seconds per survey page. After this, a final sample of N = 295 responses remained. We then coded and grouped the open responses thematically and visualized their absolute frequencies to identify the most common associations (see Figure 1).

Figure 1. Frequency of thematically coded open-ended responses to the question "What do you associate with the term 'critical raw material'?" (Prechtl et al., 2025).

In Figure 1, two observations stood out. First, students approached the topic in a strongly problem-oriented way. A large share of responses related to environmental harm and non-sustainability, indicating that students tend to frame CRMs primarily through consequences and risks. Second, many responses also referenced aspects that align with the formal notion of criticality, such as availability/scarcity and the importance of raw materials. Overall, the framing and the low number of the "no idea" category suggested that the concept is present enough in students' thinking to justify a deeper exploration of how they interpret the term.

Methods

We conducted guideline-supported interviews with open-ended questions and clarifying interventions. The study included 12 upper secondary school students (mean age: 17.75 years; 7 females, 5 males) from three schools in Hesse, Germany, who participated voluntarily in summer 2023. To support an open atmosphere, interviews were conducted in a conversational setting. The average interview duration was 64.2 minutes. The content validity of the interview questions was supported using the collect, check, sort, and subsume approach, complemented by a pilot test with two students to improve clarity and understandability. Interviews included opportunities for clarifying interventions when students' meanings required further elaboration or when relevant dimensions of availability did not emerge spontaneously. Data were analysed using adapted methods of qualitative content analysis (Gropengießer, 2008) to identify and categorize students' conceptions. Audio recordings were transcribed verbatim. Relevant statements addressing the research question were systematically coded and similar statements were grouped to form categories. To support the quality and consistency of the analysis, category definitions, anchor examples, and coding rules were reviewed iteratively (Mayring, 2022). The validity of results was further supported by comparing emerging conceptions with published studies on related topics. Initially, the German interview transcripts were analysed, and relevant statements were then translated to illustrate students' conceptions.

Selected Results

The analysis revealed five distinct conceptions regarding the availability of critical raw materials (Table 1).

Table 1. Students' conceptions of CRM availability.

	Students' conceptions	Example statements
1	Supply constraints due to GEOLOGICAL AVAILABILITY	"By scarce, I mean that the raw materials do not occur in sufficient quantities." (Amira)
2	Supply constraints due to GEOPOLITICAL INSTABILITY	"The countries where the raw materials come from are not necessarily always politically stable countries. This means that conflicts can arise there that can spill over into the economy." (Amira)
3	Supply constraints due to ECOLOGICAL AND SOCIAL ACCEPTANCE	"The mines are harmful to the environment and I can imagine that people don't want them in their neighborhood." (Sarah)
4	Supply constraints due to DEMAND GROWTH	"Population growth is connected to the raw material consumption. […] the global demand is rising, which means that there isn't enough for each individual country." (Chiara)
5	Supply constraints due to TECHNOLOGICAL ACCESSIBILITY	"Other deposits may then be very difficult to mine." (Chris)

Nearly all students associated scarcity primarily with geological availability. In their explanations, terms such as "rare", "scarce", and "available" referred to whether sufficient reserves of specific raw materials exist. Conception 1 (GEOLOGICAL AVAILABILITY) captures the view, that scarcity primarily reflects limited geological occurrence, i.e., insufficient quantities of raw materials being available in the nature. Accordingly, students often conceptualized availability as a largely fixed physical quantity and assumed that limited occurrence directly translates into limited supply. Some even described a depletion narrative, suggesting that continued extraction could ultimately lead to absolute exhaustion of resources. For example, one student stated: "There will simply be no more raw materials" (Mia).

Conception 2 (GEOPOLITICAL INSTABILITY) addressed geopolitical conflicts as a cause of supply constraints. For many participants, this perspective became more explicit after interventions concerning Europe's import dependency. Students argued that European countries such as Germany rely strongly on political and economic relations with supplying countries, which can be problematic when these relations deteriorate. Moreover, students highlighted that these dependencies are not only a passive vulnerability but can be used deliberately as a source of leverage. One student, for example, described the risk of supply being intentionally restricted in the context of geopolitical conflicts:

> "If China ends up in a major conflict with the EU and decides to say, 'No, you won't get any rare earths from us anymore,' that poses a significant risk because they hold nearly 100 percent of the market share" (Chris).

All students addressed environmental and social consequences of mining and frequently framed these impacts as a possible dimension of critical raw materials. However, only about half of the participants explicitly linked these concerns to availability constraints. Conception 3 (ECOLOGICAL AND SOCIAL ACCEPTANCE) describes the idea that supply limitations may result from low ecological and social acceptance of mining activities. Students argued that mining can cause severe environmental harm and social conflict, which may lead to public resistance, stricter regulation, or even the closure of mining sites. In this view, raw materials may be geologically present, yet effectively "unavailable" because extraction is contested or considered unacceptable.

Many students described scarcity as a function of rising demand. Conception 4 (DEMAND GROWTH) captures the ideas that a continuously increasing demand will eventually surpass an already limited geological supply. Students explained demand growth through drivers such as population growth and technological developments. In particular, some learners referred to the energy transition and the expansion of modern technologies as increasing the need for specific raw materials. One student exemplified this by linking battery technologies to future supply challenges: "For instance, lithium, which is essential for batteries, is relatively scarce. Expanding its use on a global scale will make the supply problematic" (Sebastian).

Some students additionally mentioned the technological accessibility of raw materials. Conception 5 (TECHNOLOGICAL ACCESSIBILITY) describes the idea that raw materials may become scarce because certain deposits are increasingly difficult to exploit. However, students' ideas were inclined to focus on the assumption that easily accessible deposits will eventually be exhausted. As a result, extraction would require more complex technologies or become less feasible.

Discussion

The prevalence of Conception 1 (GEOLOGICAL AVAILABILITY) indicates that students predominantly frame raw materials criticality as a problem of "how much exists". This perspective resembles an intuitive "running-out" narrative: resources are treated as a fixed stock that steadily declines with use. In contrast, scientific discussions of raw material availability emphasize that absolute geological scarcity is unlikely to constrain access to most materials in the foreseeable future, because what is considered as economically recoverable reserves changes with exploration, technology, and market conditions (Coulomb et al., 2015). From this standpoint, students' focus on depletion may obscure more relevant drivers of criticality such as supply concentration or geopolitical and socio-ecological constraints (Schrijvers et al., 2020). For instructional design, this suggests a need to explicitly differentiate the terms "resources" and "reserves", and show that both are not fixed but dynamic socio-technical concepts.

The students' ideas regarding Conception 2 (GEOPOLITICAL INSTABILITY) are broadly aligned with established CRM logic: import dependency can create vulnerability, and exporting countries may use supply restrictions as political leverage (Nuss et al., 2016). However, the fact that this conception often became salient only after interventions suggests that geopolitical supply risk is not an everyday idea for many learners and requires contextual cues (e.g., a map of Europe's import structure of raw materials) to be activated. This pattern fits well with a "knowledge-in-pieces" interpretation (diSessa, 2018): students may possess relevant fragments (e.g., "conflicts disrupt trade"), but these pieces are not reliably triggered without situational prompts. For teaching, this implies that geopolitical considerations need structured support such as supply-chain mapping or scenarios that make dependencies visible.

Conception 3 (ECOLOGICAL AND SOCIAL ACCEPTANCE) reflects a shift from purely physical

understandings of availability toward socio-environmental conditions that shape whether extraction can occur. Students' arguments resemble a "not in my backyard" logic: mining might be technically possible, yet effectively blocked by regulations or concerns. Notably, while these sustainability impacts were widely recognized, only about half of the students explicitly connected them to availability constraints. This suggests that learners often treat ecological/social harm as a separate "problem of mining", rather than as a factor that can restrict supply. In instructional terms, this indicates a learning need to explicitly link these ideas to the notion of availability.

Students' reasoning regarding Conception 4 (DEMAND GROWTH) resembles a scaling heuristic: more people and broader deployment of technologies imply more consumption, which eventually overwhelms supply. This is a plausible everyday schema and can serve as a productive starting point. At the same time, students' accounts were inclined to model supply as essentially static and demand as continuously rising, often without considering counteracting dynamics (e.g., efficiency gains, substitution, recycling). In this sense, Conception 4 parallels Conception 1: scarcity is again framed as a largely inevitable trajectory toward shortage, rather than as a system shaped by technological, economic, and political choices. From a reconstruction perspective, instruction could build on this intuitive logic but broaden it with mitigation strategies.

Conception 5 (TECHNOLOGICAL ACCESSIBILITY) expands availability beyond geology by introducing technological accessibility. However, students' ideas often remained tied to a simplified narrative: high-grade or near-surface deposits are exhausted, therefore extraction becomes more difficult. This captures an important aspect of accessibility but remains underspecified. Moreover, scientific criticality assessments highlight additional mechanisms that were not present in the students' accounts, such as by-product dependency, where production depends on the mining of the host metal (Nassar et al., 2015). For instructional design, this suggests expanding the ideas of "harder mining" with aspects of refining, co-production, by-product dependency, and processing bottlenecks.

Limitations

This study is based on a small qualitative sample from three German high schools and thus does not aim at statistical generalization. At the same time, the qualitative findings are complemented by the preceding survey (N = 295; Prechtl et al., 2025). Across both datasets, students' responses consistently foreground scarcity-related reasoning, providing converging indications of the prominence of a "running-out" narrative and a primary focus on scarcity and depletion. Therefore, these results should serve to identify possible starting points and to derive instructional guidelines for teaching the concept of CRMs. However, the learning environment developed later should be evaluated for its suitability to foster an adequate understanding of the availability of CRMs.

Conclusion

This paper provides an overview of learners' perspectives on CRM availability. Overall, the results suggest that students primarily interpret the availability of critical raw materials through a finite-stock mental model: scarcity is understood as a direct consequence of limited geological occurrence and ongoing extraction. While students are able to articulate dimensions of supply risk, these additional dimensions appear less spontaneously integrated into their initial reasoning and, in some cases, required contextual interventions. From a MER perspective, this points to fragmented, context-dependent knowledge rather than a consolidated, multidimensional understanding of criticality. Building on these entry points, the MER framework can guide the development of learning pathways that explicitly frame availability as a multidimensional concept and address common intuitive ideas such as the "running-out" narrative.

Outlook

In subsequent MER steps, the instructional guidelines derived from the present findings will be translated into an experimental learning environment in the CRC "Iron, upgraded!" context. It will utilize the case of substituting a critical platinum catalyst by an iron-based alternative in fuel cells to connect raw materials criticality to concrete mitigation strategies and their trade-offs.

ESERA 2025 Copenhagen

Sustainable Competencies In Education: Building Curricula And Advancing Teacher Training Together

Christian M. Thurn
Research on Learning and Instruction, ETH Zürich, Switzerland

Sustainable development offers a pathway to address humanity's greatest challenges such as climate change and biodiversity loss. However, current science curricula often fall short in adequately preparing students to address these complex issues. At ESERA 2025, we held an exploratory seminar addressing this gap by focusing on the interdisciplinary nature of Education for Sustainable Development (ESD) and developing ideas for effective curricula and empirical studies. We discussed two key questions: 1) How can we better prepare teachers to teach sustainability competencies? and 2) Which empirical studies are most informative for designing curricula to teach sustainability competencies?

In this text, we first describe a course for educators on integrating ESD in their lectures at a technical university. We used insights from this course to design the exploratory seminar for ESERA 2025. Then we describe the structure of the exploratory seminar, in which participants engaged in a grouped think-pair-share activity to collect ideas to answer the key questions. This was followed by short presentations from group representatives in a plenary discussion. Finally, we summarize the discussion to inform future curriculum development and research initiatives.

Keywords: Education for Sustainable Development; Competencies; Curriculum Development

Introduction: Education For Sustainable Development (ESD)

Sustainable development is such a central political goal that, in some countries, it is enshrined in the constitution (e.g., in Switzerland, Art. 2 & Art. 73; Bhutan, Art. 5; partially also in Ecuador, Art. 14). The way to achieve this goal can be informed by science. Scientifically based mitigation strategies involve a reduction of emissions at the individual and global levels (Wynes & Nicholas, 2017). In schools, however, such mitigation strategies are rarely discussed, or if so, they focus on private-sphere actions (Kranz et al., 2022). When economic alternatives such as degrowth are mentioned, this is done only sporadically or decontextualized (Díez-Gutiérrez et al., 2024). System-critical questions are rarely addressed, which led Huckle (2012) to conclude that "Mainstream ESD […] uncritically embraces economic growth, globalization and consumerism" (Huckle, 2012, p. 366).

On the other hand, ESD and sustainability competencies are increasingly included in curricula as educational goals. The goal is to prepare students for an unknown future. Many competence frameworks require students to obtain competencies in sustainable development. For example, in Switzerland, the framework curriculum for high schools, such as the Gymnasium, wants students to achieve a deepened social maturity. Such a deepened social maturity requires, among other things, networked, interdisciplinary thinking and education for sustainable development (Schweizerische Konferenz der Kantonalen Erziehungsdirektoren, 2023). As a result, there is a mismatch between current educational practices and the desired outcomes. This warrants research to identify the barriers to changing current practices and to develop effective curricula for ESD.

How should effective ESD curricula be implemented? Whereas it is desirable that ESD includes those strategies that are scientifically backed up to mitigate climate change, ESD must follow certain principles to be ethically valid. The Beutelsbacher Consensus (Wehling, 1977) prohibits instrumental education. It emphasizes that students should develop competencies to form independent opinions rather than being indoctrinated. For example, ESD must not educate pupils 'for' degrowth. On the other hand, the Beutelsbacher Consensus also mandates the inclusion of

diverse viewpoints, including those unfamiliar to students, to promote reflective thinking and avoid indoctrination through omission. Paradoxically, this turns the current practices of rarely mentioning alternatives to the current system (see Díez-Gutiérrez et al., 2024) into a form of indoctrination.

The Role Of Science Education

Every subject in science education has inherent links to sustainability: From the chemical basis of the carbon cycle or processes of material corrosion, the physics of climate change, the geographical impact of human activities, the biological damage of biodiversity loss, to the mathematical modelling of exponential growth. These links provide a foundation for interdisciplinary discussion of mitigation strategies. However, this requires that teachers are prepared to link sustainability issues to their subject and to promote sustainability competencies.

To address this need, the following sections describe an exemplary course designed to support university faculty in integrating ESD into their curricula. This course served as the inspiration for our seminar, as the experiences and pedagogical gaps identified during its implementation directly inspired the research questions and organizational structure of the exploratory seminar held at ESERA 2025. Following the description of this course, the method section details the structure of the ESERA seminar itself. We then present the results derived from that seminar and conclude with a discussion and an outlook for future research.

An Example Course

We developed a course on ESD for university educators at a technical university. The course is divided into three parts: a digital self-study activity, an in-person workshop, and an implementation phase.

Self-Study Activity

In the self-study activity, educators complete a learning module on an online platform. The module starts with a quiz as a formative assessment that also activates prior knowledge about the topic and uses pretesting effects to convey information (Pan & Carpenter, 2023). Afterward, they work through videos and texts describing the climate crisis, the idea of sustainability, and how sustainability relates to ecology, society, and economy. Afterward, to support educators in drawing connections to their teaching, we present the Sustainable Development Goals (SDGs). Using the wedding-cake depiction (see Figure 1), we draw the connection between the three pillars of sustainability (ecology, society, and economy) and cluster the 17 SDGs. The SDGs help as a framework to conceptualize sustainability from different perspectives. All educators should then identify 1-3 SDGs that relate to their teaching. Finally, they also need to formulate a teaching goal.

In-Person Workshop

The in-person workshop starts with thought-provoking quotes about sustainability and an introduction of the participants. Then we discuss the result of the quiz, highlighting questions where participants had a lot of prior knowledge as a motivation, and those questions where participants answered mostly incorrectly. We also repeat core concepts around the problem, such as the 1.5-degree goal, the tipping points, and the relation of energy use, economic growth, and emissions.

To encourage educators to reflect on the extent to which they want to integrate sustainability in their teaching, we utilize the metaphor of fluid spaces, specifically as a river (adapted from Bellina et al., 2018). This metaphor categorizes ESD engagement into three levels, as illustrated in Figure 2. At Level A) on the riverside, they could dip their feet into the water to gain initial experience of teaching sustainability issues, e.g., by adding a few teaching or learning situations related to sustainability. At Level B) they start navigating the currents. Thus, they could create a stronger focus on sustainable development by having dedicated learning goals and cross-referencing between topics that relate to sustainability. At Level C) they engage in white-water rafting in the middle of the river. There, they completely adapt their teaching toward sustainability.

Figure 2. River metaphor of integrating ESD in one's teaching.

Every level comes with challenges: At Level A) we refer to a river-swimming experience from outdoor education (Thurn et al., 2025), where in shallow waters, there is a strong eddy flowing upwards. That is, in shallow waters one is literally swimming upstream. We use this analogy, to vividly explain what could happen when educators add a single activity on sustainability and disregard it in other contexts. Such small actions might evoke the image of greenwashing or lead to rebound effects, such as the perception that sustainability is already discussed once and does not need further attention. In the literature, this is discussed as single-action bias (Zhao & Luo, 2021). It is not wrong to start with baby-steps when changing one's lecture, but one needs to be

aware of such countermovements. At Level B) teaching the complexity of the climate crisis and sustainability in relation to one's lecture topics might become overwhelming for teachers and students. It might also lead to strong reactions by students, who do not see a connection. At Level C) it will become clear that sustainable development comes with lots of ambiguity. It will also be relevant to discuss one's own personal behaviour with regard to sustainability here at the latest.

In the workshop, educators reflect on the different levels and decide at which level they want to implement sustainable development in their lecture. We assign them to groups that aim for the same level, as these groups face similar challenges. During a group activity in the form of a collegial coaching, educators present their lecture and explain which SDGs it covers and how the content relates to sustainability. They present their learning goal and how they will include it in their lecture. The other group members listen and ask themselves: Where do you see chances and risks in the plan? Then they exchange ideas before moving on to the next person presenting their lecture. In a consolidation phase with all participants, each group summarizes its discussion. We then discuss how to deal with frequently mentioned challenges such as emotions (solastalgia, Albrecht et al., 2007; climate change anxiety, Clayton, 2020), rebound effects (e.g., Colmenares et al., 2018), or the single action bias (e.g., Zhao & Luo, 2021).

Implementation And Reflection Phase

In the last phase of the course, educators work on their plan for how to include sustainability in their teaching. During the next weeks, they implement their plan. Afterward, they write a short reflection reporting what their learning goal was and how it went.

Experiences From The Course

A takeaway from the course was the effectiveness of think-pair-share activities (e.g., Kaddoura, 2013). Think-pair-share activities transcended simple classroom participation, often into a form of collegial coaching. By allowing educators to first reflect individually, we cognitively activated them. The share phase led to peer-to-peer support, discussing the complexities of teaching across disciplines.

The course also revealed two areas where even motivated educators lacked important concepts: Whereas most participants were familiar with the ecological footprint, there was a lack of awareness regarding the ecological handprint. The handprint focuses on positive actions that reduce the footprints of others and is a crucial motivator for ESD (Kühnen et al., 2019). Furthermore, there was a gap in understanding the tipping points. Participants often had not heard of this concept or viewed climate change as a linear progression.

The Exploratory Seminar At ESERA

Derived from the research desiderata described above, and the experiences we gained through giving a course on sustainability integration for educators, we aimed to work on the following questions in the exploratory seminar at ESERA 2025:

1) What barriers exist in implementing ESD curricula, and how can these be overcome?

2) How can we better prepare pre-service teachers to teach sustainability competencies?

3) Which empirical studies are most informative for designing curricula to teach sustainability competencies?

At the beginning of the seminar, we introduced these key questions and explained the structure of the seminar. In the setting of a grouped think-pair-share activity, attendees would share their views on these questions. To foster exchange and the documentation of the results, we asked that each group presents its results to the plenum at the end. Attendees could join one of the three

groups to address one of the questions. As participants favored questions 2 and 3, we did not discuss the first question in the seminar. For the sake of completion, we thus cover this question in the discussion section, where we summarize key barriers identified by scientific studies.

In the groups, attendees followed a think-pair-share activity. In the first step, they had individual time to think about answers to the respective questions. Afterward, attendees paired with their group members to discuss how they might contribute to solving their group's question.

In the share phase, all groups came together to exchange their developed ideas and receive feedback from all other attendees. The aim was to arrive at specific ideas for promising next steps in this research area. These could include collaborative research projects, theoretical or empirical research papers, or the establishment of discussion groups to continue working on the ideas after the conference.

Results From The Exploratory Seminar

Here we present the aspects that participants discussed in the exploratory seminar at ESERA 2025 regarding the two questions.

How Can We Better Prepare Pre-Service Teachers To Teach Sustainability Competencies?

Participants emphasized that teachers require tools to facilitate difficult classroom discussions. These conversations often involve navigating high levels of tension. This requires teachers to be prepared to handle the intense emotions students bring to these topics. To address this, participants specifically recommended the Climate Emotion Wheel (Pihkala, 2022, 2024). This tool serves as a reflective framework, helping teachers anticipate and categorize the wide variety of emotional responses—ranging from anxiety to empowerment—that sustainability topics can trigger.

Participants also highlighted the importance of experiential learning. They advocated for place-based education that increases immersion and nature connectedness. Place-based education grounds lessons in local environments to make abstract concepts tangible (Smith, 2013). Outdoor, project-based education is suitable for place-based education (Thurn et al., 2025). Nature connectedness is the subjective connection to nature (Capaldi et al., 2014). It describes one’s personal relationship with the natural world, and studies showed that it is a strong predictor for environmental action (Nisbet et al., 2009). Participants also named public speakers and non-profit associations that could serve as resources for teachers.

Finally, participants underscored the necessity of providing teachers with a comprehensive understanding of the sustainability competencies specific to their regions. This includes clarity on the frameworks that are used, the rationale behind why specific competencies were selected, the relevance of these competencies, and their integration into existing curricula. By analysing how different countries embed sustainability into their educational systems, teachers can establish a collective understanding of the topic. Participants termed this blend of subject expertise and teaching strategy as Pedagogical Content Knowledge (PCK) about sustainability.

Which Empirical Studies Are Most Informative For Designing Curricula To Teach Sustainability Competencies?

Participants emphasized the importance of defining sustainability competencies to ensure that they are practically applicable in educational settings. For example, useful frameworks exist, such as the Sustainable Development Goals (SDGs), the framework of Wiek (2011), or the European Green Competence Framework. However, in competence-based education, there is a challenge of teaching and assessing such competencies.

A central goal of competence-based education is the development of action-competence, which moves beyond passive knowledge toward the willingness and ability to take actions. To achieve this, a research desideratum exists regarding the professionalization of teachers. Educators require more sophisticated tools to navigate the complex landscape of emotions and norms that sustainability topics inevitably evoke. This includes developing specific strategies for dealing with controversy and facilitating meaningful climate action while maintaining pedagogical integrity. Whereas the participants did not name specific further tools for these dialogues, current research highlights approaches for dealing with emotions. For instance, Finnegan and d'Abreu (2024) argue for the integration of hope (see also Grund & Brock, 2019), while Ranney and Velautham (2021) point toward socio-emotional and social justice education as essential foundations for managing complex topics.

The participants also mentioned the necessity of more diverse and robust methodological approaches to better understand how these competencies are acquired. Participants suggested mixed methods designs and multi-lab studies to address the cultural diversity inherent in global environmental challenges. This could help identify universal versus context-specific educational strategies. It is equally vital that research investigates the progression of ESD across all age groups, which stretches from the early foundations in kindergarten all the way through to higher education.

A recurring challenge that participants named in relation to this is how to effectively connect the local with the global, a concept often referred to as the 'glocal' approach. The idea of glocal is that by rooting global sustainability issues in local contexts, educators can increase the personal relevance of the material for their students. Studies could examine how such approaches can incorporate intergenerational aspects, enabling students to see how their current local actions impact both their own future and the global community at large.

Discussion

What Barriers Exist In Implementing ESD Curricula, And How Can These Be Overcome?

As we did not cover this question in the exploratory seminar, we describe key findings from the literature here. Borg and colleagues (2012) list a lack of examples and a lack of expertise as frequent barriers. Pompeii and colleagues (2019) report a detailed list of teacher-identified barriers, with the most frequent being discipline restrictions and personal priorities. They also list student-identified barriers. Disciplinary silos and a lack of adequate professional training opportunities also appear in Parry & Metzger (2023). The barriers thus seem to revolve around a factor comprising lack of "know-how", including best-practice examples and trainings on the topic, and a factor related to the perceptions of one's discipline. Ways to overcome these barriers seem easier to implement for the first factor. More resources, such as professional training, lists of successful examples, or exchange with colleagues, could provide teachers with more ideas in implementing ESD curricula.

Conclusion

In this text we have discussed three key questions regarding the progress of ESD. For the question of existing barriers, the literature revealed that teachers lack the know-how and see discipline restrictions. In the exploratory seminar, participants' answers revealed that to prepare teachers better to teach sustainability competencies, we need to equip them with better Pedagogical Content Knowledge on ESD. This includes how to navigate emotions and norms. It also includes preparation to design experience-based instruction. For the question of informative empirical studies for the design of ESD curricula, participants' answers revealed that such studies should investigate effective strategies for dealing with controversy and emotions.

In conclusion, with a strong foundation in literature on ESD, we identified key areas to guide future research and curriculum design. Integrating these areas into teacher-education programs can enhance the preparation of teachers for building sustainability competence in their profession.

ESERA 2025 Copenhagen

‘How Sustainable Is ...?’ A Teaching Approach In The Field Of Education For Sustainable Development

Anna Klose and Annette Marohn
University of Münster, Germany

Science education can make an important contribution to supporting the 17 Sustainable Development Goals of the United Nations through Education for Sustainable Development (ESD). The paper describes the development of the teaching approach ‘sustain.able?!’ within the framework of design-based research. The approach implements ESD into science lessons by enabling students to systematically assess controversies (e.g. bio-based plastics, vegan diet) considering the three dimensions of sustainability environment, economy and society. At the core of the teaching approach are the so-called 'AssessmentBubbles'. These contain information on the respective controversy, which the students assess from different perspectives based on specific criteria. The assessments are then recorded and reflected on an AssessmentDisc by Banse & Marohn (2021, 2022). This paper outlines the development of the method AssessmentBubbles within the framework of two research cycles involving 46 teachers, 12 experts and 17 students. A trial using the example of vegan diet with 28 students (aged 14-15) shows that the AssessmentBubbles method enables students to assess information from multiple perspectives in terms of sustainability and that they evaluate the method positively.

Keywords: Sustainability, Education for Sustainable Development, design-based research

Introduction

We encounter sustainability in many areas of everyday life, from food shopping and clothing to mobility. Schools should therefore play a key role in showing students the many facets of sustainability, while also promoting their ability to make judgements and take action in this context. But how can learners assess the sustainability of controversies based on criteria?

One possible approach is offered by the teaching approach *nachhaltig.bewerten (assessing sustainability)* which enables students to assess the sustainability of controversies (e.g. *electromobility*) from multiple perspectives (Banse, 2025; Banse & Marohn 2021, 2022). Furthermore, it provides three *AssessmentLevels* (space, time and group) to guide the assessment process systematically. The *AssessmentDisc* enables a didactically reduced conclusion about the sustainability of the controversy.

Although the teaching approach has been successfully tested (Banse, 2025) there is still room for improvement, especially in terms of supporting the students during the assessment process. The teaching approach *sustain.able?!* presented below is a further development of the approach *nachhaltig.bewerten*, which aims to bridge existing research gaps.

Theoretical Background

Sustainability

The guiding principle for sustainable development, published in 1987 by the United Nations World Commission on Environment and Development, states that development is considered sustainable if it ‘meets the needs of the present without compromising the ability of future generations to meet their own needs’ (World Commission on Environment and Development, 1987, p. 16). The Agenda 2030 adopted by the United Nations contains 17 Sustainable Development Goals and expresses the multifaceted nature of sustainability. Thus, it points out that sustainable development cannot only focus on the environment (United Nations, 2015).

Instead, it raises the question of how development can be organized to be ecologically compatible, economically efficient, and socially fair, while enabling current and future generations to lead a good life (MSB NRW, 2019).

This understanding of sustainability with its dimensions of *environment*, *economy* and *society* form an important basis for the teaching approach.

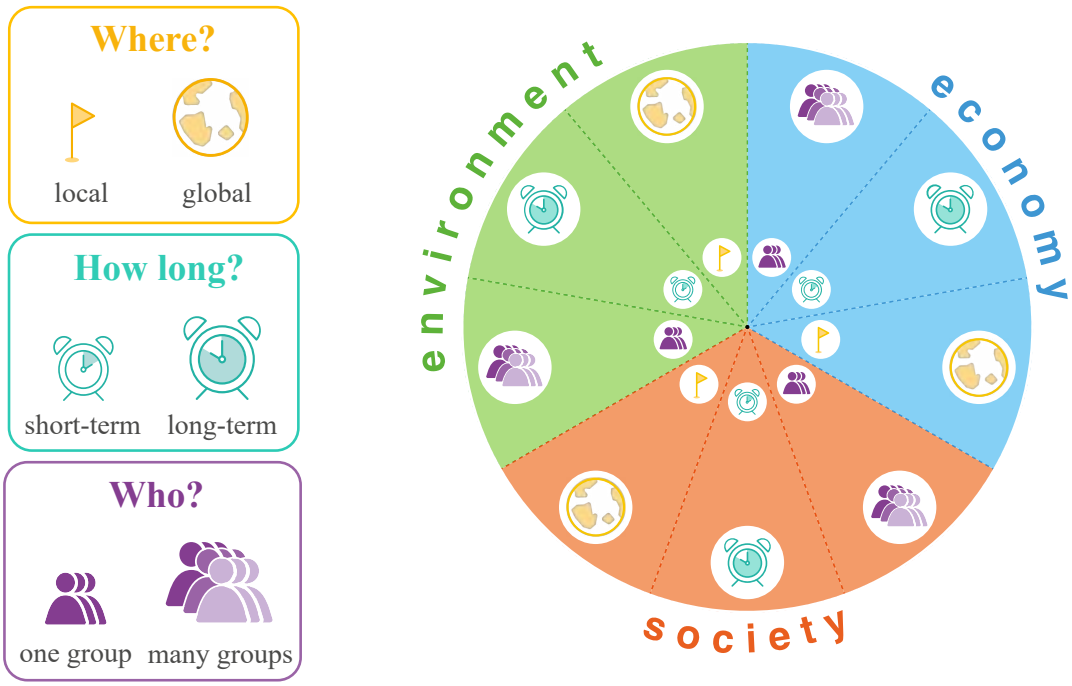
Education For Sustainable Development

Global education systems are also important for the realization of sustainable development. The global UNESCO programme 'Education for Sustainable Development, ESD 2030' emphasises the importance of ESD for achieving the Sustainable Development Goals (Bundesministerium für Bildung und Forschung, n.d.). Education for Sustainable Development should empower children and young people to take responsibility for shaping their own future and that of their generation in line with the principles of sustainable development (UNESCO, 2020).

The school should provide students with the necessary subject-specific and interdisciplinary skills to help them judge and act on important future issues (MSB NRW, 2019). In Germany, ESD is regarded as an important part of school education and is anchored as a mandatory cross-cutting topic in all subjects (ibid.). The teaching approach integrates ESD into the students' learning process.

The Basis Of The Teaching Approach *sustain.able?!*

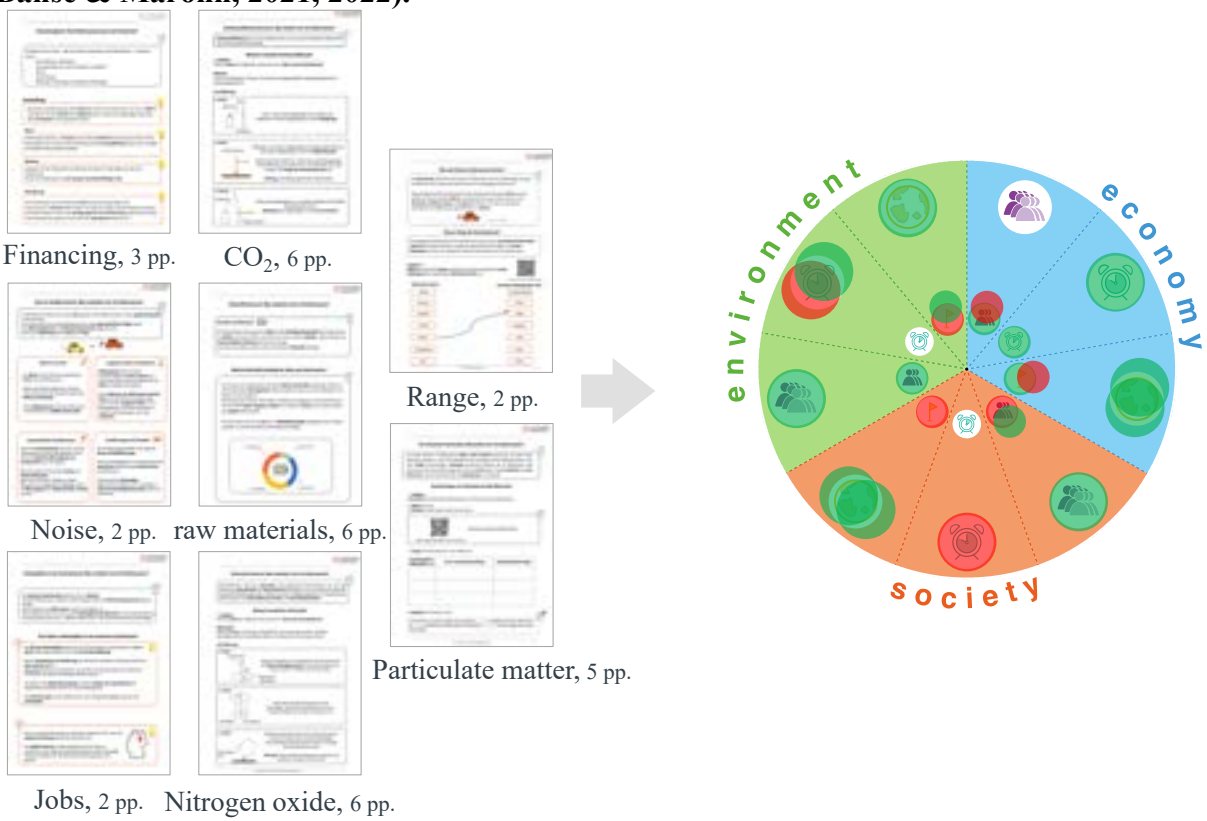
The teaching approach presented in this contribution is based on the approach of *nachhaltig.bewerten* by Banse & Marohn (2021, 2022), which will be outlined briefly below.



The teaching approach enables students to assess controversies in the context of sustainability based on criteria, taking into account the three dimensions of *environment*, *economy* and *society*.

The process of assessment involves the *AssessmentLevels* of space, time and group (Figure 1, left). When students ask whether a controversy such as the expansion of electromobility is beneficial or harmful to sustainability, they can consider it on these three levels of assessment. *Where* are the benefits or harms visible – only locally, e.g. in one city or globally, all over the world? *How long* do the benefits or harms last – are they only short-term, affecting those living today or long-term affecting future generations? *Who* benefits or suffers harm – just one group, such as farmers, or many groups? The teaching material on the controversy surrounding *electromobility* includes, for example, the information that electric cars emit less CO_2 than cars with combustion engines. This describes a *global*, *long-term* impact that affects *many groups*.

The methodological tool used to structure the assessment process is the *AssessmentDisc* (Figure 1, right), which combines the *AssessmentLevels* with the sustainability dimensions *environment*, *economy* and *society*. The *AssessmentDisc* thus visualizes that the questions about *where*, *how long*, and for *whom* a controversy has a beneficial or harmful effect can arise within all sustainability dimensions. When assessing information relating to a controversy, students can mark the corresponding symbols of the *AssessmentLevels*: green for a benefit and red for a harm.



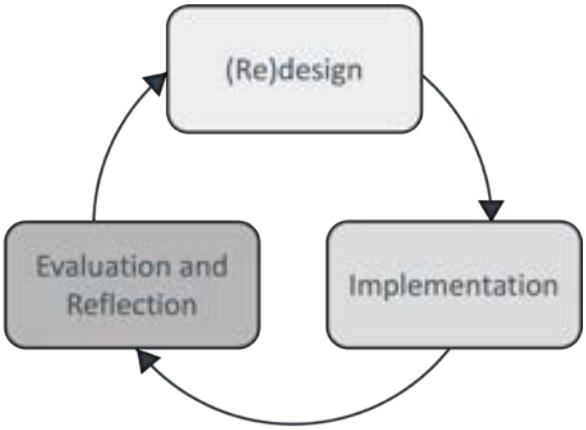
The example just mentioned regarding the reduction of CO_2 emissions describes a *benefit* provided by electric cars. Accordingly, the three *AssessmentLevels* affected – *global*, *long-term*, and *many groups* – are marked *green* on the *AssessmentDisc*. The green markings on the *AssessmentDisc* are in the area of the *environment*, as the information can be assigned to this sustainability dimension.

Figure 1. AssessmentLevels (left) and AssessmentDisc (right) (Banse & Marohn, 2021, 2022).

In order to assess the sustainability of a controversy (here: *electromobility*) the students first work out comprehensive information on various aspects of the controversy (e.g. CO_2 emissions, noise pollution or raw material extraction). To this end, they receive a total of 32 worksheets with tasks and factual information on eight aspects. In the next step, all this information is assessed and visualized using green and red markings on the *AssessmentDisc* (Figure 2).

Figure 2. Extensive information material, assessed and marked on the AssessmentDisc (Banse & Marohn, 2021, 2022).

At the end, a conclusion can be drawn. The more green markings on the outer circle, the greater the controversy's impact on sustainability, because this means a *global*, *long-term* benefit for



many groups.

Research Framework

Design-Based Research

The research uses the framework of design-based research (DBR) (Brown 1992; Collins, 1992) and follows the three phases of *Framing, Design Experiment* and *Re-Framing* (Gravemeijer & Cobb, 2006). In the *Design Experiment* phase there are iterative cycles (Figure 3) that include the development of a design (in this case: teaching approach *sustain.able?!*), its implementation and evaluation (Rohrbach-Lochner & Marohn, 2018). Each cycle is characterized by its own objectives and sub-research questions. The overarching goals of the DBR research process are to develop an innovative design for practical application (What works?) and to develop a theory about how the design works (How does it work?).

Figure 3. Iterative cycles in DBR (adapted from Rohrbach-Lochner & Marohn, 2018).

Research Gaps

A workshop with teachers ($N = 20$) showed that the teaching approach *nachhaltig.bewerten* still has some weaknesses (Banse, 2025). The majority of teachers criticized the high complexity and the large amount of information material that was provided to the students.

This resulted in students taking a long time to process the key points from the large amount of information material. Consequently, they only had little time left to assess the information. These areas for further research and additional ideas should be addressed in the approach *sustain.able?!*.

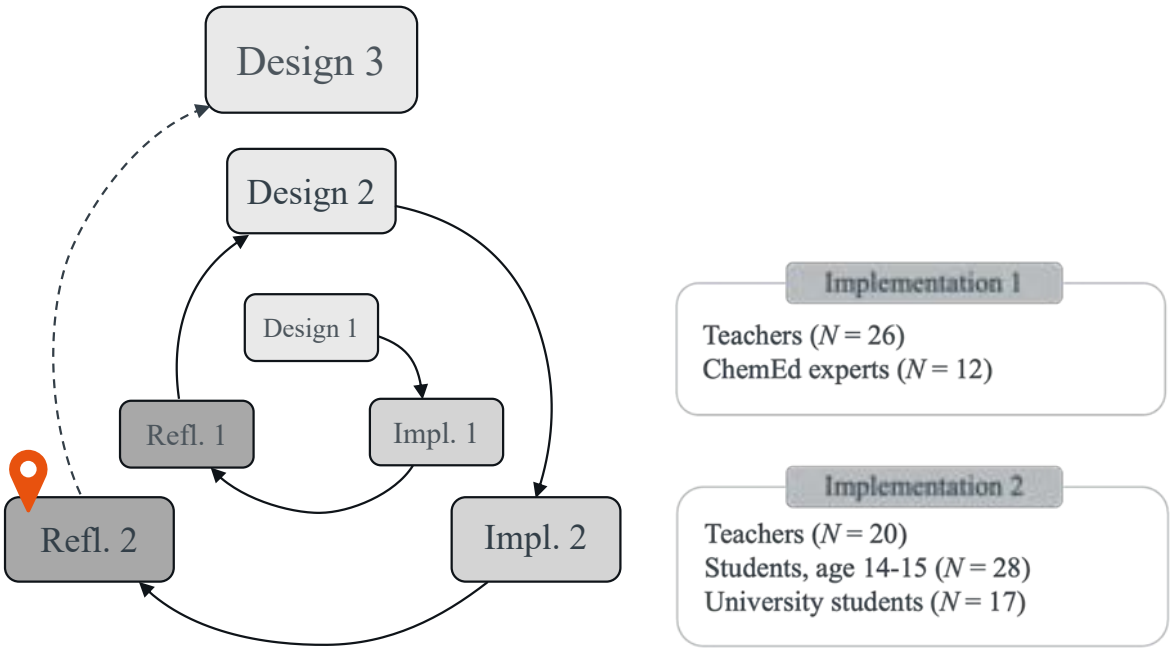
This paper focuses on just one of several research gaps and its solution.

Research Questions

Due to the research gaps described above, the presentation at ESERA focused on a stronger support for the assessment process. The following research questions were formulated:

RQ 1: How can the process of assessing information be made more structured and methodologically viable for students?

RQ 2: To what extent do students assess the information as intended?



RQ 3: How do students evaluate the new methodological tool of '*AssessmentBubbles*'?

Method

The design (here: teaching approach *sustain.able?!*) for stronger support of the assessment process was tested, analysed and optimized in several trial cycles with students aged 14-15 ($N = 28$), teachers ($N = 46$), university students ($N = 17$) and experts in chemistry education ($N = 12$) (Figure 4). Data was collected via questionnaires for all samples. During the testing with

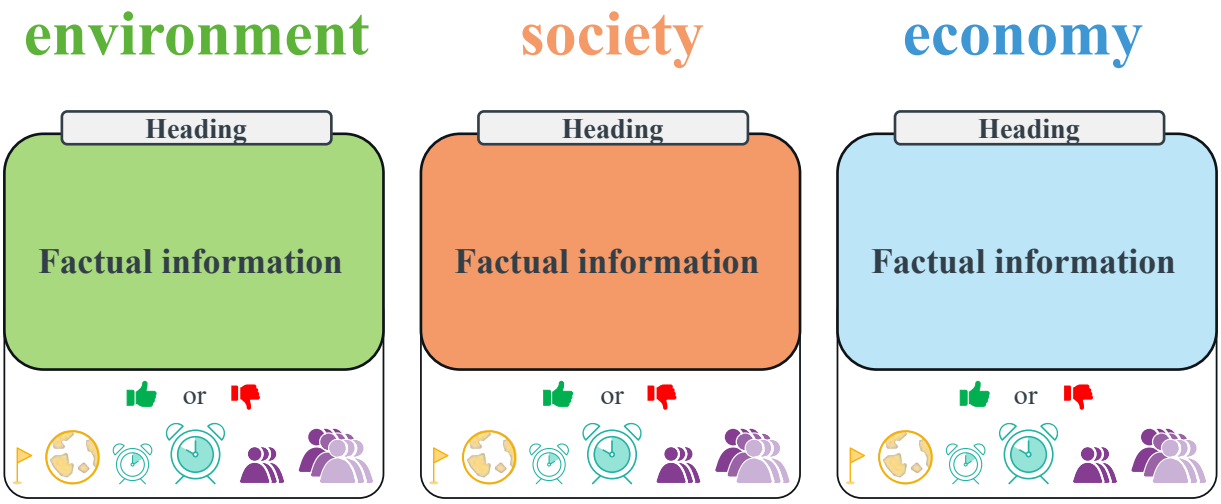
the students, pre-post-tests and audio and video recordings were also collected. This data was evaluated using qualitative content analysis (Kuckartz & Rädiker, 2024).

Figure 4. Iterative development of teaching materials within the sustain.able?! project.

Results

The Methodological Tool Of 'Assessmentbubbles' (RQ 1)

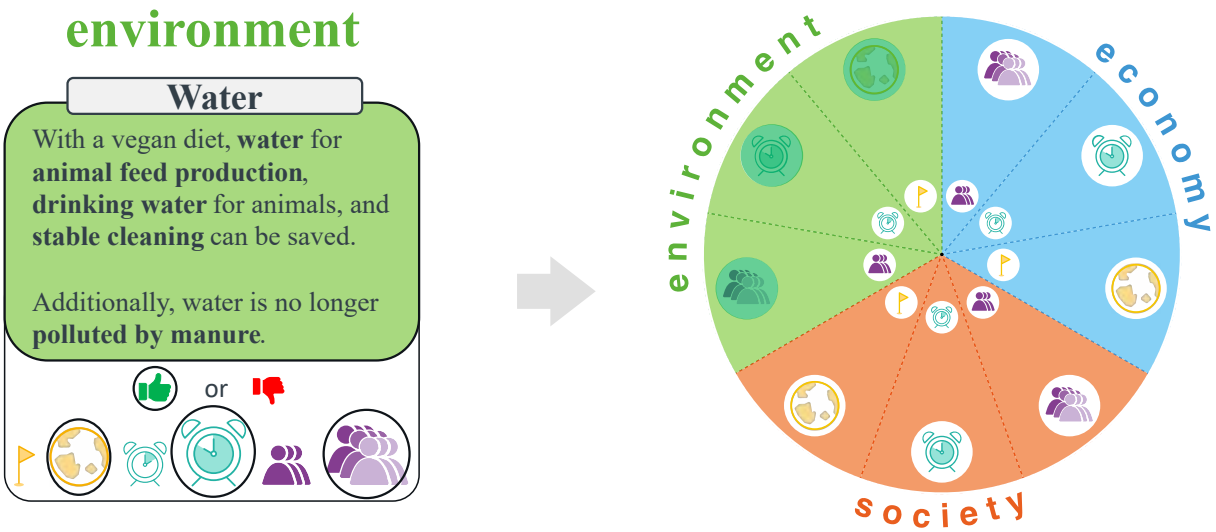
The *AssessmentBubbles* (Figure 5) were developed as direct outcomes of research question 1 to provide greater support for the assessment process for students. Compared to the previous approach, the assessment is supported by three measures:



a) Students receive much more compressed factual information. They do not have to work through numerous worksheets to gather the information themselves.

b) The information is assessed directly in the immediate proximity of the information. In addition to scientifically based information, an *AssessmentBubble* also contains an assessment section. The assessment of the information takes place in two steps. First, students decide whether the information describes a benefit or harm and circle the corresponding symbol (green or red thumb). Afterwards, they assess the *AssessmentLevels*, considering the space (*local* or *global*), the timeframe (*short-term* or *long-term*) and affected groups (*one group* or *many groups*) for demonstrated benefits or harms. They mark the corresponding symbols of the *AssessmentLevels* from Banse & Marohn (2021, 2022).

c) The colour of the *AssessmentBubble* directly indicates the dimension to which the information refers*: environment* (green), *society* (orange) or *economy* (blue).

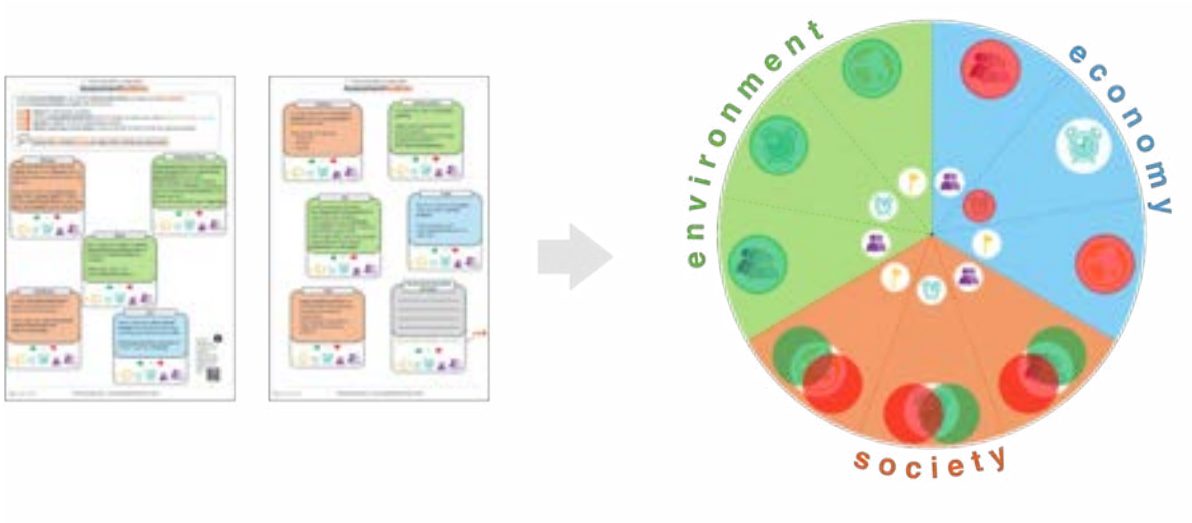


In the next step, the assessments from the bubbles are transferred to the *AssessmentDisc*. This can be illustrated with the example of *vegan diets,* where the sustainability of a plant-based diet is compared to one that includes animal products. This context was chosen because of its relevance to the students' lives, the breadth of available information and its alignment with the German biology curriculum.

Figure 5. AssessmentBubbles in the project sustain.able?!.

The ‘water’ aspect describes the lower water consumption and avoidance of water pollution caused by manure in the case of a *vegan diet*, representing a *global*, *long-term* benefit for *many groups*. Accordingly, the symbols are circled on the *AssessmentBubble* and transferred to the *AssessmentDisc* with green markings (benefit) within the *environment* dimension (Figure 6).

Figure 6. Transfer from the AssessmentBubble to the AssessmentDisc.



In a sustainability controversy students receive several *AssessmentBubbles* containing information from all three dimensions. The *AssessmentBubbles* are all included on only two worksheets (Figure 7). Once all *AssessmentBubbles* have been transferred to the *AssessmentDisc*, a differentiated picture of the sustainability of the controversy under consideration emerges (Figure 7).

Assessment Of The Information In The Assessmentbubbles (RQ 2)

To draw conclusions about the understanding of the new method *AssessmentBubbles*, the information in the bubbles assessed by the learners ($N = 28$) were analysed. Each student assessed 10 information (in 10 bubbles), so a total of 280 bubbles were evaluated.

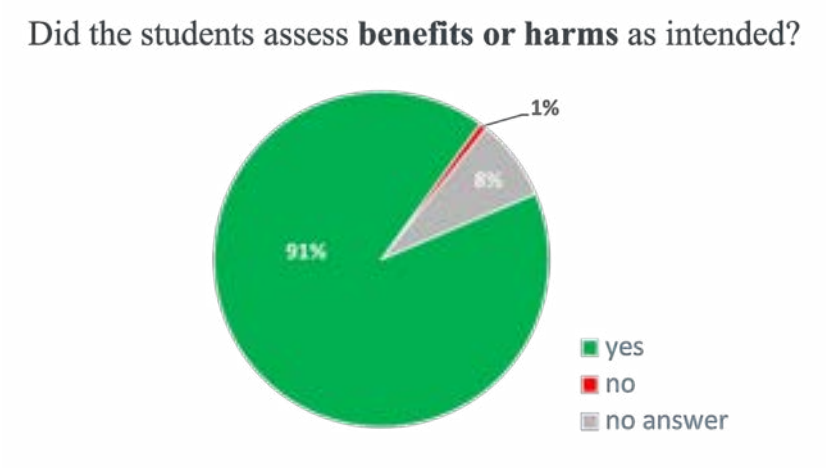


Figure 7. Example 'vegan diet', AssessmentBubbles and AssessmentDisc.

Benefits And Harms

Examining the results of the first step, in which students classified the information in the bubbles as a benefit or a harm, reveals a high accuracy: Over 90 % of the bubbles were classified correctly (Figure 8).

Figure 8. Assessment of benefits and harms by students.

AssessmentLevels

For each *AssessmentBubble* the three *AssessmentLevels* (*Where? How long? Who?*) are considered in addition to the benefits and harms. Therefore, an analysis was conducted to determine how many of the intended levels were assessed per bubble – one, two, or all three. In more than 80 % of the bubbles at least 2 out of 3 *AssessmentLevels* were correctly assessed (Figure 9).

Feedback On The Tool 'Assessmentbubbles' (RQ 3)

After the trial the students provided feedback on the method *AssessmentBubbles* via a five-point Likert scale questionnaire containing the following items, translated from German:

1 It was easy for me to assess whether the information described a *benefit* or a *harm.*

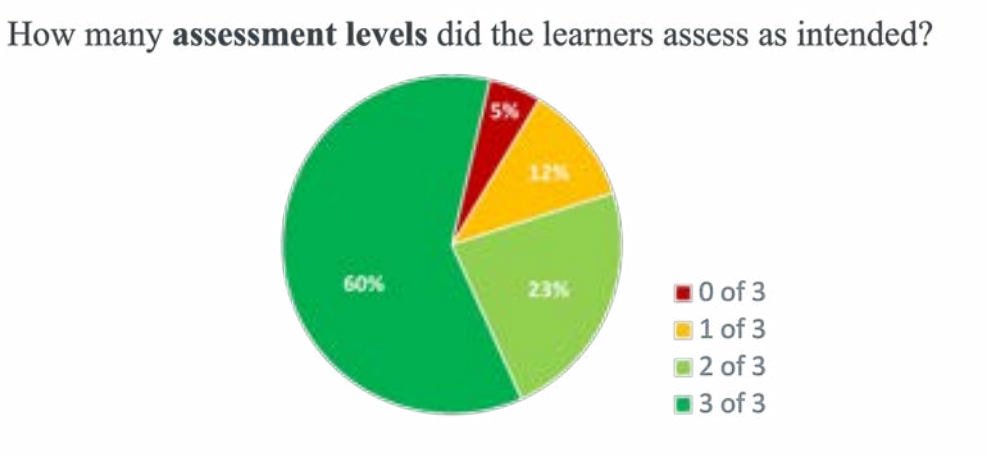
2 It was easy for me to assess *where*, for *how long*, and for *whom* the benefit or harm is shown.

3 It was easy for me to transfer from the Bubbles onto the *AssessmentDisc*.

4 The *AssessmentBubbles* gave me a good overview of the topic of *vegan die*t.

The results show predominantly positive feedback (Figure 10).

Figure 9. Assessment of AssessmentLevels by students.



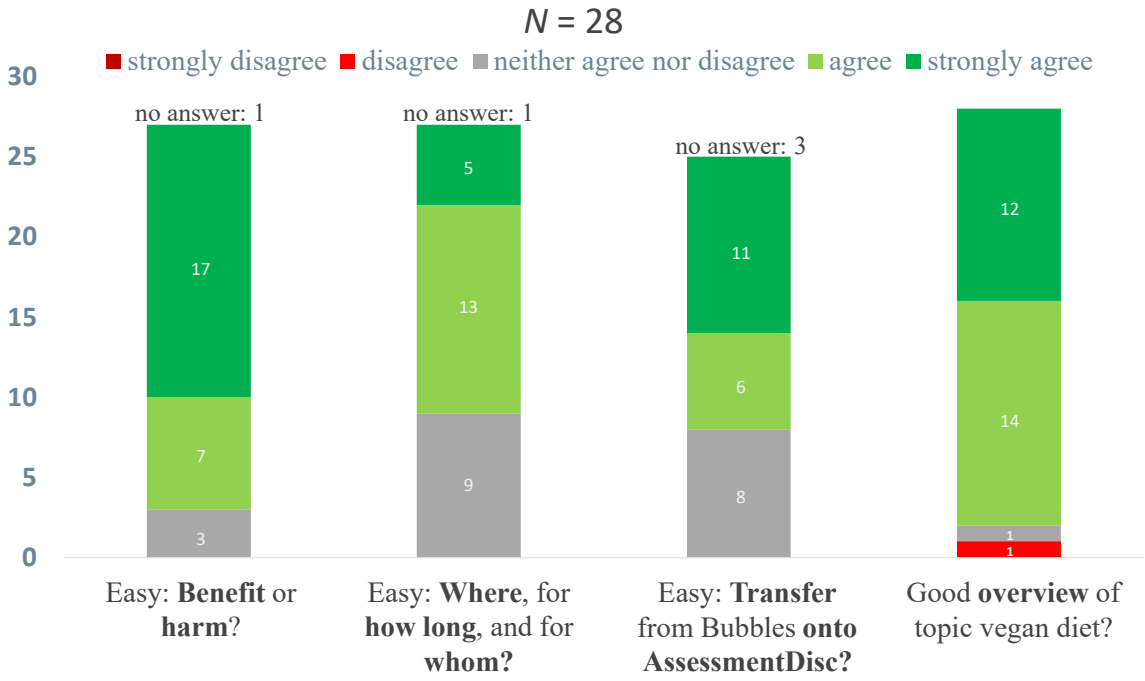


Figure 10. Assessment of AssessmentLevels by students.

The evaluations of the initial results indicate that *AssessmentBubbles* can support the assessment process for learners.

Summary And Outlook

The *sustain.able?!* teaching approach as a further development of the *nachhaltig.bewerten* approach aims to enable learners to assess the sustainability of a controversy in a criteria-based manner considering the three dimensions of *environment*, *economy* and *society*. Both approaches leverage *AssessmentLevels* (space, time, group) and the *AssessmentDisc* to guide this process.

The new methodological tool *AssessmentBubbles* in the teaching approach *sustain.able?!* has succeeded in simplifying and supporting the process of assessing information through a) compressed information, b) the immediate proximity of information and assessment and c) the color-coding of information according to sustainability dimensions.

Initial trials with students aged 14-15 demonstrate that the *AssessmentBubbles* effectively support learners in assessing sustainability controversies.

Expanding the approach to other scientific topics, increasing support for implementation in the classroom (e.g., developing a free app), and encouraging deeper reflection among students on sustainable decisions will be the next steps in this research project.

Furthermore, in line with the iterative process in DBR, Design 3 (Figure 4) is developed following an in-depth analysis of the data from the trial with the students. These revised teaching materials will then be tested with a larger sample of students.

ESERA 2025 Copenhagen

How To Teach In Times Of Biodiversity Loss: Pedagogical Approaches To Transform Our Relationship With Nature

Camilo Rojas-Valdivia
Pontificia Universidad Católica de Valparaíso, Chile

Biodiversity loss, exacerbated by climate change, represents a critical challenge that demands an integrated educational response. This article presents a narrative review exploring pedagogical approaches aimed at improving students' attitudes towards biodiversity and fostering pro-environmental behaviours. Recent literature identifies four main educational challenges: promoting positive attitudes towards biodiversity, increasing environmental literacy, fostering environmental efficacy, and reducing maladaptation due to climate anxiety. In response, three key pedagogical approaches are proposed: place-based education (PBL), Field Environmental Philosophy (FILAC), and the development of personalized ecologies. These strategies, including field trips, nature journaling, and the creation of gardens and green spaces, are highlighted for their ability to connect students with nature while fostering socioemotional and critical thinking skills. However, their implementation faces barriers such as limited time, resources, and adequate teacher training. It is concluded that integrating these approaches into school curricula can help build a citizenship committed to sustainability and environmental regeneration, especially if supported by teacher professional development programs that enhance their application across diverse educational contexts.

Keywords: Environmental education, biodiversity loss, place-based pedagogy

Introduction

Human-driven alterations to ecosystems are producing profound and cascading effects that compromise their functioning, stability, and resilience. Processes such as forest fragmentation, agricultural intensification, and the widespread use of pesticides disrupt species richness, trophic networks, nutrient cycling, pollination, and pest regulation, generating long-term consequences for ecosystem integrity (Haddad et al., 2015; Sánchez-Bayo & Wyckhuys, 2019; Dirzo et al., 2014). These pressures are expected to intensify under climate change, which further alters population dynamics, ecological interactions, habitat connectivity, and ecosystem resilience (IPBES, 2019).

Despite the magnitude of biodiversity loss, its consequences are often difficult to perceive and evaluate. Individuals, including scientists, tend to assess environmental change relative to the conditions they first experienced, a cognitive bias known as the shifting baseline syndrome, whereby progressively degraded states become normalised across generations (Soga & Gaston, 2018). This phenomenon is closely linked to the extinction of experience, referring to the gradual decline in meaningful human–nature interactions, which in turn shapes environmental attitudes and behaviours (Gaston & Soga, 2020; Colléony et al., 2020).

Understanding how people relate emotionally and cognitively to the natural world is therefore central to biodiversity conservation. Concepts such as biophilia—the affective affinity toward other living beings—and biophobia—negative emotions and attitudes toward nature—capture the emotional dimensions of human–nature relationships, both of which are strongly shaped by cultural, social, and educational contexts (Woods & Knuth, 2023; Albuquerque & Silva, 2024; Soga & Evans, 2024). While biophilic relationships are associated with greater willingness to engage in conservation actions, biophobic responses can reduce support for biodiversity protection and even promote species persecution (Soga et al., 2023). Consequently, fostering positive, experience-based relationships with nature through education has been identified as a

key strategy for counteracting biophobia and promoting conservation-oriented behaviours (Deutsch et al., 2021; Zsido et al., 2022).

However, strengthening connections with nature is not without tension. Greater environmental awareness and emotional identification with nature have also been linked to increased psychological distress, as individuals perceive climate change and biodiversity loss as threats to their own well-being and future (Curll et al., 2022; Wullenkord et al., 2024). These responses have been conceptualised as climate anxiety and eco-anxiety, which, while not pathological in themselves, may exacerbate mental health challenges and lead to maladaptive coping strategies if left unaddressed (Crandon et al., 2024). Educational approaches that seek to promote environmental engagement must therefore balance ecological awareness with emotional support and resilience.

In response to the intertwined ecological and emotional dimensions of the biodiversity crisis, educational systems are increasingly called upon to move beyond purely cognitive or technocratic models. This shift involves reimagining education as a space for cultivating ecological justice, relational understandings of humans as ecological beings, and forms of coexistence with the more-than-human world (Common Worlds Research Collective, 2020). Yet, implementing such transformations presents significant challenges for teachers, who must navigate not only curricular demands but also their own emotional responses—and those of their students—to the climate and biodiversity crises (Suarez et al., 2024). Within this context, science education emerges as a critical arena for integrating ecological knowledge, emotional engagement, and ethical responsibility in ways that support both biodiversity conservation and human well-being.

Aims Of Study

The study aims to:

1. Synthesize evidence on the formation of environmental attitudes and behaviours.
2. Synthesize the evidence on pedagogical approaches that promote positive relationships with biodiversity.
3. Propose evidence-based guidelines for designing impactful science education practices.

Methods

A literature review was conducted using Scopus, focusing on:

- Biodiversity, well-being, and human development.
- Educational strategies addressing biodiversity loss and emotional well-being.
- The intersection of environmental education and socio-emotional development.

Inclusion criteria emphasized recent (post-2014) empirical and theoretical studies relevant to primary and secondary education. Exclusions included higher education contexts, non-educational interventions, and studies addressing aspects of the climate crisis such as greenhouse gas emissions, pollution, or carbon footprints, without directly considering biodiversity. Emerging themes guided additional searches to refine the conceptual and practical recommendations.

The complete list of search terms included combinations such as:

- Biodiversity AND Wellbeing
- Environmental literacy
- Environmental literacy AND Teachers

- Climate change AND Education
- Wellbeing AND Environmental education
- Environmental education AND Chile
- Biophilia AND Education
- Biophobia AND Education

The findings of the review were synthesized and organized in alignment with the study aims. First, evidence was examined to identify key processes involved in the formation of environmental attitudes and behaviours. Second, the literature was analysed to characterize pedagogical approaches and educational strategies that promote positive relationships with biodiversity. Finally, insights from both strands of evidence were integrated to inform the development of evidence-based guidelines for the design of impactful science education practices that intentionally address both cognitive and affective dimensions of human–biodiversity relationships.

Results

The results are organized into four sections that collectively address the three aims of the study. The first two sections synthesize evidence on the formation of environmental attitudes and behaviours, responding to the first aim. Specifically, the section on *Relationships with Nature* examines theoretical and empirical contributions that explain how affective, experiential, and cognitive dimensions—such as personalised ecologies, biophilia, and species knowledge—shape human–biodiversity relationships. The section on *Climate anxiety and eco-anxiety* complements this perspective by focusing on emerging emotional responses to environmental degradation, highlighting how these emotions can both motivate and constrain pro-environmental action depending on factors such as environmental efficacy and emotional competencies.

The third section addresses the second aim by reviewing educational strategies that intentionally foster positive relationships with biodiversity in school contexts through locally grounded, experiential, and affectively rich approaches. Finally, the fourth section responds to the third aim by synthesizing evidence from the previous sections to identify key educational challenges and propose evidence-based guidelines for designing science education practices that intentionally integrate attitudinal, emotional, and action-oriented dimensions of environmental learning.

Relationships With Nature

Personalised ecologies have emerged as a useful framework for examining how individuals relate to nature through direct, sensory interactions with other species and their ecosystems (Gaston et al., 2018). These ecologies are shaped by the dynamic interplay of external and internal factors, including opportunities to engage with nature, individual capacities to participate meaningfully in such interactions, and the motivations guiding behaviour toward natural environments (Gaston, 2024). Evidence suggests that rich and diverse personalised ecologies are associated with more positive attitudes toward biodiversity and a greater willingness to engage in conservation actions, whereas impoverished or predominantly negative experiences with nature are linked to increased biophobia (Gaston et al., 2023).

This perspective aligns with broader research on the development of human–nature relationships, which highlights the importance of formative experiences during childhood. In particular, exposure to influential social models and engagement in meaningful nature-based activities, such as observing natural processes or cultivating plants, have been identified as strong predictors of higher levels of nature connectedness in adulthood (Gong & Li, 2024). Furthermore, perceived

knowledge of local species has been shown to reduce emotions associated with biophobia, including fear, disgust, and misperceptions of danger (Soga et al., 2020). In educational contexts, strategies aimed at enriching personalised ecologies, such as fostering species identification skills, providing regular opportunities for interaction with natural elements, and facilitating contact with experts in natural history and conservation, may therefore play a key role in promoting biophilia, ecological literacy, and pro-environmental behaviours.

Climate Anxiety And Eco-Anxiety

Growing evidence indicates that younger people, particularly those belonging to Generation Z, experience climate and eco-anxiety with greater intensity and emotional awareness in response to the global climate crisis (Tsevreni et al., 2023; Wullenkord et al., 2024). These heightened emotional responses are not uniformly maladaptive; when accompanied by a strong sense of environmental efficacy—the belief that individual and collective actions can meaningfully contribute to climate mitigation—climate anxiety has been shown to motivate pro-environmental behaviours (Becht et al., 2024). However, research also suggests that differences in emotional education shape how individuals cope with these emotions, with gendered patterns emerging in which men tend to report fewer emotional resources for managing climate-related anxiety (Wullenkord et al., 2024). Taken together, these findings underscore the importance of educational approaches that integrate emotional competencies to reduce distress while supporting constructive engagement with environmental challenges.

Educational Strategies

Place-based education (PBE) has emerged as a pedagogical approach aimed at addressing environmental challenges by situating learning within local communities and their socio-environmental issues, thereby integrating formal education, environmental stewardship, and community development (Smith, 2017). Drawing on multiple educational traditions, PBE employs strategies such as project-based learning, field trips, scientific camps, and nature journaling to connect disciplinary knowledge with students' lived environments (Bollich, 2023; Yemini, Engel, & Ben Simon, 2023). Empirical evidence suggests that this approach enhances learning outcomes, particularly when students perceive opportunities to make decisions about their learning processes and recognize that their work contributes meaningfully to environmental protection or restoration. Nevertheless, its implementation is often constrained by limited instructional time, insufficient funding, and gaps in teacher preparation (Hamilton & Marckini-Polk, 2023).

Complementary to this approach, playscapes—designed environments that recreate local natural landscapes under controlled conditions—seek to promote exploration, sensory engagement, and diverse forms of play (Carr & Luken, 2014). The variation in topography and the availability of both natural and artificial movable elements support predominantly exploratory and physical play, while also enabling social interaction and self-care activities (Loebach & Cox, 2022). Research indicates that learning and play within playscapes foster intrinsically motivated forms of inquiry, encourage environmentally responsible behaviours, and stimulate creativity and goal flexibility, all of which contribute to a stronger emotional bond with the environment by promoting feelings of safety and agency (Wight et al., 2016; Yuan et al., 2024).

In the Chilean context, related initiatives provide further evidence of the educational potential of locally grounded, nature-based approaches. The implementation of Life Labs—student-managed school gardens integrating emotional skills, empathy, and critical thinking—has been associated with increased pro-environmental behaviours, the development of dispositions such as open-mindedness, self-confidence, and truth-seeking, and a reduction in disruptive behaviours,

particularly among younger students (Ampuero et al., 2015). Similarly, Field Environmental Philosophy (FILAC) combines ecological and philosophical knowledge to design ethically and ecologically oriented educational experiences, including contemplative practices, drawing as a tool for observation and interpretation, sensory exploration, creative engagement with local species, and the development of school-based scientific projects linked to fieldwork (Rozzi, 2018; Lewis et al., 2018; Rendoll-Cárcamo et al., 2020).

Educational Guidelines To Promote Positive Attitudes And Relationships Toward Biodiversity

Based on the reviewed literature on the formation of attitudes and relationships with nature, as well as the challenges that biodiversity loss poses for society in general and the educational system in particular, the reviewed literature indicates that education faces the following challenges:

1. Enriching personalized ecologies by fostering biophilia and mitigating biophobia, understanding them as positive and negative emotions and attitudes toward biodiversity and living beings, respectively.
2. Increasing environmental literacy and, therefore, individuals' capacity to recognize both the different components of biodiversity and the potential threats it faces.
3. Promoting environmental efficacy, that is, the belief that individual and collective actions have a significant impact on mitigating climate change.
4. Reducing the likelihood of maladaptation due to climate anxiety and eco-anxiety through emotional management skills.

Based on the reviewed evidence, we propose that education aimed at promoting positive attitudes and relationships toward biodiversity should follow three guidelines to guide educational practices:

1. Create opportunities for meaningful interaction with nature, both inside and outside the classroom.
2. Promote positive impacts on the immediate local environment through projects that connect students with their context.
3. Develop emotional and critical thinking skills that enable students to face environmental and emotional challenges.

Discussion

Accelerated biodiversity loss, intensified by climate change, poses complex challenges that require educational responses aimed at fostering environmentally respectful societies. Within this context, incorporating the concept of personalised ecologies into education involves recognising that individuals' interactions with the natural environment vary across social groups and life experiences, and that these interactions are fundamental for building meaningful relationships with nature. Enriching students' personalised ecologies aligns with the objectives of Natural Sciences education, which seeks not only to develop scientific knowledge about biodiversity but also to cultivate curiosity, wonder, and engagement with the natural world (MINEDUC, 2024).

The literature indicates that rich and diverse personalised ecologies are associated with higher levels of environmental literacy, stronger pro-environmental behaviours, and a reduced susceptibility to shifting baseline syndrome, which limits individuals' capacity to perceive environmental degradation over time (Gaston et al., 2023). This evidence supports the integration of approaches such as place-based education (PBE) and Field Environmental Philosophy

(FILAC), both of which promote sustained, direct engagement with local environments and thus contribute to the development of enriched personalised ecologies. In Chile, environmental education teachers have emphasised the need to incorporate outdoor learning spaces and practical, collaborative approaches that actively involve local communities, reinforcing the relevance of these pedagogical frameworks (Prosser-Bravo et al., 2022).

Flexible strategies such as field trips and nature journaling further support these aims, as they can be adapted to diverse curricular contexts, contents, and time constraints. Nature journals, in particular, may function either as components of inquiry-based projects or as pedagogical activities in their own right, fostering students' connections with their environment, their peers, and themselves (Bollich, 2023; Lewis et al., 2018; Tsevreni, 2021). Through these practices, opportunities emerge not only to enrich personalised ecologies but also to strengthen positive emotions toward nature and develop socio-emotional competencies.

Despite their potential, the implementation of these approaches in the Chilean educational system faces persistent challenges, including limited time for planning and execution, restricted access to resources, uneven levels of institutional support, and variations in teachers' prior experience with environmental education (Prosser-Bravo et al., 2020). While PBE and FILAC can be integrated into the regular curriculum—particularly within subjects designed to apply scientific knowledge to interdisciplinary and socially relevant contexts—their effectiveness ultimately depends on sustained commitment from the broader school community.

Community engagement is also central to initiatives aimed at promoting biophilia through the creation of educational green spaces, such as gardens, orchards, playscapes, green roofs, and living walls. These environments have been shown to support the development of pro-environmental attitudes and socio-emotional skills; however, both the underlying biological processes and the associated attitudinal and emotional changes require time to emerge. Importantly, the skills and dispositions fostered in these settings align with Chile's Cross-cutting Learning Objectives and, in the current curricular framework, are increasingly integrated into subject-specific learning goals (MINEDUC, 2016, 2018, 2024). This alignment highlights the broader educational value of such practices, particularly in relation to emotional regulation and resilience, which are critical for mitigating the negative effects of climate and eco-anxiety.

Finally, teacher education and professional development represent key leverage points for the effective integration of these approaches. Research in Chile has documented that environmental education is frequently delivered by teachers without specialised scientific training, limiting the integration of cognitive, procedural, and affective dimensions of environmental learning (Torres-Rivera et al., 2017; Karelovic-Vargas & Kong, 2022). Moreover, these challenges extend beyond non-specialist teachers, as even educators with scientific backgrounds report insufficient preparation to address sustainability in educational contexts (Quiroz-Martínez, 2024). Consequently, embedding these pedagogical frameworks within both initial teacher education and ongoing professional development is essential. As prior studies suggest, successful environmental education requires not only exposure to natural settings but also pedagogical practices that intentionally foster affectivity, empathy, play, and interaction with both the environment and others (Bertling, 2019; Gong & Li, 2024).

Conclusion

Education is at a crucial moment to address environmental challenges, such as biodiversity loss and its effects on human well-being. This work identifies four key challenges: fostering positive relationships and emotions toward biodiversity, increasing environmental literacy, promoting environmental efficacy, and reducing eco-anxiety. Three guidelines are proposed to address these

challenges: creating meaningful interactions with nature, generating positive impacts on the environment, and developing emotional and critical thinking skills. Place-based education and Field Environmental Philosophy approaches, along with strategies such as field trips, nature journaling, and the creation of green spaces, are presented as effective tools. However, it is crucial to overcome obstacles such as lack of time, resources, and community support, as well as to have trained teachers, to achieve an education that shapes citizens committed to the conservation and regeneration of the environment.

Acknowledgement

I would like to express my sincere gratitude to Dr. Karina Madriaza Maturana for her guidance.

Cross-Cultural Analysis Of Stem Human Resources Community Influences On Gender: Focus On Higher Education Students In Japan, America, And Malawi

Tomotaka Kuroda
Tama University / Shizuoka University, Japan

In countries such as Japan, which strongly promotes science, technology, engineering, and math (STEM), human resource policies have increased. In education, the importance of a competency model is widespread; however, because many aspects of competency are influenced by the cultural background of individuals, certain considerations must be made for international comparisons. This study examines the culture of STEM and proposes a competency model for STEM human resources in a global context, particularly focusing on gender. For this, a 21-question survey was conducted among culturally diverse Higher education students (Japan, America and Malawi); 252 males and 157 females. There were significant differences between male and female students in the target country for 10 of the 21 ability elements. Significant gender differences were observed in STEM human resource consciousness and recognition, such as "collaboration," "ability to apply rules and regulations," and "ethics."

Keywords: Gender in STEM, Higher Education, STEM education

Introduction

In Japan, fostering science and technology-related human resources and innovation has become increasingly important in recent years. This is evident in the establishment of a Minister's Meeting task force at the Ministry of Education, Culture, Sports, Science and Technology (MEXT, 2018) based on the concept of "Society 5.0" (Cabinet Office, 2016). In this context, three abilities have been proposed: (1) ability to accurately interpret and respond to writing and information; (2) ability to engage in and apply scientific thinking and inquiry; and (3) sensitivity and ability to discover and create value, as well as curiosity and inquisitiveness, within a human resource profile.

However, because many aspects of competency are influenced by individuals' cultural backgrounds, certain considerations must be made when making international comparisons. This study focuses on the culture of science, technology, engineering, and math (STEM) and proposes a competency model for STEM human resources in a global context, particularly focusing on gender.

While previous studies, such as those by Kuroda (2021) and Kuroda (2022), have used Japan and Africa (Malawi) as case studies, Kuroda (2024) examined Japan and the America. This study focuses on gender and considers Japan, Malawi, and the America as case studies. America is an advanced country that has been actively promoting STEM education. In 2010 and 2012, the President's Council of Advisors on Science and Technology published reports to increase the number of people working in STEM fields (President's Council of Advisors on Science and Technology, 2010 / 2012). These policies have been in effect for over a decade. Malawi is one of the poorest countries worldwide, with a gross national income per capita of 600 US dollars (World Bank, 2023). For many years, the Japanese government has provided educational support for science and mathematics in Malawi as part of its official development assistance. Consequently, Malawi shares some characteristics of science and mathematics education with Japan, making it a suitable candidate for comparative analysis.

Therefore, the following research questions (RQs) were established to examine competencies

common to the global STEM workforce:

RQ1: What are the characteristics of the STEM human resources community among students in the target country, and do these perceptions differ by gender?

RQ2: How can RQ1 be clarified by examining common consciousness and recognition among students in the target country?

Methods

In this study, a survey was conducted among culturally diverse Japanese, American, and Malawian students. The Japanese students were first- year students in the Faculty of Science at a local national university. The survey was conducted at the end of Quarter 2, as the university operates based on a quarter system). In this faculty, students can major in mathematics, physics, chemistry, biology, and geography, with approximately 36% advancing to graduate schools. The American students were recruited from freshman biology classes at a large midwestern university, while the Malawian students were first- and second-year students at an ICT vocational school, and a survey was conducted at the end of the year.

A total of 228 Japanese (male: 172, female: 56), 116 Americans (male: 44, female: 72), and 82 Malawian (male: 36, female: 29, not answered: 17) students participated in the study. Overall, the number of males and females was 252 and 157, respectively. This study extends previous research by Kuroda (2021, 2022, 2024), and other studies, utilizing the ability elements in the survey. The questionnaire consisted of 21 items based on the Fundamental Competencies for Working Persons, published by various Japanese government departments (1; Expertise (general), 2; Leadership, 3; Management, 4; Information, Media, and Technology Literacy, 5; Initiative, 6; Ability to Influence Others, 7; Executing Plans, 8; Ability to Detect Issues, 9; Creativity, 10; Critical Thinking, 11; Collaboration, 12; Communication, 13; Innovation, 14; Ability to Deliver Messages, 15; Ability to Listen Closely and Carefully, 16; Flexibility, 17; Ability to Grasp Situations, 18; Ability to Apply Rules and Regulations, 19; Ability to Control Stress, 20; Ethics, 21; Career Development and Planning).

The questions included: “How important are these skills and abilities for people with STEM careers?” Responses were recorded on a 5-point Likert scale, where 5 indicated “very important,” 4 “important,” 3 “somewhat important,” 2 “not very important,” and 1 “not at all important.” Average values were calculated based on the responses.

Results And Discussion

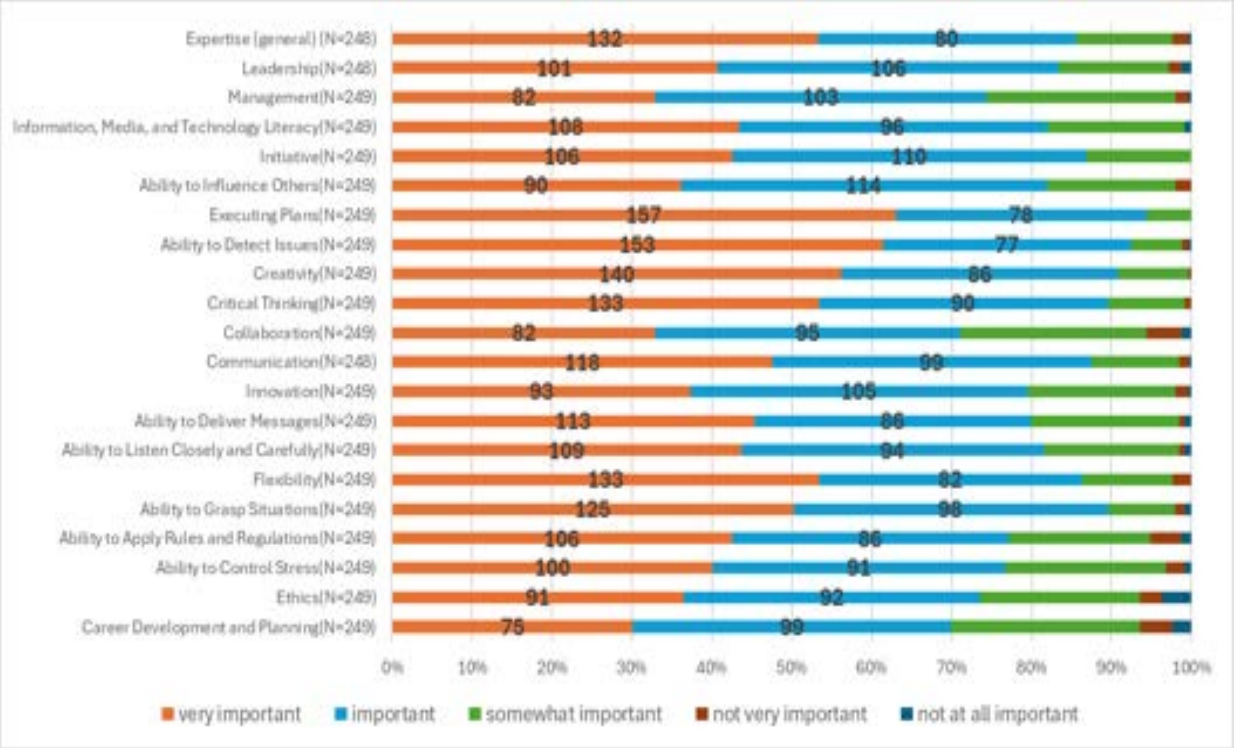
The survey results are summarized in Figure1 and Figure2. The options with more than 80% positive responses (responses to Options 4 and 5) were 13 for males (1, 2, 4, 5, 6, 7, 8, 9, 10, 12, 15, 16, and 17) and 19 for females (excluding 3 and 19). This indicates that the women exhibited a particularly strong awareness of the importance of the abilities assessed in the survey.

To confirm the difference in awareness more strongly, a *t*-test was conducted, revealing a significant difference in 10 items (Table 1). By contrast, Kuroda (2021), who focused on students in Japan and Malawi, found five items with significant differences. Thus, by expanding the target country, there is a possibility of a greater gender difference. In particular, the items “collaboration,” “ability to apply rules and regulations,” and “ethics” exhibited differences of more than 0.3 points in the responses, indicating a possibility of a greater gender-based influence.

Additionally, 11 items showed significant differences, and these items could be considered common factors for STEM human resources who can actively contribute to the STEM human resources community. However, the degree of positive response for “Management” and “Ability to Control Stress” was only approximately 70%. Therefore, the degree of positive response should

also be considered an element that must be examined.

Figure 1. Results of importance perceptions (Male)



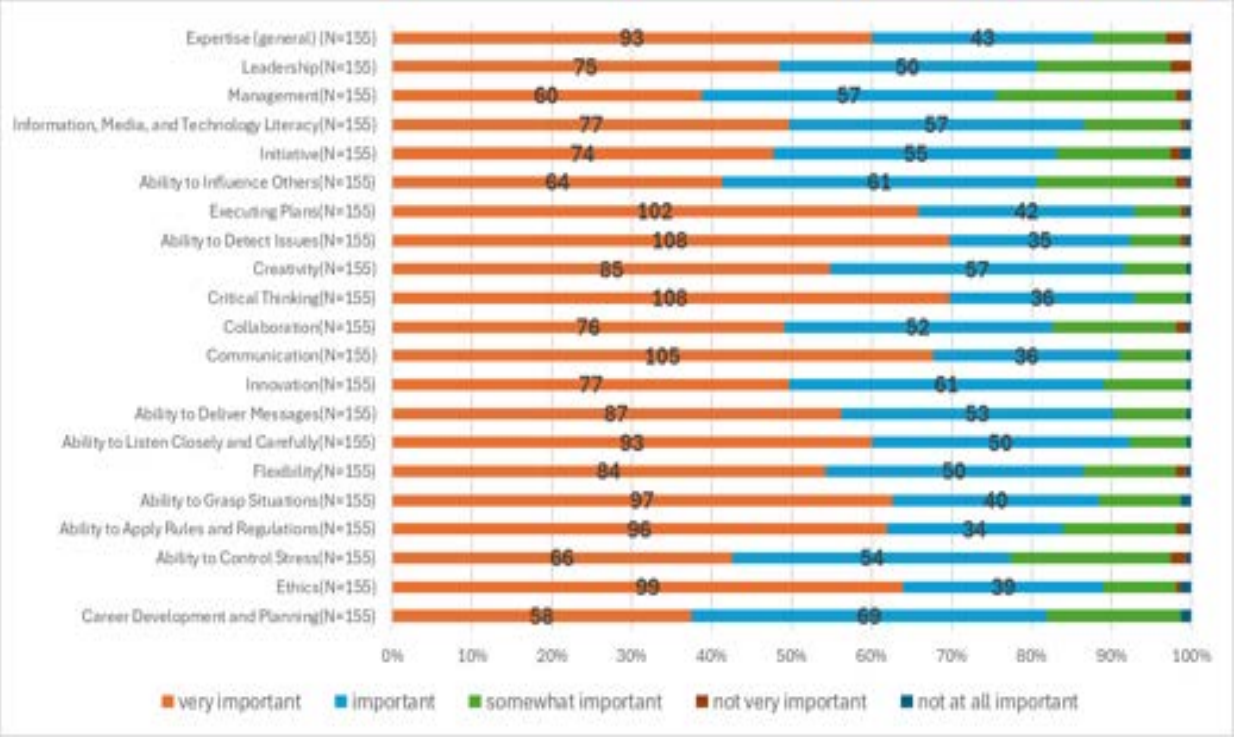


Figure 2. Results of importance perceptions (Female)

Conclusion

This study focuses on abilities within the STEM human resource community. Significant differences were found between male and female students in the target country for 10 of the 21 ability elements. Significant gender differences were observed in STEM human resource consciousness and recognition factors such as “collaboration,” “ability to apply rules and regulations,” and “ethics.”

Table 1. STEM human resources community ability *t*-test

	Male Mean(SD)		Female Mean(SD)	*t*	df
Expertise (general)	4.36(0.802)		4.44(0.815)	-0.963	323.3

Ability to Control Stress	4.13(0.870)		4.17(0.859)	-0.444	330.0
Ethics **	4.00(1.00)	<	4.50(0.793)	-5.52	379.9
Career Development and Planning **	3.92(0.955)	<	4.17(0.796)	-2.79	402.0

※ * : p <.05 ** : p <.001

However, this study has certain limitations. First, it considers data from only three countries, and second, it only considers freshman-level students. Therefore, it is necessary to collect data from different countries and grade levels. Future studies should gather information from other countries and conduct further interviews with survey respondents.

In Science We Trust? Examining Institutional Trust, Information Sources, and Climate Literacy Among Future Teachers

Eirini Chatzara[1], George Arhonditsis[2], Evangelia Mavrikaki[1] and Apostolia Galani[1]
[1]National and Kapodistrian University of Athens, Greece
[2]University of Toronto, Canada

Climate literacy is vital for future educators, the key facilitators of public understanding of climate change. This study examines how climate literacy, knowledge sources, and trust in scientific institutions interact to influence pre-service teachers' climate understanding. A survey of Greek University students assessed their climate knowledge, sources of information, environmental education, and trust in scientific institutions. Results indicate that formal education enhances reliance on structured sources, while digital platforms increase misinformation risks. A Climate Literacy Index (CLI) was developed, revealing that trust in scientific institutions strongly predicts climate literacy, while social media use correlates with climate misconceptions.

Keywords: climate literacy, teacher education, information sources

Introduction

Climate literacy is widely recognized as essential for informed decision-making and pro-environmental behaviour. For educators, and pre-service teachers in particular, climate literacy is of added importance, since they are actors of shaping public understanding of climate change. The challenge is that climate literacy extends beyond factual climate knowledge; it involves understanding climate systems, human–environment interactions, and the capacity to make evidence-based decisions (McCright et al., 2013). Accordingly, contemporary frameworks conceptualize climate literacy as a multidimensional construct that combines core climate science knowledge of the climate system, its causes, impacts, and response options (Leve et al., 2023; Aeschbach et al., 2025) with information skills related to accessing, evaluating, and communicating scientifically credible climate information (Shwom et al., 2017; Lubej et al., 2025). It further incorporates values, attitudes, and agency, including concern, responsibility, and willingness to engage in mitigation, adaptation, and public-sphere action (Choi et al., 2021; Kranz et al., 2022; Kolenatý et al., 2022), alongside a systems-oriented social-science perspective that accounts for human behaviour, social drivers, justice, and political dimensions shaping climate action (Shwom et al., 2017; Beach, 2023; Kranz et al., 2022).

Climate Literacy Components

Prior research indicates that information sources of high quality and credibility are essential to the "understanding" element of climate literacy (Dong et al., 2018). Traditional sources such as formal schooling, books, and government services have been associated with higher climate literacy scores (Höttecke & Allchin, 2020). Conversely, reliance on digital platforms, particularly social media, has been linked to greater exposure to misinformation and misconceptions about climate science (Lewandowsky et al., 2017). Therefore, integration of environmental education in academic curricula can reinforce the "decision-making" element of climate literacy as well, by enhancing learners' ability to critically evaluate information and by increasing reliance on structured sources over unverified online content (Clayton et al., 2015).

Table 1. Key components of climate literacy for educators

Component	Examples for (pre-service) teachers
Content knowledge	Greenhouse effect, drivers, impacts, solutions (Leve et al., 2023; Aeschbach et al., 2025)
Critical evaluation	Judging source credibility, evidence, statistics (Shwom et al., 2017; Ranney & Clark, 2016)
Communication	Explaining mechanisms, discussing tradeoffs (Shwom et al., 2017)
Normative/political literacy	Policy tools, justice, public vs private action (Kranz et al., 2022; Pan et al., 2023; Lestari et al., 2024)

However, climate literacy is not shaped only within academic settings. Outside formal education, individuals with greater trust in scientists, meteorological agencies, and environmental organizations demonstrate higher levels of climate literacy (van der Linden et al., 2017) and are less susceptible to climate-related misinformation (Feldman et al., 2011). Large international surveys show that scientific literacy and trust in science jointly predict climate change understanding and threat perception, with trust partially mediating the effect of literacy on understanding (Van Vleet & Fuller, 2024; Larrain et al., 2024; Pan et al., 2023).

In this study we examine how climate literacy, knowledge sources, and trust in scientific institutions interact to shape pre-service teachers' understanding of climate change.

Methodology

The study focuses on the following research questions:

RQ1: What are the primary sources of climate change knowledge for pre-service teachers, and how does having formal environmental education influence their reliance on these sources?

RQ2: How do different sources of climate information, formal education experiences, and demographic factors correlate with climate literacy (knowledge and behaviour), as measured by an integrated Climate Literacy Index?

RQ3: To what extent does trust in scientific institutions influence climate literacy among pre-service teachers, as measured by an integrated Climate Literacy Index?

Participants & Demographics

The sample consisted of 307 pre-service teachers enrolled in the 5th semester Geography course at a Greek University. Participants were 72% female, 27% male, and 1% identifying as non-binary or other. Their age ranged from 18 to 30 years old, with the majority (65%) falling within the 18-24 age range. Most participants were in their third year of study, and a small subset reported having prior degrees or higher education beyond the current program (this was captured as "higher education level" in our analysis). Participants' political orientation was assessed on a scale (ranging from more conservative to more liberal), given the potential influence of ideology on climate perceptions. Socioeconomic background information such as approximate household income and parental education was also collected for context. Participation in the study was voluntary and anonymous.

Data Collection

Data was collected through an online questionnaire administered during a scheduled laboratory session of the teacher education course. Participants received a survey link and completed the questionnaire on their personal devices under the supervision of the researchers. The survey took

approximately 20 minutes to complete. To encourage honest responses, participants were assured that their individual answers would remain confidential and would not affect their course standing. The questionnaire comprised several sections measuring climate literacy and its potential determinants, as described below.

Climate Literacy Measures

Climate literacy was assessed using a combination of knowledge-based items and behaviour/self-efficacy measures, reflecting its widely recognized multidimensional character encompassing knowledge, attitudes, and behaviours. Rather than adopting an existing single instrument, we developed a **Climate Literacy Index (CLI)** specifically for this study. This decision was informed by evidence that many available climate literacy measures are either predominantly knowledge-focused or designed for specific age groups, countries, or educational contexts, which limits their transferability to pre-service teacher populations (Leve et al., 2023; Lubej et al., 2025; Sato & Park, 2024). In addition, existing tools often insufficiently capture behavioural intentions, self-efficacy, and action readiness, dimensions increasingly considered central to climate literacy in education research (Kolenatý et al., 2022; Aeschbach et al., 2025). Developing a context-specific composite index therefore allowed us to integrate climate science understanding with behavioural and self-efficacy components relevant to the professional role and common misconceptions of future teachers, in line with contemporary calls for multidimensional and population-sensitive climate literacy assessments (Matlack et al., 2023; Nayan et al., 2020).

The knowledge component of the CLI comprised 15 multiple-choice and true/false items assessing core climate change concepts, including causes, evidence, impacts, and scientific consensus. Several items targeted well-documented misconceptions, such as confusing ozone depletion with climate change or perceiving impacts as exclusively future-oriented. Item development was informed by climate literacy frameworks and prior research on public misconceptions, and content validity was ensured through expert review by two climate science educators. Correct responses were summed to yield an individual knowledge score (range 0–15).

The behavioural component included 16 Likert-type items measuring self-reported climate-relevant behaviours and intentions related to mitigation and adaptation, such as energy conservation, sustainable transport, waste reduction, civic engagement, and climate-related discussions. Behaviours were included to capture the action-oriented dimension of climate literacy, particularly relevant for pre-service teachers as future role models. Items were adapted from established environmental behaviour instruments and contextualized for climate change.

To construct the composite Climate Literacy Index (CLI), knowledge and behaviour scores were normalized to a common 0–1 scale and then averaged, giving equal weight to both components. The resulting CLI ranged from 0 to 1, with higher values indicating greater overall climate literacy. The CLI was used as the primary outcome variable, representing the joint presence of climate understanding and climate-responsible action.

Results

RQ1: Information Sources Used And Influence Of Environmental Education

Pre-service teachers reported relying on a combination of digital, institutional, and traditional media sources for climate change information, with clear differences in frequency of use. Digital platforms dominated: the internet was the most frequently used source ($M = 3.17$ on a 1–4 scale, approaching “often”), followed by social networks ($M = 2.76$). Formal education also remained influential, with school-based sources reported at relatively high levels ($M = 2.84$). Books

constituted another important channel (M = 2.65), while family and friends played a more moderate role (M = 2.59), suggesting some informal discussion but not a primary reliance.

Institutional and legacy media were used less frequently. Government services (M = 2.27) and magazines/newspapers (M = 2.24) fell between "rarely" and "sometimes." Television occupied a similar mid-range position (M = 2.41), whereas museums and zoos were less commonly cited (M = 2.14). Cinema and radio were the least utilized sources, with mean values of 2.03 and 1.91 respectively, indicating that audiovisual and broadcast media play a comparatively minor role in shaping climate information practices among pre-service teachers.

Figure 11. Frequencies of climate information sources.

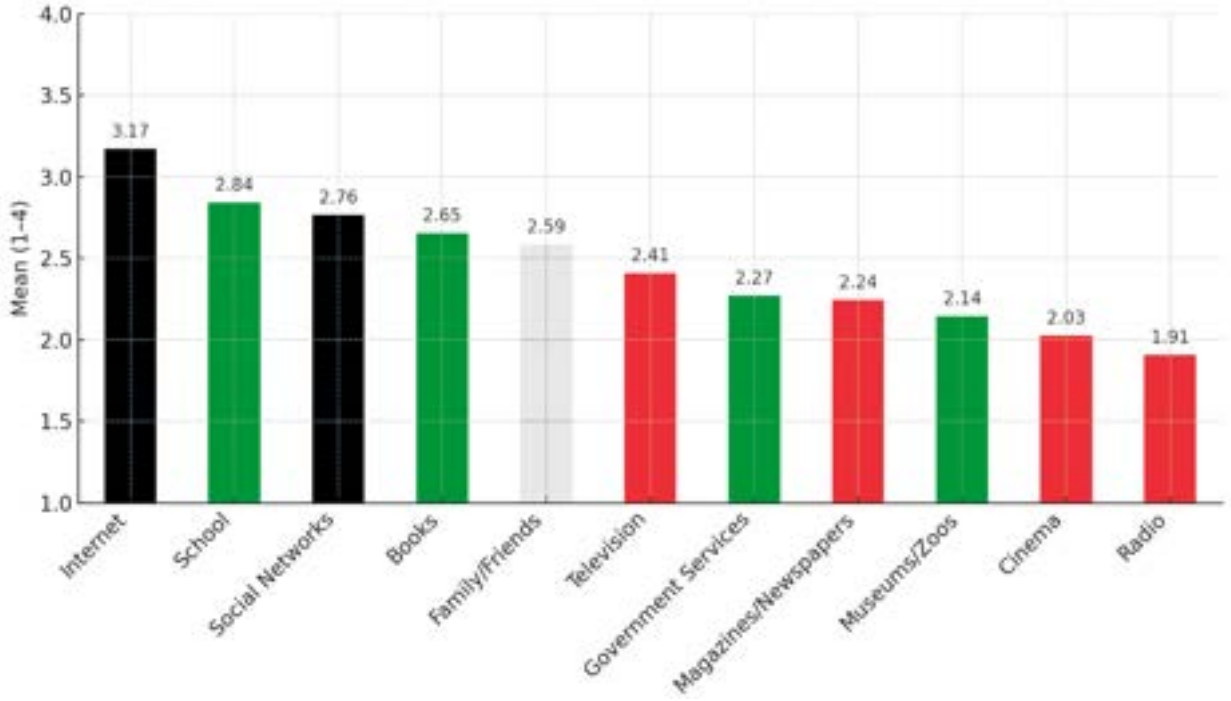

Table 2. Mean frequency of use of climate information sources with and without formal environmental education. (Scale: 1 = Never, 4 = Often).

Climate Information Source	Mean (With EnvEdu)	Mean (Without EnvEdu)	p-value
Internet	3.25	3.10	0.048
Social Networks	2.85	2.69	0.045
Books	2.73	2.59	0.038
Government Services	2.42	2.14	0.007
Magazines/Newspapers	2.65	2.54	0.062
Family/Friends	2.50	2.48	0.081

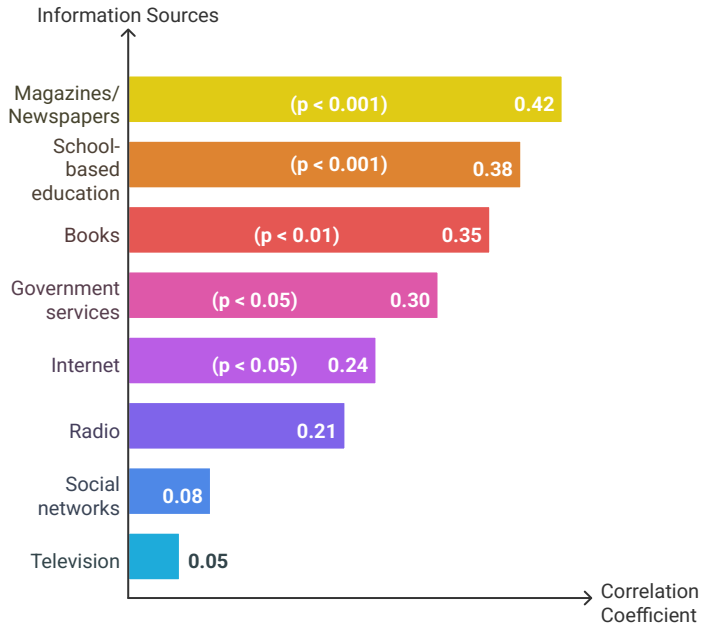

Table 2 summarizes the comparison of source usage means between those who have had formal environmental education (EnvEdu group) and those who have not. Several significant differences emerged. Pre-service teachers with an environmental education background reported greater use of authoritative sources such as books and government services, compared to those without such background. For instance, the EnvEdu group had a higher mean frequency for using books as a climate information source (Mean = 2.73) than the No EnvEdu group (Mean = 2.59), a difference that was statistically significant (p = .038). Similarly, use of government or scientific agency sources was higher among those with environmental education (Mean = 2.42 vs. 2.14, p = .007). Interestingly, those with environmental education also showed slightly higher usage of online

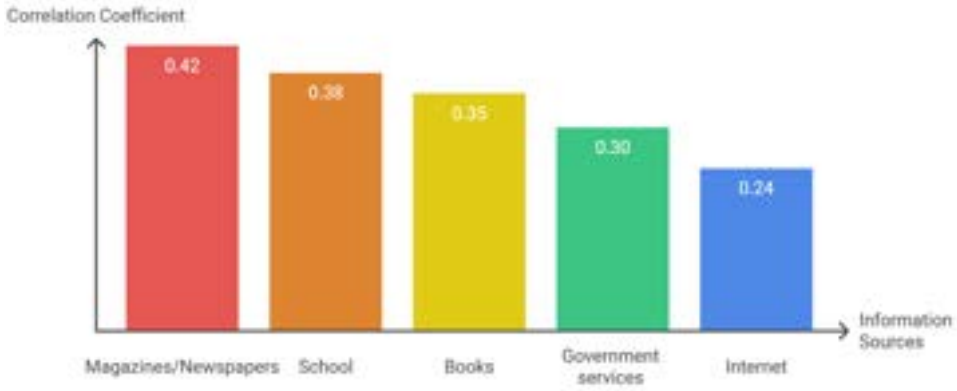
sources: they reported using the internet (general web resources) more often on average (3.25 vs. 3.10, p = .048) and similarly for social media (2.85 vs. 2.69, p = .045) compared to the group without environmental education. This suggests that students who had prior environmental lessons might be more engaged overall in seeking out climate information from a variety of sources (possibly due to greater interest or awareness of climate issues). In contrast, for sources like magazines/newspapers and family/friends, the differences between groups were small and not statistically significant (e.g., 2.65 vs. 2.54 for magazines, p = .062; 2.50 vs. 2.48 for family/friends, p = .081, both n.s.). Traditional media (TV, radio, films) had generally low usage in both groups, with no notable differences.

RQ2: Predictors Of Climate Literacy (CLI) – Information Sources, Education, And Demographics

To assess climate literacy beyond knowledge scores, we constructed a Climate Literacy Index (CLI) that integrates both climate knowledge (the respondents' score on climate-related questions) and pro-environmental behaviours, as described above.

Figure 12. Correlation of CLI with climate info sources.



Examining the relationship between information sources and CLI, we found that magazines/newspapers (r = 0.42, p < 0.001) were the strongest positive predictors of CLI, followed by school-based education (r = 0.38, p < 0.001). In contrast, television (r = 0.05, p = 0.48) and social networks (r = 0.08, p = 0.35) showed weak or negligible effects (Figure 2).

Formal nvironmental education had a significant but complex impact. Individuals with environmental education scored higher on CLI (p = 0.0255, t-test). However, multiple regression analysis showed that when examining information sources, formal education alone was not an independent predictor of CLI.

Demographic variables also influenced CLI, with higher education levels (r = 0.41, p < 0.001) and political orientation (r = 0.33, p < 0.01) being the strongest predictors. In contrast, income (r = 0.18, p = 0.08) and gender (r = 0.09, p = 0.31) showed weaker and non-significant effects.

Figure 13. Correlation between Information Sources and Climate Literacy (CLI).

RQ3: Trust In Scientific Institutions And Climate Literacy

When comparing individuals who rely on scientific institutions (universities, government research bodies, and meteorological services) vs. social media users showed significant differences in climate literacy scores. CLI scores for scientific institution users were 18% higher than for social media users. A t-test comparing CLI scores between these groups found $t = 5.37$, $p < 0.001$. Regression analysis further confirmed that reliance on scientific sources significantly predicts CLI ($\beta = 0.41$, $p < 0.001$), while social media reliance has a negative association with CLI ($\beta = -0.27$, $p = 0.002$).

A correlation analysis between social media reliance and common climate misconceptions found that social media users were more likely to believe false climate claims:

"Snowfall disproves global warming" ($r = 0.38$, $p < 0.01$)

"Climate models are unreliable" ($r = 0.34$, $p < 0.01$)

"Climate change is natural and not caused by human activity" ($r = 0.29$, $p = 0.02$)

Trust in scientific institutions is strongly associated with higher climate literacy levels. The highest correlations with the Climate Literacy Index (CLI) were found for Trust in Scientists ($r = 0.47$, $p < 0.001$), Trust in Meteorological Services ($r = 0.42$, $p < 0.001$), and Trust in Scientific TV Programs ($r = 0.39$, $p < 0.01$). Individuals with higher trust in scientific institutions had significantly higher CLI scores than those with low trust. A t-test comparing high vs. low trust groups revealed a significant difference ($t = 4.21$, $p < 0.001$), with high-trust individuals scoring, on average 14% higher on CLI score.

Discussion

Information Sources And Climate Literacy

Consistent with prior research, reliance on structured and credible information sources was found to be associated with higher climate literacy, as education and media coverage from reliable institutions significantly enhance climate understanding and policy support (Pan et al., 2023). Participants engaging with formal education, reputable news media, and written science-oriented sources demonstrate stronger climate knowledge, reinforcing the importance of science education and media literacy in fostering acceptance of climate science (Pan et al., 2023; Loy et al., 2020). Reading climate-related articles in newspapers or magazines emerges as a strong predictor of climate literacy, suggesting that self-directed engagement with quality science journalism improves both accuracy and depth of understanding (Loy et al., 2020). In contrast, social media use shows no positive association with climate literacy, supporting concerns that digital platforms

often amplify misinformation and reinforce confirmation biases (Cheng & González-Ramírez, 2020; Cosby et al., 2025). This aligns with research documenting how online environments contribute to spreading organized climate skepticism and undermining scientific understanding (Cheng & González-Ramírez, 2020). Television also shows limited contribution to climate literacy, consistent with findings that generalized or politicized broadcast coverage rarely deepens climate knowledge unless explicitly science-focused (Cosby et al., 2025; Almansa-Martínez et al., 2024).

Trust In Science As A Key Predictor

Trust in scientific institutions is one of the most robust predictors of climate literacy, with global evidence showing that trust in scientists strongly correlates with better climate knowledge and resistance to misinformation (Van Vleet & Fuller, 2024; Cologna & Siegrist, 2020; Cologna et al., 2024). In some studies, trust in science has been found to outweigh formal environmental education as a predictor of climate literacy, highlighting trust as a foundational mechanism for internalizing scientific information (Larrain et al., 2024; Osborne & Allchin, 2024). Research also emphasizes that building trust is critical for effective science communication and education, suggesting that fostering trust may be as important as delivering content in teacher education (Cooper, 2011; Lacey et al., 2017). Meta-analyses confirm that trust in scientists and scientific institutions strongly correlates with climate-friendly attitudes and behaviours, reinforcing the central role of trust in shaping climate literacy (Cologna & Siegrist, 2020). Overall, these findings underscore the importance of cultivating informed epistemic trust to enhance public understanding and engagement with climate science (Osborne & Allchin, 2024; Cologna et al., 2024).

Ideology And Demographic Patterns

Political orientation consistently predicts climate literacy, with more conservative individuals scoring lower on climate literacy indices, reflecting ideological influences on how scientific information is processed even within relatively homogeneous university cohorts (Arroyo-Barrigüete et al., 2023; Hamilton, 2011; Fischer et al., 2022). While outright climate denial is uncommon, ideological differences often appear in the depth of knowledge and perceived urgency of climate change, suggesting cultural cognition shapes interpretation rather than outright rejection of science (Arroyo-Barrigüete et al., 2023; Trémolière & Djeriouat, 2021).

No significant gender differences in climate literacy were observed, indicating a narrowing gender gap among younger populations (Kranz et al., 2022; Zummo et al., 2020). Similarly, income effects were absent in student samples (Kranz et al., 2022).

These findings highlight the importance of addressing political and cultural factors alongside education to improve climate literacy effectively.

Formal Environmental Education: Limits And Implications

Although participants with prior environmental education tended to display higher climate literacy, its effect was not independent in regression models and appeared mediated by information engagement. This suggests that the presence of environmental education alone is insufficient; its impact depends on quality, recency, and integration with active engagement. This finding aligns with research emphasizing that exposure without sustained engagement has limited long-term effects (Trott, 2020; Trott & Weinberg, 2020). For teacher education programs, this underscores the need for integrated, longitudinal approaches rather than isolated coursework.

Implications, Limitations and Future Directions

These findings suggest that formal education alone is insufficient and must be supplemented with

structured, credible knowledge sources. The negative association between social media reliance and CLI highlights the risk of misinformation, emphasizing the need for media literacy in climate education. For pre-service teachers, climate literacy is particularly crucial, as they serve as knowledge transmitters in society. The incorporation of structured, evidence-based climate education in teacher training programs can enhance their ability to evaluate sources critically and disseminate accurate climate information (Stevenson et al., 2013). Finally, the more trust fostered in scientific institutions, the better the negative influence of misinformation can be counteracted, ensuring that pre-service teachers are well-equipped to guide students toward climate-responsible behaviours.

First, the sample was drawn from a single university and largely from one teacher education program within a specific national context, limiting generalizability. Climate literacy, trust, and information practices may differ across countries, institutions, and teaching specializations. Future research should include more diverse samples and comparative designs to examine how disciplinary background, national curricula, and sociopolitical context shape pre-service teachers' climate literacy.

Second, the study relied on self-reported measures for behaviours, information sources, and political orientation, which may be subject to social desirability and reporting biases. Although anonymity was ensured, participants may have over-reported socially valued behaviours or reputable sources. More fine-grained measures of ideology and complementary behavioural or observational data could strengthen future analyses.

Finally, while the Climate Literacy Index (CLI) integrates knowledge and behaviour, it does not capture all dimensions of climate literacy. It does not directly assess higher-order skills such as critical evaluation of information, misinformation detection, emotional engagement, or communication competence. Moreover, validation of the CLI was limited to content review and internal consistency.

Future studies should extend validation using external criteria and consider expanding the index to include skills that are especially relevant to teachers' professional practice.

ESERA 2025 Copenhagen

Potentials And Challenges Of Serious Games In Environmental And Sustainability Education

Vincenzo Pace[1], Luana Silveri[2] Mita Drius[3] and Chiara Rizzi[1]

[2]University of Groningen, the Netherlands
[3]Free University of Bolzano-Bozen, Italy

Sustainability challenges are increasingly recognized as "wicked problems" that require complex, non-linear responses and systemic reasoning. Despite this, traditional education often emphasizes linear thinking, leaving a gap in students' ability to engage with the interconnections of social, ecological, and economic systems. This paper investigates the efficacy of Game-Based Learning (GBL) as a method to bridge this gap in higher education. Specifically, the study examines the FRACTALgame, a cooperative strategic board game designed to enhance awareness of Green Infrastructures (GI) and Ecosystem Services (ES) within Alpine ecosystems. Developed through an interdisciplinary process combining the Educational Game Design Model and the Three-Layered Thinking Model, the game targets three domains: ecological knowledge, EU-GreenComp competencies (such as systems thinking), and soft skills. A mixed-methods playtest involving university students revealed significant gains in conceptual clarity. Participants transitioned from vague, aesthetic definitions of GI to functional, systemic understandings. While the cooperative mechanics fostered engagement and mirrored real-world environmental collaboration, the study identified challenges, including cognitive overload from complex manuals and the "nebulous" nature of Ecosystem Services. Results suggest that while serious games are potent tools for cultivating green competencies, they require a structured GBL framework—including educator facilitation and debriefing—to prevent student paralysis when facing systemic complexity.

Keywords: Sustainability education, game-based learning,

Introduction

Sustainability is widely recognised as a *wicked problem*, defined as a complex and multi-faceted challenge that resists linear solutions and requires adaptive and evolving responses (Lönngren & Van Poeck, 2020). Sustainable land management represents a clear example of such complexity. Balancing land and resource preservation with the fulfilment of human needs remains one of the central challenges of contemporary societies (Verburg et al., 2022). Ongoing population growth and consumption patterns continue to intensify pressure on land systems, making sustainable land management essential for maintaining ecological integrity, promoting social justice and wellbeing, and supporting long-term economic development. As articulated in the UN 2030 Agenda, sustainability challenges are characterised by uncertainty, value conflicts, and strong interdependence across social, ecological, economic, and political domains. Addressing these challenges requires not only disciplinary scientific knowledge—such as ecology, biology, chemistry, and physics—but also transversal competences including systems thinking, futures literacy, negotiation, and collaborative problem-solving. These competences are explicitly articulated in the European Sustainability Competence Framework (GreenComp), which aims to equip learners with the knowledge, skills, and attitudes needed to act as agents of change while recognising human embeddedness within natural systems (Bianchi et al., 2022). Systems thinking is identified as a core competence for sustainability, defined as the ability to consider time, space, and context in order to understand interactions within and between systems. Similarly, the PISA 2025 science framework introduces the concept of *Agency in the Anthropocene*, emphasising learners' capacity to understand human–Earth system interactions, evaluate evidence-based

solutions, and navigate uncertainty and limits. However, in traditional educational settings, students are often trained to approach problems through linear reasoning and the isolation of variables. Sustainability challenges, by contrast, are inherently systemic, operating through feedback loops, non-linear dynamics, and delayed effects (Souliotis & Voulvoulis, 2025). When sustainability concepts are addressed in abstract or fragmented ways, learners may develop awareness without acquiring the analytical tools necessary for systemic reasoning and futures-oriented decision-making (Castaño et al., 2025; Weber et al., 2021). This gap highlights the need for educational approaches capable of fostering systems thinking and equipping students to engage meaningfully with the complexity of sustainability issues.

Game-Based Education For Environmental And Sustainability Education

In response, learner-centred and experiential approaches aligned with Environmental and Sustainability Education (ESE) have gained increasing attention. Among these, game-based education (GBE) offers promising opportunities to engage learners in exploring complexity, negotiating trade-offs, and experimenting with decision-making in collaborative settings (Plass et al., 2015). GBE has proven effective in sustainability education by providing immersive and interactive experiences in which learners can apply theoretical concepts in realistic contexts (Bergen & Fromberg, 2009). Environmental serious games integrate game mechanics and narrative structures to foster both scientific and humanistic competences (Fernández-Galeote & Hamari, 2021; Janakiraman et al., 2018). Grounded in an embodied–enactive cognition model, these approaches connect physical and cognitive engagement through game dynamics, supporting transformative learning experiences that translate abstract knowledge into more concrete understandings of environmental systems and behaviours (Plass et al., 2015). Game-Based Learning (GBL), as a pedagogical approach rooted in GBE, refers to the use of games—played and/or designed—as part of instructional activities, with learning as the primary intended outcome (Plass et al., 2015). Educational games, whether digital or analogue, are thus used to convey disciplinary content while simultaneously fostering transversal skills. Serious games, as a subset of educational games, are developed with explicit learning objectives and require an interdisciplinary design process that integrates pedagogy, scientific knowledge, and game design principles (Plass et al., 2015). Empirical studies indicate that well-designed serious games can increase awareness of environmental and social issues, support understanding of ecosystem complexity and decision-making processes, and enhance motivation, engagement, and information retention. By embedding learners in scenarios where decisions have tangible consequences, serious games support the development of key twenty-first-century skills essential for addressing sustainability challenges (Fernández-Galeote & Hamari, 2021). In this paper, we aim to contribute to the discussion on how game-based learning can support sustainability education goals.

Research Objective

This research is driven by the urgent need to bridge the gap in higher education curricula, where, despite growing efforts, many students still lack adequate exposure to sustainability education. Consequently, the research investigates the feasibility of GBL as a method to effectively equip learners with the necessary knowledge and attitudes to address complex sustainability challenges. More specifically we present and discuss potentials and weaknesses of the FRACTALgame, developed as part of an EU-funded project to increase the awareness of young people on Green Infrastructures and their role in supporting ecosystem services and ecosystem conservation in the Alps.

This study investigates the efficacy of serious games in sustainability education by addressing three specific research questions; i) is FRACTALgame effective in teaching specific ecological

contents, such as Green Infrastructures and ecosystem services, ii) which green, social, or emotional skills are most commonly activated from the students' perspective and iii) which skills students utilized with confidence and which were the most difficult to apply during the cooperative experience.

Methods And Materials

For the game-design process, we combined some technical and theoretical principles from the Educational Game Design Model (Ibrahim & Jaafar, 2009) and the Three-Layered Thinking Model (TLTM) (Fong-Ling, & Sheng-Chin, 2008). The EGDM and the TLM have been adopted to design the scientific contents and educational output and how to fit them with mechanics, dynamics, and aesthetics.

Game Characteristics

Table 1. List of the expected educational outcomes and game elements and rules.

Research Domain	Game Rules & Structure	Specific Mechanic / Tool
1. Ecology Knowledge	Rebuild ecosystems and restore their functions. Setup: Players must identify and manage five distinct Alpine ecosystems: mountains, forests, rivers/lakes, agroecosystems, and urban areas.	GI & ES Cards: Using Green Infrastructure (GI) and Ecosystem Services (ES) cards to counter specific threats. Point Cards: Visualizing the loss of "Supporting," "Regulating," "Provisioning," and "Well-being" services through marker placement.
2. EU-GreenComp	Anticipate and mitigate the effects of overexploitation and climate change in the year 2050. Systems Thinking: Navigating interconnections where a loss in biodiversity or soil (Supporting) leads to crises in human health (Well-being).	Threat Deck: Drawing "Extreme Weather Event" and "Overexploitation" cards that intensify systemic collapse. Resiliency Sets: Building a 5-card set (1 GI + 4 ES categories) to achieve long-term ecosystem protection.
3. Soft Skills	Goal: Cooperative gameplay where players "Team up to save Alpine ecosystems". Rules: Players are encouraged to keep hands open so everyone can see the cards in play to facilitate group discussion.	Cooperative Actions: Using moves to trade cards with other players on the same ecosystem to complete necessary sets. Characters Powers: Utilizing four distinct characters (e.g., Expert, Activist) with special powers that must be coordinated to win.

The FRACTALgame is a cooperative and strategic board game. The primary scope of the game is to bridge the gap between theoretical ecology and practical sustainability competencies. The

overall scope of the game is to foster collaboration among players to mitigate the negative impacts of overusing natural resources, rebuild ecosystems to restore their functions, and ultimately save local communities. The gameplay involves players in saving five specific at-risk ecosystems: mountains, forests, rivers and lakes, agroecosystems, and urban areas. To achieve this, players must strategically utilize Green Infrastructure (GI) and Ecosystem Services (ES) cards to address environmental challenges. Its pedagogical structure is divided into three core domains to achieve specific educational outcomes (Table 1).

In terms of ecological knowledge, the game aims to teach players what ES and GI are and how they function, alongside the ecological principles necessary for sustainable land management. Regarding skills and competencies, the game explicitly targets the development of systems thinking, helping learners identify system elements, interconnections, delays, and feedback loops. Furthermore, the cooperative mechanics require players to engage in future scenario building, problem-solving, and critical thinking. Ultimately, the game fosters social competencies by requiring negotiation to design common scenarios and cooperation to face complex future challenges.

Implementation Phase And Data Collection

Starting from the expected educational outcomes we designed two game-test rounds. The playtest of FRACTALgame took place as part of the SO|STA - Lo Spazio dello Stare project, an initiative aiming to enhance the use of green spaces of Matera University campus, involving six university students with different ages (20-20 years old) and backgrounds (Architecture, Urban Planning and science education).

The test sessions took three days (11-13 September 2024) and a total of 6 hours (2 hours for day) were used for the test session. The research employed a mixed-method approach to evaluate the game's effectiveness, utilizing four distinct tools. To measure gains in ecology knowledge, ex-ante and ex-post surveys were administered, grounded in national educational outcomes for secondary schools and civic education guidelines. To examine the stimulation of specific skills, the study used open-ended questionnaires (also pre- and post-game) based on a revised MEEGA+ model, which was aligned with both the EU Green Skills framework and the PISA 2025 Environmental Science Competences. These quantitative measures were complemented by qualitative tools, including a game-logbook for student self-reflection and a focus group session to gather deeper insights.

Results

The preliminary findings from the initial playtest of the FRACTALgame indicate a good level of student engagement and a strong alignment with sustainability education objectives. Quantitatively, the experience was positively received: five out of six participants reported enjoying the game, and four out of six expressed a willingness to play it again. A primary driver of this success was the cooperative dynamic, which players identified as an added value that effectively mirrored the collective efforts required for real-world environmental action. As one participant observed, the "*ability to save an ecosystem collectively represents one of the most educational aspects of the game*".

Conceptual Learning And Aesthetic Utility

The integration of aesthetic design with pedagogical goals proved to be a significant asset. The graphical elements served as more than mere decoration; they functioned as a powerful medium for communicating complex ecological concepts. Results suggest that the game is a potent tool for introducing nuanced topics like GI. Participants demonstrated a marked shift from vague

conceptualizations toward concrete, post-game definitions as demonstrate some of the examples reported in Table 2.

Table 2. Evolution of student conceptualization of Green Infrastructures (GI) comparing pre-game (vague/aesthetic) and post-game (functional/systemic) definitions.

Phase	**Student Conceptualizations of Green Infrastructures (GI)**
Pre-Game (BEFORE)	*"Green areas."*
Question: *Please define what a Green Infrastructure is.*	*"Infrastructures that follow low environmental impact guidelines."*
	"Infrastructures aimed at environmental protection, such as creating green spaces in urban areas."
	"Semi-anthropized spaces designed to enhance and develop ecosystem services for both humans and nature."
Post-Game (AFTER)	*"Human designed structures mimicking nature and enabling ecosystem services across different ecosystems."*
Question: *After playing the FRACTALgame, please define what a Green Infrastructure is.*	*"Natural structures designed by humans with the scope of preserving ecosystems from being altered by human activity."*
	"Structures that contribute to the proper functioning of an ecosystem (green for land/reforestation, blue for marine ecosystems)."

The transition shown **in Table 2 confirms** that the **FRACTALgame** functions as an effective vehicle for translating abstract theory into concrete understanding. This evolution is supported by the game's structural design, which explicitly targets three distinct research domains:

- **Ecology Knowledge:** *P*articipants moved from general "low environmental impact" statements to identifying specific roles in "*preserving ecosystems from being altered by human activity*". Additionally, where initial definitions were focused on "*green areas*," in the post-game responses students recognise GI as "*human designed structures... enabling ecosystem services*". Additionally,
- **EU-GreenComp:** Post-game definitions reflect an understanding of "proper functioning of an ecosystem," aligning with the EU-GreenComp goal of fostering systems thinking.

Skill Activation And Strategic Complexity

Regarding the development of competencies, the study observed a dominance of cognitive and social skills, though these were not immediate. Students noted that moving from linear to systemic reasoning required an iterative process: "*At the beginning... we didn't plan strategically. thinking strategically, understanding how the system works required time*".

The complexity of the mechanics, specifically the Threat Cards, forced students to move beyond static planning. One participant highlighted how these mechanics simulated real-world pressures: "*The cards representing the overexploitation of resources and... extreme weather events pushed to our limits... they required to change strategy, seeing different possible scenarios. Stimulating but challenging even though they were also realistic*".

Similarly, while collaboration was a key strength, it was described as a skill that had to be learned through gameplay:

Gradual Mastery: "Collaboration was the key to win... but it required some turns before we found a good way to strategically collaborate in building our deck".

Iterative Adjustment: "The collaboration wasn't immediate and required some effort, a lot of adjustments and time".

Despite these positive outcomes, the research highlighted significant barriers to autonomous learning. The concept of Ecosystem Services (ES) remains inherently "nebulous" for many students; game mechanics alone were insufficient to fully clarify the link between ES and sustainability. Furthermore, the instructional design presented a hurdle. Participants reported an "*excess of information*" in the manual, which led to cognitive overload

Conclusions

In conclusion, the findings substantiate the potential of serious games as effective instruments for advancing environmental and sustainability education, particularly in cultivating EU green competencies such as cooperative future scenario building. However, the study also revealed significant pedagogical challenges; difficulties in navigating game mechanics and conceptualizing abstract topics like Ecosystem Services indicate that the game cannot function in isolation. Instead, these findings highlight the necessity of a structured Game-Based Learning (GBL) framework where the educator's facilitation and post-game debriefing are critical to scaffolding the learning experience. Implementation in higher education remains complex, necessitating substantial educator expertise and a shift in institutional mindsets. Furthermore, students may find the demand for soft skills, such as negotiation and cooperation—overwhelming, particularly in the absence of extrinsic grade-based rewards. The results suggest that university students outside of specialized programs exhibit a marked deficit in sustainability skills. Consequently, they experience a form of paralysis, where the complexity of systemic interactions hinders their agency despite a willingness to engage. Therefore, it is imperative to advance a systemic ESE that empowers students to construct a new paradigm of sustainability, one that intrinsically links planetary well-being with peace, human rights, and cultural enrichment.

Designing Future Cities: Using Futures Literacy To Promote Youth Agency

Grace D'Arcy[1,2], Caitlin White[1], Ann Devitt[1], Mairéad Hurley[1,2], Dan Kilper[2], Clara Butz[2] and Mariana Chihenseck Blanco[2]
[1]School of Education, Trinity College Dublin, Ireland
[2]CONNECT Research Ireland Centre for Future Networks, Trinity College Dublin, Ireland

Cities are at the forefront of the climate crisis, consuming 75% of global resources and driving urgent sustainability challenges. Concurrently, the erosion of democratic norms has created a pressing need to empower young people with skills to envision and shape sustainable futures. This paper explores the potential of futures literacy in informal science education using the 'Design Your Future City' programme as a case study.

'Design Your Future City' is a week-long informal learning initiative for 15-17 year olds, combining workshops and technology demonstrations to address urban sustainability challenges. Students collaborate with experts and local stakeholders to develop and present creative solutions, fostering systems thinking, creativity and agency. Rooted in Design Thinking, the programme aims to enhance futures literacy and emphasise the ethical, social and environmental dimensions of local sustainability challenges alongside scientific and technological solutions.

This mixed-methods study examines four iterations involving 80 students, educators, and civil society partners. Preliminary findings demonstrate the transformative impact of futures literacy pedagogies on students' ability to address sustainability challenges, with student projects showcasing innovative, actionable solutions. Reflective feedback highlights increased critical awareness, creativity, and aspirations for civic engagement.

The study underscores the importance of embedding futures literacy in education to cultivate youth agency and democratise urban planning. This research contributes a scalable model for integrating futures literacy into informal science education to shape sustainable, inclusive urban futures.

Keywords: Agency, Futures-Oriented Science Education, Out-of-School learning

Introduction

Cities are central contributors to the climate crisis, responsible for 75% of global resource consumption, and this figure is projected to rise from 40 billion in 2010 to 90 billion tons in 2050 (Bibri & Krogstie, 2017). Simultaneously, the erosion of democratic norms has contributed to a growing climate of uncertainty about society's capacity to envision and achieve equitable, resilient futures (Howell, et al., 2021). These issues highlight the need to empower citizens, especially young people, with the skills to envision and shape sustainable futures. This has prompted responses from academics, cultural institutions, civic organizations, and community groups to envision alternative futures. This paper explores the role of futures literacy in informal science education programmes.

Using the 'Design Your Future City' education programme as a case study, this paper will explore how futures literacy can empower young people to address sustainability challenges. 'Design Your Future City' is a free week-long programme of workshops and technology demonstrations for 15-17 year old students exploring urban challenges and climate change. The education programme is a partnership between academia and the Dublin City local authority. Students work with city officials and domain experts in mobility, environment and sustainability, participate in hands-on creative workshops to explore city challenges, and develop creative solutions to a sustainability challenge of importance to them. Throughout the programme, technology

demonstrations are integrated to help students analyse the challenges they face and how others have addressed them. This informs the speculative design process and the envisioning of future solutions. The programme takes place in an informal learning setting outside of school time, that students apply to and attend independently. At the end of the week student present their solutions to key stakeholders including leadership in the city council, industry and academia.

The case studies discussed in this paper were developed in collaboration with the EU-funded Critical ChangeLab project. One of the project's key objectives is to strengthen critical democratic education among young people through participatory action research (PAR) and creative methods inspired by the Change Laboratory approach (Engeström, 2015) and critical pedagogies (Freire, 2017). In the examples featured in this paper, the Critical ChangeLab model has been integrated into the 'Design Your Future City'' programme to foster futures literacy and democratic engagement (Council of Europe, 2016)

Research Question And Aims

This paper will address the following research question: What is the potential of futures literacy in informal science education programmes?

To explore this question, the study focuses on three key aims:

- Identifying the barriers and enablers in promoting futures literacy among young people, particularly those from underrepresented groups.
- Examining the impact of futures literacy in informal science education on sustainability education.
- Investigating how futures literacy fosters youth agency in shaping sustainable futures.

Theoretical Frameworks

Futures literacy is increasingly recognised as an essential skill for young people. Häggström & Catarina (2021) argue that in order for young people to develop agency and voice in addressing global crises, they must acquire futures literacy—the ability to imagine and shape the future. UNESCO (2023) similarly emphasises that "being futures-literate empowers the imagination. It enhances our ability to prepare, recover and invent in the face of change" (P.1). Futures literacy is particularly important in the context of sustainability education and working with youth, as Stuart Candy (2020)) noted "our collective future as a species depends on using our capacity to imagine worlds together".

Central to fostering futures literacy is the concept of agency, as it empowers individuals and communities to take informed, purposeful action toward shaping the future. Social Cognitive Theory (Bandura, 2002) provides an initial framework for understanding agency in social contexts. Bandura identifies three forms of agency: personal agency (individual action), proxy agency (influencing others to act), and collective agency (group efforts to shape a shared future). In this project, these frameworks are integrated into the programme design by supporting young people to imagine sustainable futures, and collaborate in acting towards them.

This understanding of agency is developed through Stetsenko's Transformative Activist Stance (TAS) (Stetsenko, 2014). Rather than viewing the world as a fixed context to which individuals adapt, TAS positions the world as "in the making," realised through goal oriented action. From this perspective, agency is not only the capacity to act within existing structures but to transform them in pursuit of socially and ethically desirable futures. Accordingly in this project, the

programme design moves beyond individual foresight skill-building, toward collective, participatory activities in which young people identify issues they care about, articulate preferred futures, and collectively design actions oriented toward social and environmental transformation.

The United Nations' Sustainable Development Goals (SDGs), comprising 17 interconnected goals, aim to address global challenges related to the environment, economy, and society. These goals guide global efforts to achieve sustainability, with SDG 4 focusing on ensuring inclusive and equitable quality education (United Nations, 2015). UNESCO's Education for Sustainable Development (ESD) agenda plays a pivotal role in advancing these goals by fostering critical thinking, global citizenship, and the skills needed to address interconnected sustainability challenges. UNESCO advocates for integrating sustainability into education systems globally, empowering learners to become active agents in shaping sustainable futures (UNESCO, 2020)

Research Method And Design

This research was undertaken through four iterative cycles of the 'Design Your Future City' programme from the 2024-2025 academic year, involving 80 students, 3 researchers, 21 educators, and 2 civil society organisations. Within the programme, youth participate in workshops that draw from methodologies such as design futuring (Howell, et al., 2021), speculative design (Dunne & Raby, 2013), and speculative fiction (Haraway, 2016) as well as workshops that introduce them to scientific, ethical, social and environmental dimensions of local urban planning and sustainability challenges. They subsequently participate in a design sprint to develop and present creative solutions to these challenges, consulting with scientific experts and local stakeholders. Design Thinking—a human-centred problem-solving approach—guides students through five iterative stages: Empathy, Define, Ideate, Prototype, and Test (Razzouk & Shute, 2012).

A mixed-methods research approach was utilised to assess how the programme supported futures literacy development. Data was generated through a set of instruments, including pre- and post-programme surveys of participating students to measure attitudinal and cognitive shifts; facilitated focus groups conducted at the end of each programme iteration to capture participant experiences and perspectives; analysis of learning artifacts to assess conceptual engagement; and structured workshop observations conducted by a research observer to document pedagogical processes and interactions. These instruments were used in combination to examine participants engagement with futures literacy practices, expressions of agency and approaches to sustainability challenges across programme iterations.

Findings

Findings indicate that futures literacy exercises increased young people's confidence in articulating their vision of sustainable urban planning. Artefact analysis showed students actively designed future-oriented solutions to sustainability challenges, highlighting youth perspectives on issues such as public green space accessibility and air pollution caused by car dependency. For example, one student project, 'Traffic Jam,' proposed an interactive light installation to create safer movement through urban space, reflecting a desire to travel independently that was articulated by participants in workshop discussions. This student project illustrates how futures literacy—i.e. using a desired sustainable future to innovate in the present—cultivates systems thinking and creative problem-solving, both important sustainability competences (Bianchi et al., 2022). In the above example, the concept generated was taken up for further exploration by a local authority, with a student engaging through a short work placement. This offers an initial indication of how futures literacy practices may open pathways for youth participation in

institutional sustainability contexts.

Across participant reflections and post-programme surveys, recurring themes included increased critical awareness, creative confidence, and attention to systems-level aspects of urban challenges. A participant reflected:

> "The week really opened my eyes to the amount of things that need to be considered when trying to solve a problem. You have to think about people it will affect, the environment, different ethical issues, but I found that I really enjoyed thinking about all these things. It is something that I would like to do in the future. Before this I thought of urban planning as more just deciding where to put houses and buildings, now see how much technology is involved in it."

This reflection aligns with the aim of fostering futures literacy by cultivating systems thinking, creativity, and critical problem-solving skills.

Evaluations of the case studies indicate that futures literacy methodologies support critical reflection on eco-social challenges (Maxwell et al., 2019) foster inclusive values (Millsap-Spears, 2018) and encourage imaginative problem-solving (Hardy, 2019).

Discussion

The 'Design Your Future City' programme, uniquely utilising design thinking, and the Critical Change Lab method provides valuable practice implications by offering a scalable model for promoting futures literacy into science education. Grounding sustainability education in place based, future-focused scenarios, promotes a deeper understanding of how individual actions can shape local environments. By encouraging students to envision the future of their area and take action based on that vision, the programme supported young people's sense of agency by helping them see themselves as having the ability to shape a sustainable futures in their area.

Practical insights from implementing the programmes with different cohorts across different learning environments have informed our understanding of the barriers and enablers to imagining alternative futures and fostering futures literacy in informal science education programmes. The impact of the learning space, the methods used, and the facilitation styles can be observed in the futures imagined and solutions presented as part of the programme. These insights, alongside evaluation using a mixed-methods approach (Rincón & Díaz-Domínguez, 2022) provide the basis of our argument that futures literacy is a crucial skill to cultivate in youth.

Future iterations of the programme aim to amplify student impact beyond the programme week by developing their ideas further into pilot projects within the city. This would promote youth agency and create tangible connection between futures literacy and civic action. However, practical limitations exist when transitioning from speculative ideas into feasible solutions, particularly in the risk-averse environment of local authorities.

Conclusion

This case study of the 'Design Your Future City' programme explores how futures literacy might serve as a tool in science education by encouraging young people to envision and create sustainable futures for the areas they live in. At the time of presentation, four iterations of the programme provided a comparative empirical base for examining futures literacy in informal science education. The early findings indicate that futures-oriented, participatory approaches can

create conditions in which young people articulate preferred futures, engage with complex socio-technical issues, and experiment with forms of collective action.

Building on these insights, future research will focus on examining how expanded learning environments, such as sustained mentoring, partnerships with civic and community actors, and opportunities for continued engagement beyond the programme week, influence the development of youth agency and futures-oriented thinking. This research will explore how such conditions mediate the translation of speculative ideas into forms of civic action within the constraints of real-world contexts. This focus will contribute to a more precise understanding of how futures literacy is enacted in informal science education, and how it can support young people to see themselves having a role in shaping sustainable futures for their local area.

Implementation Process And Outcomes Of School Climate Assemblies: Exploring The Views And Perceptions Of Secondary School Students

Núria Monterde-Miralles[1], Gisela Cebrián[1] and Mercè Junyent[2]
[1]Universitat Rovira i Virgili, Spain
[2]Universitat Autònoma de Barcelona, Spain

Student participation and decision-making are essential to address various complex global challenges such as the climate crisis, biodiversity loss and social inequalities. This study presents the applied research project EDU4CLIM, which aims to involve young people in sustainability issues through the implementation of Climate Assemblies as an innovative and collaborative educational strategy. The main objectives of this research are: 1) to analyse secondary school students' perceptions of the strengths and areas for improvement of the school climate assemblies organised, 2) to explore the changes in their daily actions as a result of their participation and the sustainability competences they feel they have developed. For this purpose, an ad hoc questionnaire was designed and administered to 206 students in 7 secondary schools in the province of Tarragona (Spain) in the school year 2023-24. A descriptive and qualitative content analysis was carried out. The findings show that the assemblies promoted sustainability competences such as collective action and future thinking according to students' perceptions. Teamwork and learning new knowledge were seen as strengths, and aspects to be improved included making the assemblies more dynamic and devoting more sessions to them. Students comment that their participation in the school climate assemblies has contributed to changes in their everyday environmental behaviour. In particular, students highlight improving waste management through recycling. This study shows that assemblies can be an effective pedagogical strategy to promote sustainability competences.

Keywords: climate assemblies, secondary education, sustainability competencies

Context And Relevance To Science Education

Today's societies are characterised by their complexity and globalisation, as they face various global challenges, such as the climate crisis, and economic and social inequalities. To deal with these challenges, individuals and societies must learn how to adapt and take action. Target 4.7 of SDG 4 - Quality Education of the United Nations 2030 Agenda specifically addresses Education for Sustainable Development (ESD) and the importance of schooling and developing sustainability competencies (UNESCO, 2017). Science education for sustainability promotes natural transformation, emancipation and continuous human progress that contributes to positive change towards sustainability (Sterling, 2017).

Conceptual Rationale

EDS is focused on key learning processes such as collaboration and dialogue, systems thinking, continuous innovation of the educational curriculum and active and participatory learning, as well as learning related to asking critical questions, questioning one's values, envisioning future scenarios, responding in an informed manner and exploring the dialectic between tradition and innovation (UNESCO, 2017).

In the school context, sustainability involves reorienting the content, competencies, expected outcomes, and objectives of education (Sterling et al., 2017). To foster these curricular improvements, it is essential to define the sustainability competencies that will enable students to

critically reflect on their own actions. According to Mulà et al. (2022), sustainability competences are the combination of knowledge, skills, attitudes, and ethical values needed to effectively address sustainability challenges.

In this context, one of the increasingly popular deliberative democratic processes related to climate change are citizen climate assemblies. In recent years, school and youth climate assemblies have emerged internationally to give young people a voice and empower them on climate action (Cebrián et al., 2025; Wilson et al., 2024). These processes seek to ensure children's and youngsters' participation and environmental rights are realised, as most policy decision-making processes exclude the participation of the youngest members of society (Reid, 2023).

Research Aims

This research aims to analyse the implementation of school climate assemblies as an innovative method for learning, deliberating, and addressing climate change. The research was conducted in the EDU4CLIM project, a R&D&I project funded by the Spanish Ministry of Science, Innovation, and Universities, and the EU-Next Generation.

The specific objectives of this study are to:

1. Analyse secondary school students' views and perceptions of the strengths and areas for improvement of school climate assemblies.
2. Explore the sustainability competencies that the students have developed due to their participation in school climate assemblies.

Research Method And Design

An ex post facto study was conducted using the interpretive paradigm to analyse secondary students' perceptions of school climate assemblies (Bisquerra, 2019). The research involved 7 schools in Vendrell and Valls (Tarragona, Spain) during the 2023-24 school year, with the intervention occurring from January to May 2024. School climate assemblies were implemented, supported and guided by facilitators and experts, members of the project's research team (Cebrián et al., 2025). The assemblies are structured in three phases:

1) **Learning phase**: includes materials, preparatory activities and the participation of climate change and sustainability experts.
2) **Deliberation phase:** consists of facilitating dialogue and debate among participants on the environmental issues addressed in the assemblies, through collaborative activities.
3) **Decision-making phase:** focuses on facilitating the development of joint and consensual conclusions based on the reflections and discussions of the participants through voting.

Each assembly consisted of four sessions, organised per class group in each participating secondary school.

- **First session:** In each class, four groups focus on different climate change topics (water, energy, biodiversity, tourism and mobility), discussing both positive and negative aspects. They create a conceptual map and develop a decalogue with 10 action proposals for their community. Finally, each student votes on the top 3 priority actions.
- **Second session:** the group class reflects on the most voted actions, then holds a group vote to select the most relevant action for the community. Afterwards, students work in groups to develop and present the chosen action at the Sustainability fair (third session).

- **Third session:** meeting with the political leaders and municipal technicians of the territory to discuss and share the actions proposed and delve into it to then share and disseminate it in a Sustainability Fair.
- **Fourth session:** a Sustainability Fair is organised where all the class groups from the participating schools present their proposed actions, exchanging perspectives and receiving feedback from the political and social actors of the territory on the actions proposed by the students.

In order to determine the perception of secondary school students in relation to the climate assemblies, an ad hoc questionnaire was designed and administered to 206 students after the Sustainability Fair, at the end of educational intervention. The designed questionnaire consists of two parts; the first consists of ten items related to ten competences of the GreenComp framework (Bianchi et al., 2022), with a Likert scale 1→4, namely: Disagree (1), Neither agree nor disagree (2), Agree (3) and Strongly Agree (4). The items of this first part of the questionnaire and their link to the sustainability competences of the GreenComp framework are presented, indicating the competence and its descriptor (table 1).

Table 1. Questionnaire items, sustainability competence and descriptor from the European GreenComp framework.

	The school climate assemblies have helped me to be able to...	**Sustainability competence (acronym) and descriptor**
1	Reflect on my actions and, at the same time, detect whether they are environmentally friendly.	**Valuing Sustainability (VS):** reflect on personal values and assess them in a coherent way
2	Thinking, deciding and proposing ideas that will benefit present generations, like yours, and future generations.	**Supporting fairness (SF):** support equity and justice for present and future generations.
3	Imagine the future that is most favourable to the well-being of the planet.	**Future literacy (FL):** Projecting alternative sustainable futures.
4	Understand an environmental problem from different interconnected perspectives (personal, environmental, cultural and social).	**Systems thinking (ST)**: Address sustainability issues from all points of view.
5	Make decisions in a critical way without falling into false information.	**Critical thinking (CT):** Evaluate arguments and reflect on how they influence thinking.
6	Identify real situations that occur in my village, neighbourhood or town.	**Problem framing (PF):** Formulating current challenges to identify approaches to anticipate problems

7	Change actions in my daily life for the wellbeing of the planet.	**Adaptability (A):** Making decisions about the future in the face of uncertainty and risk.
8	To find out about activities that are organised in my village, neighbourhood or town to improve the environmental situation.	**Political agency (PA):** Navigating the political system and identifying political accountability
9	Recognise the importance of working collectively in groups to solve problems.	**Collective action (CA):** Acting for change in partnership with other actors.
10	Gain initiative and take individual action to solve a climate change problem.	**Individual initiative (II):** identify one's own potential for sustainability and actively contribute to improving the prospects of the community.

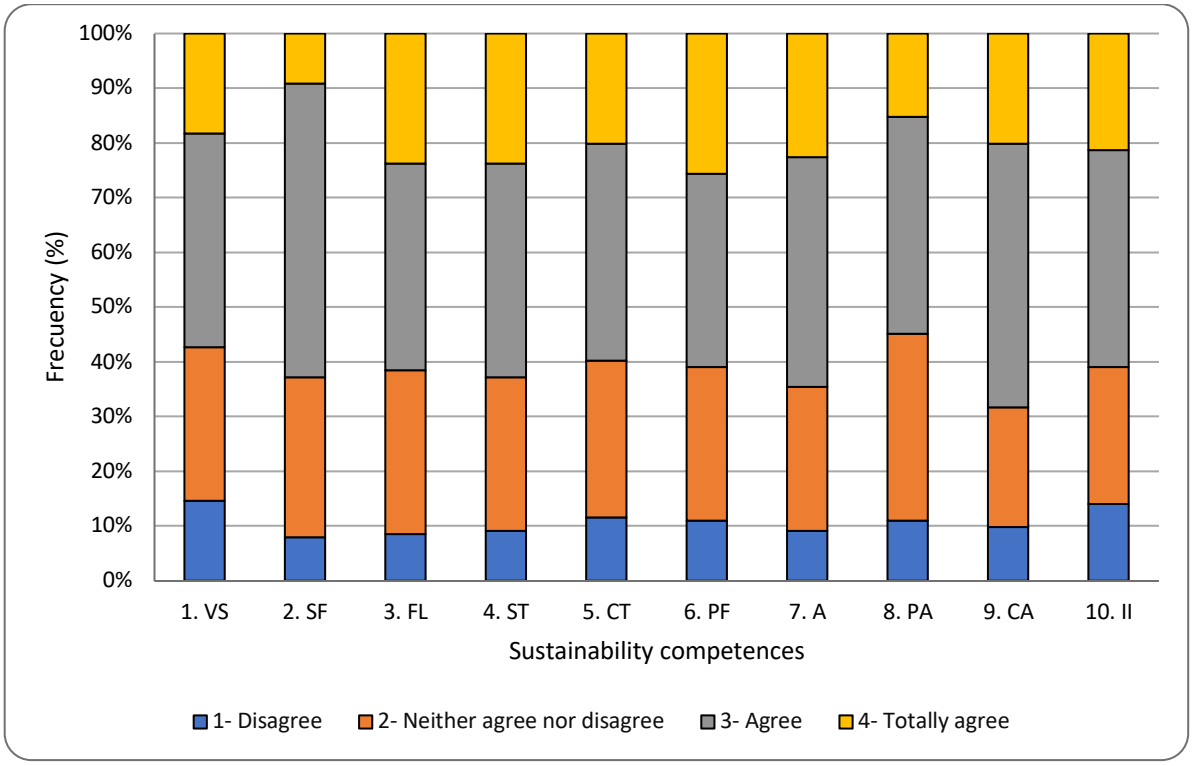
The second part includes four open-ended questions related to strengths and areas for improvement of climate assemblies.

The analysis process consisted of creating a frequency table to calculate the percentage of the different levels of agreement or disagreement in relation to the sustainability competences acquired. To analyse the responses to the open-ended questions, a qualitative content analysis was carried out, in which the responses were coded, and the codes were inductively grouped into categories to identify the main strengths and areas for improvement as perceived by students.

Findings And Coherence Of Argument

In relation to strengths, three main categories emerged: 1) new knowledge about climate change and the well-being of the planet, 2) Sustainability Fair and 3) methodology and dynamics. As students emphasised:

> [S74]: That we have proposed things to improve the situation of the planet. (category: New knowledge about climate change
>
> [P120]: A lot of people participated, and it was very cool. (category: Sustainability Fair)



In terms of areas for improvement, two categories emerged, relating to 1) Phases of the assemblies and 2) promoting awareness. As some students commented:

> [S122]: We need to do better at not polluting so much (category: promoting awareness)
>
> [S129]: The topics could be improved, not given so broad a scope. (category: Phases of assemblies)

In line with the acquisition of sustainability competencies, the findings show that the school climate assemblies promoted competences such as collective action (CA), by recognising the importance of working together to find solutions after participating in the assemblies; systems thinking (ST), understood as the ability to analyse environmental problems through multiple interconnected perspectives (personal, environmental, cultural and social) and to recognise the relationships and interdependencies among them; supporting fairness (SF), reflected in thinking, decision-making and the proposal of ideas oriented towards social and intergenerational justice, aiming to benefit both present generations, such as students themselves, and future generations;

and future literacy (FL), related to imagining the most favourable future for the well-being of the planet (Figure 1).

Figure 1. Students' assessment of sustainability competencies acquired in school climate assemblies.

Discussion Of Findings And Implications

According to the first objective focus on analysing secondary school students' views and perceptions of the strengths and areas for improvement of school climate assemblies, the findings of this research show that secondary school students consider the collective action and cooperation promoted by school climate assemblies to be a strength. In terms of areas for improvement, the students consider the dynamism and timing of the assemblies, and the need to extend the sessions and make the topics covered more specific. This is consistent with the findings of previous studies of climate assemblies, which highlight the need to allow sufficient time for deliberation and decision-making (Reid, 2023; Wilson et al., 2024).

In relation to the second research objective, which sought to the explore the sustainability competencies that the students have developed due to their participation in the assemblies, the findings of this study show that students consider that they have acquired various sustainability competences such as collective action and future thinking, which are in line with previous studies. In turn, assemblies promote critical thinking among students, which can help them become aware of climate change and strengthen their engagement and well-being (Trott et al., 2022).

In particular, this research offers contributions for interested academics, teachers and educators, such as a detailed description of the methodological phases used in the assemblies, evidence of the impact of the assemblies on the learning of secondary school students, an ad-hoc questionnaire designed to collect data on the learning achieved in the assemblies from the students' perspective, and documentation of the students' acquisition of sustainability competences following their participation in the climate assemblies from their own perspective.

In response to one of the fundamental questions raised by the ESERA Congress, which is related to living in a globalised society undergoing constant environmental change, there is an urgent need to rethink the role of education in promoting change towards a more conscious society committed to sustainability. In this sense, the implementation of the school climate assemblies presented here could be a very appropriate strategy to support this process, adaptable to different contexts and educational levels.

Acknowledgement

Placemaking Reimagined: Examining The Role Of Imagination In Critical Place-Based Learning

Hannah H. Ziegler and Heidi B. Carlone
Vanderbilt University, Nashville, TN, United States

Youth are seldom presented with meaningful opportunities to design their own futures through civic engagement and design, despite their potential as imaginative placemakers. Drawing from critical place-based scholarship, this study aims to reconceptualize placemaking as entwined processes of decolonization, reinhabitation, and imagination. Our work delves into how a critical place-based curriculum empowered youth in imagining and re-envisioning the future of Creekside Plaza, a local plaza-mall under redevelopment. The curriculum supported students' imaginative placemaking through maps, plans, community engagement, and 3D design tools. Although some of the curriculum's activities simultaneously augmented and curtailed youths' creative expression, we argue for the necessary inclusion of youth and their imagination in placemaking roles to design hopeful, vibrant futures.

Keywords: Placemaking, Critical Place-Based Education, Imagination

Introduction

Harvey (2015) speaks to people's collective rights to cities and our rights to (re)make them, where all humans should necessarily share the responsibility for shaping the future of the places we inhabit (Gruenewald, 2003a). Unfortunately, young citizens continue to be excluded from placemaking processes despite instances of youths' authentic contributions to designing for environmental change (Malone, 2013). In this study, we explore placemaking as an integral approach that enables youth to become designers of their own (hopeful) futures as rightful placemakers. We draw from Gruenewald's understanding of placemaking as "the process of shaping what our places will become" (2003a, p. 627). We argue that dwelling in imaginative, "what if" spaces is particularly critical in placemaking, which is an imaginative process in and of itself (Judson, 2019). Furthermore, this conceptualization of placemaking enables children to engage with the sense of possibility for thriving places. Hence, this qualitative study centers the following inquiry: How did youths' imaginative engagement support and constrain their placemaking practices in a local civic design project?

Conceptual Framework: Placemaking As Decolonization, Reinhabitation, And Imagination

Placemaking As Decolonization

Geographical spaces have been exploited as tools of power, domination, and control (Lefebvre, 1997). To restore democratic rights to cities, individuals must first recognize how places represent various histories of struggle and resistance (Cresswell, 2014). Mehrez (1991) writes about decolonization as contesting and liberation from dominant forms of language and ideologies or undoing the hegemonic forces of Western knowledge systems (Shaw et al., 2006). Thus, decolonization requires youth to also critically reflect on their own positions in their local communities to recognize the social and ecological harm imposed on places across temporal scales (Gruenewald, 2003b).

Placemaking As Reinhabitation

Once youth have identified the ways in which their environments have been disrupted through social hegemony, they must learn how to thrive in previously-damaged spaces amongst their

human and more-than-human cohabitants in the present day (Gruenewald, 2003b). Thus, we conceptualize reinhabitation as largely relational work that urges people to practice socioecological care despite powered nature-culture relations that might constrain youths' consideration of more-than-human perspectives. Therefore, we design ways for youth to assume shared collective responsibility towards "intergenerationally connected and morally responsible" multispecies communities (Bowers, 2001, p. 20; Kerkham & Comber, 2013).

Placemaking As Imagination

What distinguishes placemaking as a unique and invaluable practice that instills agency and critical hope in youth is the richness of possibility. However, contemporary schools have become places that suppress young people's imaginative minds rather than nurture them (Benjamin, 2024). Additionally, the romantic nature of imagination often presents questions regarding the legitimacy of imagination as a valid epistemic resource, but Egan (1977) noted that this romantic understanding of imagination is what helps youth make sense of the world in rational ways.

Methods

Study Design

Our team designed a two-week curriculum around critical place-based education and digital storytelling around Willow Creek, a local waterway that flows through a large part of the diverse neighbourhoods of Newtown. We worked with diverse middle school youth (n = 23) from two schools closely located near upstream Willow Creek. Some of the camp activities included: embodied creek play, local map studies on environmental justice, interviews of invited guests and local residents, and the creation of podcasts, zines (short for magazines), and AR (augmented reality) stories about Willow Creek.

We designed this curriculum based on the Connect–Investigate–Interrogate–Imagine–Act (CI^3A) pedagogical framework (Figure 1) developed by Carlone et al. (2024) for critical place-based education. Based on the CI^3A framework, we created opportunities for youth to connect with place through embodied and affective experiences in the field (e.g., care, wonder, joy, and stillness) (Stapleton & Lynch, 2021). We conceptualized investigation as transdisciplinary epistemic practices drawing from science, history, art, and technology. By analysing maps that illustrated relationships between environmental health and social justice, the curriculum also offered opportunities for youth to interrogate the social and environmental inequities that represent distributional injustice (Campbell et al., 2022). To design for imaginative spaces, we supported students' speculative storytelling, futuring, and placemaking practices as youth took on the role as civic designers advocating for just and sustainable futures of Willow Creek. Lastly, we provided space for youth to share their placemaking stories and act as advocates for the Willow Creek community.

Given our research question regarding the role of youths' imaginative work towards placemaking, this paper focuses on the last three days of the larger summer curriculum based on Creekside Plaza, a local area currently undergoing redevelopment located near Willow Creek and students' schools. Students engaged in a series of civic design activities using government-led development plans, local maps, community interviews, and technical tools (e.g., AR). Table 1 further outlines the central activities that took place during the AR civic design unit.

Figure 1. Connect–Investigate–Interrogate–Imagine–Act (CI³A) Framework.

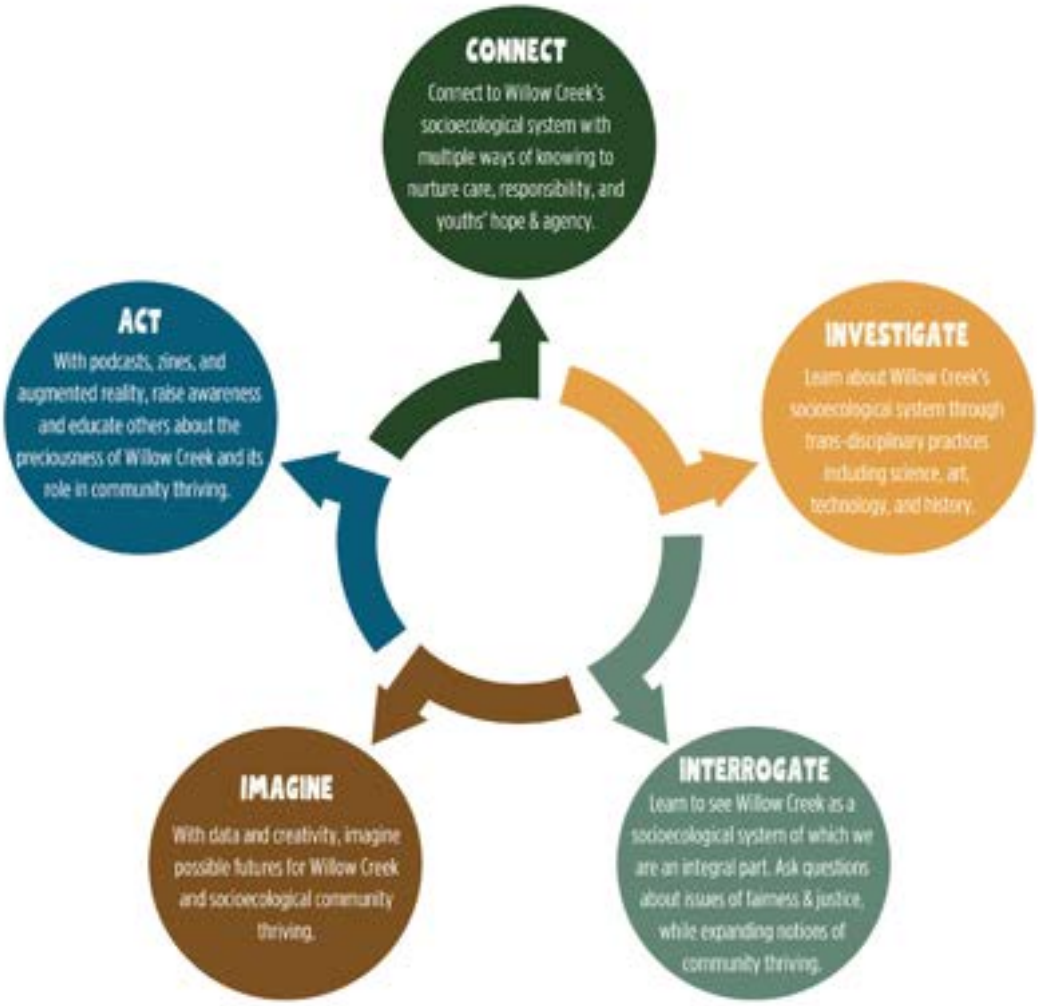

Table 1. Curricular Activities during Civic Design Project with Creekside Plaza.

Creekside Plaza Map Study	Community Eco-Survey	Collaborative Redesign	3D Design with AR
Evaluate government's master plan of Creekside Plaza in small groups	Interview local development professionals and visitors at Creekside Plaza	Generate collaborative proposals to redesign Creekside Plaza	Create individual AR projects that visualize a select portion of group's proposal

Data Collection & Analysis

Our data corpus consisted of video, student artifacts, and end-of-unit interview transcripts. Artifacts included student-created maps, plans, and AR projects that visualized youths' imagined versions of Creekside Plaza. During our first phase of analysis, we examined the videos to identify key moments in the data that informed our understanding of youths' imaginative engagement in the context of placemaking. As a result, we largely focused our analysis around the Creekside Plaza Map Study and Collaborative Redesign activities, creating content logs (Miles et al., 2013) based on those 10 hours of video data as our first "pass" of processing data. We triangulated

multiple sources of data to confirm our emerging assertions about the data. Our team drafted analytic memos related to the purposes, moments, forms, affordances, and limitations of imaginative engagement, and debriefed our analytic decisions with other researchers.

Findings

Playful (But Purposeful) Futuring

About a fourth of our students overtly presented child-like, fantastical assets in their final AR projects. In Nathan's case, his portrayal of a talking racoon named Jim as an environmental advocate illustrates an ontological shift through anthropomorphizing a racoon. He illustrates a vulnerable animal as one with agency, who is eager to educate others about her environment and is passionate about protecting their home. In essence, Nathan is layering his own advocate agenda onto this racoon. Admittedly, selecting a raccoon specifically was a rather fortunate "accident." Although Nathan's selection of a specific species was rather spontaneous, his intent to centre more-than-human advocates was part of his purposeful design: "I kind of just was thinking of someone else besides a human to use, so I just thought of a raccoon. I was just looking through everything, and I just saw a raccoon, and I was going like, "I'm going to use this, and name him Jim" (Nathan). He went ahead and named the racoon and leveraged his imagination to tell Jim's story about "how deforestation is ruining his life almost, and how his home has just been taken away, and it allows him to not be safe."

Figure 2. Nathan's AR Project.

Relational Care: Imagining *For* And *With* Others

Our design of the AR unit challenged youth to centre relationality and care for others. The intergenerational conversations in which adult facilitators modelled relational care and

perspective-taking drove students to design for others. For instance, Ms. Castillo advocated for a "young people hangout spot," such as a bowling alley. Brett pushes back, stating that not all plazas and malls have bowling alleys. Ms. Castillo models perspective-taking: "I know, but if [Creekside Plaza] doesn't have what the community needs, the only place to go is in [central] Newtown. So [as a] college student, if I don't have a car, I don't have anything to do on a Friday night." Realizing that the nearest bowling alley from Creekside Plaza's college campus is 4.5 miles away, Brett soon made space for a bowling alley in their group's proposed design. Throughout the unit, Brett had already emphasized the need to design spaces "for everybody;" yet Brett's engagement with international imagination with adults had augmented Brett's pre-existing values of collective care in their designs of Creekside Plaza.

Material Engagement In Physical And Digital Spaces

Our curriculum designed multiple opportunities for youth to interact with physical (e.g., paper maps) and digital materials (e.g., 3D assets). Youths' interactions with diverse materials allowed to expand imaginative engagement beyond cognitive and ideological spaces, towards material ones. Specifically, our use of AR and virtual visualizations of youths' futured Creekside Plaza offered opportunities for youth to be positioned as co-imaginaries. Ms. Yana noted the affordance of scanning QR codes to students' AR projects: [the audience is] gonna be able to see this world that we're creating," where she positions AR as the object that allows them to become co-visionaries of their imagined worlds. Having physical and digital artifacts when interacting with adults enabled youth to enact their voices and be positioned as advocates within their communities. When interviewing local visitors at Creekside Plaza, Addison's group requested to use their maps during their interactions, which made her "happy because then people would listen to me and stuff." Similarly, Nathan noted the important role of having a technology-enabled design that captures his imaginative work because AR "allows you to go inside of it, and get more detail of stuff" compared to "just words." As such, both physical and digital materials instilled a sense of ownership and confidence in youth as civic designers who were eager to inform adults about their imagined futures.

Conclusions

Our findings inform us about youths' imaginative placemaking during the civic design unit in three notable ways. First, youths' imagination was recognized as a legitimate epistemic resource for placemaking. Second, youth engaged in placemaking through intergenerational care, albeit reproducing anthropocentric values. Lastly, their engagement with and production of materials (e.g., maps, AR) coupled with their imagination further enabled their authority as imaginative placemakers. Though young citizens have been excluded from placemaking processes despite directives towards creating better cities for children (Freeman & Tanter, 2011), we hope this empirical example contributes to the field's understanding of youths' imagination in placemaking towards increased opportunities for youth to act as agentic placemakers in the world.

ESERA 2025 Copenhagen

A Regression Analysis Of Environmental Attitudes And Interest In Environmental Topics

Maria-Antonia Manassero-Mas and Ángel Vázquez-Alonso
University of the Balearic Islands, Spain

The 21st century has been fruitful in contributions and initiatives for the conservation and sustainability of the environment. Environmental concern is visible in public spaces and media, and environmental education has become a cross-cutting aim of science education and general education. However, the relationship between the environmental attitudes and the environmental knowledge is relatively unknown, especially for young people, because this group rarely takes part in sociological environmental surveys, which are usually focused on adults. This study addresses the empirical exploration of this relationship for a large sample of 15-year-old Spanish students who participated in an international project where they answered an environmental attitude scale and rated their interest in some environmental topics. The results show overall positive attitudes and moderate interest in environmental topics, as well as pinpoint the specific best (people should care more about the environment) and worst (science and technology can solve all environmental problems) environmental attitudes and the most (protection of endangered species) and least (improve the harvest) interesting environmental topics. In addition, the regression analysis finds the environmental topics that are the best predictors of the environmental attitudes, which share over 27% of common variance. These results are discussed in light of other studies, and some recommendations are proposed so that science education can effectively contribute to improving the environmental attitudes and the interest in environmental topics, putting especial care into teaching about the worst attitudes, the less interesting topics, and the topics that are negative predictors of attitudes.

Keywords: Attitudes towards the environment, environmental topics, prediction of attitudes, education for sustainability

Introduction

Environmental awareness, concern, or attitudes are central concepts in environmental psychology research that the emergence of climate change has turned into socially relevant and educationally unavoidable issues to promote students' pro-environmental behaviours. According to social psychology, attitudes guide behaviour in general (Eagly & Chaiken, 1993), and environmental attitudes guide sustainable actions, pro-environment behaviours, media consumption, etc. (Liu et al., 2020). Further, environmental attitudes and environmental topics are intersectional and relevant to science education (Braun & Dierkes, 2019).

According to Eagly and Chaiken (1993), attitudes are psychological tendencies that express the evaluation of an entity with a certain degree of approval or disapproval. Obviously, the knowledge of the entity that assesses the attitude must be a key factor of the attitudinal acceptance or rejection degree so that both elements are related. In this case, environmental attitudes are related to people's interest in knowing environmental topics. The evaluative summary of the entity (approval/disapproval; agreement/disagreement; interest/disinterest) is the consequence of the dynamic interaction of the three basic elements of attitudes (cognitive, affective, and behavioural).

As a consequence, environmental attitudes are today a popular topic in media and in sociological surveys (CIS, 2020; European Union, 2014). Further, education for sustainability (ESD) and sustainable development goals (SDG) permeate all the educational levels and subjects of general education and science education in particular (UNESCO, 2006; UN, 2015). Thus, the investigation of environmental attitudes constitutes today a wide field of research and education.

Most of the research literature admits that environmental knowledge contributes to developing sustainable behaviours and attitudes, but that knowledge by itself does not produce these developments, so research is needed to determine the contexts and influences of knowledge on environmental attitudes and behaviours (Braun & Dierkes, 2019). Further, although a direct correlation between environmental knowledge and environmental attitudes is generally admitted, consensus on the best measurements of environmental knowledge is scarce, and no model is considered proven (Makki et al., 2003; Liu et al., 2020).

Interest in topics is key to attaining some knowledge and the Krapp and Prenzel's (2011) concept of interest as a particular case of the conceptualization of attitudes is adopted in this study, which addresses the diagnosis of environmental attitudes and analyses its relationship with the interest in environmental knowledge topics within the framework of science education.

The conceptualization of the environmental attitudes construct assumes the original psychological sources and is operationalized here through a specific and simple measurement tool, which is based both on its relevance for science education and on its systematic approach to the multidimensional and hierarchical nature of environmental attitudes, as suggested by psychological literature (Cruz & Manata, 2020; Milfont & Duckitt, 2010).

Data on environmental attitudes and interest in environmental topics are taken from the database of the international comparative study The Relevance of Science Education Secondary (ROSES-2022). ROSES explores 15-year-old students' science attitudes and their relevance for science education around the world (Jidesjö et al., 2020).

The research questions of this study are twofold:

What are young students' environmental attitudes and interests in environmental topics today?

Which environmental topics are the best predictors of environmental attitudes?

Methodology

Materials

This study draws its data from the questionnaire applied worldwide as the tool of the international project The Relevance of Science Education Second, which explores several categories of students' experiences that may be relevant to science education. An international group of experts developed the research survey for the ROSES-2022 project (ROSES-Q). This study elaborates on data from two categories of this survey to answer the research questions (Jidesjö et al., 2020).

The environmental attitudes are operationalized from the category of ROSES-Q "Me and the environment,", which contains 13 different attitudinal statements about the environment (Figure 1). For each statement, students are asked to answer the following question: To what extent do you agree with the following statements? The students tick their answers on a 4-point Likert scale, whose points are coded as follows: 1-disagree, 2, 3, 4-agree. The confirmatory factor analysis of this category (CFI = .964; TLI = .941; RMSEA = 0.068), within the framework of relevance for science education of the ROSES project, confirms a latent structure of a single factor formed by 6 items (D2, D4, D5, D6, D9, and D13) with statistically significant loadings and good internal consistency (ordinal Omega=.769).

Likewise, data from the interest in 14 environmental knowledge topics, which are taken from the category of ROSES-Q labelled "Things I would like to know more about." All items display environmental content (i.e., "E11. How to protect endangered species"), and the participants are asked to answer the following question about the topics: How interested are you in learning more about this topic? The students tick their answers on a 4-point Likert scale, whose points are coded

as follows: 1-not interested, 2, 3, 4-very interested). The environmental knowledge is elaborated in this study as the students' interest along those 14 items (Figure 2).

The ROSES-Q items are enacted as direct, clear, simple, and short sentences (averaging eight words), mostly written in an affirmative and positive style, although some are written in a negative way to compensate for response bias.

Participants

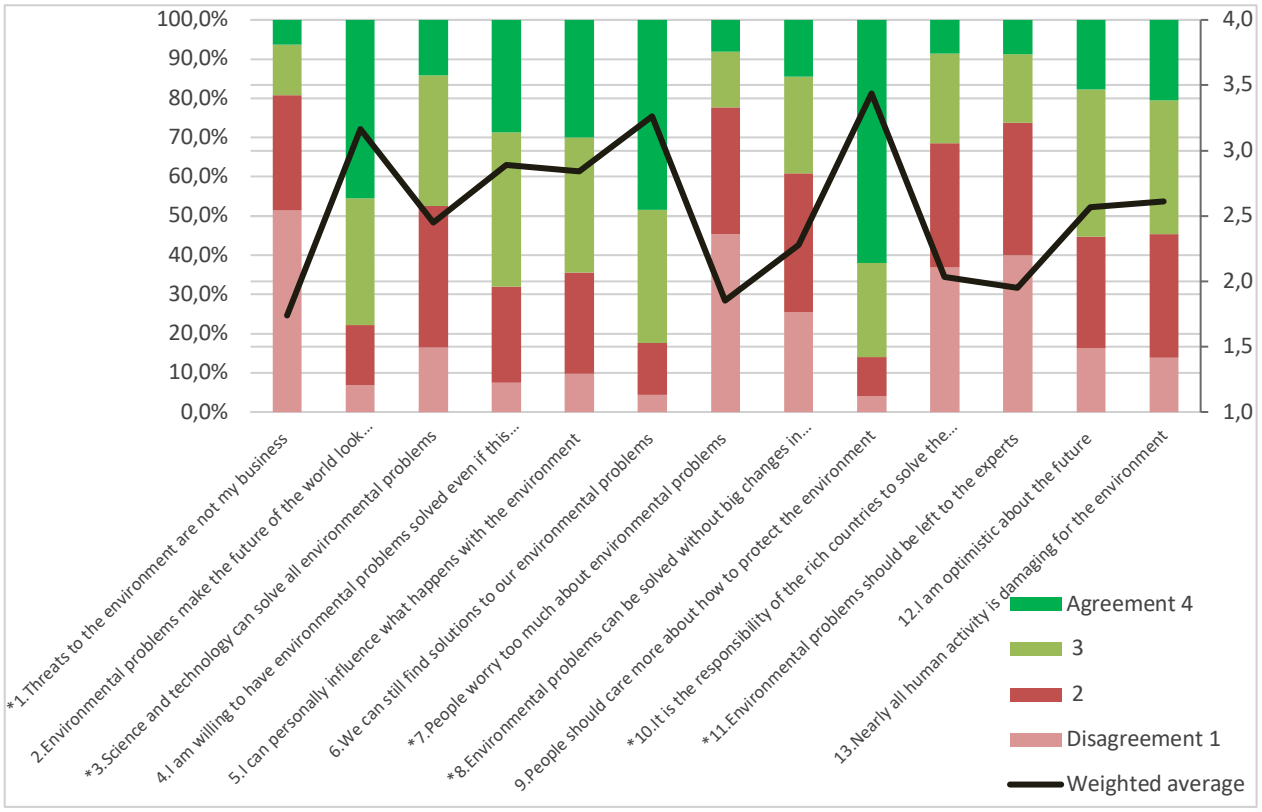
A valid sample of 1912 Spanish students was surveyed through the ROSES-Q following the protocols of the ROSES project, whose target population is 15-year-old students (grades 9 and 10). They identified themselves as girls (49.4%), boys (46.9%), or did not indicate their sex (3.7%), and attended 23 schools (14 public and 9 private) throughout a Spanish region. Almost all (97.2%) were aged between 14 and 16 years old (mean age 15.1 years), and no one received incentives for participating.

The approval of the ROSES project by the Spanish State Research Agency implied the commitment to comply with the ethical principles and the relevant national, European, and international legislation on human rights. Students were informed that answering meant consent to participate, that they could leave items unanswered, and that the survey was anonymous.

Procedures

The students answered the ROSES-Q online as a class assignment directed by their teachers within their class group and applying the same protocol. The researchers did not have any personal contact with the participants, and the teachers did not have access to the database, warranting total anonymity.

The data gathering took place between late 2020 and 2024, and some data cleansing procedures were developed to improve the quality and validity of data through controlling and deleting invalid answers (homogeneous, highly incomplete, joking, random responses, etc.).



The mixed method, quantitative and qualitative, applies to students' responses. The percent and the weighted average of the Likert scale points quantify the valid responses. The latter is a fertile parameter for simply representing items and visualizing comparisons.

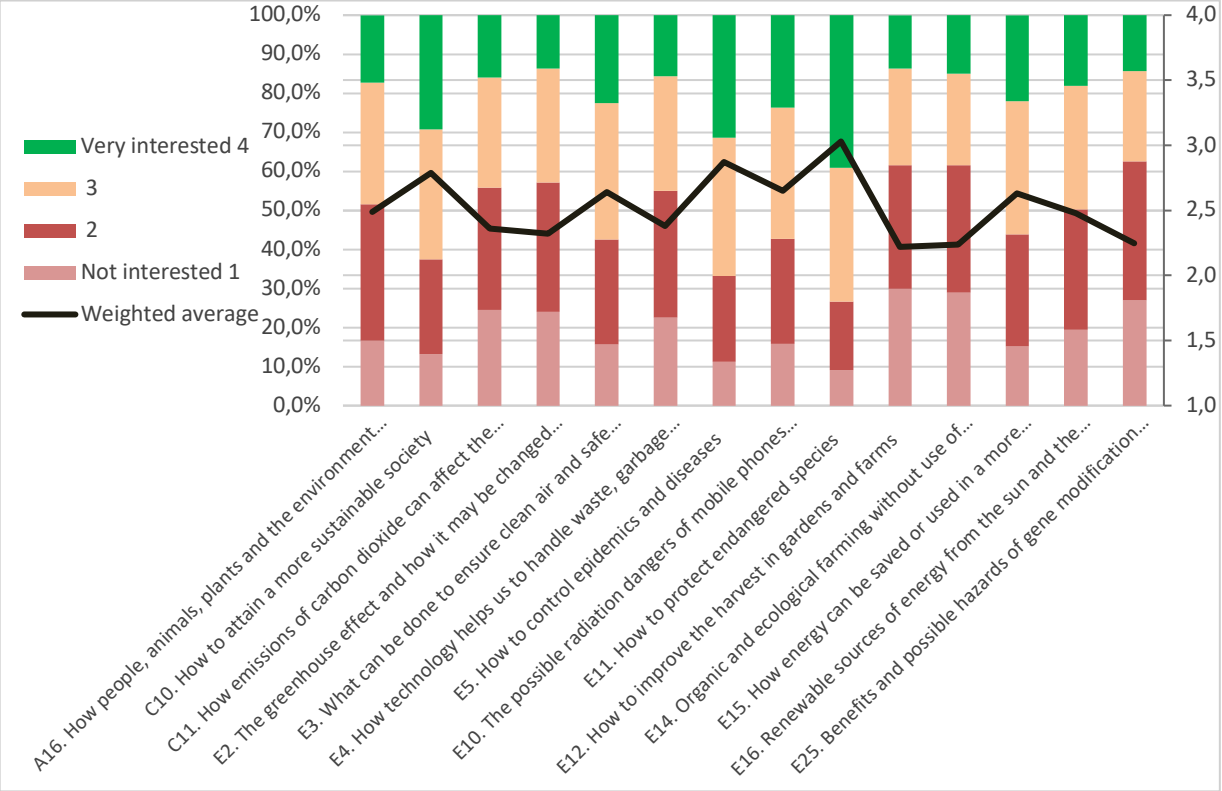
Six items from the category "Me and the environment," marked with asterisks in the figures (i.e., environmental threats are not my business), present content that is contrary (negative/anti-environment) to the direction of the remaining items (consciousness/pro-environment). The scores of these dysfunctional items must be interpreted in a complementary or reversed way to the functional/positive pro-environmental items so that the interpretation of all item scores has the same homogenous pro-environmental meaning throughout the scale.

Results

The first comprehensive finding of this study is the identification of globally positive environmental attitudes, since the responses to the functional statements of the category "Me and the environment" are above 50% global agreement (weighted averages greater than 2.50), and the dysfunctional phrases are below 50% global agreement (weighted average less than 2.50) (Figure 1).

Figure 1. Percentages of responses on each of the four points of the Likert scale (left vertical axis) and weighted averages (right vertical axis) of the 13 items of the category "Me and the environment" and the three complementary phrases.

* Items expressing anti-environmental content.



Another finding is the identification of the specific aspects that arouse the most and least favorable environmental attitudes, that is, the main strengths (agreement greater than 80%) and the weaknesses (lowest agreement) of the environmental attitudes. Three items reach the most favorable environmental attitudes scores, largely agreeing that people should feel more concerned about protecting the environment (D9, D7 reversed) and the ability to still find solutions to environmental problems (D6, D4) and largely disagreeing that environmental threats are not my concern (D1, D10, D11 reversed).

The item "D3. Science and technology can solve all environmental problems" reaches the lowest agreement rate though it is intermediate (48%; average 2.45). The remaining items display agreement scores in-between those already mentioned (note that the reversed interpretation of disagreement also applies to D8).

In regard to the students' interest in the 14 environmental topics surveyed, it could be described as moderately positive, since most of the issues reach interest percentages above 50% and weighted averages higher than the midpoint (2.5) of the Likert scale (Figure 2).

It is worth highlighting the large interest in the items about the protection of endangered species, the control of epidemics and diseases, and the path towards a more sustainable society. On the other hand, the lowest interest refers to the topics related to agricultural issues (improving crops, genetically modified organisms, and organic and ecological agriculture). The remaining eight environmental topics display intermediate interest scores that are placed between those rates achieved in the previous extreme issues.

Figure 2. Percentages of responses on each of the four points of the Likert scale (left vertical axis) and weighted averages (right vertical axis) of the 14 environmental topics.

Correlational Analysis

Most of the Pearson correlation indices between the scores of the environmental attitudes items and the items of the environmental topics reach statistical significance (Table 1).

The inspection of the correlation indices (Table 1) allows us to appreciate some general features regarding the relationships between the environmental topics and environmental attitudes.

First, the environmental attitude items displaying the highest correlation indices with the environmental topics are those items that were mentioned in the structure of the environmental attitudinal category as the most significant attitudinal in relation to the relevance of science education (D2, D6, D9, D5, D4, and D13 items).

Second, the group of attitudinal items with negative formulations clearly exhibits the lowest correlations (close to zero or negative) with topics. Item D1 (Threats to the environment are not my business), of this group, displays the lowest correlation of all.

For their part, the environmental topic items generally present a pattern of correlations quite similar among them, except for item A16 (How persons, animals, plants, and the environment depend on each other), which stands out for having significantly lower correlations compared to the others.

All in all, according to the former Pearson correlation analysis between environmental attitudes and topics, the environmental attitudes display highly different Pearson indices among them, whilst the differences of the environmental topic correlations seems much more homogeneous among them.

Linear Regression

Some linear regression analyses were performed. The total environmental attitude score obtained by adding some environmental attitude items (after reversing the scores of the dysfunctional items) is the dependent variable, and the environmental topics are the independent variables

(predictors).

Table 1. Pearson correlation indices between the scores of the environmental attitude items and the environmental topic items.

** p < .01. *p < .05.

The first linear regression analysis computed the total environmental attitudes score as the sum of all 13 items of the environmental attitudes scale (after reversing the dysfunctional items). The predictors (14 environmental topic scores) explained 22% of the environmental attitude variance (R^2), yet many predictors did not attain statistical significance. After eliminating the non-significant predictors, some different regression analyses were tried, but their estimators did not improve at all.

The second linear regression analysis computes the total environmental attitude score (dependent variable) by summing just the items (2, 4, 5, 6, 9, and 13), those obtained by confirmatory factor analysis. The linear regression analysis with all 14 environmental topics as predictors yields a model with 27.6% shared variance and four non-significant predictors. After removing the four non-significant predictors, the model (nine predictors) is more parsimonious and increases the shared variance to 28.8% (corrected $R^2 = 28.4\%$). Seven predictors display positive standardized regression coefficients, where the highest regression coefficients correspond to the three most interesting issues, and two negative predictors correspond to two of the three least interesting issues (Table 2).

The strongest predictor of environmental attitudes is the item E11 (How to protect endangered species), which also has the highest interest rate. The weakest predictor of environmental attitudes (absolute score of its estimator) is the item E10 (The possible radiation dangers of mobile phones and computers). It is also worth highlighting the two negative predictors (E4. How technology helps us to handle waste, garbage, and sewage; E12. How to improve the harvest in gardens and

farms).

Table 2. Linear regression model of the environmental attitudes (6-item empirical factor as dependent variable) with respect to environmental topics (significant predictors p < .05).

Predictors (environmental topics)	Estimator	p	Standard Estimator
Constant	11.317	< .001	
E11. How to protect endangered species	0.873	< .001	0.2353
C10. How to attain a more sustainable society	0.534	< .001	0.1510
E5. How to control epidemics and diseases	0.483	< .001	0.1329
E2. The greenhouse effect and how it may be changed by humans	0.451	< .001	0.1250
E3. What can be done to ensure clean air and safe drinking water	0.257	0.035	0.0722
E15. How energy can be saved or used in a more effective way	0.260	0.021	0.0717
E10. The possible radiation dangers of mobile phones and computers	0.218	0.028	0.0614
E4. How technology helps us to handle waste, garbage, and sewage	-0.303	0.007	-0.0843
E12. How to improve the harvest in gardens and farms	-0.340	< .001	-0.0958

All in all, the main finding of these analyses is the evidence of the overall significant and mainly positive empirical relationship between environmental attitude items (reversing the scores of negative items) and environmental topic items. Then, the regression model for the 6-item environmental attitudes (dependent variable) shows nine significant predictors, where strongest predictors are just the four most interesting environmental topics.

Discussion and conclusions

The discussion focuses first on evaluating the contribution of the results to answering the research questions. The surveyed students displayed globally positive environmental attitudes because they highly agree with the functional statements and disagree with the dysfunctional statements.

Further, the students' interests in environmental topics are also positive, but the interest-weighted mean scores are a bit lower than the environmental attitudes' agreement scores. The largest interest is displayed by the items about the protection of endangered species, the control of epidemics and diseases, and the path towards a more sustainable society. The lowest interest is displayed the topics related to agriculture (improving crops, genetically modified organisms, and organic and ecological agriculture).

In summary, the answer to the first research question is that young students hold clearly proactive environmental attitudes, while interest in environmental topics is positive, yet a bit lower and much dependent on the specific topic being considered. These overall findings on environmental attitudes confirm the results reported by Sa-ngiemjit et al. (2022) employing a sample from the same Spanish region and same age.

In the long run this study poses a fundamental question of social psychology (Eagly & Chaiken, 1993), namely, the degree that the knowledge of the attitude entity (in this case, the environment, represented by 14 environmental topics) influences the related attitudes (in this case, environmental attitudes). This question has been explored here through some correlational analyses that contribute to empirically confirming the relationship as well as to highlighting some weaknesses that provide implications for improving the educational practices on education for sustainability and sustainable development goals (UN, 2015).

The overall correlations between environmental attitudes and interest in environmental topics are significant and positive (after reversing scores of the dysfunctional attitudinal items), which gives support to the overall positive relationship between environmental attitudes and interest in environmental topics.

The linear regression analysis that takes the 6-item reduced empirical factor of environmental attitudes as the dependent variable demonstrates the significant empirical relationship between environmental attitudes and interest in environmental topics. A parsimonious prediction model consisting of nine significant environmental topics as predictors was found, where environmental attitudes and environmental topics share a significant proportion of common variance (28.8%). These results reinforce similar findings reported by Makki et al. (2003) and Liu et al. (2020) and allow drawing some educational consequences.

The implications of these results for the educational practice on sustainable development quality emphasize, as compensatory education, the careful educational planning of the less appreciated aspects of environmental attitudes and environmental topics (improving crops, genetically modified organisms, and organic and ecological agriculture) as well as of the topics identified as negative predictors of environmental attitudes (UN, 2015). The two predictor topics that display negative yet the lowest regression coefficients (garden and farm harvesting and waste management) suggest that this negative relationship may be a consequence of the invisibility of food and waste production in the current urban societies, in spite of being central elements for the sustainability of the planet. Further, in spite of the fact that mean environmental attitudes are overall positive, a minority group of students, ranging from 20% to 40% depending on the environmental attitudes item (Figure 1), hold negative environmental attitudes, so that this group should also be the preferential focus of a quality compensatory environmental education.

The main limitations of this study stand on the fact that its design is based on ROSES-Q, which provided the items on environmental attitudes and environmental topics, and these items were not specifically designed for the research questions posed in this study. For instance, the approach to environmental knowledge (as interest in environmental topics) is a bit different from the usual one, which often focuses on quantitative curricular knowledge rather than qualitative interest in knowledge (Braun & Dierkes, 2019). However, the findings are functional, since the regression confirms the empirical contribution of interest in environmental topics to predict the environmental attitudes, through the shared variance is moderate.

Finally, this study contributes a brief and reliable environmental measurement scale with universal meaning to environmental attitudes research. Further, the study opens a new approach to environmental topics through interest rather than traditional content knowledge scores.

Exploring Competences Of In-Service Teachers In Implementing Education For Sustainable Development

Zeynep Aydin and Sevda Yerdelen-Damar
Boğaziçi University, Turkiye

The 2030 Agenda for Sustainable Development underscores the importance of education in achieving its goals, with Education for Sustainable Development (ESD) pivotal in fostering sustainability competences. This study investigates in-service teachers' self-efficacy, perceived pedagogical content knowledge (PCK), and willingness to implement ESD using the Professional Action Competence in ESD (PACesd) framework. A quantitative survey design was employed with 475 in-service teachers from primary, middle, and high schools. Descriptive and inferential statistics were conducted, including MANOVA, to examine differences across professional areas and education levels where in-service teachers work (primary, middle and high school). Results showed no significant differences in PACesd dimensions among professional areas. However, among education levels, primary school teachers consistently demonstrated higher self-efficacy, PCK, and willingness compared to their middle and high school counterparts, with high school teachers scoring the lowest. Statistically significant differences in self-efficacy and willingness were observed among education levels. Post hoc analysis revealed primary school teachers scored significantly higher in these dimensions compared to high school teachers. These findings underscore the challenges faced by secondary education teachers, attributed to rigid, subject-specific curricula that hinder interdisciplinary and holistic ESD approaches. The study calls for targeted professional development, curricular reforms, and strategies to boost teachers' willingness to implement ESD, as it emerged as the lowest-scoring dimension. Future research should explore strategies for integrating interdisciplinary approaches and overcoming barriers to ESD adoption across educational levels.

Keywords: sustainability, teacher education, secondary education

Introduction

The 2030 Agenda for Sustainable Development (SD), adopted by the UN in 2015, outlines 17 Sustainable Development Goals (SDGs) and 169 targets for achieving sustainability by 2030 (UN, 2015). Reaching these goals requires individuals with the knowledge, skills, and values to become sustainability change-makers. Education for Sustainable Development (ESD), emphasized in SDG Target 4.7, is key to equipping learners with the tools to promote SD, including sustainable lifestyles, human rights, gender equality, peace, cultural diversity, and global citizenship (Rieckmann, 2017; UN, 2015). ESD fosters competences for critical reflection on actions, promoting sustainable behaviours and active socio-political engagement (Rieckmann, 2017). Its goal is to develop knowledgeable, active citizens committed to sustainability (Biasutti et al., 2016; Carbach & Fischer, 2017). Teachers, essential to ESD implementation, must have the competences to develop action-competent learners (Isac et al., 2022).

Existing studies largely emphasize teachers' knowledge and self-efficacy regarding their competences in implementing ESD or environmental education (e.g., Gardner, 2009; Moseley et al., 2010), while willingness, a crucial competence component (Sass et al., 2022; Vukelić, 2022), is often overlooked. This study adopts the Professional Action Competence in ESD (PACesd) framework by Sass et al. (2022) which integrates self-efficacy, perceived pedagogical content knowledge (PCK), and willingness to implement ESD among primary and secondary in-service teachers. The framework's holistic approach that incorporates holism, pluralism, and action-orientedness makes it particularly relevant for exploring ESD competences in depth.

The literature shows fewer studies on in-service teachers' competences in ESD or environmental education compared to pre-service teachers (e.g., Effeney & Davis, 2013; Gardner, 2009; Saribas et al., 2014). Moreover, existing research predominantly involves primary school teachers (e.g., Effeney & Davis, 2013; Gardner, 2009). While primary school teachers often find it easier to integrate ESD into their teaching practices due to the flexibility of their curricula (Taylor et al., 2019), teachers at higher education levels frequently encounter challenges arising from subject-specific curricula that limit interdisciplinary approaches (Borg et al., 2012). This highlights the importance of including teachers from higher education levels in studies on ESD competences. Investigating how teachers at these levels are challenged in implementing ESD, particularly within the constraints of their subject areas, is crucial (Isac et al., 2022). Accordingly, this study aimed to explore potential differences in ESD competences among primary (1st to 4th grade), middle (5th to 8th grade) and high school (9th to 12th grade) in-service teachers, as well as differences based on the disciplinary areas in which they teach. The research questions are as follows:

- What are the levels of self-efficacy, perceived PCK, and willingness to implement ESD among in-service teachers?
- Are there statistically significant differences in teachers' professional action competence in ESD among in-service teachers from different disciplines?
- Are there statistically significant differences in teachers' professional action competence in ESD among in-service teachers teaching at different levels of education (i.e., primary, middle, and high school)?

Method

Research Design

This study employed a cross-sectional survey research design to explore differences in self-efficacy, perceived PCK, and willingness to implement ESD among primary, middle, and high school in-service teachers.

Participants

A total of 475 in-service teachers participated, with 64.4% female and 35.5% male. Most were primary school teachers (42.5%), followed by middle school teachers (35.8%), and high school teachers (21.7%).

Instrument

The study utilized the PACesd Scale, developed by Sass et al. (2022), to assess teachers' self-efficacy, perceived PCK, and willingness to implement ESD. The reliability analysis in the current study demonstrated excellent internal consistency (Cicchetti, 1994), with Cronbach's alpha values of 0.96 for self-efficacy regarding ESD, 0.98 for perceived PCK about ESD, and 0.97 for willingness to implement ESD.

Procedure

The PACesd data collection instrument was administered collectively to in-service teachers with the majority of participants completing the survey in approximately 10 minutes. Formal approval was obtained from the university's ethics committee prior to the start of the study. Participation was entirely voluntary and respondents were not required to provide their names or any other identifying information, ensuring anonymity.

Data Analysis

Both descriptive and inferential statistical analyses were conducted using SPSS 29. Descriptive statistics were employed to summarize and organize the study's data and to address the first research question. To address the second and third research questions, multivariate analysis of variance (MANOVA) was performed at a .05 alpha significance level. Before running the analysis, all necessary MANOVA assumptions were checked and fully met.

Results

The results of descriptive statistics are presented in Table 1. The maximum possible scores are 60 for self-efficacy, 66 for perceived PCK, and 60 for willingness. The total mean scores for the dimensions of PACesd are as follows: self-efficacy is 41.5, perceived PCK is 45.2, and willingness is 37.2. Additionally, among education levels, primary school teachers consistently scored higher than middle and high school teachers across three dimensions, with high school teachers having the lowest scores.

Table 1. Descriptive statistics.

Variable	*N*	*M* (Self-efficacy)	*SD*	*M* (perceived PCK)	*SD*	*M* (Willingness)	*SD*
Discipline							
Primary	203	42.8	11.0	46.3	13.2	38.7	12.4
Science	82	42.0	9.6	46.7	11.5	37.7	11.3
Social Sciences	45	42.4	8.9	45.2	12.8	37.5	12.5
Physics	23	42.2	9.3	41.7	11.4	33.0	12.5
Biology	25	37.8	9.4	43.3	12.2	34.4	9.6
Chemistry	25	37.3	9.2	38.7	12.4	34.1	10.5
Geography	24	36.7	9.3	44.2	10.8	34.0	11.7
Visual Arts	17	38.5	11.5	43.5	13.4	32.7	9.2
Technology and Design	31	40.7	15.6	44.5	17.4	38.5	15.3
Education Level							
Primary School	203	42.8	11.0	46.2	13.1	38.6	12.3
Middle School	170	41.5	11.0	45.5	13.2	37.6	12.5
High School	102	38.8	9.5	42.5	11.9	33.8	10.7
Total	475	41.5	10.7	45.2	13.0	37.2	12.1

A one-way between-groups MANOVA was conducted to examine differences in PACesd across professional areas. The dependent variables included self-efficacy, perceived PCK, and

willingness to implement ESD. The independent variable was in-service teachers' professional area. Preliminary assumption tests revealed no serious violations. Results showed a statistically significant difference among professional areas on the combined dependent variables, F(24, 1346) = 1.99, p = .003, Wilks' Lambda = .90, partial η^2 = .033. However, when analysing the dependent variables individually with a Bonferroni-adjusted alpha level of .017, no statistically significant differences were found as indicated in Table 2.

Table 2. MANOVA results.

Variable		Sum of Squares	*df*	Mean Square	F	Sig.	Partial Eta Squared
Discipline							
	Self-efficacy	1946.7	8	243.3	2.149	.030	.036
	PCK	1952.6	8	244.0	1.462	.169	.024
	Willingness	1972.5	8	246.6	1.692	.098	.028

A separate one-way between-groups MANOVA was performed to investigate differences in PACesd based on the educational levels where in-service teachers work (primary, middle and high school). The dependent variables were the same: self-efficacy, perceived PCK, and willingness to implement ESD. Preliminary assumption tests were satisfactory. A statistically significant difference was found among educational levels on the combined dependent variables, $F(6, 940) = 2.32$, $p = .031$, Wilks' Lambda = .97, partial η^2 = .015. As seen in Table 3, when considering the dependent variables separately with a Bonferroni-adjusted alpha level of .017, statistically significant differences were observed for self-efficacy scores, $F(2, 472) = 4.58$, $p = .011$, partial η^2 = .019. Post hoc analyses revealed that primary school teachers reported significantly higher self-efficacy scores ($M = 42.8$, $SD = 11.0$) compared to high school teachers ($M = 38.8$, $SD = 9.5$), $p = .007$. Significant differences were also found in willingness scores, $F(2, 472) = 5.52$, $p = .004$, partial η^2 = .023. Post hoc results indicated that primary school teachers ($M = 38.6$, $SD = 12.3$) reported significantly higher willingness scores than high school teachers ($M = 33.8$, $SD = 10.7$), $p = .003$. Middle school teachers ($M = 37.6$, $SD = 12.5$) also had significantly higher willingness scores than high school teachers ($M = 33.8$, $SD = 10.7$), $p = .033$.

Table 3. MANOVA results.

Variable		Sum of Squares	*df*	Mean Square	F	Sig.	Partial Eta Squared
Education Level							
	Self-efficacy	1042.3	2	521.1	4.583	.011	.019
	PCK	1002.7	2	501.4	3.006	.050	.013
	Willingness	1597.1	2	798.5	5.520	.004	.023

Conclusion And Discussion

This study has shown that although there were no statistically significant differences across professional areas in terms of self-efficacy, perceived PCK, and willingness to implement ESD, statistically significant differences were found across educational levels (primary, middle, and high school) in terms of self-efficacy regarding ESD and willingness to implement ESD. This study has demonstrated that primary education teachers tend to show higher self-efficacy,

perceived PCK, and willingness compared to their peers in secondary education, similar to the findings of Isac et al. (2022). Previous studies have reported that secondary education teachers often exhibit lower levels of commitment and higher feelings of inadequacy concerning the knowledge and skills required for the implementation of ESD (Borg et al., 2012; Popova et al., 2016; Taylor et al., 2019). As Isac et al. (2022) point out, in the literature, these perceptions are attributed to the structure of secondary education which emphasizes subject-specific knowledge and provides limited opportunities for teacher training. This organizational framework restricts the adoption of interdisciplinary and holistic approaches which are essential for developing competences in ESD. Besides these, the lowest mean score for willingness might suggest a gap between teachers' capabilities and their motivation to implement ESD, highlighting the need to enhance their commitment and engagement.

Implications And Future Work

The study highlights key implications and future directions. To improve secondary teachers' self-efficacy, PCK and willingness in ESD, targeted professional development and curricular reforms promoting interdisciplinary and holistic approaches are needed. Future research should identify strategies for integrating interdisciplinarity in secondary education, assess the long-term impact of ESD training, and explore barriers and enablers of ESD adoption across professional areas. Moreover, efforts should prioritize enhancing teachers' willingness to implement ESD, as it emerged as the dimension with the lowest mean score within PACesd.

ESERA 2025 Copenhagen

Global Citizenship Education As A Transformative Framework For Reorienting Education Systems Towards Community Needs And Sustainable Development

Nonkanyiso Pamella Shabalala and Patricia Photo
University of South Africa, South Africa

Global Citizenship Education (GCE) is increasingly recognised as a transformative educational approach that equips learners with the knowledge, skills and values required to address complex global challenges such as climate change, inequality and sustainable development. Grounded in critical pedagogy, transformative learning and systems thinking, GCE challenges conventional education systems characterised by rigid curricula, standardised assessment and hierarchical pedagogies. This paper explores how GCE reorients education systems towards inclusivity, critical engagement and community relevance while supporting the achievement of the Sustainable Development Goals (SDGs), particularly Goals 4, 11 and 13. Using a qualitative, document-based multiple case study approach, the study analyses selected examples from Africa, Europe and Asia, including Ubuntu-inspired education initiatives in South Africa, the Global Learning Programme in the United Kingdom and Japan's Education for Sustainable Development initiatives, with specific reference to RCE Okayama. The findings demonstrate how GCE is enacted through participatory, context-responsive and interdisciplinary pedagogies that connect local realities with global concerns. While GCE holds significant transformative potential, the study identifies persistent challenges related to resistance to change, Western-centrism and assessment practices. The paper concludes by proposing strategies for strengthening the integration of GCE through teacher education, policy alignment, community engagement and the use of digital technologies.

Keywords: Global Citizenship Education, Transformative Learning, Sustainable Development Goals, Community-Responsive Education, Education Systems Transformation.

Introduction

Global Citizenship Education (GCE) has gained prominence in the 21st century as globalization intensifies interconnected challenges such as climate change, migration and inequality. Traditional education systems often fail to prepare learners to navigate these complexities. GCE bridges this gap by fostering global awareness, critical thinking and collective responsibility (Duarte & Robinson-Jones, 2022; Pacho, 2020). It emphasizes cognitive, socio-emotional and behavioural dimensions to enable learners to critically engage with pressing global issues (Sun, 2020). GCE aligns with SDGs, especially Goal 4 (quality education), Goal 11 (sustainable communities) and Goal 13 (climate action) (Khoo & Jørgensen, 2021; Stein, 2021). Its interdisciplinary framework equips learners to address global challenges while fostering local resilience and action.

Aim And Research Questions

This study aims to explore how Global Citizenship Education is conceptualised and implemented as a transformative framework within science and sustainability-oriented education systems and how it responds to community needs for sustainable development.

Research Questions:

1. How is Global Citizenship Education conceptualised as a transformative approach within contemporary education systems?
2. How are GCE principles enacted in selected case studies across Africa, Europe and Asia?
3. What pedagogical and contextual features characterise these GCE initiatives?
4. What challenges and opportunities emerge in implementing GCE in diverse educational contexts?
5. What implications do these cases offer for strengthening science education for sustainable development?

Current Educational Practices

Traditional education systems emphasize standardized testing, rigid curricula and rote learning, which often marginalize critical thinking, collaboration and adaptability. These systems frequently reflect Western-centric methodologies, sidelining Indigenous and local perspectives (Silva et al., 2023). GCE offers an alternative by promoting interdisciplinary learning, global interconnectedness, and active problem-solving. It shifts the focus from knowledge retention to critical engagement with real-world issues (Pacho, 2020). However, implementing GCE faces hurdles such as resistance from traditional systems, resource limitations and assessment challenges (Bamber et al., 2018).

Case Studies

The implementation of Global Citizenship Education (GCE) differs across cultural and geographical contexts, mirroring various local challenges and opportunities. Analysing case studies from Africa, Europe and Asia provides important perspectives into the integration of GCE concepts into global education systems, promoting global citizenship while considering local contexts. These examples demonstrate the versatility of GCE in building connection, critical Thinking And Sustainability Within Several Cultural Contexts.

Africa: Ubuntu Philosophy In Education

The Ubuntu philosophy, rooted in African traditions, emphasizes communal responsibility and interconnectedness. In South Africa, Ubuntu-inspired programs address social and environmental challenges by promoting collaboration and collective accountability (Sipondo, 2025). These programs connect local cultural heritage with global perspectives, fostering a sense of belonging and environmental care.

Europe: Global Learning Programme (UK)

The UK's Global Learning Programme (GLP) integrates GCE values through activities such as model United Nations debates and sustainability seminars. These initiatives enhance learners' understanding of global challenges while fostering critical thinking and empathy (Huckle, 2015). However, critics highlight challenges such as curriculum overload and resource constraints (Collado-Ruano, 2016).

Asia: Education For Sustainable Development (Japan)

Japan's Education for Sustainable Development (ESD) integrates GCE principles into formal education, emphasizing learner-centered methodologies such disaster preparedness and environmental conservation (Ferguson et al., 2022). Programs such as RCE Okayama demonstrate how contextualizing GCE within local circumstances can empower learners to address both local and global challenges. RCE Okayama (Regional Centre of Expertise on

Education for Sustainable Development) is part of a global network recognised by the United Nations University. It functions as a collaborative platform linking schools, universities, local government, civil society and communities to advance Education for Sustainable Development. In Japan, RCE Okayama exemplifies how GCE and ESD principles are embedded within local contexts through place-based learning, disaster preparedness education and environmental stewardship. Its inclusion in this study highlights the importance of community-driven, context-sensitive approaches to global citizenship education.

Methodology

This study adopts a scoping qualitative, exploratory research design grounded in an interpretivist paradigm, recognising that educational practices are socially constructed and context-dependent (Creswell & Creswell, 2018; Pervin & Mokhtar, 2022). The study is based on secondary data and does not involve primary data collection at this stage. A document-based multiple case study approach was employed to explore how Global Citizenship Education is implemented in different geographical and cultural contexts (Yin, 2009). The cases were purposively selected from Africa, Europe and Asia to illustrate different yet comparable applications of GCE within formal and non-formal education systems.

Selection Criteria For Case Studies Included:

- Explicit reference to Global Citizenship Education or Education for Sustainable Development
- Clear relevance to science, sustainability or environmental education
- Availability of sufficient peer-reviewed or institutional documentation
- Representation of different socio-cultural contexts

The literature reviewed comprised peer-reviewed journal articles, policy documents and programme reports sourced from databases including Google Scholar, JSTOR, Semantic Scholar and IEEE Xplore. Inclusion criteria focused on relevance to GCE, sustainability and educational transformation. The selected documents were analysed thematically to identify recurring patterns, challenges and pedagogical strategies related to GCE implementation (Bryman, 2016).

Discussion

This section explores the potential for change of Global Citizenship Education (GCE) as a paradigm for overcoming the shortcomings that plague traditional education systems. This presentation clarifies the benefits, challenges and solutions for enhancing Global Citizenship Education (GCE), demonstrating its capacity to provide learners with the requisite skills, information and values to adeptly go through a progressively interconnected and complicated world.

Benefits Of GCE Integration

Through the development of critical thinking, multicultural awareness and global responsibility, GCE equips learners to engage substantively with real-world challenges, including climate change, socioeconomic injustice and global health crises (Bamber et al., 2018; Pacho, 2020). Its focus on multidisciplinary and interactive learning connects education with global citizenship, guaranteeing that learning aligns with society demands. GCE supports diversity by including multiple cultural perspectives and knowledge frameworks, especially those of Indigenous and underprivileged populations. This inclusive methodology facilitates learning and guarantees that education mirrors the actual experiences of numerous communities, promoting empathy, solidarity and an understanding of global interdependence (Dreamson, 2018; Smith, 2018). To

attain genuine inclusion, GCE must transcend its dependence on Western epistemologies by integrating non-Western and Indigenous perspectives as equal contributors to its evolution (Dreamson, 2018). This strategy is consistent with coeducation principles, encouraging intercultural involvement and overcoming gaps in access to and quality of education worldwide (Ainscow, 2020).

An interdisciplinary approach to Global Citizenship Education amplifies its transformative capacity by addressing global systems of oppression and domination. Analytical categories such race, gender and class are employed to enhance learners' consciousness of their collective responsibility and culpability in these frameworks, thereby promoting political engagement and social justice outcomes (de Vries, 2020). This fundamental aspect of GCE corresponds with Freirean pedagogy, emphasising critical thinking, self-reflection and praxis as the basis for transformational action (Tarozzi & Inguaggiato, 2018). Ultimately, GCE improves learners' capacity for critical thinking and collaborative action, critical competencies for solving complicated global challenges demanding coordinated, interdisciplinary approaches. By emphasising active participation rather than passive knowledge absorption, GCE enables learners to become proactive problem-solvers and proponents of sustainable development (Khoo & Jørgensen, 2021; Santamaría-Cárdaba et al., 2021). Teacher education programs serve as crucial in this process, focussing on transformational methodologies that equip teachers to motivate and direct learners towards these objectives.

Challenges In Implementation

Although its revolutionary commitment, Global Citizenship Education (GCE) encounters major challenges in implementation across various contexts. A major challenge is the opposition from stakeholders established in traditional educational systems, such as policymakers, teachers and organisations that emphasise standardised testing and inflexible curricula. These systems frequently exhibit insufficient flexibility to support the transdisciplinary and participative nature of GCE, resulting in conflicts between traditional practices and transformational educational objectives. To overcome this opposition, systemic adjustments that emphasise innovation and adaptation are necessary.

A major challenge is the perception of GCE as Western-centric, especially given that its concepts and approaches are primarily sourced from Global North contexts. This perspective diminishes its significance and acceptance in various cultural contexts (Lauwerier, 2020; Akkari & Maleq, 2020). In West Africa, the external roots of GCE and inadequate local stakeholder engagement reduce its applicability (Lauwerier, 2020). Furthermore, South Korean teachers face challenges stemming from neoliberal and post-colonial proposals that marginalise Global Citizenship Education within the curriculum (Kim, 2019). Asian colleges experience supplementary barriers including financial constraints, inflexible curricula and challenges in maintaining cultural relevance (Sain et al., 2025). These examples emphasise the necessity for localised and context-specific strategies that integrate indigenous knowledge systems and culturally relevant behaviours (Ydo, 2023). The contested nature of GCE further hampers its execution. Various conceptions of global citizenship exist, frequently shaped by different cultural and ideological contexts (Akkari & Maleq, 2020). Certain teachers perceive GCE as a neocolonial construct, however others contend it may be adapted to address local challenges via customised strategies (Parejo et al., 2022). To maintain GCE's relevance and influence, it must acknowledge local contexts and question its dependence on Western frameworks.

Strategies For Improvement

To address the challenges of implementing Global Citizenship Education (GCE) and fully utilise its revolutionary potential, many measures must be prioritised. Integrating GCE activities with broader global targets, specifically the Sustainable Development Goals (SDGs), especially SDG 4.7, guarantees consistency and expandability (Abazov, 2021; Longueira Matos & Vela-Eiden, 2020). Programs such as Bridge 47 reflect the value of collaborative efforts in advancing Global Citizenship Education and championing educational changes aimed at social transformation (Longueira Matos & Vela-Eiden, 2020). Policymakers must devise context-specific policies and nurture collaborations across governments, non-governmental organisations and educational institutions to overcome structural challenges especially for marginalised populations (Akkari & Maleq, 2020; Vindigni, 2024). Ongoing assessment and modification of policies is required to maintain relevance in changing global environments (Vindigni, 2024). Professional development programs must prioritise interdisciplinary learning, cultural proficiency and creative pedagogical approaches consistent with Global Citizenship Education concepts (Parejo et al., 2022). Effective professional development integrates experiential learning, critical thinking and chances for reflection and practice, addressing intellectual, affective and action-oriented domains (Darling-Hammond et al., 2017).

Technology plays an important role in broadening access to GCE and augmenting its effectiveness. Digital exchanges, digital tools and online resources facilitate worldwide collaboration and mutual understanding, producing holistic and interactive learning experiences that surpass geographical limitations (Abimbola Eden et al., 2024). Academic literacy facilitators can employ multimodal literacies, such as digital discourses, to successfully communicate GCE principles (Eybers & Muller, 2023). Teachers must synchronise technological tools with instructional objectives, promote digital literacy and stimulate critical thinking to optimise technology's positive impact (Abimbola Eden et al., 2024). These strategies facilitate the creation of more inclusive, egalitarian and sustainable learning environments that equip learners to confront the complicated issues of a connected world.

Conclusion

Global Citizenship Education represents a transformative shift in education. Along fostering critical thinking, global awareness and inclusive practices, GCE prepares learners to navigate and address the complexities of a globalized world. Despite challenges, its potential to create sustainable and equitable education systems underscores its importance.

Assessing Students' Sense Of Responsibility In Chemistry Education: Development And Validation Of An STSE-Based Instrument

Xijuan Li[1] and Lei Wang[2]
[1]Beijing Normal University, China
[2]National Research Center for Educational Materials, China

Developing students' sense of responsibility is a central goal of contemporary science education, particularly in addressing Science–Technology–Society–Environment (STSE) issues. However, empirical tools for assessing students' responsibility in discipline-specific contexts remain limited. This study aimed to develop and validate an assessment tool for measuring the sense of responsibility among students in grades 9–12 within chemistry-related STSE contexts. A scale development and validation design was adopted. The assessment tool was constructed around three authentic chemistry contexts—hand warmers, global warming, and soda-making—selected for their curricular relevance and real-life significance. Based on a theoretical framework, students' sense of responsibility was operationalized into three dimensions: personal responsibility, social responsibility, and scientific responsibility. Items were developed using a storyline-based approach and refined through student interviews and expert review. The instrument was administered to 2,366 students, and its psychometric properties were examined using a Multidimensional Rasch Model. The results indicated satisfactory reliability, with Expected A Posteriori/Plausible Value (EAP/PV) coefficients ranging from 0.63 to 0.76. Item fit statistics (infit and outfit MNSQ) fell within the acceptable range, supporting the structural validity of the instrument. Students demonstrated the highest levels of performance in social responsibility, followed by scientific and personal responsibility. Furthermore, students' attitudes toward science and STSE issues, as well as their understanding of the nature of science, were positively associated with responsibility, whereas academic achievement alone showed a weaker relationship. This study provides a validated, context-based instrument for assessing students' sense of responsibility in chemistry education. The findings highlight the importance of integrating STSE issues into chemistry curricula to support students' ethical reasoning, decision-making, and engagement with real-world scientific challenges. The assessment tool offers practical value for both research and instructional design and contributes to ongoing discussions on responsibility-oriented science education.

Keywords: Sense of responsibility; Chemistry education; Instrument development; Multidimensional Rasch model

Introduction

One of the visions of science education is to nurture scientifically literate students who can make informed decisions and take responsible actions in their lives (Sjöström & Eilks, 2018). As future citizens, students will inevitably face modern scientific issues such as climate change, collectively referred to as science-technology-society-environment (STSE) issues (Kruse et al., 2024). To prepare students for citizen engagement, increasing their sense of responsibility is an effective approach for addressing STSE challenges (OECD, 2018). Adolescence can now be seen as a time of opportunity for developing a sense of responsibility. Science education can foster students' sense of responsibility, enabling them to apply their understanding of scientific concepts and processes to issues that affect their lives, culture, and the environment as a means of caring for themselves, others, and their community. It encourages them to take a critical stance towards the products of science and technology while empowering them to reduce potential harm these products may have on individuals, societies, and environments (Onwu, 2017). Previous research has indicated that various methods, including science identity, environmental identity, and citizen

engagement, can be employed to assess the capacity for taking responsibility (Louros, 2022). However, there is little research focusing on identifying the most effective approach to evaluate students' capacity for taking responsibility. In this study, we designed an assessment tool to evaluate the attitudes and sense of responsibility of students in grades 9-12 when dealing with STSE issues. In addition, we investigated the relationship between scientific knowledge, nature of science, attitudes, academic performance, teacher support, school resources, and students' sense of responsibility.

Theoretical Framework

The Concept Of Take Responsibility

Science is a social enterprise that interacts with society in complex ways (Intemann & de MeloMartin,2010). Science should be described as a human activity that acknowledges the strengths of science and technology but also recognizes their limitations. In the specific topic we are discussing, we have the responsibility to ensure the conservation of resources, and to make students aware that we are accountable to society and will not destroy the environment. In science education, students should be encouraged to adopt a “critical thinking disposition” that allows them to investigate the pros and cons of any scientific and technological developments using their intellectual and ethical skills (Fuchs & Tan, 2022).

Existing literature categorizes responsibility into three types: personal responsibility, social responsibility, and scientific responsibility. Personal responsibility primarily revolves around individual consumption habits and lifestyle choices (Aygun et al., 2024; Louros, 2022). Social responsibility aims to promote social development and environmental conservation goals, involving the analysis, judgment, prediction, regulation, and decision-making of real-world issues in social contexts, including responsibilities for social development and environmental protection (Politi, 2024). Scientific responsibility is focused on advancing social development and reducing the negative impacts of science, encompassing scientific ethical responsibility and responsibility for the development of science (De Melo-MartíN & Intemann, 2023).

The capacity to take responsibility involves considering the future consequences of one’s actions, evaluating risks and rewards, and accepting accountability for one’s work. A performance of take responsibility is a person can reflect upon and evaluate his or her actions from the view of personal and societal goals. Acting ethically implies asking questions related to norms, values, meanings and limits, such as: What should I do? Was I right to do that? Where are the limits? Knowing the consequences of what I did, should I have done it? (OECD, 2018)

Assessing The Capacity Of Responsibility

Developing instruments to assess social responsibility is a complex process that requires careful consideration of cultural, ethical, and contextual factors. One notable example is the work by Dürten Röhm and Marissa Rollnick (2010), who developed an instrument to assess science students' views on the social responsibility of scientists. Their approach was based on the Views on Science-Technology-Society (VOSTS) instrument, which was originally designed to measure students' cognitive views on the interaction between science, technology, and society. The adapted instrument included multiple phases: interviews, open-response questionnaires, and fixed-response questionnaires. These methods were used to capture a comprehensive understanding of students' perspectives.

The development of social responsibility assessment tools typically involves both qualitative and quantitative methodologies. Qualitative methods, such as interviews and focus groups, are essential for capturing nuanced views and opinions. For example, Röhm and Rollnick used group

interviews and open-response questionnaires to gather initial data, which were then analysed to identify key themes and dimensions related to social responsibility. This iterative process allowed the researchers to develop a structured questionnaire that reflected the authentic views of the target population.

Quantitative methods, such as fixed-response questionnaires, are used to validate and generalize the findings. The final instrument developed by Röhm and Rollnick included 20 statements with multiple-choice options, allowing for statistical analysis of responses. This approach ensures that the instrument can be used across larger populations while maintaining reliability and validity (González-García et al., 2019).

Factors Affecting The Capacity Of Take Responsibility

Previous research suggests that a lack of understanding of science content hinders one's ability to negotiate STSE issues (Fowler & Zeidler, 2016). Knowledge is the primary influencing factor. According to the Knowledge-Attitude-Behaviour (KAP) model, knowledge influences attitudes, which in turn affect behavioural awareness. Zoller (2013) argues that the "translation" of science and technology into actions that are responsible to society and technology depends on what the relevant personnel believe and what attitudes they hold when facing problems to be solved. Therefore, attitudes towards science and STSE issues are also important influencing factors. Understanding the nature of science helps students grasp what science is and how it works. Existing studies have shown that the nature of science enables students to be open-minded about scientific knowledge and STSE issues, rather than accepting them blindly (Abd-El-Khalick, 2013). The nature of science is an influential factor that cannot be ignored (González-García et al., 2019). In addition to this, factors such as students' academic achievement, the attitudes of teachers and parents, and other elements can also influence students' sense of responsibility.

Research Questions

In this study, we designed an assessment tool to evaluate sense of responsibility of students in grades 9-12 when dealing with STSE issues. Additionally, we investigated the relationships between scientific knowledge, the nature of science, attitudes, academic performance, the attitudes of teachers and parents, school resources, and students' sense of responsibility.

RQ-1：How can an assessment tool of students' sense of responsibility be developed within a chemistry context?

RQ-2: What are the relationships between scientific knowledge, the nature of science, attitudes, academic performance, the attitudes of teachers and parents, school resources, and students' sense of responsibility?

Research Method And Design

Study Design

This study adopted a scale development and validation design to construct an assessment tool measuring students' sense of responsibility within chemistry-related Science–Technology–Society–Environment (STSE) contexts. A mixed-methods approach was employed, combining qualitative data from student interviews with quantitative data from large-scale questionnaire administration, to ensure both content validity and psychometric robustness of the instrument.

Development Of The Responsibility Assessment Tool

This study independently designed an evaluation tool to assess students' sense of responsibility in chemistry-related STSE contexts. The development process followed three sequential stages: (1) contextual selection and framework construction, (2) item development and expert validation,

and (3) large-scale pilot testing and psychometric analysis.

Context Selection And Framework Construction

The development of a social responsibility assessment tool specific to a chemistry context requires the selection of appropriate chemistry topics and the creation of authentic scenarios that can elicit students' responsibility-related reasoning. Through curriculum analysis aligned with national chemistry standards, three chemistry contexts were purposively selected: the chemistry of hand warmers, global warming, and the soda-making process.

These contexts were chosen because they involve core chemical principles familiar to students in grades 9–12, thereby minimizing cognitive load while maximizing opportunities for responsibility-related decision-making. The chemistry of hand warmers illustrates the application of oxidation reactions in daily life and highlights scientific responsibility for consumer safety. Global warming draws on energy-related chemical knowledge and emphasizes chemistry's role in addressing global environmental challenges. The soda-making process involves industrial chemistry and wastewater treatment, requiring students to balance economic efficiency with environmental protection and social responsibility.

Based on the theoretical framework, students' sense of responsibility was operationalized into three dimensions: personal responsibility, social responsibility, and scientific responsibility. Each dimension reflects progressively complex forms of responsibility, ranging from individual behavioural choices to collective decision-making and scientific innovation.

Item Development And Validation

The assessment tool was designed using a storyline-based approach, in which each chemistry context served as a coherent narrative stimulus embedding multiple decision points. As each storyline unfolded, 10–15 items were embedded within each context, resulting in a total of 30–45 items across the three responsibility dimensions.

Each item consisted of a multiple-choice question with four response options, representing increasing levels of responsibility. Responses were scored on an ordinal scale from 1 to 4, with higher scores indicating a higher level of responsibility.

To ensure content validity, extensive semi-structured interviews were conducted with students prior to item construction. Students were asked to explain how they would respond to each scenario and why. Their authentic responses were coded and used as the basis for constructing realistic and developmentally appropriate response options.

The initial item pool was reviewed and refined by two experts in chemistry education research and one Ph.D. researcher in chemistry education, focusing on clarity, relevance, and alignment with the intended responsibility dimension. Revisions were made iteratively until consensus was reached on item appropriateness and representativeness.

An example item from the assessment tool is presented below to illustrate the scoring logic and responsibility progression:

Consumers have reported that some heat packs may become too hot, posing a risk of burns. How do you think the research team should best respond? ( )

A. I would like to adjust the thickness of the heat pack packaging to prevent consumers from feeling it is too hot. (1 point)

B. I would like to analyse the cause of overheating and improve the heating mechanism to ensure it stays within a safe range. (3 points)

C. I would like to provide more guidance on preventing burns to help consumers use the heat packs safely. (2 points)

D. I would like to develop heat packs with a temperature regulation function that can automatically adjust the heating temperature to ensure safety. (4 points)

Assessment Of Influencing Factors

In addition to the responsibility assessment tool, a separate questionnaire was developed to measure factors potentially influencing students' sense of responsibility, including attitudes towards science, attitudes towards STSE issues, understanding of the nature of science, academic achievement, teachers' and parents' attitudes, and school resources.

This instrument was adapted from established scales reported in previous research (Hillman et al., 2016) and consisted of 30 Likert-scale items rated on a five-point scale ranging from "strongly disagree" to "strongly agree." Higher scores indicated more positive attitudes or greater perceived support.

Participants And Data Collection

A total of 2,366 students in grades 9–12 participated in the study. Among them, 44.4% were female and 55.6% were male. Data were collected through a 40-minute online assessment, administered during regular school hours.

Following the quantitative assessment, 10 students were purposively selected for follow-up semi-structured interviews, each lasting approximately 30 minutes, to explore students' perceptions of the assessment tool and their engagement with the chemistry contexts.

Ethical approval for the study was obtained from the relevant institutional review board. Informed consent was obtained from all participating students and their guardians prior to data collection, and all responses were anonymized to ensure confidentiality.

Data Analysis

To examine the psychometric properties of the responsibility assessment tool, a Multidimensional Rasch Model (a form of Multidimensional Item Response Theory, MIRT) was applied. This model allows for the simultaneous estimation of item difficulty and student ability across multiple latent dimensions while accounting for the interrelationships among dimensions.

The analysis was conducted using ConQuest Version 2.0 software, which is suitable for large-scale educational assessments. Model fit was evaluated using infit and outfit mean square (MNSQ) statistics, with acceptable values ranging from 0.7 to 1.3. Reliability was assessed using Expected

A Posteriori/Plausible Value (EAP/PV) Reliability Coefficients

To address Research Question 2, correlation and regression analyses were conducted to examine the relationships between students' sense of responsibility and influencing factors, including scientific knowledge, nature of science, attitudes, academic achievement, and perceived support from teachers, parents, and schools.

Findings

Psychometric Properties Of The Responsibility Assessment Tool

The psychometric quality of the responsibility assessment tool was examined using a multidimensional Rasch model. Overall, the model demonstrated satisfactory fit and reliability,

indicating that the instrument was appropriate for measuring students' sense of responsibility across multiple dimensions.

The reliability coefficients (eap/pv), which indicate the stability and internal consistency of the measurement, ranged from 0.63 to 0.76 across the three dimensions of responsibility, suggesting acceptable reliability for an educational assessment tool. Specifically, social responsibility showed the highest reliability, followed by scientific responsibility and personal responsibility.

Item fit statistics further supported the adequacy of the model. Both infit and outfit mean square (mnsq) values for all items fell within the acceptable range of 0.7 to 1.3, indicating that the observed student responses were consistent with the expectations of the Rasch model and that no items exhibited substantial misfit.

These results provide evidence for the structural validity of the assessment tool and support the multidimensional conceptualization of students' sense of responsibility in chemistry-related stse contexts.

Differences Across Responsibility Dimensions

Analysis of students' performance across the three responsibility dimensions revealed statistically meaningful differences. Students demonstrated the highest levels of performance in social responsibility, followed by scientific responsibility, while personal responsibility scores were comparatively lower.

The consistently higher scores in social responsibility suggest that students are more inclined to recognize collective obligations and societal consequences of chemistry-related issues than to reflect on personal behavioural changes or engage in innovation-oriented scientific responsibility. No significant differences were observed across demographic variables in other dimensions.

Relationships Between Responsibility And Influencing Factors

To address Research Question 2, the relationships between students' sense of responsibility and influencing factors—including scientific knowledge, understanding of the nature of science, attitudes toward science and STSE issues, academic achievement, and perceived support from teachers, parents, and school resources—were examined.

The findings indicated that students' attitudes toward science and STSE issues were significantly associated with higher levels of responsibility, particularly in the social responsibility dimension. Understanding of the nature of science also showed a positive relationship with scientific responsibility, suggesting that students who possessed a more informed view of how science operates were more likely to engage in ethically and socially responsible reasoning.

In contrast, academic achievement alone did not emerge as a strong predictor of responsibility, indicating that responsibility-related competencies extend beyond traditional measures of academic performance. Perceived support from teachers and schools showed a moderate association with responsibility, highlighting the role of the educational environment in shaping students' responsibility-related attitudes.

Student Perceptions Of The Assessment Tool

Qualitative data from follow-up interviews provided complementary insights into students' experiences with the assessment. Participants reported that the assessment scenarios were engaging and closely connected to real-life situations, which increased their motivation to think deeply about the issues presented.

Several students noted that even when their chemistry grades were not strong, they felt capable of applying chemical knowledge to socially meaningful problems. This sense of relevance and

usefulness contributed to a feeling of accomplishment and value, suggesting that the assessment tool successfully elicited responsibility-related engagement beyond rote knowledge recall.

Discussion And Implications

Interpretation Of Findings

This study aimed to develop and validate an assessment tool for measuring students' sense of responsibility within chemistry-related STSE contexts. The findings provide empirical support for conceptualizing responsibility as a multidimensional construct comprising personal, social, and scientific dimensions, consistent with prior theoretical frameworks (OECD, 2018; De Melo-Martín & Intemann, 2023).

The higher levels of social responsibility observed among students may reflect the increasing emphasis on collective action and societal challenges, such as climate change, within contemporary science education and public discourse. In contrast, scientific responsibility—which involves innovation, ethical reflection, and long-term technological decision-making—may require more explicit instructional support to develop fully in secondary education contexts.

The significant relationships between responsibility and attitudes toward science and STSE issues underscore the importance of affective and epistemic dimensions in responsibility development. These findings align with the Knowledge–Attitude–Behaviour (KAB) framework, suggesting that responsibility is not solely driven by content knowledge but is strongly shaped by students' values, beliefs, and perceptions of science's role in society.

Educational Implications

The validated assessment tool developed in this study offers several implications for chemistry education. First, it provides educators and researchers with a practical instrument for diagnosing students' responsibility-related competencies in authentic STSE contexts. Such diagnostic information can support curriculum design that intentionally integrates responsibility development alongside conceptual understanding.

Second, the findings suggest that embedding chemistry instruction within meaningful socio-scientific scenarios can enhance students' engagement and sense of purpose, particularly for students who may not excel in traditional academic assessments. This highlights the potential of STSE-based instruction to promote educational equity by valuing diverse forms of competence beyond test scores.

Third, the observed influence of teacher and school support emphasizes the need for learning environments that encourage discussion, reflection, and ethical reasoning. Professional development for teachers should therefore focus not only on content delivery but also on facilitating dialogue around responsibility, ethics, and societal implications of chemistry.

Limitations And Future Research

Several limitations of this study should be acknowledged. First, although the sample size was large, the participants were drawn from a limited educational context, which may constrain the generalizability of the findings to other regions or educational systems. Second, the assessment relied primarily on self-reported responses to hypothetical scenarios, which may not fully capture students' actual behaviour in real-world situations.

Third, while the Multidimensional Rasch Model provided strong evidence for structural validity, future studies could further examine the external validity of the instrument by comparing responsibility scores with observed behaviours or longitudinal outcomes.

Future research should explore how students' sense of responsibility develops over time and how

different instructional interventions influence each responsibility dimension. Cross-cultural validation of the assessment tool would also be valuable to examine how responsibility in chemistry is shaped by cultural, social, and educational contexts.

ESERA 2025 Copenhagen

From Instrumental To Communicative Rationality: Reimagining Science Education For Sustainability In Socio-Political Conflicts

Saul Casalone and Olivia Levrini
Alma Mater Studiorum – University of Bologna, Italy

We present the early stages of an interdisciplinary research aimed at promoting future-oriented agency competencies to support upper secondary school students in participating in the public debate on the energy transition within their communities. As a case study, the research focuses on Sardinia (Italy), where renewable energy policies have triggered strong social tensions: while national energy policies assign a strategic role in Italy's decarbonization efforts to the island's renewable energy capacity, local activists denounce renewable energy projects as speculative ventures, with severe impacts on landscapes and land ownership. This research is structured in three phases. The first step was ethnographic fieldwork, focusing on the social movement that opposes new energy infrastructures, addressing its historical, cultural, and economic background. As a second step, we will adapt an MGA (Modelling to Generate Alternatives) energy-system model as a tool for enabling students to understand the complexity of the energy transition and to critically explore alternative energy scenarios. Finally, we will test the developed educational tools directly in the schools of the communities involved in the study. As a preliminary conclusion, we propose to interpret the tensions between the local communities' lifeworld and the development of new energy infrastructures as a conflict between communicative rationality and instrumental rationality, according to Habermas' theory of communicative action. From this perspective, the use of an MGA energy-system model within an interdisciplinary education framework appears as an attempt to rethink science education for sustainability in line with the ideal of communicative rationality.

Keywords: sustainability, communicative rationality, future-oriented science education.

Premise

In line with the Paris Agreement of 2015, the European Union aims to reach climate neutrality by 2050 through an ambitious energy transition program known as the European Green Deal. The objective of climate neutrality by 2050 became legally binding in 2021 with the adoption of the European Climate Law and the legislative package Fit for 55, which sets the intermediate target of a 55% reduction in greenhouse gas emissions by 2030.

Although the European Green Deal formally claims to reconcile environmental sustainability, economic growth, and social cohesion (European Commission, 2018), the energy transition has generated significant social tensions (Eichenauer & Gailing, 2022; Sovacool et al., 2022). European energy policies operate within a neoliberal framework (Laes & Bombaerts, 2022), as evidenced by the use of market-based instruments such as the Emissions Trading System (ETS) (Verbruggen et al., 2019). Within this framework, procurement procedures that favor large-scale capital over local actors can contribute to strong power asymmetries in electricity system governance (Kirkegaard et al., 2021). Especially in Southern Europe, a predominantly top-down approach to energy governance, characterized by massive investments in large-scale power plants and limited engagement of local communities, has triggered widespread social opposition to the energy transition (Osti, 2018; Wolsink, 2007). In Italy, energy policies have been marked by pronounced inequalities in the distribution of the costs and benefits of the transition (Albulut, 2026). These social tensions have been further exacerbated by the significant acceleration of the energy transition promoted under the RePowerEU plan in 2022 (Pavlenko, 2025), particularly as a result of land grabbing associated with the expansion of wind farms.

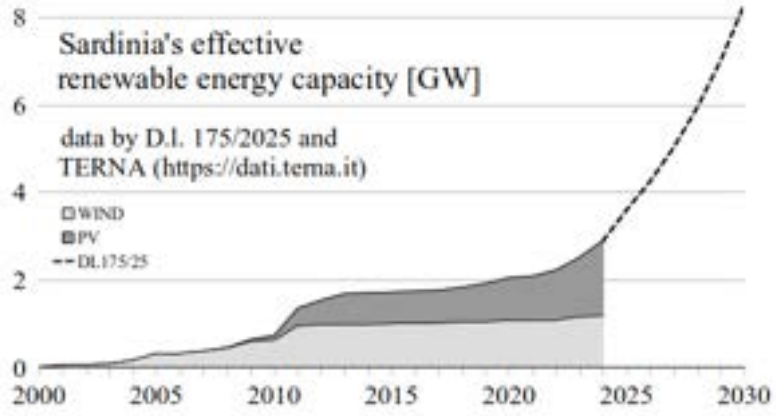
In the coming years, tensions between local communities and renewable energy projects are expected to increase due to upcoming commitments to the transition.

Research Question

According to the social science literature, the engagement of local communities in decision-making processes is effective in supporting the development of energy policies with broader social support, thereby reducing social opposition to renewable energy facilities (Wolsink, 2007). Our research aims to explore the potential role of schools, as sites of science education and critical citizenship, to increase the capacity of local communities to participate in public debate in an informed and effective way, in contexts where energy policies have already triggered social opposition. In this context, a key question is whether science education for sustainability, by equipping high school students with future-oriented agency competences, can foster their participation in the decision-making processes – thereby contributing to identifying just transition policies supported by broader social consensus.

From this perspective, science education for sustainability cannot be reduced to simply explaining the rationale for – and advocating the urgency of – decarbonization, without criticizing the power asymmetries implicit in current energy policies. This is especially true in a context where public education was long used as a tool of cultural colonization, enforced assimilation, and eradication of local languages (Bandinu et al., 2003; Sorge, 2015). Rather than dismissing local movements' concerns by labelling them as irrational and excluding them from public debate – a rhetoric aimed at legitimizing asymmetric access to decision-making spaces in many conflicts over the appropriation of resources – this research aims to develop educational practices and tools that create space for polyphonic dialogue, recognizing the legitimacy of these voices.

Case Study



This research focuses on social tensions triggered by renewable energy policies in Sardinia (Italy). Sardinia, the second largest island in the Mediterranean, has a distinctive cultural identity and strong territorial rootedness. It is recognized as a highly suitable territory for renewable energy development (Politecnico di Milano, RELab, 2020), not only because of consistent wind patterns and high solar exposure, but also due to extensive grassland areas with little human presence. The most recent legislation (D.l.175/2025) establishes the target of 8.3 GW of effective renewable energy capacity in the region by 2030 as legally binding. At the beginning of 2023, it amounted to 2.5 GW. By late 2024, Italy's grid management company had received authorization applications exceeding 50 GW in Sardinia alone, against a national target of about 70 GW (TERNA, 2023a, 2023b, n.d.).

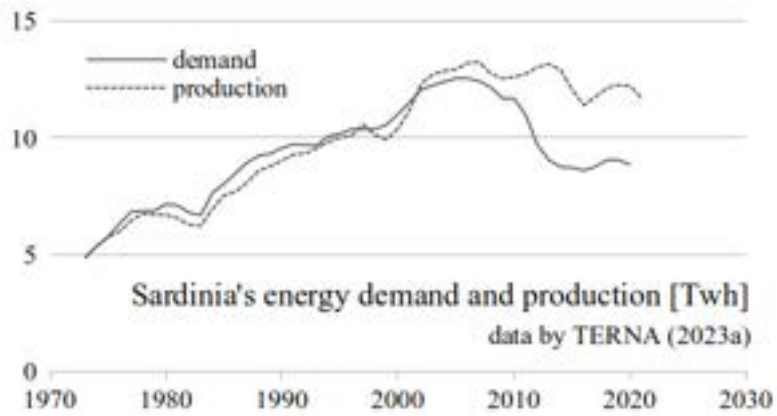
Since 2023, an increasing number of local committees have emerged in response to the surge in permit applications for wind and photovoltaic projects, denouncing this as a speculative strategy. Protests peaked between the summer and autumn of 2024, culminating both in a broadly supported citizens' initiative bill against new energy infrastructures and in a jurisdictional conflict between regional and national authorities over the allocation of decision-making authority (ANSA, 2024a, 2024b).

Structure Of The Research

The research unfolds in three phases. The first phase involved ethnographic fieldwork focused on the social movement opposing new energy infrastructures. The second phase will be devoted to developing educational tools to engage students in the public debate on the energy transition. The final phase will consist of implementing and evaluating these educational tools directly in the schools of the communities involved in the study.

Figure 1. Sardinia's effective renewable energy capacity.

Fieldwork



The first step of the research consists of ethnographic fieldwork on social opposition to energy policies. The aim of this inquiry is to provide a qualitative description of these tensions – with attention to the historical, cultural, and economic drivers of the opposition – so that these findings can be brought back to students through interdisciplinary teaching activities.

The fieldwork took place during 2025, over ten months. It was conducted using standard ethnographic methods, primarily participant observation and qualitative interviews. We conducted more than 40 hours of interviews with activists against *energy speculation* (using the movement's own definition), climate activists, teachers, local administrators, and journalists. Interviews followed an open-ended approach, starting from the central theme of the movement and concluding on the role and possibilities of younger generations in the decision-making process. Where possible, interviews were recorded. Conversely, when recording was likely to generate mistrust between the researcher and informants, conversations were summarized in field notes. We also conducted participant observation during street demonstrations and public assemblies, visited various energy infrastructures, and analysed local press and social media communication.

The movement is characterized by the demographic predominance of older adults. It is politically heterogeneous and has gained broad social support, without ideological cohesion but unified by a strong demand for self-determination – and specifically for self-determination in Sardinian energy policies. Criticism is related to a conflict over resources: land as a resource disputed between local farmers and external energy enterprises; similarly, the need to protect landscape and cultural heritage as resources for tourism; and the export of locally generated energy, judged as not sufficiently compensated by essential state services and compensatory schemes. But it goes well beyond this, involving deep symbolic factors tied to Sardinia's historical subordination to the central state, which long acted as a colonial force on the island.

For these reasons, decarbonisation policies are denounced by broad segments of the population as a new form of extractivism – one that, in Sardinia, has left a legacy of environmental degradation, public health issues, slow economic development, and demographic decline (Sorge, 2015). It is not only about the expropriation of material resources: the systematic exclusion of local communities from decision-making processes erodes spaces for dialogic debate and, in turn, leads to the collective expropriation of future-oriented agency, exacerbating social opposition.

Figure 2. Sardinia's energy demand and production.

Theoretical Framework

To support the design of the educational tools, we propose a framework grounded in Horkheimer's critique of instrumental rationality (1947/1974) and its further elaboration in Habermas's theory of communicative action (1981/1984).

In archaic Greece, a society marked by a strict hierarchy, myth held authoritative power over truth. When collective participation in the life of the polis expanded, driven by an emerging bourgeois class, new linguistic practices became necessary. The term logos – which in Homer still denoted a beguiling tale – now came to mean the common ground of discourse, where citizens could voice their demands and deliberate in pursuit of the common good, recognizing their shared belonging to the polis. Throughout its development, philosophical reflection tried to clarify the criteria for good argumentation, a process which culminated in the development of formal logic (Perelman, 2010). This can be understood as a calculative system aimed at determining an argument's validity, so as to arrive – at least ideally – at a unique conclusion to the debate, thereby closing the common ground of discourse.

As Horkheimer observes (1947/1974), when reason is reduced to mere calculation, it ceases to deliberate purposes – evaluating their legitimacy or desirability – and simply focuses on selecting the most efficient means to achieve them. It becomes instrumental rationality, aimed at pursuing goals withdrawn from public debate. Under this perspective, scientific knowledge, rather than guiding social actions toward shared values, offers legitimacy to a technocratic society where democratic dialogue loses influence on social life – a condition that can fuel violent reactions by groups excluded from decision-making processes.

Habermas (1981/1984), building on the early Frankfurt School's critique yet moving beyond it, reworks the notion of rationality into an explicitly communicative framework. Alongside purpose-oriented rational action (instrumental or strategic), he introduces the concept of communicative rational action, defined as linguistic practices aimed at mutual understanding. According to Habermas, the central conflict in contemporary society is no longer the class struggle but the conflict between instrumental rationality and communicative rationality, that is, the tendency of systemic rationality to colonize the communicative actions of a community, which he terms the lifeworld (adopting Husserl's terminology).

Instrumental And Communicative Rationality In Science Education

We propose to interpret the tensions between local communities and the development of new energy infrastructures as a conflict between communicative rationality and instrumental

rationality. If we accept this interpretation, it has significant implications for the design of teaching activities.

A science education entirely limited to instrumental rationality necessarily excludes students from any reflection on purposes, allowing only the calculation of efficient means to achieve predetermined goals as legitimate educational practice. Nevertheless, teleological reflection – such as critical inquiry into future scenarios – is essential to cultivate a future-oriented agency, which in turn is a prerequisite for addressing the current global crisis (Laherto & Rasa, 2022). Moreover, such an approach can degenerate into a form of strategic action, treating students as means to predefined ends – for example, the promotion of a specific energy policy. Thus, the same tensions driving social conflict may manifest within the school community, resulting in a biased rejection of scientific discourse.

We therefore ask whether science education practices can be oriented toward the ideal of communicative rationality, useful for deliberating on ends and not only for calculating more efficient means. We will explore this line of research by providing educators with tools to represent the complexity of the social issues involved in the conflict.

Future Steps

Engaging local communities in decision-making remains challenging, as it requires not only public spaces for collective deliberation, but also analytical tools accessible to non-specialists to evaluate alternative transition pathways. The next stage of the research will involve developing a computational model, adapted for educational use, to represent the range of possible decarbonization pathways available to policymakers.

Previous work has shown that the use of complex systems simulations in educational contexts can enable students to critically explore alternative future scenarios (Barelli, 2022; Fabbri, 2021; Miani, 2025). Building on this line of research but seeking specific tools to address issues related to the low-carbon transition, we have focused on a particular type of energy system model.

Planning a decarbonized electricity system involves complex choices due to multiple technological options and sociopolitical constraints. Energy-system design typically relies on cost-optimal models, which may neglect other viable system configurations and overlook social factors essential for political feasibility. The Modelling to Generate Alternatives (MGA) approach, rather than identifying a single cost-optimal solution, explores the space of sub-optimal solutions to generate qualitatively different configurations. This wide range of energy alternatives provides a deliberative space for policymakers and local communities (Lombardi, 2020).

Our aim is to adapt these tools for educational use, allowing students to engage in energy-system design, acquire knowledge repertoires, and support debate among peers, within families, and ideally within their communities.

In the final step, we will test the developed educational tools directly in the schools of the communities involved in the study. Social tensions triggered by the energy transition will be framed as topics for interdisciplinary inquiry, drawing on ethnographic findings and the energy-system model. On this basis, students will be asked to elaborate sustainable and desirable future scenarios and to participate in the public debate within their communities, according to the future-oriented science education approach (Laherto et al., 2023; Levrini, 2019)

Conclusions

Finally, we will evaluate the reception, outcomes, scalability, and potential for further development. We will also assess to what extent these educational experiences contribute to redefining how scientific knowledge becomes embedded in local social life. If these experiences

prove capable of fostering students' engagement in the public debate on the energy transition, they will be consistent with the ideal of communicative rationality.

Greek Chemistry Teachers' Perspectives On The Integration Of Green And Sustainable Chemistry Practical Activities In Secondary Education

Georgios Ampatzidis[1] *and Konstantinos Korfiatis*[2]
[1]University of Thessaly, Greece
[2]University of Cyprus, Cyprus

Green and sustainable chemistry, aimed at minimizing environmental impact and supporting resource efficiency, has gained significant attention in recent decades. This shift has promoted a strong global community of practitioners and advocates, and increased interest in integrating these principles into school and university education. While various strategies have been developed to incorporate green and sustainable chemistry into curricula, there is limited data on the extent of its integration across different countries. This study examines the integration of green and sustainable chemistry into secondary education in Greece, with a focus on practical activities conducted by chemistry teachers. Data were collected from 92 teachers via an online questionnaire, developed for an international survey by the International Union of Pure and Applied Chemistry (IUPAC). Participants reported that averagely 29,9% of their practical activities incorporated green and sustainable chemistry. Moreover, they highlighted the importance of such activities in promoting critical thinking and problem-solving skills, and introducing green chemistry and sustainability through hands-on activities. However, some teachers reported not incorporating such activities, reflecting challenges in integration. Our findings highlight the increasing role of green and sustainable chemistry in education and underline the need for further research concerning its integration into curricula and teaching practices.

Keywords: Secondary education, sustainability, teacher beliefs

Introduction

In an era of growing environmental concern, green and sustainable chemistry has gained substantial interest, leading to the establishment of a robust community of practitioners and advocates within the global chemistry field. Green and sustainable chemistry adopts a holistic perspective through life-cycle analysis and systems thinking, ensuring that sustainability is considered at every stage – from raw material sourcing to product disposal. This comprehensive framework not only advances scientific innovation but also aligns with broader global goals, such as dealing with climate change, conserving resources, and enhancing economic development in harmony with environmental protection (MacKellar et al., 2020).

Green and sustainable chemistry refers to the concept of designing processes and products that improve the way natural resources are used to meet the needs of present and future generations, without causing harmful impacts on humans and ecosystems. It is guided by specific principles that emphasize environmentally friendly methods for conducting chemical reactions and producing chemical products. These principles promote practices such as using environmentally friendly auxiliaries like solvents for reactions and separations and streamlining processes to reduce the number of steps. These ideas form the core of green chemistry, focusing on more sustainable and efficient chemical production (Anastas & Zimmerman, 2019; Clark, 2016).

Over the years, various strategies have been employed to incorporate the principles and practices of green and sustainable chemistry into the chemistry curriculum in secondary education and undergraduate studies. Concerning the latter, some universities have developed independent, stand-alone green chemistry elective courses, others have fully integrated green chemistry

principles throughout their entire chemistry curriculum, and some universities have incorporated green chemistry laboratories as substitutes in laboratory courses (MacKellar et al., 2020). Concerning school education, four basic models of integrating green and sustainable chemistry have been developed: (a) integrating green and sustainable chemistry practices into school chemistry practical activities, (b) integrating green and sustainable chemistry practices as core content within the chemistry curriculum (c) using socio-scientific issues related to sustainability and chemistry as a foundation for learning chemistry and understanding the relevance of green and sustainable chemistry to sustainable development, and (d) using sustainability as a driver for school reform, transforming school life in alignment with sustainability principles, including aspects related to chemistry and its applications (Burmeister et al., 2012).

Focusing on school education, we note that despite the various strategies that have been developed to incorporate the principles of green and sustainable chemistry into the curriculum, it seems that there are not enough data concerning the extent of this integration across different countries. The present study was conducted as part of a global survey coordinated by the International Union of Pure and Applied Chemistry (IUPAC) (Delaney et al., 2024) and aims to investigate the integration of green and sustainable chemistry practices into chemistry practical activities within secondary education in Greece. The research questions addressed are the following:

RQ1: What percentage of the chemistry practical activities that teachers conduct is connected to green and sustainable chemistry approaches?

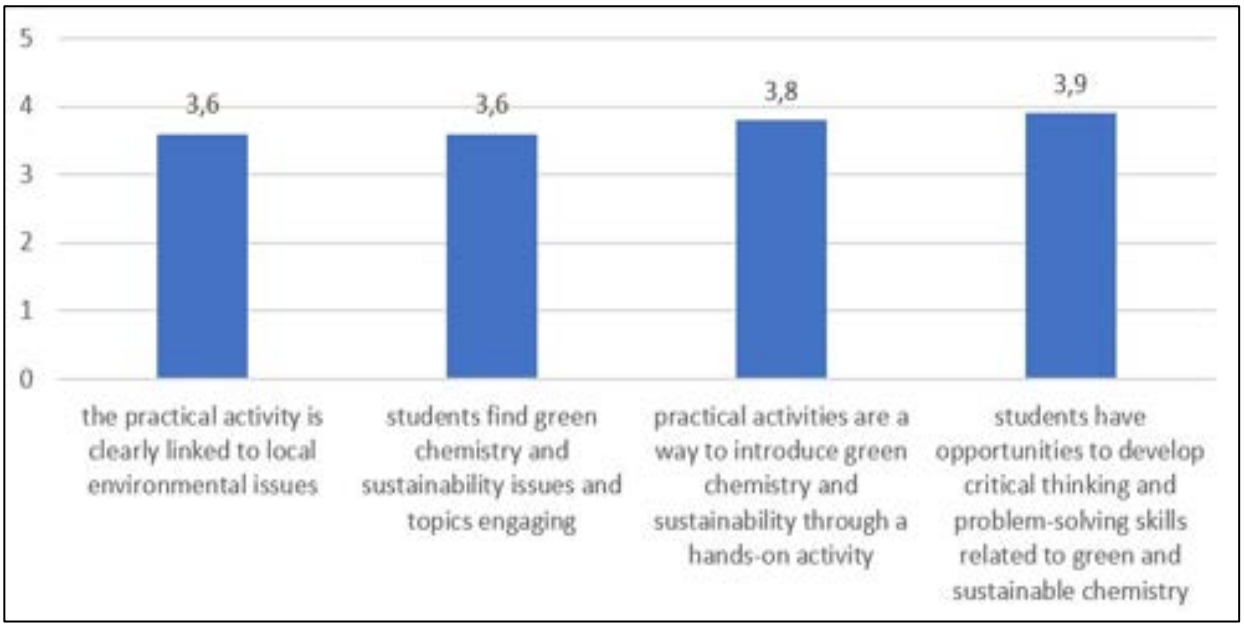
RQ2: Which factors do teacher consider important when choosing chemistry practical activities to do with their class?

RQ3: Where do teachers normally obtain their chemistry practical activities related to green chemistry and sustainable chemistry?

Methodology

The data of this study were collected through an online questionnaire created within an international IUPAC project (Delaney et al., 2024) and translated into Greek by the authors of this paper. The questionnaire included items concerning the integration of practical activities into teaching of chemistry in general, the integration of green and sustainable chemistry practical activities into teaching of chemistry in particular and demographic questions. The questions included were open and closed ended. Here we are concerned with the part of the questionnaire that deals with the integration of green and sustainable chemistry practical activities into chemistry teachers' practice. More specifically, we report on three closed ended items that concern (a) the percentage of practical activities implemented by teachers that are related to green and sustainable chemistry approaches, (b) the factors that teacher consider important when they choose chemistry practical activities to do with their class, and (c) the sources that the teachers use to obtain green and sustainable chemistry practical activities.

For the first item, participants had to choose the percentage of practical activities they did with their class which was related to green and sustainable chemistry approaches using a slider. For the second item, participants had to answer about the importance of four factors when choosing chemistry practical activities to implement into their teaching using a 5-point Likert scale. More specifically, they had to answer whether the following factors were "not at all important" (1), "slightly important" (2), "moderately important" (3), "very important" (4) or "extremely important" (5) when choosing practical activities to use in class: (i) the practical activity is clearly linked to local environmental issues, (ii) students find green chemistry and sustainability issues and topics engaging, (iii) practical activities are a way to introduce green chemistry and



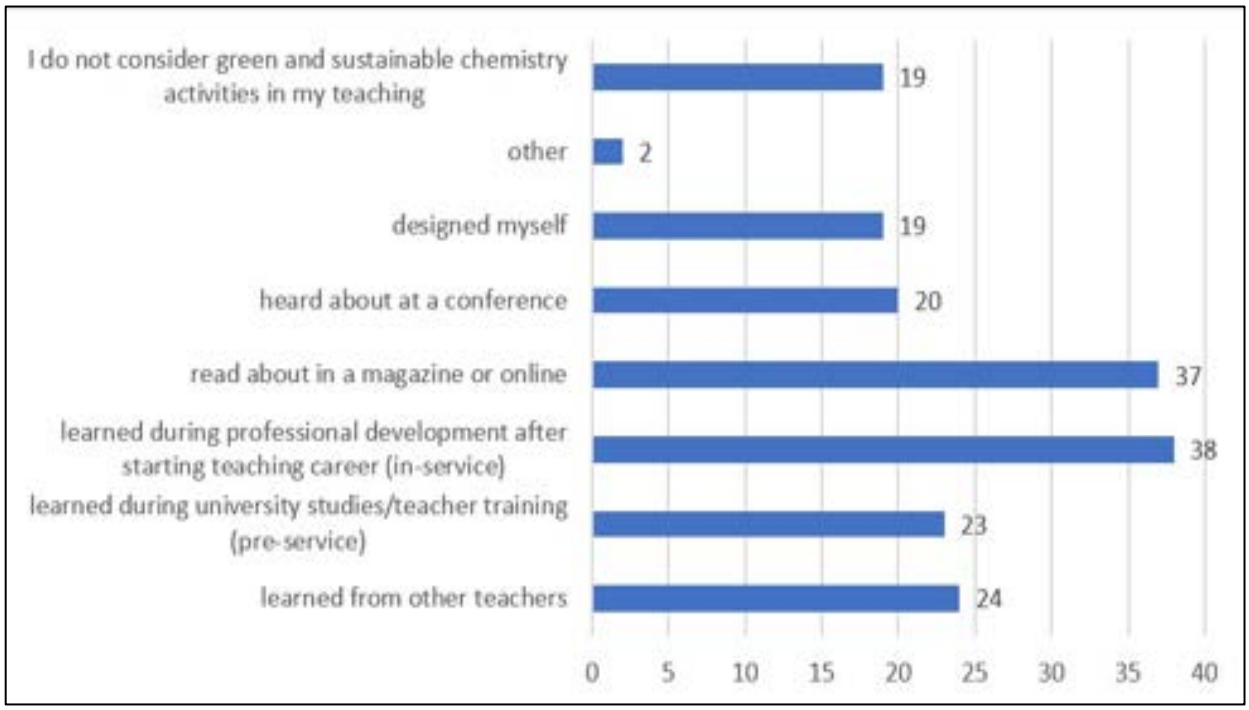
sustainability through a hands-on activity, and (iv) students have opportunities to develop critical thinking and problem-solving skills related to green and sustainable chemistry. Finally, for the third item participants had to answer how they obtain green and sustainable chemistry practical activities among the following choices: (a) learned from other teachers, (b) learned during university studies/teacher training (pre-service), (c) learned during professional development after starting teaching career (in-service), (d) read about in a magazine or online, (e) heard about at a conference, (f) designed myself, (g) other, (h) I do not consider green or sustainable chemistry activities in my teaching.

The part of the questionnaire that concern us in this paper was filled in by 92 teachers teaching chemistry in secondary education in Greece. They were selected by convenience sampling (Bryman, 2012) and they agreed to participate in the study after receiving (i) detailed information about the study's objectives, and (ii) confirmation that their participation would remain anonymous. Concerning their experience in teaching chemistry, 7 teachers answered that it was their first year, 13 teachers had 2-5 years of experience, 25 teachers had 6-15 years of experience, 38 teachers had 16- 30 years of experience, and 9 teachers had more than 30 years of experience. Finally, 12 teachers stated that they were currently teaching in Grade 7, 33 teachers were currently teaching in Grade 8, 35 teachers were currently teaching in Grade 9, 56 teachers were currently teaching in Grade 10, 52 teachers were currently teaching in Grade 11, and 59 teachers were currently teaching in Grade 12. It should be noted that in most cases the participating teachers were teaching in more than one Grade in order to complete the required schedule.

Results

The mean percentage mentioned by participants concerning the implementation of green and sustainable chemistry practical activities was 29,9. It should be noted that the standard deviation was quite large (26,9) indicating that there was a high level of variability within their answers.

Figure 1. Average importance of factors concerning selecting practical activities for classroom use.



Regarding the factors that the participants considered important when choosing practical activities, it seems that the most important factor was that through them students have opportunities to develop critical thinking and problem-solving skills related to green and sustainable chemistry. We noticed that averagely all factors that had to do with green and sustainable chemistry were considered rather important by the participating students concerning

selecting practical activities for their teaching (Figure 1).

Finally, concerning the sources that teachers use in order to obtain green and sustainable chemistry practical activities, it seems that the most popular ones are continuing professional development programs (38) and magazines/online sources (37). It is worth noticing that several teachers answered that they do not consider green or sustainable chemistry activities in their teaching (19) (Figure 2).

Figure 2. Frequencies of sources that teachers use in order to obtain green and sustainable chemistry practical activities.

Discussion

Green and sustainable chemistry has gained significant attention in the last decades, enhancing the development of a strong community of practitioners and advocates in the global chemistry landscape. Moreover, it seems that a strong interest in ways to integrate the approaches of green and sustainable chemistry into education has also been developed (Dicks & Bastin, 2019). Green and sustainable chemistry education has been present in educational research and practice already from 1990s. Zuin et al. (2021) researched the number of papers that concerned green and sustainable chemistry education and reported that more than 500 papers were available in the literature spanning a period from 1998 to 2021. Most of them focused on developing curricular materials and evaluating student learning outcomes and attitudes. Discussing their results, the authors concluded that various institutions have created tools and resources to facilitate the integration of green and sustainable chemistry into high school and even elementary education.

While several strategies have been developed to embed the principles of green and sustainable chemistry into curricula, there appears to be a lack of sufficient data on the extent of this integration across various countries. In this study we investigated Greek chemistry teachers' practice and ideas concerning green and chemistry practical activities and some interesting results arose. For example, it seems that a considerable percentage of the practical activities conducted in their class concerns green and sustainable chemistry approaches. Moreover, participants seem to find the dimension of green and sustainable chemistry rather important when they choose practical activities to implement into their teaching. For instance, they averagely assigned a 3,9 score (ranging from 1 "not at all important" to 5 "extremely important") to the importance of

practical activities offering students the opportunity to develop critical thinking and problem-solving skills related to green and sustainable chemistry.

Finally, regarding the sources that participants use in order to obtain green and sustainable chemistry practical activities, it seems that the most popular one was continuing professional development programs. This may not agree with relevant literature at certain level, since chemistry teachers around the world seem to mention the lack of in-service training as a main barrier to integrating green and sustainable chemistry content into their teaching (MacKellar et al., 2020). Other popular source of green and sustainable chemistry practical activities were magazines and online sources, while fewer participants stated that they obtained a practical activity by attending a conference or they designed it themselves. We should note that some teachers reported not incorporating green and sustainable chemistry practical activities in their teaching, reflecting challenges in integration.

Science Teachers' Democratic Assignment: A New Vision Of Scientific Literacy And Civic Engagement For A Futuristic, Fair And Sustainable Europe

Geraldine Mooney Simmie
School of Education, University of Limerick, Ireland

There are calls today from several directions, including from UNESCO 2021 for a new social contract for education, and by implication science education. This begs the question what this might mean for the framing of scientific literacy and civic engagement in a futures-oriented Europe, aspiring for fair and sustainable green and digital transitions. This newly desired subjectivity, centred on repairing former colonial injustices, requires reimagining a new vision of scientific literacy and civic engagement, one that is attentive to human emancipation, and to the knowledge(s), cultures, ethical values, care and justice needs of a fair and sustainable economy, society and environment. Here I draw from Mooney Simmie and Edling's (2019) theorisation of Teachers' Democratic Assignment (TDA), Giroux (1988/2024) and Hordern's (2024, 2022) theorisations of teachers' identities and knowledge base, and Bang's (2017) assertion of the ontological indeterminacy embedded in science education. I use these theoretical perspectives to critically scrutinise the mainstream framing of scientific literacy and civic engagement, and to consider the exponential growth in the literature of an alternative emancipatory framing of science TDA for learning to live well with others in pluralistic democracies. The study reveals a reframing of science TDA in the direction of a knowledgeable, care-based, critically reflexive and activist citizenry in a highly complex, scientific and technological world. The emerging critical insights reveals that reframing science TDA needs to move beyond evidence and externally provided norms and to include the interruptive power of the arts, humanities and the deliberative traditions.

Keywords: *scientific literacy, civic engagement, science teachers' democratic assignment*

Introduction

Since the start of this century, and the policy imperatives embedded in a fast-globalising education reform movement, the education and training of science teachers, their identities and knowledge base, are often defined within reductionist views of science teacher's responsibilities in relation to the preparation of young people for a life of active engaged citizenship. While citizenship, and becoming a citizen, rests on a political concept of membership of a nation state, the concept in general education today, and in science education is more often framed as a neutral and apolitical concept unrelated to power and privilege and whose interests are being served. It may well be that, working within the boundaries of the nature of science, and scientific pedagogies, science teachers' task is confined to primarily providing a scientifically literate population, for the ever-changing qualification and socialisation needs of the economy and society (e.g. the pipeline of talent) and within an appreciation of science-in-society and real-world applications.

Levrini et al. (2025) argue the this mainstream framing of science education is underpinned by a rather naïve positivistic framework, where there appears to be little or no requirement for science teachers to engage young people with the messiness of real world ethical, scientific and political dilemmas and/or to build capacities to interplay with other knowledge(s) and ways of knowing (e.g. cultural and historical memory) in order to critically question, debate and debunk issues of public interest values (e.g. climate change) so pertinent today for the successful future of democratic societies and the planet.

There is already a pressing need recognised by the European Commission in Europe to reframe education and skills, and by implication the relations between scientific literacy and civic engagement for a futures-oriented fair and sustainable green and digital transition (Mooney Simmie, 2025b). How this is to be done in theory, policy and practice remains an open question and one this is increasingly complicated by the neoliberal imaginary underpinning science education, including scientific literacy and science teachers' work practices (Mooney Simmie, 2025a, 2023). Neoliberalism continues to act as a highly successful and hybridised project of governance in science education today. Sant (2019) reveals that this political project of governance relies on an ideological governing form that is anti-democratic at heart and based on the normalisation of elite ruling by (scientific) experts and market leaders. Neoliberalism therefore frames science teachers' knowledge base and practices in the direction of evidence-based and standardised practices, all known in advance, manageable and measurable (Mooney Simmie & Tolbert, 2025).

This neoliberal framing of science education is taking place at a time of unprecedented change in Europe, a time of marked increase in the rise of injustices and fascist ideologies. The historian, Gerstle (2024) argues that the neoliberal social order, rising to prominence in the 1980s nowadays reveals serious fault lines, especially since, the global recession in 2008-2009, the rise of technoscience and the unprecedented threats to the western economy and democratic politics by the Trump administration in the US (Tolbert, 2025).

UNESCO's *Reimagining Education Report* (2021) asserts a new urgency for general education, and science education, to arrive at a new social contract and to build capacities to repair past injustices of colonisation. The UN Sustainable Development Goals act as a blue print for this social contract that aspires, amongst others, to end poverty, secure climate justice and digitisation through empowering new transformative social partnerships. The American philosopher of education, John Dewey, asserted that democracy is remade with each new generation and that education, and science education, always acts as the mid-wife of democracy (Dewey, 1916/2024). This begs the question how democracy is discerned in science education, and in science teachers' felt sense of obligation to democracy, in a future-oriented science education and its relation to scientifically literate and activist citizens.

Theoretical Perspectives

Here I draw from critical and feminist perspectives to frame the problem of *Science Teachers' Democratic Assignment* (STDA) as a sociological problem connected to the teachers' obligation for a humanising and (re)constructivist discourse of science education embedded in a relational ethic of care and justice, in theory and in practice (Mooney Simmie & Edling, 2019). From this way of reasoning democracy is positioned as an ever-changing politics in the wider society whose purposes, principles and practices change as change is needed in the economy, society and the environment. Unlike systems of majority rule, democracies by design are always in the political direction of equality, diversity and justice, with stated protections for the rights of minorities.

A feminist perspective places the human subject (subjectivity) at the heart of science education as a relational and dialogical practice that pays attention to the situational and the interplays between knowledge(s) and different ways of knowing, In this way, a critical and feminist framework for science education positions science teachers' identities, knowledge base, and work practices more as a cultural problem – with science teachers as public intellectuals with cultural responsibilities and obligations rather than as clinicians, technicians and/or as mere delivers of instruction for a system of compliance (Giroux, 1988/2024; Howie, 2020).

While Levrini et al. (2025) reveal the naïve positivism underpinning the mainstream framing of

science education and scientific literacy today, the science educator Lars Bang draws on the postmodern work of Deleuze to reveal the necessary ontological indeterminacy and crack at the heart of science education (Bang, 2017). This way of reasoning is further supported by the theorisation of the science educator, Jesse Bazzul, who starts from the paradoxical premise that the purposes of science education are multiple and contradictory, that can be grasped as a perpetually open ethical question that seeks to, on one hand conserves culture and heritage, and on the other, leaves the way open for the new to emerge.

What might this mean for science teachers' knowledge base today and for a future of uncertainty? Will it be sufficient for science teachers to have access to constant upskilling and reskilling in content knowledge (e.g. knowledge of science and science pedagogies), and externally provided norms and values, or will something else be needed? Given that feminist perspectives foreground intersectionality, the human at the centre and the relational capacity for teacher-student dialogue, and critical theories highlight the need to develop critical consciousness, for the affective equality needed for the greater good of society and public interest values (Lynch & Crean, 2019), then policies of content knowledge and externally provided norms, while necessary will be far from sufficient to assure scientific literacy works for a futures-oriented citizenship tasked with human emancipation, and the greater good of fair, sustainable and care-based pluralist democracies and eco-friendly environments.

In teasing out teachers' knowledge base today, drawing for the concept of teaching as an advanced professional practice, Hordern (2022, 2024) presents a three-dimensional concept that aligns well with the argument above. Hordern theorised that (science) teacher's knowledge base is nuanced and sophisticated and calls on knowledge(s) and different ways of knowing that needs access to three distinctive sources: (1) the sciences (2) the arts and humanities and (3) the deliberative traditions.

This three-dimensional concept of science teachers' knowledge base accepts the premise that science teaching needs access to the sciences for sense making practices, to the foundational disciplines in the arts and humanities - such as, philosophy, history and sociology – for strange making practices, such as, interruption of the discourse to leave spaces open enough to think otherwise, for the not-yet-thought, to sap power, and finally, access to the deliberative traditions, so that science education is understood as a holistic and dynamic practice for a desired subjectivity that is considered to be more than the sum of the parts.

Aims And Research Questions

This contested literature opens new spaces for reclaiming and reframing scientific literacy and civic engagement, and especially for consideration of what it means to be a desired human subject today (subjectivity) in a complex and highly scientific and technological society. The study therefore aimed to conduct a critical scrutiny of a select literate, albeit a limited and small scale study of the contemporary literature to better understand how fresh calls for a new social contract today in science education for a fair and sustainable Europe need to play out differently from a neoliberal imaginary and what this might mean for science teachers' knowledge base and for a new and different vison of science teachers' democratic assignment (STDA).

Findings

The framing of the purposes of science education in the life of the young person in schools today, and its relation to the journey of human becoming (subjectivity) as a scientifically literate, engaged and active, if not fully an activist, citizen is deeply contested in the literature of science education. What started off in the 1950s, as a desire for a scientifically literate general population, with a positive disposition toward science, and to support publicly funded scientific research has

changed, even if not dramatically, to different visions of 'scientific literacy', and also found in such concepts as contextualised images of Science-in-Context, and Science-in-Society and more recent notions of 'citizen science', 'transformative science' and 'argumentation'.

The concept of scientific literacy itself has gone through multiple iterations since the 1950s (Bybee & Mc Crea, 2011, Roberts, 2007). The rationale behind the concept was to develop an uncritical appreciation of science and science research and to identify a pipeline of elite talent (abstract thinkers) to enter career pathways in the sciences, and as researchers connected to economic competitiveness and national security. The first vision, Vision I centred on propositional knowledge, while the more recent vision, Vision II while connected to contexts and to real world applications was largely confined to a notion of human becoming that Bang (2017) identified as a 'Cartesian understanding of knowledge and Cogito, the Dogmatic Image of Thought' (p.810). More recently, a third vision, Vision III seeks to reclaim science education as a human centred and socio-cultural endeavour, a sociological project whose rationale in concerned with supporting a transformative view of science education. Sjostrom & Eilks (2021) present Vision III as a *Critical Reflexive Scientific Literacy,* drawing from the Northern European concept of *Bildung* and its connection to holistic traditions for an expansive notion of education for human development in the wider world rather than confined to curriculum studies.

Ast the same time as the ongoing development of scientific literacy for a new vision of a scientifically literate citizenry, Bencze et al. (2020) reveal the forty year history of struggle in the science education literature and in globalising reforms, reframing a rich variety of constructs seeking to connect school science to society and the wider world, such as *Science-in-Context*, *Socio-Scientific Issues* (SSI) and *Critical Science Questioning*.

More recently, the science education literature and policy reforms are framing new notions of 'citizen science' and 'argumentation' as novel ways of reconnecting science and scientific literacy to new notions of engaged citizens, often apolitical notions of what it means to be a citizen in a nation state and/or in the wider global world today. For example, a study by McNew-Birren & Gaul-Stout, 2022) taking pace in an urban research centre in Milwaukee, Wisconsin in the US constructed 'citizen science' and positioned citizen volunteers as additional place-based 'data gatherers' for the research centre, provided with the necessary resources of equipment and technical training, rather than any collectivist (political) notion of citizenship in relation to how ethics, science, and politics plays out for the greater good of society, economy and the environment. In a similar, and related construct, a notion of 'argumentation' in science education is currently employed for debating socio-scientific issues while drawing only from science, analytical thinking, data and empirical evidence. Kim & Roth (2018) reveal the process involved when children and young people are coached in higher order thinking to support these domain specific skills of argumentation. In this way, the concept of 'argumentation' appears tightly confined to Bang's (2017) 'dogmatic image of thought' where right answers are valued, dialogue with other ways of knowing are closed down, and there is no recognition of the necessary ethical and political dilemmas and/or struggles with multiple knowledge(s) and different ways of knowing. In this regard, the diversity of new constructs seeking to connect scientific literacy to the development of engaged citizens today, largely disappoints given that they are often under-theorised and assume a normative consensus (Mooney Simmie & Tolbert, 2025).

A New Social Movement Reimagining Science Education

At the same time, there is also a deeply contested science education literature, and a growing global social movement, involving science education researchers in the US, New Zealand, Australia, UK and Canada with advocacy for Reimagining Science Education in the Anthropocene – the term given to the geological footprint in the planet largely coming from man-

made exploitation of the Earth's natural resources (Tolbert et al., 2024; Wallace et al., 2022). This fast-globalising social movement reveals inherent dangers in viewing science education and its relation to society and the planet in reductionist ways. Instead, they advocate for a philosophically grounded and problem-posing approach to science education which can humanise the discipline and leave sufficient open spaces for scientific, critical and reflexive literacies and futures thinking about the importance of scepticism in science education and its ethical and political relation to personal, social and planetary justice.

Critical pedagogy researchers in science education, such as Hodson (2003), and feminist thinkers in science education, such as Colucci-Gray (2014) reveal how novel concepts in science education, scientific literacy and civic engagement are all hampered in different ways by the rather naïve positivistic framing of science education that continues to persist in mainstream policy and research in neoliberal times (Bang, 2017; Bazzul, 2023; Levrini et al., 2024). Howie (2020) a school principal in Australia shows how this political project frames education and teaching for compliance and self-imposed responsibility rather than agency:

In closing down dialogue and setting normative standards, an evidence hierarchy is inherently anti-democratic, as it closes the public space, so to speak, reducing social relations to obligation. The barriers of the political-administrative establishment go up around the public educational research space. What should be open to question and not reductively represented as self-evident, including research methodologies and outcomes, are standardised and ranked (p.683).

Discussion And Conclusions

The selected theoretical lens used here became a powerful explanatory framework for interrogating the contemporary problem of how to reframe scientific literacy and civic engagement in ways that are actively connected to the socio-scientific, ethical and socio-political issues of the moment, and for a futures-oriented, fair and sustainable Europe. Based on the critical insights emerging, albeit from what was a small scale study of a select literature, a number of key research questions emerged that can guide this new framing of STDA in a future of uncertainty, where science will need to play out in a futures-oriented science classroom in ways that are problem-posing, philosophically grounded, and connected to the critical consciousness needed for the greater good of a desired subjectivity, society and planet (Mooney Simmie & Moles, 2025)

Starting with Hordern's (2022, 2024) rubric, any reframing of STDA will clearly need to draw from the three-domains of science teachers' knowledge base in ways that are inclusive of the meaning-making and interruptive power of the sciences, arts and humanities respectively, as well as the deliberative tradition that secure the holistic and dynamic nature of science education. Besides, any new framing of scientific literacy and its connectivity to civic engagement will need to offer affordances for critical appraisal of the power and limits of evidence and rely on an interplay with a rich variety of literacies found, for example, in the sciences, ethics, politics and in ways that can release the transformative potential of the learner for care based, fair and just sustainability (Colucci Gray 2014).

In conclusion, the following key questions emerged from the study as a preliminary way of distinguishing between a neoliberal framing of STDA for compliance with the contemporary social order (status quo), or for affordances for human emancipation and a futures-oriented fair, just and sustainable economy, society and planet:

How are science teachers' democratic assignments (STDA) framed - as a problem-solving exercise or as a philosophically grounded problem-posing exercise?

Are science teachers expected to interplay with other literacies, values, cultures, knowledges and

different ways of knowing in relation to the necessary (scientific, ethical and political) struggles with contemporary issues in the wider world?

Are science teachers expected to engage in the deeply personal work of critical reflexivity to improve their self-awareness and justification of selections?

Are science teachers required to challenge and to move ('affect') their students to action (affectivity) in relation to socio-scientific issues of injustice in the wider world?

Are science teachers expected to develop students' capacities for an appreciation of science-in-society and/or for a critical appraisal of the power and limits of science?

The critical insights emerging suggest that a problem-posing and transdisciplinary approach is needed in any new reframing of science teachers' democratic assignment (STDA), a framing that will need to be inclusive of the sciences, the arts and humanities for the necessary productive clashes between their sense-making and interruptive powers, and the deliberative traditions. This supports Bang's (2017) assertion of ontological indeterminacy and the need to hold any new framing of scientific literacy and civic engagement open to scrutiny and problem posing while providing productive pedagogical spaces in the science classroom and school for dialogue, critical debate, and provocation for eliciting self-awareness, agency and action to occur.

ESERA 2025 Copenhagen

Empowering Children As Agents Of Climate Action: A Case Study Of A Teacher's Enactment Of Socio-Scientific Inquiry-Based Learning In A Kindergarten

Jingwen Song, Andri Christoudoulou and Wonyong Park
University of Southampton, UK

Kindergarten-aged children, although often considered to be too young, have the right to know about the uncertain world they are living in and to have their voices heard in climate action. Climate change education equips students with the knowledge, skills and values of climate change, and empowers students for climate change mitigation and adaptation. However, children in kindergartens tend to receive less education in climate change compared to other school periods, and teachers often lack the subject knowledge and teaching skills needed to address climate change with kindergarteners. To explore how early childhood teachers can enact climate change lessons in age-appropriate ways, we implemented a teacher professional development programme, which supported teachers to enact four climate change lessons based on the socio-scientific inquiry-based learning (SSIBL) approach consisting of three stages (Ask, Find out, and Act). In this proposal, we present a qualitative case study focusing on how one teacher enacted her lessons in a kindergarten in Shanghai, China. Semi-structured interviews, lesson video recordings and teacher's reflection journals were collected and analysed qualitatively. The findings of instructional strategies the teacher used in each SSIBL stage are: (1) Ask - the teacher created a need to know with personally and locally relevant topics about climate change; (2) Find out - the teacher used iconic representation to help children concretise their reasoning process in personal inquiry, and used a sensory approach in scientific inquiry to teach abstract scientific knowledge; (4) Act - the teacher encouraged children to take indirect climate action through family or community stakeholders.

Keywords: climate change education; early childhood science education; socio-scientific inquiry-based learning

Introduction

For the sake of addressing climate change urgently and promoting sustainable development, the United Nations (2017) proposes to empower climate action through education such as curriculum inclusion and teacher education. Climate change education (CCE) entails equipping students with knowledge of the concepts, causes, impacts and solutions related to climate change, as well as the skills, values and attitudes needed to empower them for climate change mitigation and adaptation at local and global scales (Hung, 2014; Kavanagh, Waldron and Mallon, 2021). Young children are more likely to act in a pro-environmental way than they are in later life (Collado et al., 2015), making this period critical for CCE by developing their knowledge and attitudes and building the foundation for future learning. However, the challenges posed to young children by complex and abstract knowledge (Copple and Bredekamp, 2009) and the lack of teachers' relevant background knowledge (Kavanagh et al., 2021) might be reasons that inhibit CCE in early childhood education.

Climate change as a socio-scientific issue (SSI), involves controversial opinions on how it impacts society with a connection to scientific concepts and applications (Zeidler, 2014). In this research, the pedagogical framework of socio-scientific inquiry-based learning (SSIBL) (Levinson, 2018) is adapted by teachers to enact climate change lessons. SSIBL has three practical stages: (1) Ask - asking authentic questions and creating a need to know related to SSI; (2) Find out – finding the evidence for answering the questions through inquiry-based learning, which includes scientific, social and personal inquiry; (3) Act – taking action to address SSI.

SSIBL involves integrating SSI into classroom teaching that leads to action-oriented CCE where children are empowered to make informed decisions and take action.

To address the scarcity of CCE studies in early childhood, this research explores the strategies of teaching about climate change used by a kindergarten teacher, with support from a teacher professional development (TPD) programme that included the subject knowledge of climate change and the teaching skills aligned with SSIBL. The overall research question was: What strategies do an early childhood teacher use to enact climate change lessons based on the SSIBL approach?

Methods

Teacher Professional Development Programme

In accordance with Desimone's (2009) five core features of the effective TPD programme - content focus, active learning, collective participation, coherence and duration - we developed a TPD programme that consists of four workshops, to prepare teachers with the subject knowledge of climate change (Workshop 1) and the SSIBL pedagogy (Workshop 2) for enacting the climate change lessons. Workshops 3 and 4 facilitated teacher's reflection on what they had done and for improving lessons. Teachers attended Workshops 1 and 2 before they selected teaching topics related to climate change and then co-designed the four lesson units. Following that, teachers enacted Lessons 1 and 2 before they attended Workshop 3 and enacted Lessons 3 and 4 before Workshop 4. The programme spanned four months, from March to June 2024.

Participants And Data Collection

This study is a qualitative case study. Four teachers participated in the TPD programme, but in this proposal, we focus on one teacher's experience for an in-depth analysis. The teacher had been teaching in kindergarten for 11 years and was working with children aged 5-6. This teacher had been living in Shanghai for 39 years and had some familiarity with the impacts of climate change that Shanghai experiences. The research context was a public kindergarten in Shanghai, China, that follows the governmental kindergarten educational policy of enacting inquiry-based science learning.

Data were collected through semi-structured interviews, lesson video recordings, and the teacher's reflection journals to explore how the teacher enacted the action-oriented climate change lesson with the SSIBL approach in kindergarten. Three semi-structured interviews were conducted. The initial interview was conducted before the TPD programme, to find out about the teacher's background and her understanding of climate change and inquiry-based learning, so that the workshops can be designed to better support their subsequent lesson enactments. The mid-interview was conducted after Lesson 2, focusing on the teacher's rationale for choosing teaching topics and enacting certain instructional strategies of Lessons 1 and 2. At the end of the programme, the teacher's rationale for certain instructions of Lessons 3 and 4 was explored in the final interview. Four lessons were video-recorded to observe what and how the teacher enacted in the classroom. The interviews conducted after observing the teacher's lesson enactment can improve the reliability of interpretation (Desimone, 2009). Teacher reflection journals were recorded throughout the TPD programme and focused on her experience and feelings about lesson enactments and participation in workshops.

Data Analysis

The interviews and teachers' reflection journals were analysed by thematic analysis (Terry et al., 2017). The lesson video recordings were first segmented into episodes based on activity, and then the activity contents were summarised. Secondly, the lesson recordings were transcribed into

written documents, and the classroom discourse was coded based on two frameworks. One framework focuses on the dimensions of SSIBL, such as the codes 'Contextualise the controversy to a locally/personally relevant experience' 'Encourage action taking through indirect action' etc. The other framework is about accountable talk (Michaels et al., 2008). The teachers' talk moves were coded deductively from this framework to represent the functions of the discourse and how it interacts with SSIBL. Sequentially, the codes were categorised by the three stages of SSIBL (Ask, Find out and Act), to explore what strategies the teacher used for each SSIBL stage in CCE within a case. The rationales for the teacher's use of the strategies were compared with the data from interviews and reflection journals.

Findings

The analysis revealed the teacher's strategies for CCE in early childhood based on the SSIBL approach. We present the strategies of how the teacher enacted each SSIBL stage (Ask, Find out and Act) for teaching climate change to her 5-6-year-old class of 15 children.

(1) Ask stage: Creating the need to know by contextualising locally and personally relevant controversy related to climate change

The teacher asked the children to survey the local neighbourhood regarding the changes of green spaces being replaced by car parks before the lessons. As shown in Table 6.1, the teacher illustrated the dilemma that existed in the neighbourhood with pictures (turn 5), and raised an open question 'Should we build car parks or green spaces in the community?' (turn 7) to invite children's ideas for further inquiry activities. She introduced the issue from real life that is personally and locally relevant to young children, to create a need to know related to climate change.

Table 1. The Ask stage in Lesson 1 was implemented by the teacher.

Turns	Speaker	Lesson discourse	Codes
5	T	Oh, this is the community being renovated, right? The neighbourhood committee issued a notice. This notice, said that the neighbourhood was going to be renovated. What was being renovated? Some parents of children said that there are not enough parking spaces in the neighbourhood, and they want to add more parking spaces. Some people said that they like greening, right?	Contextualise the controversy to a locally/personally relevant experience; Raise authentic/open questions; Invite students to express personal opinions;
6	T	So let's have such a voting [activity].	
7	T	Hey, do you think we should add more parking spaces or increase green spaces?	

The teacher elaborated on the importance of personal experiences when discussing her rationale for choosing this topic and designing such an activity in her mid-interview:

> 'Neighbourhood conversion is something this area has been going through recently, so I think that personal experience is more useful to inspire children to learn more about this [climate change] topic.'

(2) Find out stage: Iconic representation (e.g. drawings) serves as a communication tool, helping young children concretise their reasoning process in personal inquiry

The teacher gained additional information about children's opinions through their drawing, in terms of their choice of keeping car parks or green spaces, to press for further reasoning, as shown in the example in Table 2.

Table 2. Analysis of the teacher's lesson discourse in personal inquiry in Lesson 1.

Turns	Speaker	Lesson discourse	Codes
38	T	Which child drew this point of view [in the picture]? I will invite him to talk about it.	Iconic representation Encourage reasoning
39	S7	My family has a car, so I want to draw a parking garage. There are always many parking spaces in my community, but they are all taken by other people, so I want to build a parking garage.	Invite students to express personal opinions (say more)
40	T	Well, she built a parking garage here, so why is there green on it [car park -the bottom right part of Figure 6.2.2]?	Support students in deepening their reasoning drawing on everyday life
41	S7	I think the parking garage is pretty hot. I'm going to make some vines to cover it so it won't be that hot.	

The teacher encouraged Student 7 to share her reasons for supporting increasing the car parks with the picture (turn 38). From the student's response, the teacher realised that the viewpoint expressed in Student 7's spoken language did not entirely correspond to the one she sought to represent in her drawing (turn 39, Figure 1), so she pressed further reasoning by asking what the green stuff above the car park in her drawing (turn 40). From Student 7's response in turn 41 about how to keep the car park while keeping green spaces, the teacher then better understood that Student 7's choice was not only in support of the car park drawing on her family experience in turn 39, but also seeking a balanced solution to the issue. In the teacher's lesson, the drawing represents the child's complete ideas that helped the teacher identify the child's additional unarticulated personal thoughts and made the child's reasoning process visible.

Figure 1. Student 7's picture visually represents her personal opinions on whether to keep green spaces or build car parks.

(3) Find out stage: Using a sensory approach in scientific inquiry to teach abstract scientific knowledge as evidence for climate action

In Lesson 2, the teacher taught children to learn about the cooling effect of the trees. The children felt different temperatures under the trees and in the places without the trees, by touching different materials (i.e. floor, tile, soil), as shown in Figures 2 & 3, during the extreme hot weather in Shanghai at the end of May. The teacher simplified the complex principles behind the cooling effect produced by trees through transpiration and shading into a scientific phenomenon that could be used as evidence for making informed decisions by using a sensory approach.

Figure 2. Children were feeling the temperature under the trees..

Figure 3. Children were feeling the temperature in places without trees

The teacher used the senses to make the scientific knowledge accessible to young children, such as why planting trees contributes to reducing the temperature, and adapted to the hot weather caused by climate change in Shanghai. The teacher discussed that the young children can learn about science by using a sensory approach in her reflection journals:

> 'It is easy for students to learn through feeling and touching, but when knowledge is taught in the form of abstract theory, it is difficult for children to understand.'

(4) Act stage: Encouraging young children to take indirect climate action through family or community stakeholders

In Lesson 4, the teacher led children to draw posters in relation to protecting the trees, put up their posters at the school gate, and encouraged children to introduce their solutions to their families when they go back home (Figure 4).

Figure 4. Posters drawn by children advocating for tree protection as a climate action.

The teacher believed that because children's ability is limited, what they can do is to take indirect climate action by encouraging their family and others to take direct action. She said in her final interview:

> 'The ability of children is to encourage the adults, that is, the adults in their family, and then go on to contribute more to society. Their ability is only to change a small part of the people around them and to change their own mind first before they can help more people.'

Discussion And Conclusions

The teacher's instructional strategies in this case study indicate more possibilities of having CCE in early childhood with the SSIBL approach. Although the knowledge of climate change is often claimed to be too complex and abstract for kindergarten children, this study suggests that the teacher is capable of teaching climate change to children through everyday experiences (Ginsburg & Audley, 2020) that are personal and locally relevant to them, by being immersed in a contextualised learning scenario related to climate change, and inquiring through iconic representation and sensory appraoch. These strategies can help young children develop their conceptual understanding and empower them as agents of action.

This research contributes to the theoretical knowledge on how SSIBL can be enacted as an action-oriented approach for CCE. The implications for teachers and teacher educators will involve guiding them in adopting age-appropriate approaches to teaching climate change and enacting SSIBL.

Facing Scenarios Of Ontological And Epistemic Uncertainty In Science Teaching: Perspectives On Agency In The Literature In The Field

Gabriel Lanzillotta[1] and Maurício Pietrocola[2]
[1]Programa de Pós-Graduação Interunidades em Ensino de Ciências, School of Education, University of São Paulo, Brazil
[2]Department of Teaching Methodology and Comparative Education, School of Education, University of São Paulo, Brazil

Advances in science and technology have intensified social and educational challenges in which uncertainty shapes how individuals and collectives are able to act. In science education, this calls for approaches that promote students' agency, understood as the capacity to participate meaningfully in knowledge construction and to act in uncertain contexts, rather than merely acquiring established knowledge. This study examines how the literature has conceptualised and promoted agency in situations and scenarios of uncertainty within science education. A systematic literature review was conducted using the ERIC and Web of Science databases, resulting in the selection of 15 relevant articles. The analysis identifies two main macro-trends. One, predominantly associated with European research, conceptualises agency in future-oriented educational approaches that emphasise collective and projective forms of action, using narratives, simulations and interdisciplinary practices to engage with ontological and epistemic/epistemological uncertainty. The other, largely linked to studies from the United States, focuses on agency as students' participation in scientific practices, highlighting epistemic and consequential agency in contexts of epistemic and conceptual uncertainty. Although distinct, these approaches are complementary in showing how different forms of agency emerge in response to different types of uncertainty. The findings suggest that science education should integrate these perspectives to support students in developing agency to act, decide and take responsibility in complex and uncertain worlds.

Keywords: agency / uncertainty / literature review

Introduction

The world we live in has become increasingly complex as advances in science and technology have confronted us with challenges whose outcomes are ever more uncertain. New challenges such as climate change, artificial intelligence, food security, genetic engineering, and energy transition, among others, have required action under conditions of risk and uncertainty that do not lend themselves to simple solutions, since neither accumulated knowledge nor our projections are capable of providing the certainties, we seek (Giddens, 1990; Beck, 1992, 2009; Rosa, 2020). Schools face the challenge of preparing students to deal with problems of this kind, while simultaneously attempting to reinvent themselves in order to position their practices within this changing world.

Historically, determinism has constituted the foundation of science and, consequently, of science education (Levrini et al., 2024), sustaining the idea that, once the initial conditions and governing laws of a system are known, its future behaviour can be predicted with precision. This epistemological environment contributed to the construction of an image of science as a producer of certainty, control, and predictability. However, social and scientific developments have shown this view to be limited and insufficient. Contemporary understandings of complex systems reveal that natural and social phenomena are frequently non-linear and composed of multiple interacting variables (Prigogine & Stengers, 1984; Funtowicz & Ravetz, 1994). Moreover, uncertainty has become an inseparable element of the scientific process of knowing and acting in the world,

including in its various forms of appearance, such as epistemic, ontological, scientific uncertainty, *etc.* (Kirch, 2012; Njå et al., 2017). Recognising complexity and uncertainty in natural and social processes is therefore fundamental to a more comprehensive understanding of the world we inhabit and of the role attributed to scientific knowledge in the education of citizens (Pietrocola & Souza, 2019).

The OECD (2019), in the report *The Future of Education and Skills 2030*, states that students must be prepared for "the mobilisation of knowledge, skills, attitudes and values to meet complex demands in situations of uncertainty" (p. 25). Accordingly, science education must move beyond the transmission of deterministic knowledge and incorporate explicit engagement with uncertainty and with ways of acting in contexts marked by its presence. Scientific education must acknowledge that we live in an increasingly volatile, uncertain, complex, and ambiguous world, requiring the construction of an ethical stance towards scientific knowledge that assigns responsibility to students as agents in the construction of desirable futures (Bell, 1998). This calls for progress towards a more transformative conception of scientific literacy, one capable of fostering participation, social activism, and agency in response to contemporary challenges (Valladares, 2021).

Within the literature, particularly in approaches that mobilise socioscientific issues, decision-making occupies a central place in the analysis of students' actions. While this emphasis has contributed to shifting science education beyond the mere transmission of content, understanding formative processes exclusively through the lens of decision-making proves conceptually limited, especially in complex situations. Such an approach tends to capture only isolated moments of action, often conceived as discrete rational choices, while overlooking the temporal and social conditions that structure the very possibility of deciding (Emirbayer & Mische, 1998).

It is within this context that the notion of agency offers a more robust analytical framework for thinking about action in socioscientific situations. Some studies have addressed how agency can be promoted in educational contexts where students encounter complex and uncertain problems. However, to date, there has been no work synthesising these contributions in a way that supports reflection on science education in a world marked by uncertainty, where traditional school knowledge was not designed to prepare citizens capable of acting and making decisions under such conditions. Although there is a broad body of literature on uncertainty, not all of it engages with the question of how, in uncertain scenarios, students' agency can be fostered. Accordingly, this study seeks to address the following research question: how has the literature proposed the promotion of agency in situations and scenarios of uncertainty within the context of science education?

Methodology

To achieve the defined objectives, we conducted a systematic reviews search (Pollock & Berge, 2018) in two databases: ERIC (Educational Resources Information Center) and Web of Science, during the second half of 2024. ERIC is aimed specifically at publications in the field of education, while Web of Science covers a broader spectrum of areas of knowledge. The combination of these two databases allowed for a comprehensive reach, guaranteeing a more detailed and complete review of the topic in the educational context. This method also enabled us to understand how the topic is approached from different perspectives, enriching the analysis and broadening the possibilities for contributions to the field.

In both databases, we used the keywords "uncertainty" and "agency" together, without restricting the period of publication, evaluating all titles and abstracts to identify articles relevant to the scope of the study. In ERIC, we limited the search to "peer review" studies, which resulted in

122 articles, of which 27 were considered relevant. On Web of Science, as it is a broader database, we applied filters to articles in English and within the "Education Educational Research" category, obtaining 133 articles in total. Of these, 31 were relevant, but 11 were already present in the ERIC search, resulting in 20 relevant articles to be added in the base. In all, we came up with 47 articles. We didn't make a specific selection of journals in order to obtain a more robust sample, but one that took into account the selection criteria. For this work, we cut out these 47 articles, analysing only those that fell within the field of science teaching or that investigated central themes of interest to this area (such as climate change, agriculture, *etc.*). As a result, 15 articles were selected and analysed in detail.

Results And Discussion

Table 1. Future-orientated articles in science education.

Title	Authors	Year of Publication	Nature of the article	Journal	Author's institutional country
Facilitating transformative science education through futures thinking	Laherto, A.; Rasa, T.	2022	Theoretical	On the Horizon	Finland
Futurising science education: students' experiences from a course on futures thinking and quantum computing	Rasa, T.; Palmgren, E.; Laherto, A.		Empirical	Instructional Science	
Imagining the School of the Future Through Computational Simulations: Scenarios' Sustainability and Agency as Keywords	Barelli, E			Frontiers in Education	Italy
Making sense of youth futures narratives: Recognition of emerging tensions in students' imagination of the future	Barelli, E; Tasquier, G; Caramaschi, M; Satanassi, S; Fantini, P; Branchetti, L; Levrini, O				
Scientific Literacies for Change Making: Equipping the Young to Tackle Current Societal Challenges	Tasquier, G; Knain, E; Jornet, A				Italy; Norway
Enhancing relevance and authenticity in school science: design of two prototypical activities within the FEDORA project	Cassina, FD; D'Orto, E; Tasquier, G; Fantini, P; Levrini, O	2023			Italy
Quantifying and communicating uncertain climate change hazards in participatory climate change adaptation processes	Müller, L; Döll, P	2024		Geoscience Communication	Germany

Table 2. Articles focusing on scientific uncertainty in science teaching.

Title	Authors	Year of Publication	Nature of the article	Journal	Author's institutional country
Enlisting Supervised Machine Learning in Mapping Scientific Uncertainty Expressed in Food Risk Analysis	Rona-Tas, A.; Cornuéjols, A.; Blanchemanche, S.; Duroy, A.; Martin, C.	2019	Empirical	Sociological Methods & Research	USA; France
Explicit Instruction of Scientific Uncertainty in an Undergraduate Geoscience Field-Based Course	Bateman, K.; Wilson, C.; Williams, R.; Tikoff, B.; Shipley, T.	2022		Science & Education	USA
The glue that makes it hang together: A framework for identifying how metadiscourse facilitates uncertainty navigation during knowledge building discussions	Ko, MLM; Luna, MJ	2023		Journal of Research in Science Teaching	
Course-Based Undergraduate Research Experiences in a Chemical Engineering Laboratory Promote Consequential Agency	Wilson-Fetrow, M.; Svihla, V; Burnside, B.; Datye, A.			Journal of Chemical Education	
Student Uncertainty as a Pedagogical Resource (SUPeR) approach for developing a new era of science literacy: practicing and thinking like a scientist	Chen, Y.; Jordan, M.			Science Activities	
Cultivating a higher level of student agency in collective discussion: teacher strategies to navigate student scientific uncertainty to develop a trajectory of sensemaking	Chen, Y.	2024		International Journal of Science Education	
Navigating student uncertainty for productive struggle: Establishing the importance for and distinguishing types, sources, and desirability of scientific uncertainties	Chen, Y.; Jordan, M.; Park, J.; Starrett, E.		Theoretical	Science Education	

The articles were read in full and some information about them can be seen in Table 1 and 2. Only one of them was published before 2020, which appears to be a timely cut-off, as the COVID-19 pandemic seems to have spurred researchers worldwide to reflect on the issue and propose

interventions in science education. More than half of the articles analysed cite the pandemic in their text, corroborating this trend. What's more, a large proportion of the articles are empirical - around 80% - based on analysing data collected in practical applications in the classroom or analysing educational materials. Although the publications are distributed across several journals, *Frontiers in Education* stands out, hosting ⅓ of the articles, probably due to its focus on global challenges in education, as pointed out in its scope. In addition, 80% of the authors of the articles in this journal are Italian, reflecting an influence from the researchers' country of origin. The other journals are varied, without repetition.

It was noted that there are two macro-trends in the articles analysed. The first is linked to authors from European institutions and focuses on future-oriented education, on the one hand looking exclusively at climate threats and their uncertainties (Müller & Döll, 2024) and, on the other, those that focus on the application of Future Studies in science teaching, as can be seen in Table 1, with many of these studies associated with I SEE and FEDORA project, further corroborating their similarity in focus. If you look at the keywords in the articles, you'll notice that the words “agency” and “future” appear a lot, but this isn't a rule. However, the word ‘uncertainty’ does not appear. These articles use methodological strategies such as the use of narratives, simulations, interdisciplinary practices and others to work with futures and their uncertainties.

The second macro-trend is linked to US authors and is focused on understanding how students deal with scientific uncertainty (conceptual and epistemic) during teaching and learning processes and how they construct knowledge, as can be seen in Table 2. If you look at the keywords in the articles, you'll notice that the word ‘uncertainty’ is the most common and has three forms, while ‘agency’ only appears once. The last article on this list (Ferguson & White, 2023) does not fit into any of these macro-trends, as it brings a theoretical perspective on addressing socio-ecological challenges, in this case climate change, through student action and community involvement.

These macro-trends are not arbitrary; they reflect ways of addressing different types of uncertainty. Studies on scientific uncertainty in the classroom focus on epistemological uncertainty, examining what we know about a subject and how that knowledge is constructed and validated. Such approaches confront the limitations of current knowledge, where uncertainty can be reduced through new data collection or alternative models and theories. Categorising uncertainty types clarifies their distinct origins, characteristics, and implications, helping to determine the most appropriate response. By differentiating them, researchers propose strategies to equip students and educators with critical adaptation and action skills.

Within these studies, agency is understood not merely as an individual capacity to act, but as a sociocultural process through which students assume authority and responsibility both for their own learning and for the collective construction of knowledge within the school community. This perspective distinguishes different levels of agency, contrasting low-level forms, typical of transmissive teaching models, in which students act as passive recipients, with high-level forms, in which learners position themselves as knowledge producers and active participants in scientific practices. In such contexts, agency becomes visible when students identify gaps in their own understanding, formulate guiding questions and collaborate with peers to deepen their comprehension, thereby shifting from a relationship of knowledge consumption to one of authorship and production.

This conception is further expanded through specific forms of agency that emerge in scientific and inquiry-based practices, particularly epistemic and consequential agency. Epistemic agency refers to students’ opportunities to participate meaningfully in knowledge-building practices, contributing to the formulation, evaluation, and direction of investigations, while consequential

agency is expressed through decision-making processes that directly shape the course of work and learning. In learning environments marked by scientific uncertainty, this agency is strengthened, as engagement with the unknown creates conceptual and epistemic demands that motivate action. Agency thus becomes visible not only in students' choices, but also in discursive interactions and in the opportunity, structures afforded by instructional design, especially when students engage in authentic practices and move from peripheral positions towards more central roles within communities of inquiry. In this sense, agency emerges when learners move beyond merely "learning about" science and begin to "figure out how" explanations are produced, mobilising their own ideas, intuitions and experiences to address real-world problems.

Future-orientated work approaches uncertainty in a different way. Although epistemological and epistemic uncertainty are present, arising from the limitations inherent in the methods and frameworks used to think about the future, ontological uncertainty appears to be central. Ontological uncertainty is recognised as inherent to the future, as it involves phenomena that are, by nature, unpredictable, chaotic or emergent. This uncertainty cannot be eliminated, even with perfect information or better models, because it is embedded in reality itself. An example of this is the construction of desirable future scenarios, with the intention of thinking about what, through agency, can be done to reach a desirable future, even if we don't know everything. In this context, the two types of uncertainty are connected in the epistemological reflections on the limits of projections, which can touch on ontological uncertainties, especially when dealing with chaotic or emerging phenomena, with climate change being addressed more than once.

Overall, in this macro-trend, agency is conceptualised as the capacity to intentionally influence and transform social and material worlds, extending beyond a strictly individual notion of action to include shared and collective forms. This conception is strongly grounded in Emirbayer and Mische's framework, in which the projective dimension of agency occupies a central position. By enabling subjects to momentarily disengage from limiting assumptions and to imagine desirable futures guided by values, this dimension underpins educational practices oriented towards futures thinking. In this sense, students are positioned as protagonists capable of constructing pathways of action towards preferable scenarios, shifting from an adaptive stance towards the future to an active and intentional engagement with it.

This understanding of agency is further articulated through models of transformation that integrate personal, practical, and political dimensions, highlighting that action involves connecting values, everyday choices, and broader institutional structures. Agency thus emerges as the capacity to move across these spheres, shifting from a condition of being "objects of change" to that of "subjects of change". In the contexts analysed, science and technology play a fundamental role in this process, particularly through non-deterministic approaches that emphasise the social construction of technology and the role of individuals and collectives in shaping global dynamics. In scenarios marked by uncertainty, agency is understood as the ability to act without guarantees, planning action in relation to multiple possible futures. Strategies such as back casting and the use of complexified narratives reinforce this perspective by framing the future as an open field of possibilities, in which action does not eliminate uncertainty but is constituted precisely through it.

Conclusion

This review identified two main macro-trends in the literature addressing agency and uncertainty in science education, which offer complementary but distinct ways of conceptualising both uncertainty and agency. One macro-trend, largely associated with studies from the United States, focuses on scientific uncertainty within classroom practices, particularly epistemological and epistemic uncertainty arising from the limits of current knowledge. In these studies, uncertainty

is treated as a pedagogical resource, and agency is understood as a sociocultural process through which students assume authority and responsibility for inquiry and knowledge construction. Agency emerges through participation in authentic scientific practices, where epistemic and consequential forms of agency are central: learners identify knowledge gaps, formulate questions, make decisions that shape investigations and collaborate within communities of inquiry. Instructional designs that provide meaningful structures of opportunity are therefore crucial in supporting students' transition from passive reception to active authorship of knowledge.

A second macro-trend, predominantly associated with European research, approaches uncertainty through a future-oriented perspective in which ontological uncertainty occupies a central position. Rather than focusing solely on what is not yet known, these studies recognise uncertainty as an inherent feature of future realities shaped by complex, emergent and unpredictable phenomena, such as climate change. Within this framework, agency is conceptualised as the capacity to intentionally influence and transform social and material worlds, extending beyond individual action to include shared and collective forms. Grounded in the projective dimension of agency, these approaches position students as protagonists capable of imagining desirable futures and constructing pathways of action towards them, even in the absence of certainty.

Taken together, these macro-trends point to the need for science education to integrate epistemological, epistemic and ontological dimensions of uncertainty while foregrounding agency as a central educational outcome. Whether through engagement in knowledge-building practices or through futures-oriented pedagogies, the literature converges on the importance of preparing students to act without guarantees in complex and uncertain contexts. At the same time, the strong geographical concentration of the analysed studies highlights the need for broader contributions from contexts in Latin America, Africa and Asia, where uncertainties may take different forms and educational priorities and resources differ significantly. Expanding this body of research is therefore essential for developing more diverse and globally informed perspectives on agency and uncertainty in science education.

As global challenges intensify, science education is uniquely positioned to bridge knowledge and action by fostering agency in learners. However, traditional approaches often only focus on individual behavioural change, neglecting the collective and political dimensions essential for systemic transformation. This symposium examines the multifaceted nature of agency and its role in empowering learners to navigate the complexities of the Anthropocene through interdisciplinary, transformative education. The symposium integrates insights from environmental psychology, philosophy, futures studies, and science education to explore the idea of collective and political agency as crucial educational outcomes. It highlights three key contributions: a systematic review of the conceptual landscape of agency in climate change education, an interdisciplinary framework that proposes a three-lens model (epistemic, ethical, pragmatic) to conceptualise agency, and an empirical case study applying futures literacy in teacher education to strengthen collective and political agency. By connecting theory and practice, this symposium contributes to the ongoing dialogue about the transformative potential of science education in the context of sustainability and the climate crisis.

Keywords: Agency, Climate change education, Transformative science education

Introduction

Climate change, biodiversity collapse, and socio-environmental injustice increasingly challenge the adequacy of traditional models of science education. In the context of the Anthropocene, education is called upon not only to equip learners with scientific knowledge but also to prepare them to engage meaningfully and responsibly with complex, uncertain, and contested socio-ecological realities (Levrini et al., 2024; Latour, 2018; Sjöström et al., 2018). As such, the concept of *agency* has gained prominence in recent educational discourse. However, it remains far from clear what is meant by *agency* in the context of science education, how it can be fostered, and why it matters.

Although frameworks such as GreenComp (Bianchi et al., 2022) and the PISA 2025 Science Framework (White et al., 2023) conceptualise agency as a multifaceted competence, educational practices, particularly in the context of science education, tend to emphasise individual dimensions, such as behaviour change or personal responsibility. This may limit attention to broader systemic and collective dimensions of agency that are crucial for transformative engagement (Kranz et al., 2025). Particularly in climate change education, the dominant orientation tends to privilege personalised responses and lifestyle choices, while overlooking the more systemic, collective, and political dimensions that underpin the potential for effective social transformation (Kranz et al., 2022; O'Brien, 2015; Otto et al., 2020).

Within the field of science education, the concept of agency is frequently invoked but rarely subjected to rigorous theoretical scrutiny. As highlighted in prior literature (e.g., Marsh et al., 2019; Schubatzky et al., 2026), the concept of agency is often invoked using a variety of related terms, which are not always clearly defined or theoretically distinguished. This contributes to a degree of conceptual ambiguity that may hinder coherence in both research and practice. This lack of clarity risks undermining both research coherence and pedagogical design, as it becomes uncertain which capacities science education is meant to develop and why. At the same time, a growing body of research – initially from social sciences and humanities (e.g. Emirbayer & Mische, 1998) and more recently within science education research - has highlighted the need for a relational collective and political understanding of agency (e.g. Tasquier et al., 2022; Kranz et al., 2022; Levrini et al., 2019). While not entirely new, this view has often remained underdeveloped in science education, particularly in relation to climate change.

Against this backdrop, the ESERA 2025 symposium titled "Expanding perspectives on Agency within Climate Change Education debate" presented aims to advance a theoretically grounded and empirically informed dialogue around the role of climate agency in science education. We argue that science education must not only acknowledge agency as a learning outcome but also expand how agency is conceptualised, operationalised, and supported across curricula, pedagogical practices, and teacher education. More specifically, we contend that collective and political forms of agency, understood as the capacity to act with others to influence structural and systemic conditions, should receive the same attention as the individual dimension, sincethey are essential goals of science education in the Anthropocene (Kranz et al., 2025a).

The symposium brings together three complementary studies that address a shared research problem: *How can science education develop ways to conceptualise, support, and assess agency in light of the scale, complexity, and socio-political nature of the climate crisis?* The first contribution examines this question by mapping how agency is conceptualised in current climate change and sustainability education research, identifying dominant framings and theoretical blind spots. The second contribution develops a theoretical framework that reconceptualises agency through three interrelated lenses, epistemic, ethical, and pragmatic, articulating a normative and multidimensional perspective. The third contribution presents an empirical case study illustrating how futures literacy–oriented pedagogical practices in teacher education can support agentic engagement with uncertain futures and make collective and political dimensions of agency more visible.

Together, these contributions articulate a coherent yet pluralistic effort to reimagine agency beyond individualistic and behavioural paradigms. The symposium thus seeks to strengthen the theoretical foundations of agency in science education while offering practical directions for designing educational experiences capable of fostering the forms of collective engagement and transformative capacity that are urgently needed for a just and sustainable future.

Problematizing The Concept Of Agency In Climate Change Education

In recent years, agency has become a prominent yet theoretically unstable concept in climate change and sustainability education. Across science education research, policy frameworks, and curriculum documents, agency is frequently invoked as a key educational aim, often framed as essential for enabling learners to respond to the climate crisis (White et al., 2023; UNESCO, 2021). However, this growing prominence has not been accompanied by conceptual coherence across different research traditions (e.g., Priestly et al., 2015). Instead, agency is used in markedly different ways, ranging from psychological readiness and pro-environmental behaviour to civic participation and action.

The first contribution to this symposium addresses this problem through a systematic scoping review of agency in climate change and sustainability education research. Analysing 110 peer-reviewed studies published between 2004 and 2024, the review maps how agency is defined, theorised, and operationalised in school-level science education. A central finding is the widespread absence of explicit definitions: fewer than one third of the reviewed studies provide a clear theoretical definition of agency, while the majority use the term implicitly or without clarification. This pattern exemplifies what Marsh et al. (2019) describe as a jingle–jangle fallacy, where the same label refers to different constructs, or different labels describe overlapping phenomena.

This lack of definitional clarity has concrete consequences. Studies labelled as fostering "agency" often pursue fundamentally different educational goals: some focus on strengthening students' hope, motivation, or self-efficacy; others aim at developing sustainability-related competencies; still others foreground participation, identity work, or civic engagement. Without explicit conceptual positioning, it remains unclear which forms of agency are being aimed to be supported, how they relate to one another, and which are adequate for addressing the systemic and political nature of the climate crisis. From a pedagogical perspective, one might argue that this diversity is of secondary importance, as the central concern of climate change education is to support students in doing something in the face of the climate crisis, rather than remaining passive or disengaged. In this sense, different pathways to agency may appear equally legitimate.

However, precisely because agency is increasingly framed as a key educational response to a systemic and political crisis, it is not trivial which forms of agency are being promoted. Without explicit conceptual positioning, there is a risk that agency becomes reduced to individual coping, lifestyle choices, or isolated actions, thereby obscuring questions of collective responsibility, power, and structural change. Clarifying how agency is conceptualised is therefore not a purely theoretical concern, but a prerequisite for aligning educational aims with the transformative demands of the climate crisis.

To bring analytical structure into this fragmented landscape, the review identifies five recurring conceptualisations of agency in the literature. These include (1) agency as a psychological resource, emphasising hope, self-efficacy, and emotional resilience; (2) agency as competence, framing agency as a set of learnable and assessable knowledge–skill–attitude configurations aligned with policy frameworks such as PISA 2025; (3) critical-emancipatory agency, rooted in Freirean and critical science education traditions, foregrounding empowerment, justice, and collective struggle; (4) temporally embedded sociocultural agency, highlighting identity, participation, and the integration of past experiences and imagined futures; and (5) action-oriented or problem-solving agency, focusing on concrete participation and locally situated sustainability actions.

Importantly, these conceptualisations are not mutually exclusive. Rather, they emphasise different clusters of attributes and rest on distinct theoretical traditions. The review therefore proposes conceptualising agency as a family resemblance concept (Podsakoff et al., 2016), characterised by overlapping features rather than a single defining essence. Across traditions, several central attributes recur, including a perceived capacity to act, situatedness in socio-cultural contexts, participation with others, and a future-oriented perspective. At the same time, each conceptualisation foregrounds distinctive elements—such as psychological resources, competencies, empowerment, identity work, or local problem-solving—that shape how agency is enacted and studied.

This diagnosis sets the stage for the subsequent contributions in the symposium. Building on the conceptual mapping provided by the review, the second contribution advances an

interdisciplinary framework that reframes agency through epistemic, ethical, and pragmatic lenses. The third contribution presents an empirical case study illustrating the role of futures literacy in shaping agency-related orientations in teacher education, including collective and political dimensions of agency. Together, these contributions respond to the conceptual challenges identified here by moving beyond individualistic and behavioural paradigms toward a more robust understanding of agency suited to science education in the Anthropocene.

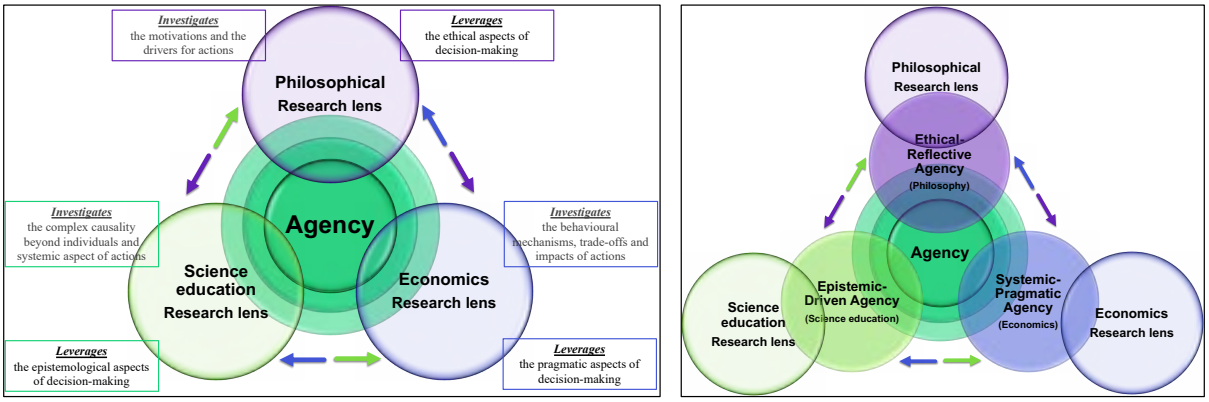
Reframing Agency Through Interdisciplinary Perspectives

Building on the need for greater conceptual clarity, the second contribution proposes a theoretical framework that redefines agency as a multidimensional educational construct. Tasquier, Pongiglione, and Ricci (2026) argue that science education must be expanded through the integration of insights from philosophy and economics to address the ethical, epistemic, and pragmatic dimensions of agency.

Their model, developed in the context of the ENCOMPASS research programme, moves beyond conventional notions of agency as primarily psychological or behavioural. It aims to capture the complex and situated nature of agency as it manifests in the climate crisis, where action must often be taken despite uncertainty, structural constraints, and conflicting values. Through a theoretically grounded synthesis of three disciplinary perspectives - science education, philosophy, and economics - the model proposes an educational response that recognises the plurality and interdependence of the competencies required for transformative engagement (Tasquier et al. 2026; Sezen-Barrie et al., 2026).

Central to this model is the articulation of three interwoven lenses through which agency can be rethought. First, epistemic-driven agency refers to the capacity to critically engage with scientific knowledge. In the context of climate science, this entails grappling with complex systems, probabilistic models, and the provisional nature of evidence. Students must be able to navigate contested knowledge claims, evaluate the reliability of sources, and understand how scientific knowledge interacts with political and social interests. This epistemic engagement is essential to avoid both naïve scientism and paralysing relativism.

Second, ethical-reflective agency foregrounds the importance of moral reasoning in contexts characterised by uncertainty and normative pluralism. Climate change raises profound ethical questions about responsibility, justice, and intergenerational equity. Philosophical reflection offers tools for deliberating about what is at stake, for whom, and according to which values. By integrating ethical reflection into science education, learners are not merely trained to know or to act but to judge. This form of agency requires sensitivity to others, awareness of ethical complexity, and the capacity to live with ambiguity.



Third, systemic-pragmatic agency refers to the ability to understand and act within real-world constraints, considering trade-offs, opportunity costs, and institutional limitations. Drawing on economic reasoning, this dimension of agency attends to the feasibility and effectiveness of climate actions. Students are invited to think strategically, acknowledging that ideal solutions may not always be viable and that action requires negotiation and compromise. Systemic-pragmatic agency thus aligns action with context, enabling learners to move from aspiration to implementation.

Taken together, these lenses offer a reframing of agency as a distributed and educable capacity. Rather than treating agency as a fixed trait or an individualised outcome, the framework situates it within learning environments that scaffold deliberation, judgement, and action. It calls for science education to be reimagined as a site of public reasoning, where students engage not only with scientific content but with the socio-political and ethical dimensions of science-in-society.

This perspective resonates with Vision III of scientific literacy (Sjöström et al., 2017), which advocates for the development of critical and transformative competencies that enable students to participate in shaping more just and sustainable futures. It challenges the epistemological reductionism of traditional curricula and calls for an expansion of educational aims to include the cultivation of political imagination, collective responsibility, and civic engagement.

Importantly, the framework is not merely theoretical. It has informed the development of design principles that guide the creation of pedagogical environments where these forms of agency can emerge (Sezen-Barrie et al., 2025). These environments are characterised by exposure to uncertainty, authentic problem contexts, deliberative dialogue, and opportunities for situated action. They invite students to encounter complexity not as a barrier but as a condition of responsible engagement. By positioning agency at the intersection of epistemic, ethical, and pragmatic reasoning, this contribution offers a powerful vision for rethinking science education in the Anthropocene.

Futures Literacy And Agency In Teacher Education

The third contribution examined how futures literacy is related to the development of agency in the climate crisis, with a particular focus on pre-service teachers (PSTs). In contrast to the conceptual plurality highlighted in the other symposium contributions, this study deliberately adopts an explicit working definition of agency to enable empirical analysis. Here, agency is understood as the capacity for autonomous social action through which individuals intentionally transform their social and material worlds (e.g., Biesta & Tedder, 2007). It is further viewed as inherently future-oriented, as people's anticipations and visions of the future shape how they act in the present (Lombardo, 2016; Ojala, 2012).

Two interrelated conditions described in the literature motivated this focus. First, research on young people's future thinking points to a lack of constructive future perspectives, often characterised by dystopian and fixed visions of the future (e.g., Miller, 2018). Second, studies in science education on climate change suggest that educational approaches frequently remain passive with regard to agency, prioritising individual agency or knowledge acquisition rather than fostering learners' capacities to shape social and material conditions (Kranz et al., 2022; Kranz, 2024), including collective and political forms of agency. Together, these patterns risk constraining both how the future is imagined and how agency is perceived. This gap is particularly consequential in teacher education as PSTs can be understood as future change agents whose own sense of agency and future imaginaries are likely to shape how they later engage students with the climate crisis (Winter et al., 2022). Yet, there is still limited research on how science teacher education can deliberately support the development of futures literacy and agency. Building on these motivations, the contribution addresses the guiding question of how a

climate-focused intervention can support the development of agentic, sustainability-oriented future thinking in PSTs. To this end, an interdisciplinary teaching module named (*FULit - Shaping the Future in Times of the Climate Crisis*) was implemented in the physics teacher programme at Freie Universität Berlin (Germany), integrating futures studies methods with transformative action-oriented approaches (Kranz et al, 2025b). The study involved 15 PSTs and followed an exploratory qualitative pre–post design. Focusing, among other data sources, on patterns in PSTs' future narratives, the analysis was structured along three dimensions: (1) the perceived quality of the future, (2) the perceived agency to shape the future, and (3) sustainability-related agency.

Regarding the perceived quality of the future, pre-intervention future narratives were predominantly articulated as ambiguous and uncertain. Rather than clearly dystopian or utopian visions, many accounts emphasised uncertainty, for example with respect to how climate change might develop or how societal responses could unfold. Dystopian elements were present but did not dominate, while utopian visions were rare. Post-intervention analyses indicate a slight shift: dystopian future visions declined, while ambiguous and uncertain futures became more prominent. The prevalence of ambiguity did not decrease and explicitly utopian futures remained rare.

With regard to the perceived agency to shape the future, pre-intervention narratives were equally distributed between active and passive orientations. Following the intervention, a slight shift toward agentic framings was observed (e.g., *'We redesign school life'*), more often positioning participants as potential actors capable of contributing to change. This shift was particularly visible in the combination of ambiguous future scenarios with agentic orientations. In contrast, utopian futures, when present, were more often paired with passive framings, indicating that positive visions did not necessarily coincide with a stronger sense of agency.

Finally, analysis informed by the EU GreenComp framework showed additional qualitative changes. Post-intervention narratives more frequently articulated, for example, acting for sustainability. While references to collective action remained rare, political agency became more visible. Participants more often framed the climate crisis as a socio-political challenge and referred to systemic or policy-related solutions rather than exclusively to individual behaviour.

Overall, the findings suggest that futures-oriented, transformative approaches hold the potential to support agentic engagement under uncertainty in the context of the climate crisis. Participants' future visions remained largely ambiguous rather than optimistic but were more frequently paired with agentic orientations. This pattern may be interpreted as a form of constructive hope (Ojala, 2012), oriented toward navigating uncertainty and reflecting on multiple possible futures rather than striving for idealised outcomes. The study followed an exploratory qualitative approach focused on identifying patterns rather than assessing intervention effectiveness. It examined prerequisites of agency, such as future imaginaries and perceived possibilities for action, rather than agency as an outcome per se. The findings point to the need for more structured opportunities for collective action and inform future comparative and longitudinal research on how different pedagogical elements support distinct dimensions of agency.

Discussion

Together, the three contributions in this symposium articulate a coherent and multilayered response to the central research problem: How can science education conceptualise, support, and assess forms of agency that are adequate to the scale, complexity, and socio-political nature of the climate crisis? Each study illuminates distinct facets of this problem, yet they also converge

in affirming the need for a paradigmatic shift in how agency is understood and cultivated within science education.

The first contribution offers a panoramic diagnosis of the current conceptual landscape, highlighting the conceptual fragmentation and the risk of a dominance of individualistic framings in empirical research. This mapping underscores the importance of developing and using theoretically robust and pedagogically meaningful definitions of agency that transcend behavioural models and foreground relational, collective, and political dimensions. It provides the groundwork for understanding why existing approaches often fall short in addressing the systemic nature of the climate crisis.

The second contribution builds on this diagnosis by offering an interdisciplinary model that reconceptualises agency through epistemic, ethical, and pragmatic lenses. Rather than viewing agency as a static competence, it frames it as a dynamic and educable process embedded in deliberation, judgement, and strategic action. This model provides a normative vision of what agency *should* entail in the context of climate change, anchoring educational goals in democratic reasoning, moral complexity, and institutional awareness. Crucially, it affirms that science education must not only transmit knowledge but also scaffolded forms of agency that enable learners to navigate and shape contested socio-ecological futures.

The third contribution translates this vision into pedagogical practice through the integration of futures literacy into teacher education. It offers an empirical illustration of how futures-oriented educational approaches can be associated with shifts in learners' future imaginaries and perceived agency, including greater attention to collective and political dimensions of climate action. In doing so, it illustrates the pedagogical viability of the theoretical claims advanced in the second contribution. Taken together, the three studies advance the proposition that science education must be reoriented to explicitly cultivate agency not only as individual agency but also as a collective and political practice. Addressing agency in science education therefore requires conceptual clarity about which forms of agency are being invoked (Contribution 1), a theoretical reframing of agency as an epistemic, ethical, and pragmatic educational capacity (Contribution 2), and an empirical illustration of how these conceptual insights can be taken up in futures-oriented pedagogical practice (Contribution 3). Rather than being treated primarily as a by-product of knowledge acquisition or an individual trait, agency can be conceptualized as a central educational aim that is intentionally designed for. The three contributions in this symposium do take important steps to contribute to this aim. Rather than prescribing a singular model of agency, they point to the need for science education to become a space where different forms of agency can be recognised, interrogated, and deliberately cultivated, through research, curriculum design, and teacher education. This, we argue, is essential if science education aims to play a meaningful role in shaping responses to the climate crisis.

Conclusion And Outlook

This symposium contributes to an emerging educational discourse that seeks to reimagine science education as a site for cultivating transformative forms of agency. By interrogating how agency is defined, theorised, and enacted, the three contributions collectively make the case for a shift away from narrow, behavioural models toward more expansive and politically engaged framings. They argue for the design of educational environments where students are equipped to challenge, critique, and change the conditions that produce it.

Importantly, the symposium also points forward. It lays the conceptual and empirical foundations for future research and innovation in science education, particularly in the context of the newly funded EU Erasmus+ project TRACE (Transformative Agency in Climate Education),

coordinated by the University of Innsbruck. TRACE builds directly on the theoretical and pedagogical advances discussed in this symposium, aiming to foster teachers' capacity to design and implement climate education that cultivates collective and political agency. Through a transdisciplinary, practice-based approach, TRACE focuses on supporting students and teachers in exploring how collective and political dimensions of agency can be addressed through climate education. It does so by involving them in the design and implementation of teaching scenarios that integrate other perspectives beyond science education, while also developing tools for self-reflection in regard to agency in the climate crisis.

The work presented here thus represents both a reflection on current limitations and an invitation to envision what science education towards agency could become in the Anthropocene. It affirms that agency is not a peripheral theme but a central challenge, one that demands conceptual precision, interdisciplinary imagination, and pedagogical innovation. Responding to this challenge means creating educational spaces where science is not merely learned but lived, where learners become co-authors of their futures, capable of engaging with complexity not with resignation, but with constructive hope and collective intent.

Strand 10 of the ESERA conference focuses on the intersections of environment, health, and science education, bringing together research that examines how learners and teachers engage with scientific ideas closely connected to individual well-being, societal challenges, and environmental sustainability. Research in this strand addresses pressing issues such as climate change, environmental degradation, and health-related socioscientific issues, while also exploring the pedagogical, conceptual, and affective dimensions of teaching and learning science in these contexts. The papers in this chapter reflect the breadth of work within Strand 10, with a strong emphasis on learners' and teachers' conceptions of environmental and health-related phenomena. Contributions were organized into five subsections, namely, "Climate Change Education and the Climate Crisis", "Transformative Learning in Environmental Education", "Getting Engaged with Nature and Environment", "Sex Education, Equality, and Menstruation", and "Health Conceptions in Social Media".

Most contributions investigate learners' and teachers' understandings and competencies related to environmental topics, including the greenhouse effect, groundwater systems, climate change, and the ozone layer, examining both scientifically accurate conceptions and persistent misconceptions among students and preservice teachers. Together, these studies highlight the complexity of climate science learning and the need for instructional approaches that explicitly attend to systems thinking, uncertainty, and human influences on environmental processes as well as addressing obstacles to integrative, action-competence-oriented climate education. Related papers extend this focus on conceptual understanding to other environmental and health topics, including menstruation and metabolic disease. These contributions illustrate how scientific knowledge in environmental and health domains is intertwined with everyday experiences, cultural norms, and personal relevance. By analysing learners' and teachers' existing ideas, these studies provide insights into challenges for teaching conceptually demanding and socially sensitive topics in science classrooms.

Beyond conceptual knowledge, several papers address environmental competencies, action-oriented education, behaviours, and dispositions. Research on children's connection to nature and preservice teachers' environmental behaviours foregrounds affective and ethical dimensions of science education, emphasizing the importance of fostering responsibility, care, and engagement alongside scientific understanding. Studies examining climate change competence similarly adopt a broader perspective on learning, focusing on the integration of knowledge, skills, and attitudes necessary for thoughtful participation in societal decision-making. Studies on health conceptions argue for inclusive education that addresses stigma and fosters gender equity. A related contribution examines how health knowledge is conceptualized and communicated through digital and social media sources.

Pedagogical design is another key theme across the chapter. Contributions examining the use of learning cycles in high school environmental education and students' development of prototype environmental sensors highlight inquiry-based and design-oriented approaches that actively engage learners in scientific practices. These studies also point to the potential of digital tools and hands-on technologies for supporting data-informed reasoning and deeper engagement with environmental issues.

A notable trend across the chapter is the central role of teacher education. Multiple papers focus on preservice teachers' conceptions, competencies, instructional practices, and behaviours related to environment and health, underscoring the importance of teacher preparation for addressing socioscientific issues in meaningful ways. A second trend is the field's movement toward competency-based and action-oriented frameworks that integrate knowledge, skills, values, and agency. Third, questions of equity — relating to gender, culture, and social justice — recur across subsections, reflecting a broader understanding of what science education in these domains is for. In this regard, these studies highlight both opportunities and tensions in supporting future teachers as they navigate curricular expectations, scientific complexity, and societal relevance.

Positioned within the wider field of science education research, the work in this strand contributes to ongoing debates about the purposes of science education in the context of global environmental change and public health challenges. The papers advance conceptions of scientific literacy that extend beyond content mastery to include critical thinking, ethical awareness, and agency. In doing so, they align closely with the conference themes of sustainability and digital advances, illustrating how environment and health education can support learners in engaging with complex challenges that will shape present and future societies.

Section: Climate Change Education And The Climate Crisis

Alternative Conceptions About The Greenhouse Effect: An Analysis Across Educational Stages

Carmen Brenes-Cuevas, María Armario and Natalia Jiménez-Tenorio
Area of Science Education (Didactics of Experimental Sciences), Department of Didactics, University of Cádiz, Spain.

This study analyses alternative conceptions of the greenhouse effect among high school and postgraduate participants. To this end, responses to an open-ended questionnaire were qualitatively evaluated, using as the analytic instrument one dimension of a construct map developed within a broader study to explore students' initial ideas about the regulation of the planet's climate. The sample comprised 131 participants, divided into two groups: Middle school, high school students, and postgraduate students and active teachers. The findings show that, although educational level influences the level of technical detail in the responses, alternative conceptions persist across all levels. The most frequent include identifying the greenhouse effect as part of the ozone layer, equating it with climate change, and failing to acknowledge its regulatory role in the Earth's climate system. While this latter difficulty is more evident at initial stages, it also appears at advanced levels, underscoring the need to implement targeted teaching, learning strategies that explicitly address these alternative conceptions across all educational stages.

Keywords: Greenhouse effect, alternative conceptions, persistent ideas.

Introduction

Science education plays a pivotal role in shaping an informed citizenry capable of making evidence-based decisions regarding contemporary environmental challenges such as climate change. A sound understanding of the factors that regulate the climate is essential for students, from primary education through university, to develop a critical perspective on human influence on the environment (Morote et al., 2021). Indeed, UNESCO (2021) emphasizes the importance of integrating climate knowledge into school curricula, noting that a deep understanding of these issues is crucial for future citizens.

Nonetheless, numerous learning difficulties persist regarding the regulation of the Earth's climate and its regulatory factors. In particular, a recurrent difficulty is the alternative conception that the ozone layer is a climatic regulator or forms part of the greenhouse effect. This idea often arises from its confused treatment in textbooks (Sakarya et al., 2023), where explanations of these two atmospheric phenomena are insufficiently differentiated, the terminology is complex, and both elements are intrinsically challenging to grasp (Andersson & Wallin, 2000).

This study therefore aims to analyse participants' conceptions of the greenhouse effect across different educational stages, and thus their persistence, with a view to informing future instructional designs that help students overcome these learning difficulties.

Background

In the field of science education, didactic transposition adapts complex phenomena to make them more accessible to students, aligning with their cognitive capacities and supporting progression (Adúriz-Bravo, 2009). In this study, we define the school-science idea of the greenhouse effect

as the atmospheric process of absorption and re-emission of infrared radiation, explicitly highlighting its positive nature as a regulatory factor of the climate, essential for life.

A range of studies has examined the ideas that students and teachers hold about atmospheric phenomena and components. Papadimitriou (2004) investigated prospective primary teachers' conceptions of climate change, the greenhouse effect, and the ozone layer using open-ended questionnaires. The study concluded that most of these preservice teachers struggled to differentiate among these concepts. For example, they believed that the ozone hole is directly related to global warming or that gases in the ozone layer contribute to the greenhouse effect. Along similar lines, though focused exclusively on the greenhouse effect, Sakarya et al. (2023), using open-ended questionnaires, found that students in a Master's program in Environmental Education maintained alternative conceptions about this phenomenon, showing difficulties in understanding the role of atmospheric gases involved and the physical mechanisms underlying the retention of terrestrial heat.

These findings underscore the need to explore new instructional approaches that can help overcome such learning difficulties. In this regard, model-based teaching is conceived as a comprehensive didactic approach in which the teacher structures learning around activities that foster deep understanding and critical thinking, thereby enabling more accurate and reflective explanations of the phenomenon (Oliva, 2019).

This strategy rests on the idea that school models function as representations mediating between learners and scientific knowledge, whose relationship to phenomena is one of similarity rather than exact reproduction of reality (Adúriz-Bravo, 2009). From a semantic view of theories, a theoretical model may take multiple forms, diagrams, tables, physical mock-ups, or drawings, provided it serves to describe, explain, and predict the phenomenon under study (Oliva, 2019).

This approach is particularly powerful in school contexts because it enables work with progressively more complex models that are close to students' initial ideas yet oriented toward more rigorous explanations. Thus, instruction is organized around cycles of model construction, comparison, revision, and application, rather than the transmission of closed definitions (Soto & Couso, 2023). In this sense, structuring learning around models offers a plausible pathway to re-channel alternative conceptions without dismissing them, integrating them instead as a starting point within conceptual progression trajectories (Oliva, 2019).

Analogies play a prominent role within model-based teaching because they help students imagine, visualize, and reason about unobservable entities and complex processes, and they support the organization of knowledge through provisional versions of the model prior to application (Harrison & Treagust, 2006; Jorba & Sanmartí, 1996). However, their effectiveness depends on the teacher's guidance, explicit or otherwise, in helping students recognize both the similarities and the limitations between the analogy and the target phenomenon (Harrison & Treagust, 2006). For the greenhouse effect, carefully designed analogies can anchor core ideas such as radiative balance, absorption/reflection, and its natural regulatory role in maintaining the planet's temperature (Eriksson et al., 2024).

Methodology

Participants

A total of 131 participants residing in the province of Cádiz (Spain) took part in this study: 74 students in 3rd and 4th grades of middle school, 11 students in 1st grade of high school, 39 Master's students (8 from the Master's in Aquaculture and Fisheries, and 31 from the Master of Education), and, finally, 7 in-service teachers at the high school, and university levels.

To explore the presence and persistence of alternative conceptions across educational stages, participants were grouped into two cohorts: Group 1 comprised the 85 middle and high school student participants, and Group 2 comprised the 46 university-level participants (Master's students and practicing teachers). This study forms part of a broader research project aimed at designing, implementing, and evaluating a teaching–learning sequence on the regulation of the planet's climate. In this phase, the analysis focuses on validating a construct map; consequently, the groups were not balanced a priori in the initial design. The configuration of this particular study was established post hoc, once the data had been analysed and the persistent ideas to be characterized in greater depth had been identified.

Instrument

A validated open-ended questionnaire (Brenes-Cuevas et al., 2024) was used as the data collection instrument, consisting of four questions. These questions were designed to address different factors regulating the Earth's climate, such as global ocean circulation, atmospheric circulation, and the greenhouse effect. The present study focused exclusively on the question related to the greenhouse effect: *"What is the greenhouse effect? Why does it occur? Explain it in your own words and represent it using the following diagram."*

Data Analysis Procedure

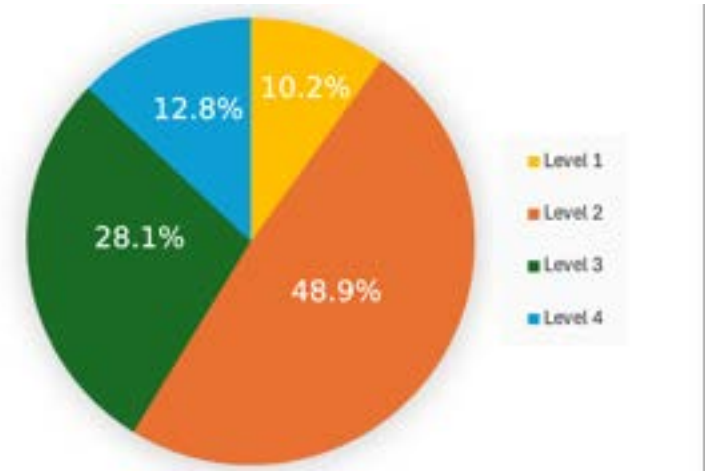
A construct map was developed and validated to analyse the responses related to each of the factors regulating climate. However, as previously mentioned, the present study focuses specifically on one of the dimensions of this construct map, that corresponding to the greenhouse effect (Table 1).

To address the aim of this study, analysing participants' conceptions of the greenhouse effect, a three-phase analytical procedure was applied. In the first phase, responses were classified according to the levels defined in the construct map (Table 1), with the objective of identifying the overall frequency distribution.

Table 1. Greenhouse effect dimension of the construct map.

LEVEL 1	LEVEL 2	LEVEL 3	LEVEL 3
Trivial or blank responses.	Identifies the greenhouse effect as a phenomenon occurring in the atmosphere, possibly mentioning the absorption and/or reflection of solar radiation. Does not clearly define the process and/or interprets it as synonymous with other phenomena (climate change, ozone layer, etc.). Makes no reference to its nature (neither as a natural phenomenon regulating the climate nor as an anthropogenic factor).	Identifies the greenhouse effect as the phenomenon of absorption and/or reflection of solar radiation in the atmosphere, without reference to other phenomena (climate change, ozone layer, etc.), but does not clearly define the process. Makes no reference to its nature (as a natural phenomenon regulating the climate), or attributes it exclusively to anthropogenic factors with negative consequences for the planet.	Identifies the greenhouse effect as the phenomenon of absorption and reflection of solar radiation in the atmosphere, possibly without clearly defining the process. Refers to its positive nature as a regulatory factor of the climate, potentially recognizing it as an essential factor for life.

Subsequently, in the second phase, the set of responses corresponding to participants classified at Level 2 was analysed in greater detail. An emergent system of non-exclusive categories was established to characterize the responses and examine frequency distributions, given the high number of participants identified at this level, as will be discussed in the following section. The resulting categories were:



- Atmospheric phenomenon: Participants identify the greenhouse effect as a phenomenon that occurs in the atmosphere.
- Phenomenon functioning: Participants mention the absorption and/or reflection of solar radiation.
- Nature of the phenomenon: Participants identify the greenhouse effect as either a natural or an anthropogenic phenomenon.
- Ozone layer: Participants associate the ozone layer as part of the greenhouse effect.
- Climate change: Participants identify the greenhouse effect as synonymous with climate change.
- Other: This category includes other low-frequency alternative conceptions that are not trivial enough to be classified under Level 1.

Finally, in the third phase, the frequency of these categories was compared between the two groups of participants classified at Level 2, differentiated by educational level: Group 1 (middle and high school students) and Group 2 (participants with university studies). The aim was to analyse the persistence of alternative conceptions across educational stages.

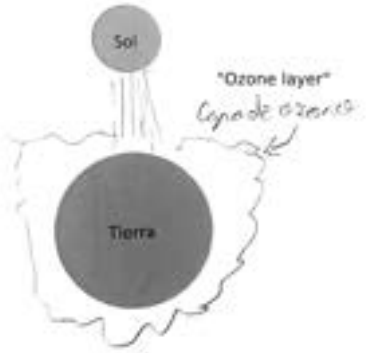
Results And Discussion

Following the established sequence of analysis, the first phase consisted of classifying the responses about the greenhouse effect according to the levels defined in the construct map (Table 1). The analysis revealed a distribution of participants' ideas across all levels (Figure 1), showing a similar percentage (around 10%) at Levels 1 and 4. However, the most representative level was Level 2, accounting for 48.9% (64 out of 131 participants). These participants understood the greenhouse effect as a phenomenon occurring in the atmosphere but did not clearly define the process and/or interpreted it as synonymous with other phenomena, such as climate change or the ozone layer, without referring to its nature. For this reason, Phase 2 of this study focuses on the distribution and categorization of these ideas.

Fig. 1. Distribution by levels of participants' responses about the greenhouse effect.

In the second phase of the study, the responses of the 64 participants classified at Level 2 were analysed in detail according to the categorization described in the previous section. The results show, first, that 93.8% of the participants at this level (60 out of 64) identified the greenhouse effect as an atmospheric phenomenon. However, this identification was not always accompanied by complete explanations of how the phenomenon operates (Figure 2).

Figure. 2. Example of a participant's representation at Level 2.



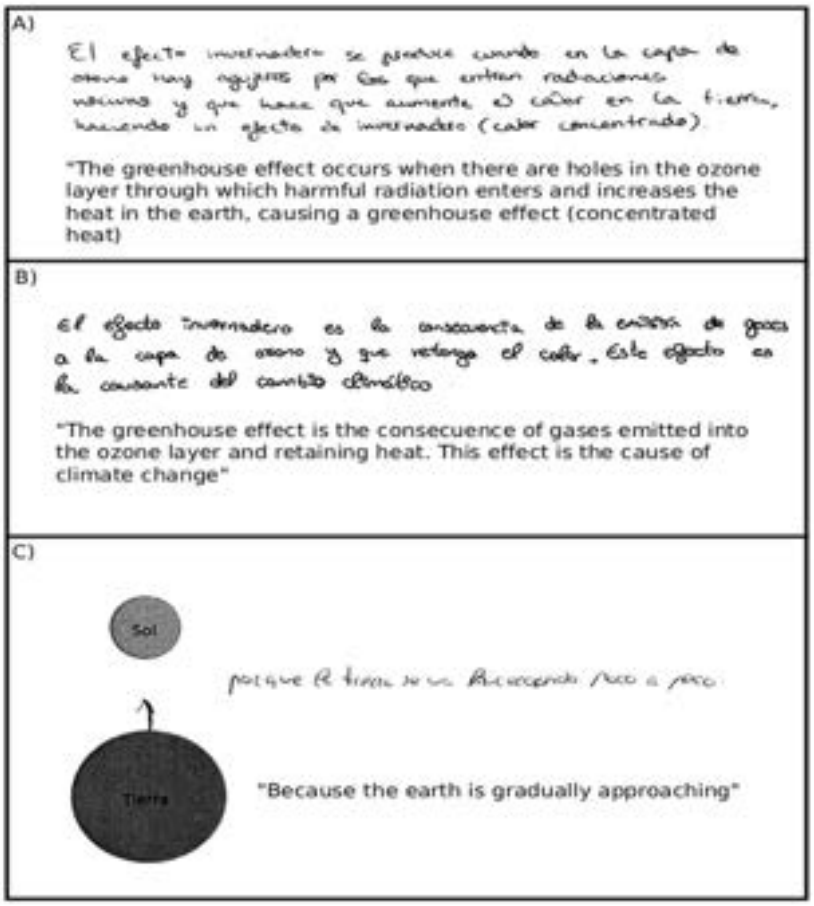


Figure. 3. Example of Level 2 participants' responses classified into different categories. a) Ozone layer, b) Climate change, and c) Other.

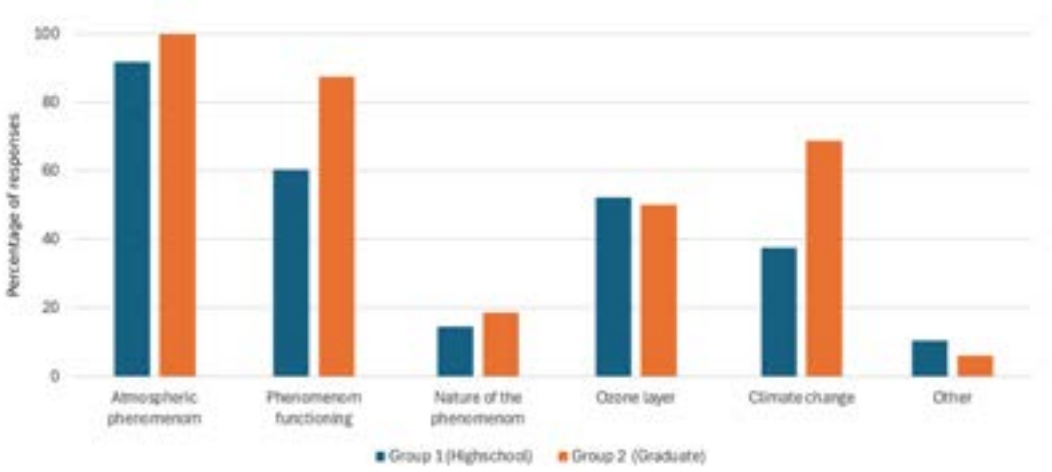

Regarding the functioning of the phenomenon, 67.2% of participants (43 out of 64) mentioned that the greenhouse effect involves the absorption and/or reflection of solar radiation. Despite this, it is noteworthy that the category "Nature of the phenomenon" shows an absence of reference to the natural character of the greenhouse effect in 54 out of 64 participants (84.4%). Likewise, in the "Ozone layer" category, 33 participants (51.6%) associated this element as part of the greenhouse effect. Finally, confusion between the greenhouse effect and climate change was

observed in 23 responses (35.9%), while 6 of the 64 participants (9.4%) provided answers included in the "Other" category (Figure 3).

Finally, in the third phase of the analysis, with the aim of examining the persistence of alternative conceptions across different educational stages, the responses of participants classified at Level 2 of the construct map from the previous phase were separated according to their educational level. The first group consisted of middle and high school students, while the second group included participants with university studies. The frequencies obtained for each category were compared between the two groups.

Figure 4 presents the results of this analysis. It can be observed that all university-level participants (100%) (Group 2) identified the greenhouse effect as an atmospheric phenomenon without clearly defining the process, which is why they are placed at Level 2 of the construct map. Similarly, although with a slightly lower percentage (91.6%), middle and high school student participants (Group 1) also mentioned this category at this level.

Fig. 4. Percentage of responses according to the Level 2 categorization for both participant groups. Non-exclusive categories.

Furthermore, 88% of Group 2 participants mentioned that the greenhouse effect involves the absorption and/or reflection of solar radiation, while only 60% of Group 1 participants expressed this idea. This suggests a greater ability to describe specific physical aspects of the phenomenon at more advanced educational stages, which seems logical given their training. However, both groups showed similar percentages of responses that did not reflect an understanding of the nature of the phenomenon, 85.4% in Group 1 and 81.3% in Group 2. In other words, only 14.6% and 18.7%, respectively, identified the greenhouse effect as a natural or anthropogenic phenomenon, revealing an incomplete understanding of the phenomenon at both educational levels.

Regarding alternative ideas, the results show that a similar percentage of participants in both groups considered the ozone layer to be part of the greenhouse effect, 52% in Group 1 and 50% in Group 2. These findings suggest that this alternative conception persists even at advanced educational stages. However, confusion between climate change and the greenhouse effect was more prevalent among university students (68.8%) than among middle and high school students (37.5%). This finding highlights the complexity that university-level participants face when differentiating between related climatic phenomena or elements, despite their advanced education. It also shows that, while alternative conceptions are present in both groups, the characteristics of each educational stage influence the type of ideas expressed.

In the case of university students, this tendency may be explained by deeper but fragmented knowledge, which allows them to recognize the relationship between the greenhouse effect and

climate change. However, they fail to clearly distinguish the nature of the former as a natural phenomenon, in contrast to the anthropogenic increase in greenhouse gases that intensifies this effect and contributes to climate change. This partial understanding may lead to associations with other atmospheric elements, such as the ozone layer (Roßbegalle & Ralle, 2016). Conversely, middle and high school students, having less structured knowledge, tend to provide simpler and shorter explanations, which reduces associations between phenomena, although this does not imply stronger understanding, but rather lower conceptual complexity (Shepardson et al., 2011).

Alternative conceptions related to the ozone layer and climate change persist over time, consistent with the findings of Sakarya et al. (2023), who conducted a study with Master's students in Environmental Education. This pattern of alternative conceptions across different educational stages confirms the need for model-based teaching that promotes the integration and articulation of the various atmospheric phenomena and components.

In order to improve educational practice and in line with the results obtained, it is proposed to integrate analogies within model-based teaching–learning sequences to facilitate the shift toward Level 3 or 4 explanations, in which students cease to associate these phenomena indiscriminately and begin to recognize the greenhouse effect as a natural process regulating the climate. Analogies, by involving the comparison between elements of the target phenomenon and those of the model, make it possible to identify both the similarities and the differences between them. This comparative process helps distinguish the mechanisms characteristic of each phenomenon or element, fostering a more structured and accurate understanding of the processes involved. In this case, it enables comprehension of the natural greenhouse effect as a physical process of infrared radiative energy balance, while the ozone layer acts as a UV filter, without intervening in this balance (Harrison & Treagust, 2006). In this way, analogies serve as cognitive anchors that help students establish clear conceptual boundaries, supporting the construction of mental models and a more precise interpretation of atmospheric processes (Eriksson et al., 2024).

Conclusions

This study analysed participants' conceptions of the greenhouse effect, identifying alternative conceptions that persist across different educational stages, even among students at higher levels. The results reveal difficulties, particularly in differentiating between the greenhouse effect and concepts such as the ozone layer and climate change. Although the university-level participants in this study demonstrated a greater ability to integrate technical aspects, such as the reflection and absorption of solar radiation, other alternative conceptions persist, such as viewing the ozone layer as part of the greenhouse effect, which hinders the achievement of the reference school-science model.

These findings highlight the need to implement educational strategies that address these difficulties from early stages, designing teaching–learning proposals that promote a clear and precise differentiation of these concepts (Andersson & Wallin, 2000). Model-based teaching strategies and the use of modelling resources may be effective approaches to this end (Papadimitriou, 2004). In this regard, the use of carefully selected analogies, guided by the teacher, is understood as a viable option to facilitate the understanding of the physical processes involved (Harrison & Treagust, 2006; Eriksson et al., 2024).

ESERA 2025 Copenhagen

Assessing Climate-Change Competence in Pre-Service Teachers: Knowledge, Attitudes, and Behavioural Engagement in Climate Education

Blanca A. García Yelo, Vanessa Ortega Quevedo, Ana Cano Ortiz, Elena García Buitrago and Eugenia García García
Facultad de Educación – CFP (UCM), Spain

The effects of accelerated climate change on nature and society are evident, primarily driven by human-induced greenhouse gas emissions, causing severe and often irreversible damage. Despite scientific consensus, climate change denial has increased, particularly among far-right political groups, hindering mitigation efforts and heightening societal uncertainty. Education plays a crucial role in addressing this challenge by fostering climate literacy, equipping individuals with knowledge, skills, and attitudes necessary for action. The Climate-change Competence (C3) framework was introduced to assess climate literacy in education, later refined to evaluate pre-service teachers in different countries, emphasizing its role in shaping future societal responses. This study seeks to assess the level of climate-change competence among pre-service teachers at Universidad Complutense de Madrid, contextualizing the C3 framework within their specific educational environment. Our findings align with previous research, indicating that pre-service teachers in Madrid demonstrate high levels of climate- change competence, particularly in knowledge and attitude dimensions. They recognize the causes and consequences of climate change and express a proactive stance toward mitigation. However, their commitment to concrete actions remains moderate, especially in areas related to food and diet. No significant differences were found based on academic background or gender, except in attitudes, where undergraduate and female students showed greater commitment. These results reinforce the need to strengthen behavioural engagement strategies in climate education to enhance real-world action

Keywords: Climate Change Competence, Pre-Service Teachers, Spain

Introduction

Context And Theoretical Framework

The impacts of accelerated climate change on natural systems and human societies are indisputable (Wheeler and Von Braun, 2013; Dao et al., 2023; Abbass et al., 2022). In its most recent report published in 2023, the Intergovernmental Panel on Climate Change (IPCC) has reaffirmed the anthropogenic origin of global warming, primarily driven by greenhouse gas emissions, which is leading to significant, and in some cases irreversible, damages and losses. However, despite the scientific consensus confirming accelerated climate change as a factual phenomenon, climate change denial has intensified in recent years (Washington and Cook, 2011; Dunlap & Brulle, 2020). In this context, far-right parties and political actors are increasingly promoting denialist narratives regarding the consequences of climate change (Gruber, 2025), hindering the adoption of mitigation measures, complicating efforts to alleviate current impacts, and increasing societal uncertainty (Wong-Parodi and Feygina, 2019).

Nevertheless, governments have access to a broad range of policies and strategies to address climate change. Among the various actions aimed at mitigating its effects, education emerges as a central element for enhancing knowledge, skills, and attitudes in response to the social and environmental challenges posed by climate change. Numerous studies highlight the importance of climate change literacy as a key tool to confront this issue effectively (Johnston & Cook, 2019; Nusche et al., 2024). Given their pivotal role within educational systems, teachers constitute one

of the fundamental pillars for fostering climate change literacy among students, who are future citizens and among those most vulnerable to climate change impacts. However, there is currently no clearly defined approach or legislative framework to systematically guide the implementation of this educational responsibility across different states.

To begin developing a strategy that positions education as a driving force for societal mobilisation, it is essential to assess the extent to which current educational systems prepare students to understand climate change, raise awareness, and promote action (Fuertes et al., 2020). In their seminal work, Fuertes et al. (2020) introduced the concept of Climate Change Competence (C3), defined as a "framework to develop understanding, awareness and abilities related to Climate Change through Education", enabling individuals to effectively address the global crisis through formal education. Subsequently, Ferrari et al. (2022) operationalised this competence by defining three distinct dimensions through a validated assessment questionnaire comprising 36 items, administered to a sample of over 500 primary and secondary school teachers. More recently, these dimensions were revised and adapted for pre-service teachers in Honduras and Spain using an updated set of items (Ferrari et al., 2024).

Aims Of The Research And Hypothesis

This study aims to determine the degree of climate-change competence of the pre-service teachers from the Universidad Complutense de Madrid (Madrid, Spain), defining the C3 competence in their context.

In the Spanish context, pre-service teachers are trained within higher education programs that increasingly acknowledge sustainability and climate change, yet research consistently shows important gaps between curricular intentions and actual competences. Previous studies indicate that Spanish pre-service teachers tend to display limited and fragmented environmental and climate-related knowledge, while simultaneously expressing generally positive attitudes, a sense of responsibility, and a moderate level of pro-environmental behaviour (Álvarez García et al 2018). This imbalance suggests that favourable dispositions towards environmental issues are not always accompanied by sufficiently robust conceptual understanding or by a strong capacity to translate concern into effective educational practice. Moreover, recent evidence highlights the central role of affective dimensions in this context (Ballegeer et al, 2024; Fuertes-Preito, et al, 2024). Subject-matter knowledge alone does not directly predict pre-service teachers' willingness to engage in climate change education, but rather exerts an indirect influence mediated by attitudes and emotional engagement. Emotions related to climate change appear to act as key activating or inhibiting factors, shaping both mitigation-oriented behaviours and the intention to include climate change in future teaching. In fact, Spanish pre-service teachers can be broadly characterized into distinct profiles, ranging from more "concerned" individuals, who show higher levels of climate-change competence and a stronger willingness to act as educational change agents, to more "sceptical" ones, who exhibit lower competence and reduced engagement. Taken together, this body of research suggests that the specific context of Spanish pre-service teachers is defined by a combination of insufficient knowledge, generally positive but unevenly operationalized attitudes, and emotionally driven dispositions that critically condition their readiness to teach about climate change.

Research Methodology Design And Materials.

Following the methodology described by Ferrari et al (2022), and considering the adaptations proposed by Ferrari et al (2024) where the main dimensions and subdimensions of the Climate-Change Competence (C3) were redefined (table 1), the climatic competence of preservice teachers from the Comunidad de Madrid (Spain) was determined. By means of a closed-ended Likert-scale test formed by 53 questions (Ferrari et al., 2024), with five response categories (from false/never/totally disagreed to true/always/totally agreed), the C3 competence spectra was defined for a total of 316 students from six different degrees, all pertaining to the Facultad de Educación – CFP (Universidad Complutense de Madrid). The mean values of the whole set of questions defining the subdimensions of the climate competence spectra were calculated, together with the means for the dimensions.

In order to determine if gender or university background condition the C3 competence spectra, U-Mann Whitney (non-parametrical) and T-Student (parametrical) analyses on C3 competence dimensions were performed (depending on the distribution of the data groups).

Results

Tables 1 (previous page) and 2 resume the results for these analyses defining C3 competence spectra of preservice teachers from the Universidad Complutense de Madrid and its relationship with gender and university background.

Table 2. Results of the statistical analysis to compare C3 competence dimensions between students from different university backgrounds and between genders.

		n	KNOWLEDGE		ACTION		ATTITUDE	
			Mean	Statistics	Mean	Statistics	Mean	Statistics
University background	**Degree**	259	4,11	p = 0.289 U = 1.059	3,32	p = 0.590 U = 0.590	4,09	**p = 0,048** **T = 1.681**
	Master	57	4,16		3,35		3,98	
Gender	**Male**	44	4,18	p = 0.096 U = -1.667	3,38	p = 0.403 U = -0.837	3,94	p = 0.055 T = -1.629
	Female	271	4,10		3,32		4,09	

Discussion

Our results are aligned with those exposed by Ferrari et al (2022) and (2024), with relatively high values for all three dimensions of the Climate-change competence. Pre-service teachers from Madrid demonstrate an adequate capacity to identify the principal causes and consequences of climate change (mean scores for knowledge dimensions and subdimensions close to 4, reflecting agreement with the test items and statements), and they also display a proactive stance towards addressing climate change (mean values for attitude dimensions and subdimensions near 4, indicating agreement with the proposed actions included in the questionnaire). However, in line with previous research on climate change mitigation behaviours among both pre-service and in-service teachers (Seroussi et al., 2019; Banos-Gonzalez et al., 2021; Tolppanen et al., 2021), our results reveal a moderate level of commitment regarding the actions undertaken to reduce the

causes and impacts of climate change (mean values for action dimensions and subdimensions around 3.5, suggesting partial engagement in climate action), with behaviours related to food choices and dietary habits obtaining the lowest scores. Conversely, no significant differences were observed in C3 competence according to university background or gender, apart from the attitude dimension, in which undergraduate students showed a higher level of commitment to combating climate change than postgraduate students

These patterns are evident not only when analysing the full sample, but also when considering university background and gender, with consistently higher scores in the knowledge and action subdimensions. No statistically significant differences were found (results not shown) across most subdimensions between undergraduate and postgraduate students, nor between males and females, except for LOC and WTT, which did show significant differences. However, minor variations can be identified in the attitudinal subdimensions. Overall, these findings are consistent with previous research on climate change awareness influenced by academic background and gender (Clayton et al., 2023). In general, undergraduate students obtained higher scores than master's students, reflecting a more proactive attitude towards addressing the causes of climate change. A plausible explanation for this pattern is that the more advanced and specialized training of master's students may be associated with a higher level of critical awareness, scepticism, and a deeper understanding of the structural limitations, uncertainties, and shortcomings of many climate change mitigation actions implemented in practice. This greater recognition of complexity may, in turn, reduce their perceived efficacy and willingness to adopt a proactive stance. The same difference can be observed for male and female students, where women are more willing to take action to preserve the environment.

Conclusions

Our findings shown that pre-service teachers from Madrid exhibit relatively high levels of Climate-change competence, particularly in knowledge and attitude dimensions. They recognize the causes and consequences of climate change and express a proactive stance toward mitigation. However, as observed in previous studies, their actual commitment to climate action is moderate, with lower engagement in behaviours related to food and diet.

No significant differences were found in Climate-change competence across academic backgrounds or gender, except in the attitude dimension, where undergraduate students displayed greater commitment than postgraduates. Similarly, female students showed a higher willingness to act than males, consistent with prior studies. These results reinforce the importance of integrating behavioural engagement strategies in climate education.

Following the exploration of Climate-change Competence (C3) among pre-service teachers (PSTs) at the Facultad de Educación – CFP of the Universidad Complutense de Madrid (UCM), future research aims to further investigate this competence in relation to didactic variables that reflect PSTs' concerns regarding Climate Change Education. This study will extend beyond the Comunidad de Madrid, incorporating samples from other Spanish regions as well as countries such as Honduras.

Students' Misconceptions About Heatwaves And Their Interconnection With Climate Change

Maria Christoforaki, Evangelia Mavrikaki and Apostolia Galani
National and Kapodistrian University of Athens, Department of Pedagogy and Primary Education, Greece

The increasing frequency and severity of heatwaves globally highlights the urgency of integrating this pressing issue into education. Providing future generations with the knowledge to comprehend the science behind heatwaves and their relationship to climate change is essential. Such knowledge empowers students to adapt effectively, develop resilience, and acquire skills necessary for a sustainable future. This study assesses school students' perceptions and knowledge of heatwaves among secondary students from Belgium, Greece, Italy and Romania. A quantitative approach was employed, with data gathered through a questionnaire (N=392). The findings reveal that while some students have basic understanding of heatwaves, significant misconceptions persist, particularly concerning the connection between heatwaves and climate change. Furthermore, many students cannot directly decide the relation between heatwaves and health risks. These results underscore the need for targeted educational interventions. By enhancing students' understanding of the causes and effects of heatwaves, educators can foster a more engaging and impactful learning experience. These efforts are crucial for enhancing preparedness and creating a generation better equipped to tackle climate change challenges.

Keywords: Environment, Science Education, Sustainability

Introduction

Heatwaves pose a growing natural hazard with severe consequences for human health, ecosystems and infrastructure (Murray et al., 2012). Despite the scientific consensus on the interconnectedness of climate change, global warming, and heatwaves, pervasive misconceptions continue to endure (Bostrom et al., 1994). These misconceptions encompass a lack of clarity regarding the relationship between heatwaves and climate change confusion surrounding the mechanisms that cause heatwaves (Williams et al., 2019), underestimation of the health hazards posed by heatwaves, and a widespread deficiency in knowledge about proactive measures for heatwave preparedness (Lampl et al., 2023). These arise from complex factors, hindering public understanding and response such as, (a) limited scientific literacy (Chowdhury et al., 2012), (b) representations in the media (Perkins, 2015), (c) personal experience bias (Ruth et al., 2019), (d) information overload and fatigue (Perkins, 2015), (e) lack of trust in authorities (Chowdhury et al., 2012).

The need for targeted public education campaigns that emphasize the dangers of heatwaves and provide clear guidance on risk abatement and preparedness strategies is evident (Yepéz et al., 2019). By incorporating the issue of heatwaves into school curricula, we foster climate literacy to make informed decisions and advocate for effective mitigation and adaptation strategies (VanderMolen et al., 2022). Understanding students' existing perceptions of heatwaves, including their potential misconceptions, is important for designing targeted educational interventions that foster scientific knowledge and promote responsible environmental stewardship (VanderMolen et al., 2022). Based on the above, we considered it valuable to investigate whether school students are aware of the widespread presence of heatwaves and their associated health risks. The research questions guiding our study are:

(R.Q.1) How do students self-report their level of environmental awareness ?

(R.Q.2) How well are students informed about (a) the prevalence of heatwaves and (b) the associated health risks, while interrelated with climate change, across the countries of the research?

(R.Q.3) What is the relationship between students' self-reported environmental awareness and experience of teaching with their perceived knowledge of heatwaves and their interconnection with climate change?

Materials And Methods

To address the above-mentioned questions, we conducted quantitative research involving N=392 students (grades 5–8) from Belgium, Greece, Italy and Romania. The participants were selected through convenience sampling, with their age and gender distribution shown in Table 1. Both ethical approval and license were obtained to conduct the research.

Table 1. Age and gender of the sample per country and in total.

		Country				
		Belgium N=62	**Greece N=120**	**Italy N=70**	**Romania N=140**	**Total N=392**
Age	mean±SD	13.77±0.15	12.55±0.07	12.81±0.167	15.62±0.14	13.69±0.13
Gender	Male N(%)	30(48.4)	59(49.2)	39(55.7)	84(60.0)	212(54.1)
	Female N(%)	32(51.6)	58(48.3)	31(44.3)	56(40.0)	177(45.2)
	Other N(%)	-	3(2.5)	-	-	3(0,7)

A 31-item questionnaire was developed and distributed online to students via Google Forms during the November of 2023, to evaluate their knowledge of heatwaves, including their prevalence and associated health risks. The questionnaire has been based on insights from relevant literature (Arslan et al., 2012; Cheng et al., 2019; Fernandez et al., 2015; Huang et al., 2011; Macintyre et al., 2018; Koutra-Heliopoulou et al., 2023; Meehl & Tebaldi, 2004). Besides questions about the profile of the sample (6 items addressing age, country, grade, gender, environmental awareness, and students' teaching experiences), 25 5-point Likert scale items (1=totally disagree to 5=totally agree) focused on:

(a) *General Knowledge* about heatwaves (GK) (C1-C16) including heatwaves' prevalence, and their interconnections with climate change,

(b) *Health Knowledge* (HK) about Heatwaves and their associated health-risks (C17-C25). Negatively worded items were reversed so that scores ranged from 1 (low knowledge) to 5 (high knowledge).

It is important to clarify that the item on students' teaching experiences referred to any formal lessons, workshops, or classroom discussions students had received about heatwaves, climate change, or related environmental topics.

The reliability of the instrument and the two subscales was estimated based on Cronbach's alpha and the results were considered moderate and acceptable (Nunnally, 1978; Taber, 2018) (Table 2).

Table 2. The questionnaire's and subscale's reliability.

Subscale	Cronbach's Alpha	Items
General_ Knowledge about heatwaves	.695	8
Health_ Knowledge about heatwaves	.612	17
Total	*.740*	*25*

Results

Students self-reported a medium level of environmental awareness (3.48±0.87), and a low level of exposure in heatwaves teaching (1.58±0.49), which varied significantly across the countries (F=15.646, p<.001). Students from Italy have received the most extensive teaching about heatwaves (=1.91±0.28) compared to the others.

They demonstrate a medium level of knowledge about heatwaves and their health-related issues (Health Knowledge – HK), as well as their prevalence and connections to climate change (General Knowledge – GK), However, scores differ significantly between countries (Table 3), with students from Greece and Romania showing the highest levels.

Table 3. Students' knowledge about heatwaves.

	Belgium	Greece	Italy	Romania	Total
Health _ Knowledge*	3.26±0.306	3.63±0.695	3.34±0.438	3.61±0.712	*3.52±0.635*
General _ Knowledge**	3.00±0.304	3.48±0.459	3.08±0.343	3.40±0.420	*3.30±0.444*

*F=7.209, p<.001, **F=25.65, p<.001.

Going deeper on students' answers (Table 4) regarding their General Knowledge of heatwaves, our findings show that 53.9% of students recognize the link between climate change and heatwaves (Q5) and 56.4% of students recognize that climate change makes heatwaves more frequent and intense (Q3), whereas only 22.2% are aware of the broader economic impacts of heatwaves on European cities, such as reduced productivity and tourism (Q10).

Regarding students' Health Knowledge of heatwaves (Table 4), the data reveal significant gaps. Only 49.5% of students correctly associate extreme heat with heat-related illnesses (Q22). Furthermore, 46.9% identify excessive sweating as a sign of heat stress (Q23) and only 55.8% of students recognize that individuals with heart problems are more vulnerable during heatwaves (Q24). However, 49.6% understand that the elderly and young children are more susceptible (Q25), showing that nearly one-fifth may not fully grasp the disproportionate risks for these groups.

Table 4. Students' distribution of answers in each item regarding their knowledge about heatwaves.

Questions	Disagree*	Neutral	Agree
General Knowledge			
Climate change is making heatwaves less frequent and less intense.	32.6%	32.4%	34.9%
Climate change is making heatwaves more frequent but less intense.	36.4%	36.5%	26.5%
Climate change is making heatwaves more frequent and more intense.	17.6%	26.0%	56.4%
Climate change is making heatwaves less frequent but more intense.	34.3%	36.1%	29.6%
Climate change has no connection to heatwaves.	53.9%	24.6%	21.5%
Heatwaves do not affect European cities differently from other regions.	35.1%	35.3%	29.6%
Heatwaves can lead to an increase in air pollution in European cities.	15.8%	29.9%	54.2%
Heatwaves can cause an increase in energy demand and strain on the power grid in European cities.	16.1%	36.8%	47.0%
Heatwaves can cause negative health impacts for vulnerable populations in European cities.	14.6%	31.2%	54.2%
Heatwaves can lead to economic impacts such as decreased productivity and tourism in European cities.	18.6%	34.5%	49.9%
Heatwaves can exacerbate the urban heat island effect in European cities.	17.7%	42.4%	39.9%
Heatwaves affect cities the same way across Europe.	33.2%	31.6%	35.2%
Sprinklers in open grounds and fans can play a role in cooling.	20.7%	41.6%	37.8%
Creating forests within cities and green corridors are an effective way to shift airmass to cool large areas within a city.	17.3%	32.3%	50.4%
If you wear dark clothes you feel cool in summer.	55.4%	23.3%	21.3%
Windows and doors should be opened at noon on hot days.	36.8%	28.9%	34.2%
Health Knowledge			
Fever, fatigue, and chest tightness are common symptoms of heat stroke.	16.3%	35.5%	48.2%
Some medicines can increase the risk of heatstroke.	23.8%	38.6%	37.6%
High environmental temperature can cause death.	14.6%	31.9%	53.5%
Heat waves are caused by high temperature and low rainfall.	15.8%	29.4%	54.8%
Extreme heat exposure is responsible for heat-related illnesses.	16.8%	33.7%	49.5%
Excess sweating during a heat wave can be a sign of heat stress.	14.9%	38.1%	46.9%
Individuals suffering from heart problems are highly vulnerable during a heatwave.	13.6%	30.6%	55.8%
The elderly and young ones are more vulnerable during a heat wave.	18.1%	32.3%	49.6%
The greenhouse effect is mainly caused by the depletion of the ozone layer.	17.6%	40.1%	42.3%

Students' environmental awareness and teaching experience show a very low but statistically significant correlation with HK and GK (r= .147, r=.005) (r= .134, r=.011).

Discussion

Our results highlight gaps in heatwave education despite students reporting a moderate level of environmental awareness. The findings reveal notable differences in students' environmental awareness across countries, reflecting disparities in the prioritization of heatwave education. These variations may stem from differences in national curricula, the perceived local relevance of heatwaves, or broader environmental education policies, issues that merit further exploration. Greece and Romania demonstrated higher, though still moderate, levels of knowledge, suggesting either a stronger educational emphasis or more extensive public awareness initiatives. However, additional research is needed to substantiate these interpretations. Targeted educational interventions may be particularly beneficial for Belgium and Italy, where students' understanding appears more limited.

Students' knowledge about heatwaves also varied substantially. Many were unaware of the broader economic consequences of heatwaves on European cities, indicating a need for more comprehensive climate education that addresses both direct and indirect impacts. Only about half of the participants correctly associated extreme heat with heat-related illnesses or recognized excessive sweating as a symptom of heat stress, findings that reinforce earlier calls (Knowlton et al., 2009) for more systematic education on the health dimensions of heat exposure. As Hajat et al. (2014) emphasized, the lack of recognition of heat stress symptoms can delay appropriate responses, thereby increasing health risks.

Furthermore, nearly one-fifth of students did not fully grasp the disproportionate risks that heatwaves pose for vulnerable populations such as the elderly, young children, and individuals with pre-existing health conditions. The weak correlation between students' environmental awareness, teaching experiences, and their knowledge of heatwaves underscores the need for targeted educational strategies that explicitly link these domains.

Overall, although many students recognize the connection between climate change and heatwaves, significant gaps in understanding remain. Addressing these through focused climate and health education could strengthen students' preparedness, enhance adaptive behaviours, and build resilience to climate-related challenges.

Taken together, future directions in climate change and heatwave education should move beyond the mere transmission of scientific facts toward cultivating students' sense of agency and connection to global environmental challenges. Educational interventions must be intentionally designed to embed these topics within science curricula in ways that are both contextually meaningful and socially relevant. Such approaches should aim to challenge misconceptions, deepen conceptual understanding, and foster adaptive and responsible action. Cross-national research will be essential to continue to explore how diverse educational contexts can sustain these transformative learning experiences, ensuring that education in climate change and sustainability becomes an empowering dimension of students' scientific literacy and civic identity.

Limitations

The small sample size per country limits the generalization of our conclusions to the broader population in the countries researched. At the same time, relying on self-reported measures introduces potential biases like social desirability and recall errors. Additionally, while demographic factors were considered, other relevant variables were not included.

First Approaching To Preservice And Inservice Teachers Conceptions About Groundwater

Eugenia García-García[1], Vanessa Ortega-Quevedo[1], María Antonia López-Luengo[2] and Blanca Ana García-Yelo[1]
[1]Faculty of Education-CFP, Complutense University of Madrid, Spain
[2] Faculty of Education, University of Valladolid, Segovia Campus, Spain

Meeting the enormous water needs of the human population and the agricultural, industrial and technological sectors is a sustainability challenge recognised by the United Nations. The overexploitation and pollution of aquifers pose a major threat to freshwater availability, especially in a context of climate change and increasing demand. This situation, in addition to being an environmental challenge, represents an educational one: understanding how groundwater systems function is essential for preparing citizens to make informed decisions about water management. This study explores the knowledge of primary and secondary school teachers (78 trainee and practising teachers) about groundwater and aquifers through an exploratory design with quantitative and qualitative analyses. The results show limited knowledge of the concept of aquifers and groundwater, as well as of their distribution and movement. Therefore, there is a need to reinforce and improve teachers' understanding of this topic, given its importance for humanity and ecosystems.

Keywords: Science Literacy, Teacher Beliefs, Groundwater

Introduction

The demand for water has increased exponentially over the last century (Boretti and Rosa, 2019), leading to the overexploitation of aquifers (Andreu Rodes and Fernández Mejuto, 2019), as well as the effects of climate change (Abtew and Melesse, 2013) and pollution (Andreu Rodes and Fernández Mejuto, 2019). Ensuring the availability of water for humanity and ecosystems is therefore considered essential for sustainability and is explicitly reflected in the SDGs. However, several studies have shown that groundwater—the largest reservoir of liquid freshwater on Earth—barely appears in students' representations of the water cycle (Ben-Zvi-Assarf and Orion, 2005a; Pan and Liu, 2018), or appears exclusively as lakes, rivers or underground caves (Ben-Zvi-Assarf and Orion, 2005a; Ben-Zvi-Assarf and Orion, 2005b; Covitt et al., 2009; Unterbruner et al., 2016). Textbooks also show room for improvement in this respect (Reyero et al., 2007; De Pedro Rodríguez & de Soto García, 2023), contributing to the persistence of alternative conceptions.

Teachers play a key role in educating a citizenry that is aware of and responsible for these challenges. However, research on teachers' conceptions of groundwater is scarce, despite its relevance for scientific literacy and sustainability education. This preliminary work therefore seeks to answer the following questions: Do teachers know the quantitative importance of groundwater within total continental liquid water? Do they have an adequate understanding of what an aquifer is and how groundwater behaves?

Methodology

The research has an exploratory scope. Data collection combines quantitative and qualitative approaches through a questionnaire containing open and closed questions. It was administered anonymously at the beginning of several groundwater workshops, meaning that sampling was

non-random and based on convenience. Table 1 shows the questions linked to the research questions posed.

Table 1. Survey questions regarding groundwater.

It marks the percentage represented by groundwater among continental liquid waters <5; 5-20; 20-40; 40-60; 60-90; >90%
What is an aquifer?
Draw how the water is found in the subsoil, take a photograph and upload your drawing here.
How does groundwater move?

A total of 78 individuals participated in the study, providing informed consent: 32 pre-service primary school teachers (PSTP), 31 pre-service secondary school teachers (PSTS) (graduates in Biology, Environmental Sciences, Geology, Geological Engineering and Biochemistry, in decreasing proportion), and 15 in-service teachers (IST), including 8 graduates in Education or other non-scientific fields and 7 with scientific degrees.

Quantitative data analysis focuses on describing the results obtained. Qualitative analysis was conducted using a category system defined inductively through an in-depth reading by the authors (Table 2). The reliability of this system was verified through an inter-observer process in which two researchers applied the category system to a 20% sample of the responses. The resulting coding was subjected to a concordance analysis (Cohen's kappa) using Epidat software. The value obtained (0.849) indicates a high level of agreement (Landis and Koch, 1997). The few discrepancies were resolved among the authors, and the final application of the system was carried out on the full set of qualitative data.

Table 2. Inductively generated system of categories and subcategories.

Category	Subcategory (code)	Description
Definition/representation of aquifers and groundwater	Material capable of holding water	Rock formation or geological material with pores or holes in which water can be stored by infiltration.
	Lake/Pond/River/Place where the water is found in the subsoil	Cavity, stream, or area where groundwater is located
	Reservation/Deposit/Warehouse	Water storage susceptible to exploitation by man
	It is connected to the outside (rivers, sea, sea, etc.).	The water in the subsoil is not stagnant, but communicates with rainwater and/or water from rivers/lakes
Groundwater behaviour	Infiltrates (without specifying where)	Penetrates down
	Moves between pores, capillaries	It penetrates, infiltrates through the gaps in the ground and rocks
	It moves by currents, roads	Similar to rivers or external streams
	Moves (others)	Other factors that condition movement such as gravity, water pressure, tides, etc.
	Unclear/ Don't know/doesn't answer	They do not answer or answers that are difficult to categorize.

Results

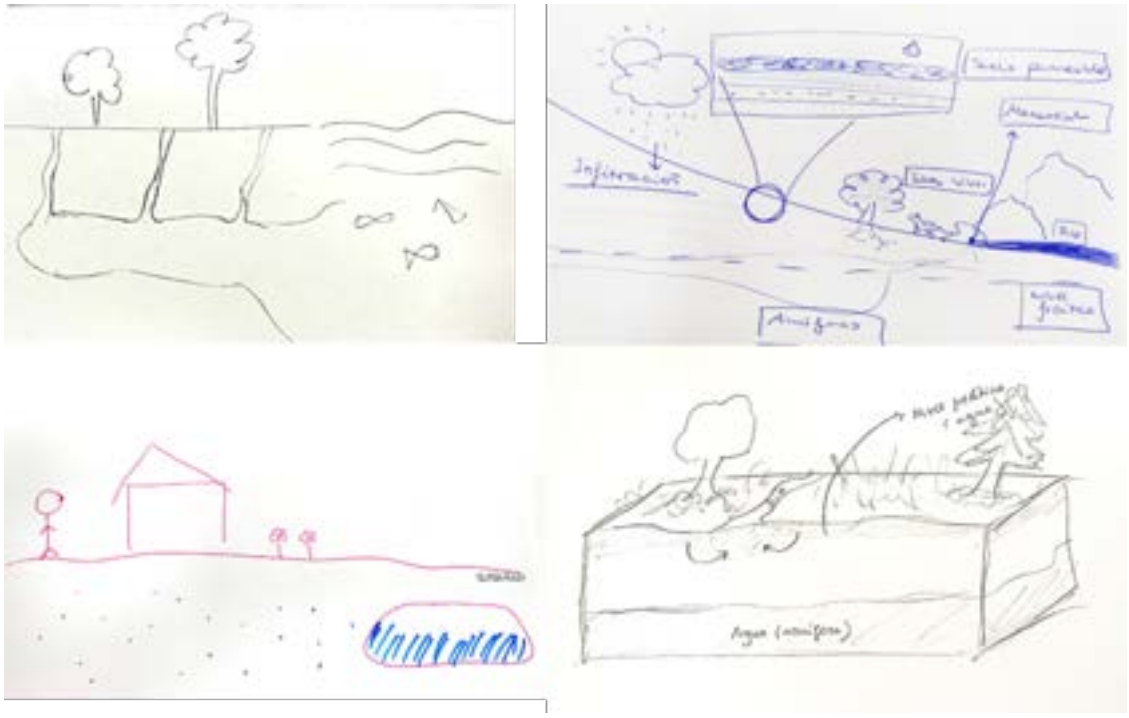
The first research question—whether teachers know the percentage of freshwater that groundwater represents within total available continental water—is addressed through the quantitative results of the first questionnaire item. Table 3 shows the results by participant group. Of the total sample, more than 30% believe that less than 20% of continental freshwater is stored underground (mainly among ISTs). Only 3 participants (4.2%) correctly identified the very high relative abundance of groundwater (>90%). Another 14 participants (17.9%) indicated that there is much more groundwater than surface water (PST). Among those who clearly recognised the subsurface as the main reservoir of available water, pre-service teachers stand out.

Table 3. Participants' estimates of groundwater abundance within total continental liquid freshwater.

SUBT WATERS	PSTP (n/%)	PSTS (n/%)	ACTUAL (n/%)	TOTAL (n/%)
<5%	0/0.0	3/9.7	3/20.0	6/7.7
5-20%	7/21.9	8/25.8	3/20.0	18/23.1
20-40%	7/21.9	3/9.7	3/20.0	13/16.7
40-60%	10/31.3	9/29.9	5/33.3	24/30.8
60-90%	6/18.8	7/22.6	1/6.7	14/17.9
>90%	2/6.3	1/3.2	0/0.0	3/3.8

The second research question—whether teachers have an adequate understanding of what an aquifer is and how groundwater behaves—is answered through the qualitative analysis. Regarding the definition of an aquifer, 47.4% associate it with an underground river, lake, stream or cavity, referring to it as "an underground lake". Another 20.5% (mainly PSTS and science-trained ISTs) define it correctly as a material or rock formation with pores that contain water, using expressions such as "a geological formation capable of storing water". A total of 28.2% (across all groups) describe it as a water reserve or reservoir, emphasising its usefulness for humans, e.g., "a water reserve underground". Only a minority (3.8%) mention infiltration from the surface. A single participant (PSTS) refers to the connection between aquifers and rivers from the inside out: "They recharge/discharge into areas such as rivers and lakes and through infiltration".

Regarding groundwater movement, no participant questioned whether groundwater moves. A total of 16.7% compare it to movements similar to those of rivers or surface streams ("through underground channels"). Another 17.9% describe circulation through pores or capillaries in the soil and rocks ("between the pores of the rocks"). Only 10.2% refer to flow velocity, using terms such as "slowly". A total of 24.3% mention factors that may influence movement, such as "pressure differences", "gravity", "capillarity", "following the slope from higher to lower areas", or "filtration". Finally, 3.8% refer to unrelated processes such as "tectonic movements" or "tides".



In the drawings, both the representation of groundwater and its connection with the surface and its movement were analysed. Most participants (73.1%) imagined groundwater as underground rivers or pockets (Figures 1a, 1c), sometimes as deep lakes, suggesting that they conceive of groundwater as the lower part of surface water bodies. A total of 21.8%, mainly science graduates, represented porous materials in some detail (sometimes with a magnifying glass), showing water between the pores (Figure 1b). Some drawings were clearly influenced by geology class diagrams, including elements such as the water table, arrows indicating water movement, and specific terminology.

A total of 62.5% of participants represented groundwater as connected to the surface, sea, rivers or springs (Figures 1a, 1b, 1d), while only 5.1% depicted connections from the subsurface to

rivers (winning streams, Figure 1d). Conversely, some drawings showed rivers, ponds or porous layers completely disconnected from the surface (Figure 1c). Only 7% included rainfall (only PSTS), despite it being the main source of groundwater recharge (Figure 1b).

Groundwater movement was represented by arrows or dashed lines in 30.7% of drawings, sometimes labelled as "infiltration" (Figures 1b, 1d). Only 3.8% appear to suggest movement through rock materials. In addition, 13.8% included human use of groundwater, depicting wells.

Figure 1. Drawings showing how participants imagine groundwater. 1a (top left), 1b (top right), 1c (bottom left), 1d (bottom right).

A minority of participants (less than 20%) are aware that groundwater accounts for a much larger volume than surface water. In addition, teachers' understanding of aquifer functioning is quite limited. This is worrying, as it aligns with findings in secondary school students (Ben-Zvi-Assarf & Orion, 2005a; Covitt et al., 2009; Pan & Liu, 2018). PSTS and IST science majors typically offer more precise definitions of aquifers, highlighting porous, permeable materials capable of harbouring water. Many participants consider groundwater an important reserve, which contrasts with their perception of its limited abundance.

The groundwater drawings analysed are excessively schematic, lacking representation of recharge (rain, rivers, lakes) and discharge into rivers or lakes, as well as indications of water movement (arrows). These results are consistent with previous studies (Ben-Zvi-Assarf & Orion, 2005a; Reyero et al., 2007; Pan & Liu, 2018). Recognising groundwater as the main contributor to surface freshwater is crucial, as aquifer overexploitation is aggravated by population growth and climate change.

Some drawings reflect common classroom images (underground layers, karstic aquifers), sometimes with inaccuracies. This highlights how representations influence participants' understanding (Reyero et al., 2007).

Our results urge a review of teacher training, given teachers' central role in citizenship education. Understanding groundwater is essential for addressing challenges such as overexploitation, pollution and the responsible management of this resource. The existing awareness of its importance is a valuable starting point for improving teacher education.

Key hydrogeological issues should be more present in curricula to advance sustainability. This study provides data on teachers' conceptions of groundwater. Despite being preliminary and based on a limited sample, it offers valuable insights into a population that is key to sustainability education.

Acknowledgement

We thank all participants for their valuable contribution. This study was carried out within the Pensaciencias University–school collaboration network (No. 111) and supported by the research groups UCM 910607 and UCM 970826. It was funded by the Spanish Ministry of Science and Innovation (PGC2018-094955-A-I00; PID2022-138275NB-I00; PID2020-114358RB-I00) and by a project of the University of Valladolid (2024–2025, No. 124).

Pre-Service Teachers' Behaviours Toward Environmental Problems

Aslı Saylan Kirmizigül[1], Nagihan Tanik Önal[2] and Esra Kizilay[1]
[1]Erciyes University, Turkey
[2]Niğde Ömer Halisdemir University, Turkey

Environmental issues pose significant challenges to ecosystems, biodiversity, and human health, making it crucial to examine behaviours that contribute to sustainability. Teachers play a key role in shaping students' environmental attitudes and actions. However, there is limited research on how pre-service teachers engage with environmental problems in their daily lives. This study aims to investigate pre-service teachers' behaviours toward environmental problems across different grades and departments. A survey research design was employed, and data were collected from 829 pre-service teachers from science, mathematics, social sciences, and primary education departments at a university in Turkey. The Environmental Problems Behaviour Scale, consisting of six sub-dimensions (perception, formation, guidance, skill transformation, adaptation to the situation, and creation), was used as the data collection tool. Descriptive and inferential statistical analyses, including t-tests, ANOVA, correlation, and multiple regression analyses, were conducted using SPSS 26. The findings revealed that pre-service teachers scored positively on the environmental behaviour scale. No significant differences were found in total scores based on gender, grade level, or department. However, significant positive correlations were observed among all sub-dimensions of the scale. Regression analysis showed that gender and grade level significantly predicted environmental behaviours, though the explained variance was low.

Keywords: Environmental education, pre-service teacher education, quantitative research

Introduction

Environmental issues have become one of the most pressing global challenges, impacting ecosystems, biodiversity, and human health. These issues threaten not only the environment but also future generations, making it even more critical to address them. Addressing these challenges requires a fundamental shift in individual behaviours toward sustainability. Teachers, as role models in society, play a significant role in shaping environmental attitudes and behaviours among students (Clayton et al., 2021).

From a behavioural perspective, environmental sustainability is often discussed in the literature as extending beyond environmental awareness or knowledge and involving how individuals respond to environmental issues in their daily lives. Previous studies have suggested that environmental knowledge and concern do not always directly translate into pro-environmental behaviour, and this relationship has been examined from different theoretical perspectives (Kollmuss & Agyeman, 2002; Kaiser & Wilson, 2004). In this respect, focusing on behaviours toward environmental problems may provide a descriptive understanding of how sustainability-related orientations are reflected in everyday practices.

However, there is limited research on how pre-service teachers from different disciplines personally engage with environmental issues and adopt behaviours toward environmental problems in their daily lives (Kollmuss & Agyeman, 2002; Monroe et al., 2019). Most existing studies focus primarily on environmental awareness, attitudes, or knowledge levels, while empirical evidence on behavioural dimensions—particularly multi-dimensional behavioural constructs—is still scarce. This gap is especially critical in teacher education, as pre-service

teachers are expected not only to possess environmental knowledge but also to model sustainable behaviours for their future students. Teacher education programs are therefore strategic contexts for fostering environmentally responsible behaviours. Understanding whether such behaviours differ according to gender, grade level, or disciplinary background can inform curriculum design and policy decisions aimed at strengthening environmental education in higher education. Examining these differences may also reveal whether current teacher education programs provide equitable and effective opportunities for developing sustainable behaviours across different subgroups.

Therefore, this study aims to examine the behaviours toward environmental problems of pre-service teachers from various grades and departments. Specifically, the study seeks to determine (a) the general level of pre-service teachers' behaviours toward environmental problems, (b) whether these behaviours differ according to gender, grade level, and department, and (c) the extent to which these demographic variables predict environmental behaviour. Understanding these behaviours can help develop targeted strategies and educational policies to enhance environmental responsibility among pre-service teachers, ultimately contributing to a more sustainable future.

Method

Research Design

Survey research design was used to achieve the purposes of this study. In survey research, researchers are generally interested in how and to what extent responses vary -their variability- how closely some responses are related to others, and how responses differ based on specific demographic variables or measures of social, political, or psychological factors (Fraenkel & Wallen, 2009). In line with this approach, the present study aimed to describe pre-service teachers' behaviours toward environmental problems and to examine how these behaviours vary according to selected demographic variables.

Participants

Convenience sampling, a technique that selects settings, groups, or people who are easily accessible and willing to participate in research, was used to determine the participants (Onwuegbuzie & Collins, 2007). Due to their logistical advantages in terms of time and money, pre-service instructors who were enrolled at the university where one of the researchers was based were included in this context. 829 pre-service teachers (581 females, 248 males) from science (161), mathematics (277), social sciences (195), and primary education (196) departments of a university in the Central Anatolia Region of Turkey participated in the study.

Data Collection Tool

Data for this study were collected using the Environmental Problems Behaviour Scale developed by Güven and Aydoğdu (2012). The scale consists of 40 items designed to measure individuals' behaviours toward environmental issues. Items are rated on a 3-point Likert-type scale.

The scale is structured around six factors: Perception (four items), formation (eight items), guidance (six items), skill transformation (10 items), adaptation to the situation (five items), and creation (seven items). The total score obtained from the scale was used as an overall indicator of behaviours toward environmental problems.

Data Analysis

The data were analysed using descriptive and inferential statistics. In order to examine the relationships between participants' behaviours and demographic variables, inferential statistics,

including independent samples t-tests and one-way ANOVA, were applied. A correlation analysis was also performed to assess the relationships between the sub-dimensions of the environmental behaviour scale. Lastly, multiple regression analysis was conducted to identify the factors that significantly predict pre-service teachers' behaviours toward environmental issues. In the multiple regression analysis, the total environmental problems behaviour score was treated as the dependent variable, while gender, grade level, and department were included as independent variables. All data analyses were performed using SPSS 26.

Findings

The results indicated that the mean total score of all pre-service teachers on the 40-item 3-point Likert scale was 90.64 (*SD* = 9.94), suggesting a generally positive level of behaviours toward environmental problems among the participants. Mean total scores for the six dimensions were as follows: Perception (*M*=9.05, *SD*=1.81), formation (*M*=17.60, *SD*=2.58), guidance (*M*=13.33, *SD*=2.03), skill transformation (M=23.73, *SD*=3.25), adaptation to the situation (*M*=11.47, *SD*=1.78) and creation (*M*=15.45, *SD*=2.24).

According to the independent samples t-test results, no significant difference was found in the total scores between male (*M*=88.59, *SD*=9.93) and female pre-service teachers (*M*=91.51, *SD*=9.83), indicating that gender did not lead to a meaningful difference in overall environmental behaviour scores at the group comparison level.

Table 1. Intercorrelations among the sub-dimensions of Environmental Problems Behaviour Scale.

	Perception	Formation	Guidance	Skill Transformation	Adaptation	Creation
Perception	-					
Formation	,510**	-				
Guidance	,356**	,382**	-			
Skill Transformation	,556**	,570**	,395**	-		
Adaptation	,455**	,436**	,304**	,490**	-	
Creation	,413**	,345**	,296**	,385**	,379**	-

One-way ANOVA results revealed no significant difference in total scores between pre-service teachers from the 1st (*M*=90.12), 2nd (*M*=90.07), 3rd (*M*=90.40), and 4th years (*M*=91.99) (*F*=1.755, *p*>.05). Moreover, one-way ANOVA results revealed no significant difference in total scores between pre-service teachers from the science (*M*=91.40), mathematics (*M*=89.86), social sciences (*M*=91.44), and primary education (*M*=90.33) departments (*F*=1.367, *p*>.05).

According to the correlation analysis results between the sub-dimensions of the environmental problems behaviour scale, all of the six sub-dimensions showed significant positive correlations with other five sub-dimensions (Table 1).

A multiple regression analysis was conducted to investigate how well gender, grade, and department predict pre-service teachers' behaviours toward environmental problems. In this analysis, the total environmental problems behaviour score was used as the dependent variable.

Regression analysis revealed that gender and class year significantly predicted total scores. The first model, including only gender, explained 1.8% of the variance in total scores ($R^2 = 0.018$, $F = 15.244$, $p < 0.001$). When grade level was added to the model, the explained variance increased to 2.5% ($R^2 = 0.025$, $F = 10.727$, $p < 0.001$). Gender was a significant predictor ($B = 2.92$, $p < 0.001$), with males scoring higher than females, while grade level also showed a significant effect ($B = 0.752$, $p = 0.014$). Department was excluded as it did not contribute significantly. Collinearity diagnostics indicated no issues (VIF values near 1).

Discussion And Suggestions

The average score of 90.64 indicates generally positive behaviours toward environmental issues among pre-service teachers, which aligns with previous studies showing that educators are more likely to engage in environmentally responsible actions (Kollmuss & Agyeman, 2002; Monroe et al., 2019). Although previous studies have reported gender-based differences in environmental behaviours (Kollmuss & Agyeman, 2002), the present study did not reveal a statistically significant difference between male and female pre-service teachers when group comparisons were conducted. This finding suggests that, at the descriptive level, environmental behaviours are distributed similarly across genders within the sample. One possible explanation for this could be the increasing efforts in educational institutions to promote environmental awareness equally among all students, regardless of gender.

The findings indicate no significant differences in the total scores of pre-service teachers from different departments (science, mathematics, social sciences, and primary education) on environmental issues. This suggests that there is no discernible difference in the environmental behaviours of pre-service teachers across disciplines. Studies in the field of environmental education often show that individuals from various academic backgrounds do not exhibit significant differences in their environmental awareness and behaviours (Monroe et al., 2019; Erdogan, 2013). The similarity in environmental attitudes across departments emphasizes the importance of interdisciplinary approaches in environmental education programs. Such programs can be effective in enhancing environmental consciousness among all teacher candidates, as fostering sensitivity to environmental issues should not be limited to a specific discipline.

The significant correlations between the sub-dimensions suggest that the formation and perception of environmental issues play a central role in influencing other behaviours such as skill transformation, guidance, and adaptation to the situation. This aligns with the works of Clayton et al. (2021) and Monroe et al. (2019), who highlighted that teachers' environmental perceptions significantly shape their ability to guide students toward sustainable behaviours. Moreover, the study shows that pre-service teachers' perceptions and the formation of environmental knowledge are strongly interconnected, which reinforces the idea that effective environmental education programs should focus on both cognitive and affective components (Erdogan, 2013).

The regression analysis revealed that gender and class year significantly predicted pre-service teachers' behaviours toward environmental problems. Interestingly, although no significant difference was found in the t-test, females scored higher than males, which contrasts with typical

findings (Kollmuss & Agyeman, 2002). The effect of grade suggests that more experienced students may be more engaged in environmental behaviours, potentially due to cumulative exposure to environmental education throughout their academic journey (Monroe et al., 2019). Interestingly, the department variable did not significantly contribute to the model, supporting the idea that environmental awareness is shaped more by broader educational experiences than by specific disciplines (Erdogan, 2013). This suggests that an interdisciplinary approach to environmental education might be more effective than focusing on particular fields of study.

Based on the findings of this study, several suggestions can be made for future research. Future studies may benefit from incorporating additional psychological, contextual, or institutional variables to better explain variations in environmental behaviour. Longitudinal research designs could be employed to examine how behaviours toward environmental problems develop over time throughout teacher education programs.

In addition, qualitative or mixed-methods approaches may provide deeper insights into how pre-service teachers interpret and enact environmental responsibility in their daily lives. Expanding the research to include multiple institutions or different cultural contexts could also enhance the generalizability of the findings.

Studying Students' Reasoning About The Ozone Layer Depletion In The Context Of Argumentation

Nikolaos Zarkadis[1], Constantinos P Constantinou[2], Panos Papanastasiou[3] and George Papageorgiou[4]

[2]Department of Educational Sciences, University of Cyprus, Cyprus

[3]Department of Civil and Environmental Engineering, University of Cyprus, Cyprus

[4]Department of Primary Education, Democritus University of Thrace, Greece

The study focuses on the reasoning of 64 Greek upper secondary school students articulated in the context of an argumentation process about the ozone layer depletion, as part of a teaching-learning sequence regarding electromagnetic radiation, atmospheric-related issues and relevant policies. Participants were provided with a scenario specially designed for this purpose, which included evidence that could be used to support claims for or against specific actions, through the elaboration of particular reasoning. Results show that argumentation processes based on appropriately designed scenarios for the factors affecting ozone layer depletion could help students, to a certain degree, in developing reasoning to support claims such as in support of the ban of CFCs. We have identified specific elements of students' reasoning and organized them according to complexity, variability and flexibility. We also identified evidence of students' reasoning fragmentation.

Keywords: Ozone layer depletion, Reasoning, Argumentation

Introduction

Several studies in recent science education research literature explore students' understanding of the electromagnetic radiation-related atmospheric issues, including the relevant mechanisms of interactions between electromagnetic radiation and substances (e.g., Howard et al., 2013; Papadimitriou, 2004). Many of these studies highlight student difficulties related to understanding of such mechanisms involving relevant types of electromagnetic radiation, including those connected with ozone layer depletion (e.g., Çokadar, 2013; Kaya, 2009; Nyarko & Petcovic, 2021; Papadimitriou, 2004). The corresponding students' mental models seem to be particularly interesting, not only because it is found that, across educational levels, they include many misconceptions (Çokadar, 2013; Leighton & Bisanz, 2003), but also, because those concerning the ozone layer formation appear to be incoherent (Howard et al., 2013). We note specifically the existing evidence supporting the fragmentation of knowledge about the ozone layer itself and the ozone hole in particular (Leighton & Bisanz, 2003).

This fragmentation and inconsistency in students' mental models, as well as the lack of understanding and their misconceptions, are expected to have an impact on their reasoning, when issues related to the ozone layer depletion are discussed in the context of an argumentation process. This is the main purpose that framed the design of this study.

Theoretical framework

Students' understanding of the concepts of ozone, ozone layer and ozone depletion has attracted major interest from science education researchers. The relevant literature provides us with findings at various educational levels, from kindergarten to undergraduate students and pre-

service teachers (Leighton & Bisanz, 2003; Nyarko & Petcovic, 2021; Kaya, 2009). Although often students of different ages and educational levels are aware of some characteristics of the ozone layer, such as its nature, location and/or composition (Boyes et al., 1995; Boyes et al., 1999; Kaya, 2009; Nyarko & Petcovic, 2021; Pekel & Özay, 2005), various difficulties are identified, such as those related to the type of radiation involved in ozone layer depletion and function (Çokadar, 2013) or the understanding of the mechanism through which, electromagnetic radiation causes the ozone depletion and/or formation and the function of ozone broadly or the ozone layer in the earth's atmosphere (e.g., Nyarko & Petcovic, 2021; Çokadar, 2013; Howard et al., 2013). In addition, students appear to have difficulty in identifying ozone at ground level (e.g., Çokadar, 2013; Dove 1996;) and in the upper atmosphere (e.g., Çokadar, 2013). In line with this finding, problems are also identified at different ages and grades due to students' confusion with respect to the role of ozone in the stratosphere and troposphere (Bodzin et al., 2014; Howard et al., 2013; Kılınç et al., 2008). For instance, college students commonly believe that ozone formation in both the stratosphere and troposphere is attributed to one and the same single mechanism and that possible scepticism concerning the ozone layer is attributed to the role of ozone as a greenhouse gas (Howard et al., 2013). Students' confusion between ozone layer or ozone layer depletion and acid rain is also documented, since for instance, ozone depletion is being associated with acid rain, with students considering that the ozone layer protects Earth from acid rain (e.g. Nyarko & Petcovic, 2021).

Students' misunderstandings are also reported in relation to difficulties in identifying specific substances causing the ozone depletion, since confusion appears with the greenhouse gases (Kaya, 2009; Nyarko & Petcovic, 2021; Papadimitriou, 2004). Relevant studies that have been conducted across various ages and grades, provide us with findings indicating confusion between greenhouse effect (or global warming) and ozone layer depletion, based on the idea that ozone layer depletion and/or ozone holes are often believed to cause the greenhouse effect (or global warming) due to the increased solar energy, radiation or heat reaching the Earth through those ozone holes (e.g., Boyes & Stanisstreet, 1997; Dove, 1996; Kılınç et al., 2008; Österlind, 2005; Papadimitriou, 2004; Rye et al., 1997), or specifically due to increased ultraviolet radiation reaching the Earth's surface through them (e.g., Boyes & Stanisstreet, 1997; Çokadar, 2013; Dove, 1996; Kaya, 2009; Nyarko & Petcovic, 2021; Österlind, 2005; Papadimitriou, 2004; Rye et al., 1997). This idea has been found to be often expressed in a variety of students' mental models with coherent characteristics (e.g., Niebert & Gropengießer, 2014). On the other hand, knowledge about the ozone layer and ozone hole seems to be fragmented for younger students, in the elementary grades, due to the use of partial models and the absence of complete ones (Leighton & Bisanz, 2003), while incoherent models for the ozone layer formation are also found to be expressed by college students (Howard et al., 2013).

Research Questions

The lack of students' understanding of the concepts of ozone, ozone layer and ozone depletion, as well as, their relevant misconceptions, are expected to have an impact on students' reasoning when issues related to the ozone layer depletion are discussed. Thus, in this study, 11th grade upper high school students' reasoning is investigated during the development of arguments concerning the ozone layer depletion in the context of a teaching-learning sequence on climate change. Our main research questions were:

1. To what extent can students exploit data available in a given scenario concerning the ozone layer depletion in order to develop reasoning supporting a particular claim?

2. What are the basic elements of the reasoning that students develop within an argumentation context for the support of a particular claim concerning whether students are for or against the ban of CFCs?

Methodology

Participants were 64 Greek upper secondary students of the 11th grade of public schools who voluntarily participated in the study during the academic year 2023-2024, after informed consent had been obtained from their parents/legal guardians. In the context of a wider teaching-learning sequence about argumentation, electromagnetic radiation-related atmospheric issues and relevant policies, participants attended (among others) one 1-hour lesson about the ozone layer and its depletion, which was designed on the basis of the 5E teaching model.

Thus, after the initial stage of 'Engagement', students were attended relevant to ozone layer formation and depletion videos and simulations, during the 'Exploration' and 'Explanation' stages. In those stages, the ways, in which ozone layer is formed and those, in which it could be depleted, were explored with references to the effect of both the UV radiation and the catalytic action of some agents like CFCs, while the relevant explanations included mechanisms at the molecular level and further analyses with references to also other affecting factors like solar radiation intensity. In the 'Elaboration' stage, further discussion took place for the causes and the consequences of the whole phenomenon. Finally, in the 'Evaluation' stage of this model (about 15 min duration), students were provided with a specially designed scenario, in which two opposing views are developed in the context of relevant argumentation concerning the banning of CFCs in relation to the ozone layer depletion.

According to this scenario, the Montreal Protocol has banned the use of certain substances (commonly called CFCs) in order to protect the ozone layer. Several years after the ban, the ozone layer has indeed recovered to a significant extent, but depending on the year, its concentration exhibits significant fluctuations. Thus, scepticism developed about whether the annual fluctuations in the intensity of solar radiation or the action of CFCs is the most decisive factor in the ozone layer depletion, what would have happened if CFCs had not been banned, and whether all this effort was worth it.

Students were asked to study the scenario and to develop reasoning in the context of an argumentation process, supporting one of the claims provided, i.e. whether they are for or against the ban of CFCs. In brief, claims can be articulated as follows:

C1: I do not support banning the use of CFCs

C2: I support banning the use of CFCs (according to the Montreal protocol)

Students' responses were qualitatively analysed according to a three-step scheme as follows:

1. Students' responses were categorized according to the claim (C1, C2...) they supported.
2. For each one of the claims, students' reasoning was analysed by two independent raters (two of the authors) to isolate every distinct reasoning element (R1, R2….) that had a specific meaning.
3. Based on the isolated reasoning elements, students' reasoning was articulated accordingly, and a relevant categorization was followed.

Results

Students' reasoning was analysed by two independent raters (two of the authors) and every reasoning element having a particular meaning was recorded. Following this procedure, 14

reasoning elements (R1-12) were isolated, where 6 of these have a frequency from 15 to 45. Table 1 presents these reasoning elements.

Table 1. Students' reasoning elements (frequencies per category).

	Reasoning elements	N
R1	UV radiation breaks down the ozone molecule (forming oxygen molecule and oxygen atom)	8
R2	CFCs break down the ozone molecule (forming oxygen molecule and oxygen atom)	18
R3	CFCs under UV radiation break down the ozone molecule (forming oxygen molecule and oxygen atom)	12
R3a	UV radiation breaks down CFCs molecules forming chlorine atoms	15
R3b	A chlorine atom reacts with an ozone molecule forming oxygen molecule and ClO (and Cl is regenerated)	15
R4	Depletion of the ozone layer happens	45
R5	Ozone layer protect us from the UV radiation	1
R6	Penetration of UV radiation (through the atmosphere) happens	4
R7	Banning CFCs does not help	2
R8	The use of CFCs has been forbidden	27
R9	CFCs are not necessarily useful for us	1
R10	Total destruction of the ozone layer is avoided	33
R11	Comparing rates of destruction and regeneration	4
R12	The ozone layer is affected by variations in solar radiation	8

Based on the above reasoning elements (R1-12), students' responses were categorized as shown in Tables 2 and 3, with the exception of four students who did not respond. Specifically:

Table 2. Categories of students' reasoning leading to C1 (Number of students).

Category	Reasoning	N
1	Due to R1, then R7, thus C1	1
2	Due to R1, then R4 and R7, thus C1	1
3	Vague	3

Discussion And Conclusions

As shown in Tables 2 and 3, only few students (N=5) support C1 (*I do not support banning the use of CFCs*) based on the role of the UV radiation and ignoring the role of CFCs in the destruction of the ozone molecules (2 students), supporting the aspect that, substances causing the ozone layer depletion are not always recognizable by the students (Kaya, 2009; Nyarko & Petcovic, 2021). The vast majority of the students (N=55) support C2 (*I support banning the use of CFCs*). A number of them (N=15) focus on the catalytic destruction of the ozone molecules

(R3a, R3b), without taking into account the contribution of the UV radiation, advocating those suggest students' difficulties in problems understanding of the relevant mechanism (Nyarko & Petcovic, 2021; Çokadar, 2013). However, many of those supporting C2 (a total of 27 students, R8) take into account this contribution to the CFCs action, whereas some of them (15 students) can describe the mechanism of such an action, reporting the two relevant stages (R3a and R3b).

Table 3. Categories of students' reasoning leading to C2 (Number of students).

Category	Reasoning	N
1	Due to R1 and R2 then R4, thus, in order to R10, C2	2
2	Due to R1 and R2 then R4 and R6, thus, in order to R10, C2	1
3	Due to R2 then R4, thus C2	2
4	Due to R2 then R4 and R6, thus C2	2
5	Due to R2 then R4, and due to R9, thus C2	1
6	Due to R2 then R4, thus, in order to R10, C2	1
7	Due to R2 then R4, thus, in order to R10, and although R12, C2	1
8	Due to R2 then R4, thus, in order to R5, C2	1
9	Due to R2 then R4, and due to R8 then R10, thus C2	3
10	Due to R2 then R4, and due to R8 then R10, although R1, thus C2	1
11	Due to R2, and due to R8 then R10, thus C2	2
12	Due to R2 then R6, although R1, thus C2	1
13	Due to R3 then R4, although R12, thus C2	2
14	Due to R3 then R4, and due to R8 then R10, thus C2	6
15	Due to R3 then R4, and due to R8 then R10, and R11, thus C2	4
16	Due to R3a and R3b then R4, thus C2	4
17	Due to R3a and R3b then R4, thus, in order to R10, C2	2
18	Due to R3a and R3b then R4, and due to R8 then R10, thus C2	3
19	Due to R3a and R3b then R4, thus, in order to R10, and although R1, C2	1
20	Due to R3a and R3b then R4, although R12, thus C2	1
21	Due to R3a and R3b then R4, and due to R8 then R10, although R12, thus C2	2
22	Due to R3a and R3b then R4, although R12, and R8 did not stop R4, thus C2	2
23	Due to R8 then R10, thus C2	4
24	Vague	6

Among the reasoning elements used by the students, R4 (Depletion of the ozone layer happens) is the most frequent, whereas it is quite common for the students to recognize that the use of CFCs has been forbidden (R8), a fact that led to R10 (Total destruction of the ozone layer is avoided). However, it is quite interesting to see that some combinations of reasoning elements appear more frequently than others. The combination of reasoning elements R3 then R4, as part of a larger set of reasoning elements, appeared 12 times. The reasoning category "Due to R3a and R3b then R4, thus C2" appeared 4 times on its own, whereas the same combination of reasoning elements, as part of a larger set of elements, appeared 11 times. Also, the reasoning category "Due to R2 then R4, thus C2" appeared 2 times on its own, whereas the same combination of reasoning elements, as part of a larger set of elements, appeared 13 times. In addition, the reasoning category "Due to R8 then R10, thus C2" appeared 4 times on its own, whereas the same combination of reasoning elements, as part of a larger set of elements, appeared 21 times. Thus, it is apparent that, although there is broad variation in the reasoning patterns displayed by the students in response to the ozone layer depletion scenario, there are some combinations of reasoning elements that appear more frequent, facilitating the articulation of the whole students' arguments. Some of these combinations, especially in cases of students supporting C2, lead to the development of quite sophisticated reasoning involving adequately relevant elements, whereas in other cases, the whole reasoning appears to be quite simple.

However, more interesting is to focus on the variability existing in students' reasoning, where various reasoning emerge across students from the combination of different reasoning elements. Based on this variability it could be quite safe to a certain degree, to conclude that the classroom discourse has not reached coherent group knowledge and the group's understanding displays signs of fragmentation. In addition to the variability of the distinct reasoning elements that were identified, the same reasoning element or the same combination of reasoning elements can be activated, organized and function as part of a larger set of various interconnected reasoning elements or/and combinations of them leading to the articulation of multiple reasoning patterns, indicating the flexibility of these reasoning elements (e.g., Zarkadis & Papageorgiou, 2020). In addition to the variability and flexibility of students' reasoning elements, the reasoning elements, especially those supporting C2, appear to vary in their level of complexity, with reasoning element R3 [CFCs under UV radiation break down the ozone molecule (forming oxygen molecule and oxygen atom)] being more complex compared to R2 [CFCs break down the ozone molecule (forming oxygen molecule and oxygen atom)] and R1 [UV radiation breaks down the ozone molecule (forming oxygen molecule and oxygen atom)], reflecting a varying level of complexity of their reasoning which can fluctuate depending on how many and which reasoning elements are activated and the way they are organized as well.

In addition, it is important to notice, that many of the students' reasoning elements have common characteristics with the rationale, the elaborations and explanations developed during the lesson implemented in the context of the present study. As a result, it seems that argumentation processes based on appropriately designed teaching interventions, including scenarios for the factors affecting ozone layer depletion, could help students, to a significant degree, in developing reasoning in order to support their claims, such as those supporting the ban of CFCs.

ESERA 2025 Copenhagen

Action Research On Climate Change Education In Lower Secondary School – Students' And Teachers' Experiences

Jesper Haglund, Kristin Gustafsson, Sofie Nilsson and Nina Christenson
Karlstad University, Sweden

An action research study on the topic of climate change education was conducted in collaboration between science and social science education researchers and teachers at three lower secondary schools. After joint literature seminars, teachers planned and conducted teaching sequences on climate change, including an out-of-school visit to the collaborating university with a focus on increased local risk of flooding due to climate change. Interviews with students at the end of the study revealed that they appreciated the teaching sequence, tried to lead their personal lives in a climate-friendly way, but were not very engaged emotionally in climate change as an issue. Meeting notes and interviews with teachers show that science teachers prioritized teaching climate change as a physical phenomenon, but social science teachers expressed frustration with students' lack of emotional engagement and a perceived disconnect between students' knowledge of climate change and choices in their personal lives. Challenges in conducting action research in a situation with different objectives across the initiating municipality, and participating researchers, teachers, and students are discussed.

Keywords: Action research; Sustainability; Secondary Education

Introduction

Science education on the topic of climate change has primarily focused on students' development of knowledge of involved scientific phenomena, such as the greenhouse effect, and how they can contribute individually to mitigate climate change (Bofferding & Kloser, 2015). By limiting the focus to students' scientific knowledge and individual actions, there are many aspects of climate change that are not addressed in science teaching, including how society needs to adapt to climate change (Bofferding & Kloser, 2015; Kagawa & Selby, 2012), students' risk perception with regard to climate change (Aksit et al., 2018), and dealing with students' often negative emotions in relation to climate change (Ojala, 2016).

One important aspect of students' climate literacy is its influence on their willingness to act in climate-friendly ways (Garrecht et al., 2023). In this regard, climate-change education should aspire to develop of students' action competence, with the aim "to make present and future citizens capable of acting on a societal as well as a personal level" (Jensen & Schnack, 2006, p. 472).

Schools and teachers often lack tools for handling such complexities associated with climate change, and collaboration with educational researchers is an attractive option to develop relevant teaching approaches. In this light, the present study was initiated by the school administration of Karlstad, a medium-size municipality in Sweden, who contacted us as educational researchers regarding perceived anxiety in relation to climate change among secondary students in the municipality.

Aims And Research Questions

The overall aim of the study was to develop, conduct and analyse teaching sequences on the topic of climate change, with the ambition of supporting students' development of climate literacy (Garrecht et al., 2023). The study was guided by the following research questions:

- What didactical choices do teachers make and didactical challenges do they encounter in the context of teaching climate change?
- What are lower-secondary school students views on climate change, its impact on their everyday lives, and climate-change education?

Research Method And Design

A research project was formed with the purpose of developing, conducting, and analysing teaching sequences on the topic of climate change. The project team consisted of science and social science teachers from three lower-secondary schools in the municipality, and science education and social science education researchers.

The project team had a series of project meetings, that included literature seminars on the topic of climate psychology (Andersson et al., 2019), and sharing experiences of teaching climate change before and during the project. Our initial intention was to design the study as a participatory action research project (Eilks, 2018), where researchers and teachers collaborate in formulating research questions, designing teaching sequences, and analysing the enacted teaching. However, in reality, we came to take on more traditional roles, where researchers formulated research questions and analysed collected data, and teachers designed and carried out teaching sequences.

Teachers formed groups within the three schools and collaborated in planning the teaching of climate change (Nilsson, in press). In addition, students from the three schools (N = 150, age 14-15 years) visited the university for an out-of-school activity on climate change-related risk of flooding and local adaptations to such risk (Haglund et al., 2025).

Within the project, the following data have been collected:

- Meeting notes from the project meetings.
- Individual interviews and focus-group interviews with four (N = 4) of the participating social science teachers regarding their didactical choices and didactical challenges during planning and conducting climate change education (Nilsson, in press).
- Interviews with six (N = 6) of the participating students conducted after the teaching sequence on their experiences of the climate change education and their perception of climate change.
- Video data of pupils' engagement during the out-of-school activity (Haglund et al., 2025).

The present study focuses on the teachers' and students' experiences from the project. The student interviews have been analysed through thematic content analysis (Bryman, 2016).

Findings

Teachers' Views Of Climate Teaching

In the initial project meetings, some of the teachers, in particular science teachers, expressed that they did not recognise the description from the school administration that students have strong, negative emotions in relation to climate change. Instead, rather than being worried about increasing global temperatures, students were perceived to express concern about high petrol prices for their mopeds, in line with the focus of media and political debate in society during the time of data collection. In this light, these teachers prioritised teaching about the greenhouse effect as a physical phenomenon rather than addressing students' emotions with regard to climate change.

However, the interviews with the social science teachers revealed a more complex picture, identifying didactical challenges and dilemmas (Nilsson, in press). They expressed frustration that the students have a solid, factual knowledge of climate change, but do not manage to connect it to local risks or consequences for their everyday life. The students are concerned about getting high grades and cheap petrol, but not how to act in a climate-friendly way. Greta Thunberg, with her engagement in climate change, comes across as annoying to many students. With students' narrow focus on "will this be on the test?", the teachers struggled to bring global challenges into the classroom. In this regard, the teachers' personal values clashed with those of the students.

The teaching sequences that the social science teachers designed included watching the documentary film *2040* (Gameau, 2019), where students were introduced to examples of how current technologies and strategies might be used to mitigate climate change in the near future in order to stimulate a sense of hope. Students also compared the local risk of flooding and draught in locations close to rivers in Sweden and in Spain, and considered local adaptations and conflicts of interest in use of water (Nilsson, in press). In this way, the classroom teaching aligned with and built on the out-of-school visit to the university with a focus on flooding (Haglund et al., 2025).

Students' Views Of Climate Change And Climate Teaching

In the student interviews, the students expressed that they had enjoyed the climate change education, including the visit to the university. They appreciated the focus on concrete local risks of flooding during the visit to the university and getting to know how it has been addressed in urban planning:

> But it was also a bit, like… a wake up, or, what should I say… that we're in a risk zone in Karlstad, too… with flooding and things… /…/ to walk there and see places that you really know of and see that it can go bad. (Interview 1)

The students also appreciated the creative nature of the activities, such as how to respond to possible flooding scenarios, and the social setting during the out-of-school visit where they got to interact with students from other classes and representatives from the university student organisation Climate Students.

The students described that they try to act in a climate-friendly way in their families. In this regard, they showed an awareness of individual activities that are known to have a high impact on CO_2 emissions, such as flying on vacation, driving cars, and eating meat (Wynes & Nicholas, 2017), but also mentioned other activities that have less impact, such as reducing waste and recycling.

In line with the impression from the teachers, most of the students did not express strong, negative emotions with regard to climate change and how it is likely to affect their own future. However, after initial reassuring statements, more subtle worries were revealed. Three of the students said the following about their feelings in relation to climate change and its potential consequences in the future:

> Well, I sure don't have angst. /…/ I would say that if I have angst, it is angst about the animals. /…/ I mean, I care about the climate. And, of course, I think about the future, but… I am in the age where you focus on yourself, and mopeds… (laughter) (Interview 3)

> I don't get very anxious, but you can get a bit anxious about what will happen to future generations. Of course, if we don't stop… don't try to stop it now, there will be more and more problems for our children that will come. (Group interview, student 4)

> I don't want to live in a world that is horrible. And I don't want to give… to have my children live in a world that is horrible. You want to… but it is a bit tough to see that we will maybe live in a world where it is, like, crap to live. [laughter] (Interview 1)

In these interview excerpts, the students express concern about climate change, but do not see an immediate risk for themselves here and now, but rather for future generations or animals.

On the topic of how they may be affected by climate change, two of the students reflect on the consequences:

> And it is going to get a lot warmer, and we will maybe not have any snow in the winter, and things… so you will not be able to go skiing in Sweden, for example. (Interview 1)

> That we in Sweden maybe not will have access to as many different exotic fruits and stuff. There will not be enough to bring here, and that. It won't grow as well. (Group interview, student 5)

Not being able to ski or having a limited supply of exotic fruit come across as small and quite insignificant changes to their current way of living, which can be interpreted as naivety with regard to the likely impact on society of climate change.

Discussion

The study revealed large differences in perspectives on climate change among the teachers and researchers in the project team, the school administration that initiated the project, and the students that took part in the teaching. One reason for the different perspectives might be the rapid changes in the media focus, turning from sympathies with Greta Thunberg when the project was initiated to a concern about petrol prices when the teaching was planned. There may also be a difference in attitudes towards climate change depending on the place where the students lived and their schools were located, in a city or on the countryside.

However, there might be more fundamental reasons behind the differences between science teachers and social science teachers. The science teachers tended to prefer a focus on students' knowledge of climate change as a physical phenomenon, adhering to a traditional Vision I (Roberts, 2007) of scientific literacy. In contrast, the social science teachers had an ambition to address consequences for how the students lead their everyday lives and can engage in the community, which relates more closely to an alternative Vision II (Roberts, 2007) of scientific literacy.

The study highlights the need for a more integrated and interdisciplinary approach to teaching climate change in schools, one that bridges the differing perspectives among educators. While science teachers often prioritize a Vision I framework of scientific literacy, focusing on the physical phenomena that cause climate change, social science teachers emphasize the societal implications and students' roles as active citizens. These differing priorities reveal an opportunity for collaboration, where scientific understanding is combined with empowering students to develop the skills and confidence needed to make informed and responsible decisions in addressing climate change.

Acknowledgement

We would like to thank our colleagues within the project Bringing Climate Change to Schools (BriCCS), Carola Garrecht, Ute Harms, and Niklas Gericke, for valuable comments on the design and results of the study, and at the Center for Societal Risk Research (CSR) at Karlstad University, for the teaching resources and engagement in activities on the local risk of flooding. We are also grateful to the teachers and students that participated in the joint research effort and teaching activities. The project has been funded by the Swedish Research Council under grant number 2019-0360.

Fostering Environmental Science Competencies In The Anthropocene: Implementation Of The Four-Step AAAR Learning Cycle Using PISA 2025 Framework

Nitjaree Sikarinkham[1] and Suthida Chamrat[2]
[1] Faculty of Education, Chiang Mai University, Thailand
[2] Department of Curriculum, Instruction and Learning, Faculty of Education, Chiang Mai University, Thailand

The Anthropocene highlights the growing impact of human activities on Earth's systems, creating complex environmental challenges that require more than scientific knowledge alone. This study investigated the effects of implementing the Four-Step AAAR (Awareness–Anticipation–Action–Reflection) learning cycle on upper secondary students' environmental science competencies, as defined in the PISA 2025 Science Framework. The study employed a mixed-methods, one-group pre-test–post-test design with 24 students in Northern Thailand, using community-based environmental issues, particularly plastic waste management, as the learning context. Quantitative data were collected through a PISA-aligned cognitive test and the Environmental Action Scale, while qualitative data were gathered from student reflections, classroom observations, and learning artifacts. The results showed a significant improvement in students' overall environmental science competencies, with large effect sizes across all competency dimensions. Qualitative findings indicated increased environmental awareness, stronger systems thinking, and the emergence of student agency through both everyday participation and leadership-oriented actions. The findings suggest that the AAAR learning cycle can effectively support competency-based and action-oriented environmental science education in the context of the Anthropocene.

Keywords: Citizen Science, Environmental Education, PISA

Principle And Rationale

From the late 19th century to the 21st century, human activities have profoundly disrupted Earth's ecological balance, ushering in an era termed the Anthropocene. The defining challenges of this epoch—climate change, biodiversity loss, and plastic pollution—threaten the sustainability of life on Earth. Among these issues, plastic pollution stands out due to its ubiquity, persistence, and severe ecological consequences. Poor waste management and excessive reliance on single-use plastics exacerbate global environmental degradation, making the problem a pressing educational priority.

The Anthropocene underscores the power of human activities to reshape Earth's systems—from the fossil-fuel combustion of the industrial revolution to the global proliferation of plastic waste. While plastic use has enabled various economic conveniences, it has also generated persistent waste that infiltrates landfills, rivers, and oceans. In Northern Thailand, such environmental degradation converges with the cross-border haze crisis. For decades, Chiang Mai and Chiang Rai have experienced PM2.5 pollution that exceeds international standards. This air pollution is further exacerbated by cultural and economic practices, including large-scale cremations, waste burning, and agricultural burning—collectively posing serious threats to public health and elevating rates of lung cancer and respiratory diseases (Masters et al., 2021; OECD, 2023).

The Anthropocene also manifests through extreme weather events in Thailand's northern regions. The 2024 flood in Chiang Rai, for example, caused widespread damage to infrastructure, agriculture, and local communities, amplifying economic burdens and health risks. The flood also

generated large volumes of waste—including household garbage, construction debris, and plastic materials—that overwhelmed existing waste management systems. Meanwhile, repeated open-air cremations in some areas, traditionally practiced as part of funerary rites, release additional pollutants into an already compromised atmosphere. Consequently, Northern Thailand has emerged as a vivid case study of the Anthropocene's complexity, illustrating how localized cultural practices and socio-economic factors intersect with global environmental crises.

Educational efforts to address these challenges increasingly focus on equipping students with the competencies to understand, evaluate, and mitigate environmental problems. UNESCO's vision of Education for Sustainable Development (ESD) and the OECD's Programme for International Student Assessment (PISA) 2025 Science Framework converge on this point. Both emphasize action-oriented learning that integrates scientific knowledge with community engagement.

Purposes And Research Questions Of The Study

The purposes of this study were (1) To investigate the effects of implementing the four-step AAAR (Awareness–Anticipation–Action–Reflection) learning cycle on upper secondary students' environmental science competencies, as defined in the PISA 2025 Science Framework. (2) To examine changes in students' environmental science competencies before and after participation in the AAAR-based learning intervention.

Accordingly, this study was guided by the following research question, which asks how the implementation of the four-step AAAR learning cycle influences upper secondary students' environmental science competencies based on the PISA 2025 Science Framework.

Conceptual Definitions

Environmental Science Competencies (ESC)

According to the PISA 2025 Science Framework, three Environmental Science Competencies (ESC) guide the educational preparation of 15-year-olds to face complex socio-ecological challenges (OECD, 2023):

(1) Explaining the impact of human interactions with Earth's systems. This refers to the understanding of the relationships among physical systems, living organisms, and Earth systems. It includes recognizing both the positive and negative impacts of human activities over time, and the ability to comprehensively analyse social, cultural, and economic factors that affect the environment.

(2) Making informed decisions and taking action based on diverse evidence. This refers to the capacity to access and critically evaluate evidence from various sources, and to design environmental solutions using creativity and systems thinking. It also involves civic engagement, goal-setting with people across generations, and working towards environmental restoration and sustainability from the local to the global level.

(3) Demonstrating hope and respect for diverse perspectives. This refers to acting ethically and demonstrating care for living beings, recognizing and addressing social injustices, showing determination in the face of ecological crises, and respecting diverse viewpoints. It includes seeking solutions to restore the environment in inclusive and hopeful ways

Four-Step AAAR Learning Cycle

The Four-Step AAAR Learning Cycle is an iterative learning cycle consisting of Awareness, Anticipation, Action, and Reflection, designed to continuously develop learners' thinking

through intentional and responsible engagement, leading to positive change for self, society, and the environment.

The AAAR cycle is adapted from the OECD Learning Compass 2030 AAR cycle (Anticipation–Action–Reflection) by explicitly adding Awareness as a preparatory step.(Mangkhang, C., 2021)

Conceptual Framework

Based on preliminary findings from surveys, interviews, and student reflections, the study revealed that while students demonstrated awareness of environmental issues, particularly plastic waste, their understanding of systemic environmental impacts and confidence in taking action remained limited. These findings indicated a gap between environmental awareness and meaningful engagement in environmental problem-solving. In response, this study focused on community-based environmental issues, specifically waste management and plastic pollution, as authentic learning contexts. To address this gap, the Four-Step AAAR (Awareness–Anticipation–Action–Reflection) learning cycle was employed as a pedagogical framework to guide students through recognizing local environmental problems, anticipating future consequences, engaging in responsible actions, and reflecting on their learning experiences. Through this iterative learning process, students were expected to develop environmental science competencies aligned with the PISA 2025 Science Framework, including systems thinking, informed decision-making, and student agency.

Figure 1. Research conceptual framework.

Literature Review

The Anthropocene And Environmental Challenges In Education

The Anthropocene highlights the profound influence of human activities on Earth's systems, resulting in complex environmental challenges such as climate change, biodiversity loss, and pervasive plastic pollution (OECD, 2019; White et al., 2024). These challenges are not only global but also deeply embedded in local socio-cultural contexts. In many regions, including Northern Thailand, environmental problems such as plastic waste accumulation, air pollution, and extreme weather events increasingly affect community well-being. Addressing such complexity requires educational approaches that move beyond content knowledge toward

empowering learners to understand and engage with real-world environmental issues (UNESCO-UNEP, 1978; OECD, 2023).

Environmental Science Competencies And The PISA 2025 Framework

In response to the demands of the Anthropocene, the PISA 2025 Science Framework emphasizes the development of Environmental Science Competencies (ESC) that enable students to explain human–environment interactions, make informed decisions based on evidence, and demonstrate respect for diverse perspectives (OECD, 2023). Central to these competencies is the notion of student agency, which involves learners' capacity to participate meaningfully in addressing environmental challenges. Research suggests that while students may demonstrate awareness of environmental problems, they often lack opportunities to develop the competencies and confidence required for informed action (Masters et al., 2021). Consequently, educational frameworks increasingly highlight competency-based and action-oriented learning as essential for environmental education in the Anthropocene.

Action-Oriented Learning For Sustainability

Action-oriented and competency-based learning approaches have been widely advocated within Education for Sustainable Development (ESD) as a means to bridge the gap between awareness and action (UNESCO-UNEP, 1978). Such approaches emphasize authentic learning contexts, community engagement, and reflective practices that allow students to connect scientific knowledge with everyday environmental issues. Studies have shown that context-based and community-oriented learning can support students' systems thinking and ethical awareness, particularly when learning activities are grounded in local environmental challenges (Mangkhang et al., 2021; Masters et al., 2021). However, there remains a need for structured pedagogical models that systematically guide learners from recognizing environmental problems to taking responsible action.

The Four-Step AAAR Learning Cycle

The Four-Step AAAR (Awareness–Anticipation–Action–Reflection) learning cycle builds upon the OECD Learning Compass 2030, which emphasizes anticipation, action, and reflection as key processes for developing learner agency (OECD, 2019). By explicitly incorporating awareness as a preparatory stage, the AAAR cycle provides a structured framework for engaging learners with environmental issues in a holistic manner. The cycle guides students to recognize environmental problems, anticipate future consequences, take informed and responsible action, and reflect on their experiences to inform subsequent learning. This iterative process aligns closely with the goals of environmental science competencies and supports the development of student agency in addressing complex environmental challenges (OECD, 2023).

Taken together, existing literature highlights the need for pedagogical approaches that integrate local environmental contexts, competency-based learning, and action-oriented processes. However, limited empirical research has examined how structured learning cycles such as the AAAR model can be used to foster environmental science competencies within the framework of PISA 2025, particularly in culturally and contextually specific settings. This study seeks to address this gap by implementing the AAAR learning cycle in the context of community-based environmental issues.

Research Design, Scope, And Methods

Variables

- **Independent Variable:** The implementation of the four-step AAAR learning cycle integrated into science learning activities.

- **Dependent Variables:** Students' environmental science competencies as defined by the PISA 2025 Science Framework

Participants

The participants were 24 upper secondary students aged 15–17 years from a public secondary school in Northern Thailand. The school is situated in an area facing environmental challenges such as plastic waste, air pollution, and periodic flooding. Participation was voluntary, and informed consent was obtained from both students and their guardians prior to data collection.

Instruments

Types Of Research Instruments

To address the research objectives, both quantitative and qualitative research instruments were employed.

(1) Cognitive Test

A PISA-aligned cognitive test was developed to assess students' environmental science competencies, with a focus on problem-solving related to plastic pollution and waste management. The test measured students' ability to apply scientific knowledge, interpret data, and propose evidence-based solutions to environmental problems. The instrument was administered before and after the AAAR-based learning intervention.

(2) Environmental Action Scale (EAS)

The Environmental Action Scale, adapted from Alisat and Riemer (2015), was used to assess students' self-reported pro-environmental behaviours and intentions. The scale consisted of Likert-type items addressing daily environmental practices, participation in environmental activities, and willingness to engage in community-based environmental actions.

(3) Qualitative Instruments

Qualitative data were collected to capture students' learning experiences, engagement, and emerging agency throughout the AAAR-based learning activities. Three qualitative instruments were employed: student reflection logs, classroom observations, and student worksheets, all of which were aligned with the four phases of the AAAR learning cycle.

Steps To Create And Validate Research Instruments

This study followed a systematic process to develop and validate research instruments aligned with the research objectives, the Environmental Science Competencies in the PISA 2025 Science Framework, and the Four-Step AAAR learning cycle.

First, the Environmental Science Competencies defined in the PISA 2025 framework were analysed and translated into measurable learning outcomes, which guided the development of all research instruments and learning activities.

Second, both quantitative and qualitative instruments were developed, including a cognitive test of environmental science competencies, an adapted Environmental Action Scale (EAS), and qualitative tools such as student reflection logs, worksheets, and classroom observation protocols. Four AAAR-based lesson plans were also designed as the instructional framework and sources of qualitative evidence.

Third, all instruments and lesson plans were reviewed by experts in science education and curriculum studies to evaluate content validity, clarity, and alignment with the research objectives. Expert feedback was used to revise the instruments.

Finally, the revised instruments were piloted with a small group of students outside the main study, and minor adjustments were made before final implementation for pretest, posttest, and ongoing qualitative data collection.

Data Collection And Analysis

Data Collection

Data were collected throughout the implementation of the four AAAR-based lesson plans using both quantitative and qualitative approaches. Quantitative data were obtained through a cognitive test aligned with the PISA 2025 Science Framework and the Environmental Action Scale (EAS). The cognitive test and EAS were administered to students before and after participation in the AAAR-based learning activities to examine changes in environmental science competencies and pro-environmental behaviours.

Qualitative data were collected concurrently during the instructional intervention. Sources of qualitative data included student reflection logs, classroom observations, and student worksheets produced during the Awareness, Anticipation, Action, and Reflection phases of each lesson plan. These data captured students' learning experiences, engagement, reasoning processes, and emerging agency related to community-based environmental issues, particularly plastic waste management and pollution.

Data Analysis

Quantitative data were analysed using descriptive and inferential statistics. Descriptive statistics, including means and standard deviations, were calculated to summarize students' pretest and posttest scores. Due to the small sample size and non-normal distribution of the data, the Wilcoxon Signed-Rank Test was used to examine differences between pretest and posttest scores. Effect sizes were calculated to determine the magnitude of learning gains following the AAAR-based learning intervention.

Qualitative data were analysed using thematic analysis. Student reflection logs, observation notes, and learning artifacts were systematically reviewed and coded to identify recurring patterns and themes. The analysis focused on themes related to environmental awareness, systems thinking, decision-making, values and responsibility, and student agency. The identified themes were then interpreted in relation to the phases of the AAAR learning cycle and the Environmental Science Competencies defined in the PISA 2025 framework.

To enhance the credibility of the qualitative findings, data triangulation was employed by comparing evidence across multiple data sources, including reflections, observations, and student-produced artifacts.

Research Advantages

This study demonstrates how the Four-Step AAAR learning cycle can be effectively applied to foster environmental science competencies aligned with the PISA 2025 framework. By grounding learning activities in real-world, community-based environmental issues such as plastic waste, the study enhances the relevance of science learning and supports the development of student agency. The findings also provide practical AAAR-based lesson plans that can be adapted by educators to promote action-oriented and competency-based environmental education.

Results

Quantitative Results

Table 1. Descriptive Statistics and Wilcoxon Signed-Rank Test of Environmental Science Competencies before and after

N	Mean of Pre-test	Mean of Post-test	Mean difference	Statistic	P-value	Effect Size	Interpretation
24	78.9	90.8	11.00	300	<.001*	1.00	Large Effect

Note *P-value <.05 interpreted as significant. Effect Size interpreted according to Cohen (1988): .00-.09 Negligible, .10-.29 Small, .30-.49 Medium, ≥ .50 Large

Table 2. Descriptive Statistics and Wilcoxon Signed-Rank Test of Environmental Science Competencies Before and After in Each Dimension

Components of Environmental Science Competencies	N	Mean of Pre-test	Mean of Post-test	Mean difference	Statistic	P-value	Effect Size	Interpretation
1. Explain the impact of human interactions with Earth's systems	24	24.2	30.5	6.00	300	<.001*	1.00	Large Effect
2. Make informed decisions to act based on evaluation of diverse sources of evidence and application of creative and systems thinking to regenerate and sustain the environment	24	48.0	52.8	5.00	246[a]	<.001*	1.00	Large Effect
3. Demonstrate respect for diverse perspectives, and hope, in seeking solutions to socio-ecological crises	24	8.50	10.21	2.00	186[a]	<.001*	0.958	Large Effect
4. Environmental Action Scale								
4.1 Participatory Actions	24	11.7	18.1	7.00	211[a]	0.007	0.664	Large Effect
4.2 Leadership Actions	24	1.13	4.04	4.50	88.5[a]	0.026	0.686	Large Effect

Note P-values <.05 interpreted as significant. Effect Size interpreted according to Cohen (1988): .00-.09 Negligible, .10-.29 Small, .30-.49 Medium, ≥ .50 Large

Quantitative analysis revealed a significant improvement in students' overall environmental science competencies following participation in the AAAR-based learning activities. Post-test scores were significantly higher than pre-test scores, as indicated by the Wilcoxon Signed-Rank Test ($p < .001$). The results demonstrated a large effect size, suggesting that the learning gains were not only statistically significant but also educationally meaningful.

Further analysis by competency dimension showed consistent improvement across all components of environmental science competencies as defined in the PISA 2025 Science Framework. Students demonstrated increased ability to explain the impact of human interactions with Earth's systems, make informed decisions based on evidence and systems thinking, and demonstrate respect for diverse perspectives in addressing socio-environmental issues. In addition, scores on the Environmental Action Scale (EAS) showed statistically significant improvement, indicating positive changes in students' reported pro-environmental behaviours and intentions. Overall, the quantitative findings indicate that the AAAR-based learning intervention supported students' competency development across multiple dimensions.

Qualitative Results

Emerging Themes From Qualitative Data

Qualitative analysis of student reflection logs, classroom observations, and learning artifacts revealed several recurring themes that supported the quantitative findings.

The first theme was environmental awareness and real-life connection. Students demonstrated increased awareness of local environmental issues, such as plastic waste, flooding, and air pollution, and were able to connect these issues to their daily lives and community contexts.

The second theme was systems thinking and future-oriented reasoning. Students increasingly described environmental problems in terms of cause–effect relationships and long-term consequences, including links between waste accumulation, greenhouse gas emissions, and climate-related impacts.

The third theme was values, responsibility, and participation. Many students expressed a growing sense of responsibility toward environmental protection and reported changes in daily behaviours, such as waste separation and reduced plastic use. Some students also shared their learning with peers and family members.

Evidence Of Student Agency

Qualitative evidence further highlighted the development of student agency during the AAAR learning cycles. Some students, particularly those involved in student councils, demonstrated leadership by initiating environmental projects, such as organizing waste separation points and designing community-based campaigns to reduce plastic use. Other students expressed agency through personal behaviour change and future-oriented commitments, as reflected in reflective journals and letters to their future selves. These findings indicate that the AAAR learning cycle supported students in moving beyond awareness toward participation and leadership in environmental action.

Discussion

The findings indicate that the AAAR learning cycle effectively supported the development of environmental science competencies aligned with the PISA 2025 Science Framework. The significant overall improvement suggests that the integration of awareness, future-oriented thinking, action, and reflection created meaningful learning experiences that extended beyond knowledge acquisition toward competency development (OECD, 2023). By engaging students with community-based environmental issues, particularly plastic waste management, the learning process enabled students to connect scientific concepts with real-world contexts, which has been widely recognized as a key condition for effective environmental science education (Stevenson et al., 2013; Wals, 2012).

One important explanation for the observed gains lies in the structure of the AAAR learning cycle itself. The Awareness phase helped students recognize environmental problems as personally and socially relevant, increasing their motivation to engage with scientific content. The Anticipation phase encouraged systems thinking and future-oriented reasoning, allowing students to explore cause–effect relationships and long-term consequences of human–environment interactions, which are central to environmental science competencies in PISA 2025 (OECD, 2023). These phases prepared students to move beyond fragmented understanding toward a more holistic view of environmental challenges characteristic of the Anthropocene. However, differences were observed in students' environmental action and leadership outcomes. Student council members tended to demonstrate stronger gains in leadership-oriented actions compared to their peers. This pattern may be explained by their prior experience in decision-making, collective responsibility, and participation in school governance, which likely enhanced their perceived self-efficacy and ability to translate learning into visible leadership actions (Bandura, 2001). Similar findings have been reported by Alisat and Riemer (2015), who noted that students with previous leadership opportunities are more likely to engage in collective environmental action and advocacy. Most students in the classroom showed growth primarily in participatory and everyday environmental actions, such as changing personal behaviours, engaging in group activities, and sharing environmental knowledge with peers and family members. These outcomes reflect forms of "everyday agency," which are often more accessible and immediately achievable for learners than formal leadership roles (Kollmuss & Agyeman, 2002). Such findings align with research suggesting that environmental engagement typically begins at the individual level before developing into broader social or political action (Chawla & Cushing, 2007). A small number of students demonstrated limited improvement or slight decreases in leadership-related scores. Rather than indicating a failure of the learning intervention, this result highlights that student agency develops at different paces and is influenced by multiple internal and external factors, including motivation, personal values, social norms, and perceived opportunities for action (Ajzen, 1991). Environmental competence should therefore be understood as a dynamic and contextual process rather than a uniform outcome for all learners. Previous studies in environmental education similarly report that increased awareness does not always lead immediately to observable action or leadership, particularly within short intervention periods (Chawla & Cushing, 2007).

Importantly, the qualitative findings suggest that even students who did not show strong quantitative gains in leadership began to recognize their own potential roles in environmental action. Reflective journals and learning artifacts indicated emerging awareness of personal responsibility and future commitments, suggesting that agency may be developing in less visible but still meaningful ways. This supports the view that education for sustainability is inherently a long-term process, shaped by both individual trajectories and socio-cultural contexts (UNESCO, 2020; Wals, 2012).

Overall, these findings highlight that while the AAAR learning cycle can foster environmental action and student agency, differentiated support and extended time may be necessary to engage all learners meaningfully, particularly those who are less inclined toward leadership roles. Providing diverse pathways for participation—ranging from personal behaviour change to collective and leadership-oriented action—may help ensure that all students can develop environmental science competencies in ways that align with their capacities and contexts (White et al., 2024). In this sense, the AAAR learning cycle offers a flexible and promising framework for competency-based, action-oriented environmental science education in the Anthropocene.

Conclusion

This study demonstrates that the Four-Step AAAR learning cycle can effectively support the development of environmental science competencies aligned with the PISA 2025 framework. Through the integration of community-based environmental issues into science learning, students showed improved understanding of human environment interactions, stronger evidence-based decision-making, and emerging forms of student agency. While not all students demonstrated leadership-oriented actions, the findings highlight that environmental agency can develop through diverse pathways, including everyday participation and personal **behaviour** change. The study contributes empirical evidence on how action-oriented and competency based learning can be implemented in upper secondary science classrooms using a structured learning cycle. Future research may extend this approach across longer timeframes or varied contexts to further explore how different forms of agency can be fostered in environmental science education.

Implications

The findings suggest that the AAAR learning cycle can serve as a flexible framework for designing competency-based environmental science learning across various contexts, not limited to waste-related issues. Teachers may adapt this approach to address different environmental challenges relevant to their local settings. In addition, future research may benefit from longer-term implementations to examine how environmental competencies and student agency develop over time.

Acknowledgement

This research was completed with the support of many individuals and institutions. The author sincerely thanks the participating students, the thesis advisor for valuable guidance and feedback, and the school for permission and support during data collection. The author also gratefully acknowledges my parents and friends for their encouragement and support throughout the research.

Rapid socio-environmental change calls for science education that equips students to reason and act on complex sustainability challenges. This study examined the effectiveness of a Trans-Contextualization Learning Process Using Socio-Scientific Issues (TCUSSI) in strengthening Grade 8 students' environmental competencies (EC) and environmental identities (EI) through two SSI contexts—fossil fuels and food waste—sequenced across micro (personal), meso (local), and macro (global) levels. Grounded in the PISA 2025 Science Framework, the intervention engaged learners in evidence-based reasoning, systems thinking, and reflection on civic responsibility. Participants were 32 Grade 8 students in Lampang Province, Thailand. A mixed-methods design employed an Environmental Competencies Test (ECT) adapted from PISA-style tasks and an Environmental Identities Questionnaire (EIQ) based on Clayton (2003), complemented by open-ended responses and reflective journals. Findings indicated significant gains in all EC components and in four of five EI components, with large effect sizes, and a moderate post-intervention correlation between EC and EI. Qualitative evidence corroborated increased awareness, local–global sustainability linkages, and emerging youth agency, while highlighting challenges in quantitative reasoning and behaviour–intention alignment. Overall, TCUSSI demonstrates strong potential as a contextually grounded socio-scientific pedagogy for lower secondary sustainability education.

Keywords: Trans-Contextualization Learning Process Using Socio-Scientific Issues, Environmental Competencies, Environmental Identities

Introduction

Rapid societal changes in science, technology, economics, and the environment have produced interconnected impacts at both local and global levels. In recent decades, fluctuating economies, aging populations, disease outbreaks, borderless information exchange, and escalating climate crises underscore the urgent need for awareness and preparedness (Holbrook et al., 2022). In this context, education is critical for equipping young people to respond to current and future challenges. Contemporary educational goals increasingly emphasize holistic well-being by integrating health, civic engagement, social connection, and environmental stewardship (OECD, 2023), and the OECD (2019) highlights that such outcomes support the development of active global citizens who can contribute to sustainable development and social responsibility.

Science education, in particular, must prepare learners to engage with complex socio-environmental problems by strengthening their capacity to navigate multifaceted issues (Sadler & Zeidler, 2009). Many contemporary challenges—such as nuclear risks, genetic dilemmas, global warming, and resource depletion—are inherently socio-scientific because they require scientific understanding alongside ethical and social judgment (Chowdhury, 2022). As a result, educators increasingly adopt socio-scientific issues (SSI)—controversial topics that connect social contexts with scientific inquiry—to foster evidence-based argumentation and responsible decision-making (Presley et al., 2013). A key pedagogical support for SSI is context-based learning, which anchors scientific ideas in familiar situations and gradually expands learning

toward broader contexts (Chowdhury, 2022; Holbrook et al., 2022). This staged movement across micro (personal), meso (local), and macro (global) contexts is also consistent with the OECD's PISA 2025 Science Framework (OECD, 2023).

In addition, responding to environmental crises such as climate change requires attention not only to what students know and can do, but also to how they perceive their relationship with nature. EI influences whether learners see themselves as part of interconnected ecosystems and engage in ecological problem-solving (Clayton, 2003). Therefore, integrating SSI with identity-oriented and contextualized learning may support the development of both EC and EI that underpin environmentally responsible citizenship.

In response to these needs, this study examines the effectiveness of TCUSSI for lower secondary students. The study investigates whether TCUSSI strengthens Grade 8 students' EC and EI and examines the relationship between EC and EI following participation in the TCUSSI intervention among 32 Grade 8 students in a district secondary school in Lampang Province, Thailand. Accordingly, the study addresses two research questions:

(1) To what extent does the TCUSSI intervention enhance Grade 8 students' EC and EI?

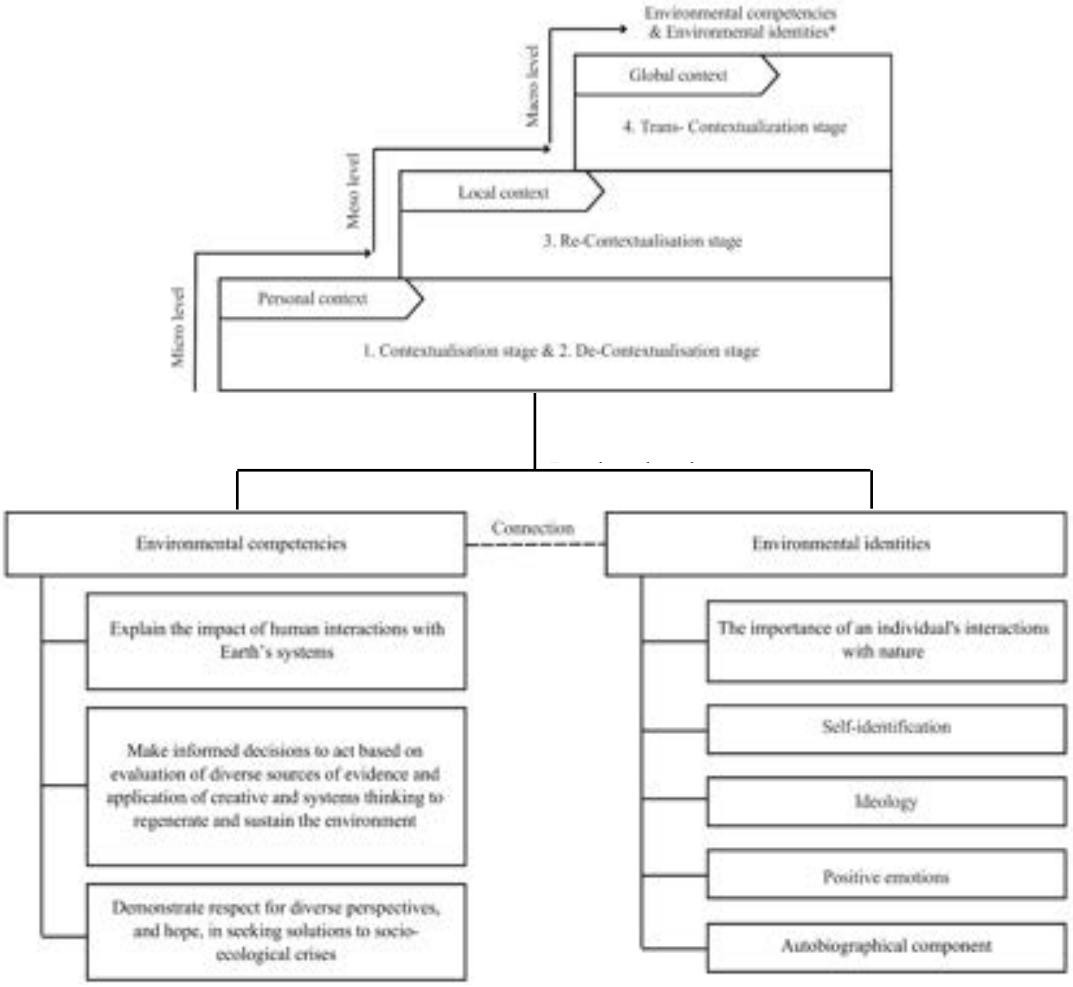
(2) What is the relationship between EC and EI among students after participating in the TCUSSI intervention?

Theoretical Background

SSI are open-ended problems in which scientific knowledge intersects with ethical, social, and political considerations. SSI-based learning is therefore a key approach for developing evidence-based reasoning and responsible decision-making in science education (Sadler & Zeidler, 2009). A persistent limitation, however, is that SSI learning can remain confined to classroom argumentation without systematically connecting students' reasoning to lived experiences or to wider societal and global realities. This study therefore adopts TCUSSI, which structures learning across micro (personal), meso (local/community), and macro (global) contexts so that learners revisit the same issue with increasing systemic complexity and civic relevance (Holbrook et al., 2022). This sequencing follows the logic of context-based learning—starting from familiar situations and extending understanding across broader contexts—while providing a coherent trajectory for sustained meaning-making (Chowdhury, 2022). In this study, TCUSSI is enacted through the unit Our World using fossil fuels and food waste as SSI contexts and implemented through four stages: contextualization, de-contextualization, re-contextualization, and trans-contextualization (Holbrook et al., 2022).

Within TCUSSI, the study targets two complementary outcomes—EC and EI. EC represent students' capacity to understand and respond to socio-ecological challenges in the Anthropocene (Ketsing, 2023). Consistent with the PISA 2025 Science Framework, EC are defined as the ability to explain human interactions with Earth's systems, make informed decisions using diverse evidence and systems thinking, and demonstrate respect for diverse perspectives and hope when addressing socio-ecological crises (OECD, 2023). Developing EC requires learners to interpret information and justify decisions through evidence-based and systems-oriented reasoning, which aligns with competence development in SSI-based learning (Presley et al., 2013).

EI complement competence-based outcomes by explaining how learners perceive their relationship with nature and their role within socio-ecological systems. EI are defined as how individuals perceive and define their relationship with nature, encompassing the importance of personal interactions with nature, self-identification within ecosystems, commitment to sustainability, positive emotions toward nature, and autobiographical memories of engaging with



nature (Clayton, 2003). Empirical work suggests that stronger EI are associated with pro-environmental attitudes and behavioural change, particularly when learning invites reflection and connects environmental issues to students' sense of self (Blatt, 2013).

Prior studies indicate that SSI and contextualized learning can deepen understanding, improve argumentation, and foster ethical awareness (Tal & Kedmi, 2006), while staged contextual movement can support learners' agency in addressing both everyday and global dilemmas (Sadler et al., 2016). Trans-contextual learning further extends this potential by linking local concerns to global sustainability challenges and strengthening orientations aligned with active informed citizenry (Chowdhury et al., 2020; OECD, 2019). Yet, evidence remains limited on whether trans-contextual SSI learning can simultaneously strengthen EC and EI and bring these outcomes into closer alignment. This study therefore examines TCUSSI as a coherent theoretical approach for investigating growth in EC and EI among lower secondary students and for exploring whether the relationship between EC and EI becomes stronger following the intervention.

Conceptual Framework

The conceptual framework of this study, outlining the expected linkage between TCUSSI and the concurrent development of EC and EI, is presented in Figure 1.

Figure 1. Research conceptual framework.

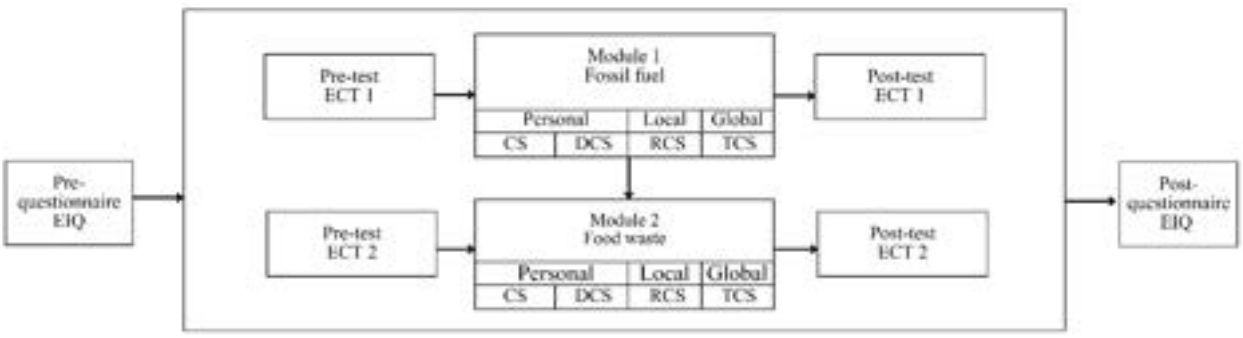
This study conceptualizes TCUSSI as a mechanism that integrates SSI-based learning across micro–meso–macro contexts to support the concurrent development of EC and EI. As students progress from personally meaningful situations to local and global sustainability challenges, they are expected to strengthen their ability to explain human–Earth system interactions and make evidence-informed decisions (EC), while also deepening their sense of connection, responsibility, and self-identification in relation to nature (EI). This pathway illustrates how trans-contextual sequencing within TCUSSI—implemented through SSI learning in Our World—is theorized to foster integrated growth in EC and EI.

Methodology

Participants

Participants were 32 Grade 8 students from a district-level secondary school in Lampang Province, Thailand, selected purposively to reflect typical academic backgrounds and local living contexts.

Instruments



This study used three instruments. EC were assessed using an Environmental Competencies Test (ECT) consisting of two parallel 3-item forms (fossil fuels; food waste) adapted from PISA-style tasks (12 points per form; 24 points in total). EI were measured using a 24-item Environmental Identities Questionnaire (EIQ), a 5-point Likert scale adapted from Clayton (2003). Reflective journals were used to capture students' evolving ideas and experiences.

All instruments were expert-reviewed for content validity and alignment, and items were screened using IOC (≥ 0.67; Turner & Carlson, 2003). While all six ECT items met the criterion, Item 3 in both forms was revised from multiple-choice to open-ended to better elicit real-world actions aligned with EC. EIQ items below the IOC criterion were removed and wording refined for Grade 8 appropriateness. The EIQ demonstrated excellent internal consistency in a pilot test ($\alpha = .927$; Taber, 2018).

Data Collection And Analysis

Data were collected across two TCUSSI modules. For Module 1 (Fossil Fuels), students completed the EIQ and ECT pre-test, followed by the ECT post-test after 6 class hours. For Module 2 (Food Waste), students completed the second ECT pre-test and post-test after another 6 class hours, and the EIQ was administered again after both modules. Quantitative data were analysed using descriptive statistics, Wilcoxon signed-rank tests, and Spearman's rho. Qualitative data from open-ended ECT responses and journals were thematically coded (Creswell, 2014).

Figure 2. Data Collection Procedure.

Ethical Considerations

This study was approved by the Chiang Mai University Research Ethics Committee (CMUREC No. 68/144; COA No. 165/68) through an expedited review process. All participants and their legal guardians provided informed consent after receiving detailed information about the study's objectives, procedures, and their right to withdraw at any stage without penalty. To ensure confidentiality, all data were collected and reported in aggregated form, and no personally identifiable information was disclosed. Photography or video recordings were limited to group learning activities and were conducted only with explicit permission from participants and their guardians. In accordance with institutional research ethics guidelines, all research materials and data will be securely stored and destroyed within three years after publication.

Results

Effects Of The TCUSSI Learning Process On Grade 8 Students' EC

Components of EC	Pre-test		Post-test		Mean difference	Statistic	p-value	Interpretation	Effect Size	Interpretation
	Mean	S.D.	Mean	S.D.						
1. Explain the impact of human interactions with Earth's systems	4.09	1.47	5.44	1.52	1.50	370[a]	<.001*	Significant	.699	Large Effect
2. Make informed decisions to act based on evaluation of diverse sources of evidence and application of creative and systems thinking to regenerate and sustain the environment	7.28	2.84	12.75	2.65	6.00	488[a]	<.001*	Significant	.968	Large Effect
3. Demonstrate respect for diverse perspectives, and hope, in seeking solutions to socio-ecological crises	15.10	3.17	16.40	2.73	2.00	224[a]	.009*	Significant	.620	Large Effect

Table 1. Descriptive Statistics and Wilcoxon Signed-Rank Test of EC before and after TCUSSI Participation

Note: 1. *p < .05 2. Effect size interpreted according to Cohen (1988): .00 – .09 negligible, .10 – .29 small, .30 – .49 medium, ≥ 0.50 large

After participating in TCUSSI, students showed significant improvement in all three EC components. They demonstrated a stronger understanding of human impacts on Earth's systems, with a large effect size. The greatest gain was in their ability to make informed and creative decisions for sustainability, which showed a large effect. Respect for diverse perspectives and hopeful engagement with socio-ecological problems also increased significantly. Overall, TCUSSI produced strong, meaningful gains in students' environmental competencies.

Influence Of TCUSSI On Grade 8 Students' EI

Table 2. Descriptive Statistics and Wilcoxon Signed-Rank Test of EI before and after TCUSSI Participation.

Components of EI	Pre-test		Post-test		Mean difference	Statistic	p-value	Interpretation	Effect Size	Interpretation
	Mean	S.D.	Mean	S.D.						
The importance of an individual's interactions with nature	13.50	3.10	14.50	2.27	2.00	142[a]	.014*	Significant	.661	Large Effect
Self-identification	17.30	3.94	18.60	3.07	1.50	285[a]	.005*	Significant	.621	Large Effect
Ideology	13.2	2.91	14.40	2.56	2.00	233[a]	.018*	Significant	.553	Large Effect
Positive emotions	17.80	4.14	18.60	3.46	1.00	230[a]	.169	Not Significant	.311	Medium Effect
Autobiographical component	7.09	1.89	7.59	1.56	1.00	190[a]	.038*	Significant	.498	Medium Effect

Note: 1. *p < .05 2. Effect size interpreted according to Cohen (1988): .00 – .09 negligible, .10 – .29 small, .30 – .49 medium, ≥ 0.50 large.

TCUSSI led to significant improvement in four of the five EI components. Students strengthened their sense of connection to nature, environmental self-identification, and ideology, all with large effect sizes. The autobiographical component also increased significantly with a moderate effect. Although positive emotions toward nature did not significantly change, it still showed a modest improvement. Overall, TCUSSI effectively enhanced students' identity-based engagement with the environment.

Relationship Between EC And EI Following TCUSSI Participation

Before TCUSSI, EC and EI were not significantly related. After the intervention, the correlation became moderate and statistically significant, indicating that students who developed stronger environmental identities also demonstrated higher environmental competencies. This suggests that TCUSSI fosters a connected growth between what students know/do and who they perceive themselves to be regarding the environment.

Variables	ρ (Spearman's rho)	Test Statistic	p-value	Interpretation
EI (Pre-test) and EC (Pre-test)	.21	1.17	.25	Not Significant
EI (Post-test) and EC (Post-test)	.46	2.86	.01*	Significant

Table 3. Spearman's Rank Correlation between EC and EI Scores before and after TCUSSI Participation.

Note: *p < .05

At the same time, the students proposed diverse solution pathways. They emphasized reducing and phasing out fossil fuel use, shifting to renewable and clean energy (solar, wind, biomass, hydrogen), conserving energy in daily life, and adopting circular-economy practices such as recycling, reusing, repairing, composting, and reprocessing leftovers. They also valued local wisdom in food preservation as a way to extend shelf life and reduce food waste. Yet, their proposals were mostly qualitative: students rarely used quantitative evidence such as carbon footprints or cost–benefit considerations, and they seldom analysed trade-offs among different options. Moreover, while many expressed intentions to "eat just enough", "finish all food", save electricity, use cloth bags, or choose sustainable travel modes, some students admitted that they were unlikely to change their behaviour despite understanding the impacts, revealing a gap between awareness and action.

Across the reflections, worksheets, and creative products, the data strongly indicate the emergence of environmental identity and youth agency. Students described feelings of peace, happiness, and attachment when in natural places and expressed a desire to protect these environments. Experiences of environmental degradation, especially around the coal mine, triggered concern and a sense of injustice, which motivated them to "take care of nature together". Through letters to their past and future selves and Fossil Fuel Comics, they showed guilt about past behaviours but also a clear commitment to becoming people who use energy wisely and live more sustainably. They increasingly recognized that environmental problems require shared responsibility and systemic change, not just individual actions. Students called for collaboration among government, communities, schools, and households; for listening to community voices; for transparent monitoring of large projects; and for stronger policies and laws, inspired by international examples such as France's anti–food waste legislation. At the same time, they realistically acknowledged challenges in the transition to 100% renewable energy, including technological, financial, infrastructural, and political–economic constraints.

Conclusion And Discussion

The findings indicate that TCUSSI substantially enhanced students' environmental learning across cognitive, affective, and identity-based dimensions. By engaging students with SSI contexts grounded in everyday life, the intervention enabled them to situate global sustainability challenges within local realities—particularly fossil fuels, coal mining, food systems, and carbon footprints—thereby strengthening the relevance and coherence of their learning experiences. Quantitative results show significant improvements across all EC components with large effect sizes, including clearer understanding of human–Earth system interactions and stronger evidence-based, creative, and systems-oriented decision-making for sustainability. EI also increased significantly in four of five components, especially connection to nature, environmental self-identification, and ideology. However, positive emotions toward nature did not show a clear change. This may reflect a ceiling effect, as students already held relatively positive feelings

toward nature prior to the intervention, and because affective development often requires longer-term, repeated, and more embodied experiences in natural settings than a classroom-based SSI sequence can typically provide. Importantly, the moderate post-intervention correlation between EC and EI—absent at pre-test—suggests that TCUSSI aligned students' developing competencies with their environmental self-concept.

These outcomes provide empirical and theoretical support for TCUSSI as a response to limitations reported in context-based and SSI-oriented science education. Real-world contexts may enhance relevance yet remain bounded within classroom understanding, with weak links to societal engagement (Fensham, 2009; Swirski et al., 2018). Likewise, SSI pedagogy can strengthen argumentation and ethical reasoning but still struggle to bridge classroom decision-making and real-world action (Sadler, 2011; Zeidler et al., 2009). In contrast, the findings suggest that explicit trans-contextualization—sequencing learning across micro (personal), meso (local), and macro (global) contexts—helps address this gap by enabling learners to revisit the same SSI with increasing systemic complexity and civic relevance. Across contexts, students increasingly framed fossil fuels and food waste as interconnected socio-ecological systems requiring collective responses, supporting the shift from science through education toward education through science, where societal relevance and citizen engagement become central outcomes (Holbrook & Rannikmäe, 2007; Holbrook, 2010).

The significant gains in EC, particularly in evidence-based and creative decision-making, indicate that TCUSSI operationalizes key competencies emphasized in the PISA 2025 Science Framework, including systems thinking and informed action in the Anthropocene (OECD, 2023). This addresses concerns that SSI reasoning may remain largely qualitative or opinion-based, with limited integration of evidence and systemic analysis (Hodson, 1999; Yacoubian & Khishfe, 2018). Qualitative evidence further corroborates students' internalization of SSI related to fossil fuel use, air pollution, coal mining, food waste, and carbon-intensive diets, alongside proposed solutions such as renewable energy, energy conservation, circular-economy practices, traditional food preservation, and community-based waste management. However, many responses still lacked quantitative evaluation and explicit trade-off analysis, underscoring the need for stronger scaffolding in analytic reasoning.

A further contribution lies in clarifying the relationship between competence development and identity formation. Although EI has been widely recognized as influencing pro-environmental concern and behaviour (Clayton, 2003; Green et al., 2016), empirical work connecting identity development to competence-based science frameworks remains limited. The post-intervention EC–EI correlation suggests that TCUSSI may better integrate these outcomes, responding to calls to connect identity and competence that have often been treated as parallel but weakly related in environmental education (Hinds & Sparks, 2008; Lou & Li, 2021). Qualitative findings reinforce this interpretation through students' expressions of emotional attachment to nature, heightened moral concern, and growing responsibility, consistent with strengthened EI.

At the same time, qualitative data reveal an awareness–action tension: some students recognized environmental impacts yet expressed reluctance to change behaviour. Rather than signaling failure, this pattern reflects socio-scientific reasoning that acknowledges technological, economic, and political constraints on sustainability transitions, consistent with accounts of mature SSI engagement emphasizing uncertainty, trade-offs, and power relations (Sadler, 2011; Levinson, 2018). In this sense, TCUSSI appears to support not only action-oriented thinking but also adaptive capacity, which is crucial under rapid socio-environmental change.

Overall, TCUSSI proved effective in strengthening EC, EI, and early systems thinking, while addressing a key research gap by showing how trans-contextual SSI learning can integrate

competencies, identity, and emerging agency within a coherent pedagogical model. Consistent with active informed citizenry, the findings suggest that TCUSSI moves beyond preparing informed individuals toward fostering learners who can locate themselves within complex socio-environmental systems and reflect critically on their roles in societal transformation (Holbrook, 2010; Chowdhury et al., 2020). Future work should strengthen scaffolding for quantitative reasoning, systemic trade-off analysis, and behaviour–intention alignment to deepen students' capacity to engage meaningfully with complex socio-scientific issues.

Acknowledgement

We gratefully acknowledge the support of Chiang Mai University and the Faculty of Education. We also thank the participating students and their guardians, as well as the school staff, for their cooperation throughout the study. Finally, we appreciate all individuals who provided support and encouragement during the research process.

Children's Connection to Nature: Do Forest Schools Make a Difference?

Daphne Goldman[1] and Daniel Malamud Bleier[2]
[1]Beit Berl College, Israel
[2]Tel Aviv University, Israel

In times of global environmental unsustainability, there is growing advocacy for reconnecting people, especially children, with nature towards countering current environmental problems. With increasingly urban lifestyles, people spend most of their time indoors, leading to a growing disconnection from nature. Children, especially, are losing opportunities to be outside and engage in nature. Contemporary environmental issues are linked to this human-nature disconnect. Forest Schools (FS) hold significant potential to address these issues. A tenet of FS is that learning in nature is not sporadic but regular and continual. Correspondingly, one objective of FS is cultivating connection-to-nature and fostering a sense-of-concern and responsibility for the environment. This study addresses a gap in empirical literature - do children attending FS differ in their connection-to-nature than those who learn in traditional non-Forest school settings? Employing three different tools (previously used with children)- a close ended questionnaire and two visual tools, this studied compared cognitive, affective, experiential, and behavioural aspects of the psychological construct connection-to-nature between primary schoolchildren who learn in two FS and those who learn in a traditional non-FS. Results clearly show that FS children have a stronger emotional connection-to-nature, they comprehend more the importance of the natural environment and have greater intention for pro-environmental behaviours compared to their traditional school peers. FS children identify nature as part of their personal identity in contrast to non-FS children, and wild nature stands out as their most preferred place for playing. This study provides direct evidence that learning in FSs enhances children's connection to nature.

Keywords: Forest School, Connection to Nature, Primary School Children

Introduction

In the context of global environmental unsustainability, fostering a connection between people and nature has become increasingly critical towards countering current environmental problems. With increasingly urban lifestyles in an industrialized technology-driven world, people spend the bulk of their time indoors, leading to a growing disconnection from nature. Children, especially, are losing opportunities to be outside and engage in nature. Contemporary environmental issues are linked to this disconnection from nature. Ecologist Aldo Leopold, already in 1949, argued that when individuals perceive the "land" as a commodity rather than identifying themselves part of it, respect for the environment diminishes, ultimately leading to its careless exploitation. Research supports that nature-connectedness is a critical psychological driver providing intrinsic motivation for environmentally responsible behaviour in adults (Frantz & Mayer, 2014; Nisbett et al., 2009) and in children (Otto & Pensini, 2017).

Nature connectedness (also termed connection to nature or nature connection) is a multidimensional psychological construct illustrating positive human-nature relationships, with cognitive, affective, experiential and behavioural aspects (Frantz & Mayer, 2014; Nisbett et al., 2009; Schultz, 2002).

Since connection-to-nature can be nurtured through direct interaction with nature, frequent and prolonged immersion in nature is more likely to influence ecological behaviours compared to

brief and sporadic encounters (Otto & Pensini, 2017). More access and experience of young people in nature reflects higher levels of nature connection (Barrable & Booth, 2020; Cheng & Monroe, 2012), while lower levels of childhood nature connection are related to increased time indoors, with digital entertainment (Larson et al., 2019). Two main driving forces for connecting children with nature are the importance for their wellbeing (O'brien, 2009) and environmental conservation, the latter grounded in connection-to-nature as a motivational factor to pro-environmental behaviour.

This study addresses the role of Forest Schools (FS) in enhancing children's connection-to-nature. Forest School Education is a distinctive educational approach that utilizes forest/woodland settings as an immersive environments for deeper more holistic learning experiences. As a specific subfield within outdoor environmental education, FS supports the overarching goals of environmental education (Grimm et al., 2011; Tal et al., 2023). The FS approach builds on the wide range of cognitive, affective, physical, interpersonal and behavioural benefits of learning outdoors (O'brien, 2009). A basic principle of this approach is that learning within natural environments occurs regularly and repeatedly, and is linked to the national curriculum (FSA, 2021; O'brien, 2009). With increasing concerns regarding children's disconnect from nature and the implications of the consequential lack of familiarity and appreciation of the natural world on their likeliness to care for their world and adopt pro-environmental behaviours, FS hold significant potential to address these issues. Emerging from the Scandinavian tradition of outdoor kindergartens, FSs have gained popularity in primary schools across Europe and North America (Harris, 2017).

An objective of FS is to cultivate a connection-to-nature and foster a sense-of-concern and responsibility for the environment (Grimm et al., 2011). Hence, while it is presumed that FS will enhance children's connection-to-nature, empirical evidence that learning in a FS promotes this attribute is lacking. Although studies have investigated children's connection-to-nature (Chawla, 2020; Cheng & Monroe, 2012; Larson et al., 2011; Otto & Pensini, 2017; Richardson, 2019), evidence directly linking FS participation and increased nature connectedness is wanting. This study responds to this gap. It explored whether children attending a FS differ in their connection-to-nature compared to those in traditional non-Forest school settings. This study forms part of a broader research examining the FS approach in Israel. The study was conducted in two of the three FS that existed in Israel.

Methodology

Research Settings And Participants

The study was conducted in three primary schools- two FSs (further termed YR and BY) and one traditional non-Forest School (further termed NH), all situated in rural communities and serving communities with similar socio-economic attributes. The participating FSs comprise two of the three existing FSs in the country. In them learning is fully outdoors, in nearby woodland adjacent to a local nature reserve. They are relatively young, growing schools, and consequently are smaller than the reference school. Participating students were from middle (3rd grade, 8-9 years old) to upper grades (5th grade, 10-11 years old) ensuring the study is conducted with children who have experienced learning in a FS. All students in each grade participated, except for the reference fifth grade, in which half of the classes participated. The research population comprised 104 FS students and 87 non-FS students.

Instrumentation

The study employed three instruments that have been found suitable for children.

Questionnaire

The questionnaire comprised two validated questionnaires previously employed with children. (1) The Nature Connection Index (NCI) (Richardson, 2019) addresses different aspects of a sense-of-connectedness to nature; (2) The Children's Environmental Perception Scale (CEPS) (Larson et al., 2011) assesses two components reflecting ecological appreciation and environmental concern: Eco-affinity (interest in nature and intentions to engage in pro-environmental behaviour) and Eco-awareness (cognitive grasp of environmental issues related to ecological sustainability). The questionnaire was translated into Hebrew and slightly adapted for Israeli children. Internal reliability of the whole questionnaire and its sections ranged between 0.84-0.93.

Inclusion Of Nature In Self (INS)

This visual scale (Shultz, 2002) assesses the extent to which individuals identify nature as part of their personal identity by a series of two overlapping circles- "Self"/"Nature". The greater the overlap, the greater the inclusion-of-nature-in-self. Participants selected the extent of overlap that best describes them.

Photographs Of Play Settings

This visual tool, adapted from Shepardson (2005), employs a series of five photographs of children playing in different settings ranging from indoor and technological to untamed natural environment: indoor digital games, urban street, urban playground, cultivated woodland, natural woodland. Participants selected in which settings they prefer most to play and feel most comfortable.

Data Collection

The researcher administered the tools accompanied by the class teacher. In the reference school, the tools were administered in the classroom, in the forest schools - outside.

Data Analysis

Due to the small number of students in each grade in the FSs, data were aggregated from the three levels. ANOVA and Scheffe Post Hoc examined differences among students from each school. For the visual tools, the frequency of each option was calculated and Chi squared for independence examined for differences in the distribution among students from each school.

Ethics Statement

The study was approved by the Chief Scientist, Ministry of Education. Data collection from the students received parental approval and was fully coordinated with the school administration.

Results

Connection-To-Nature Questionnaire

No significant differences were found between the two FS. FS students scored higher in all connection-to-nature measures and standard deviations were smaller (Table 1). They exhibit stronger emotional connection-to-nature (NCI), comprehend more the importance of the natural environment (Eco-Awareness) and have greater intention for pro-environmental behaviours (Eco-Affinity) compared to their peers in the traditional school.

Table 1. Comparison of connection-to-nature variables between children who learn in FS and those who learn in a traditional school.

Connection-to-nature variable	Mean ± SD		F-value	Significance
	Forest Schools (n=85)	Reference School (n=94)		
NCI	3.75±1.01	3.30±1.28		
Eco-Awareness	4.58±0.84	3.92±1.34		
Eco-Affinity	3.94±1.13	3.31±1.42		
Total mean	4.10±1.07	3.51±1.39	33.74	<.001

Inclusion Of Nature In Self

No differences were found in the extent of inclusion-of-nature-in-self between the FSs. FS children identify nature as part of their personal identity: the greater the self/nature overlap, the higher the percentage of children that chose this option. In contrast, children in the traditional non-FS displayed a distribution among options, with no clear trend in the extent to which they include nature as part of their self-identity (Table 2).

Table 2. Comparison of the distribution (%) of choices of Inclusion-in-Self (INS) between children in FSs and the traditional school.

Group	Self/Nature fully separated	Self/Nature small overlap	Self/Nature extensive overlap	Self/Nature fully overlapped	Chi Square test		
					Chi value	df	significance
FSs	2.30	14.94	37.93	44,83	22.72	3	<.001
Ref school	15.38	31.73	17.31	35.38			

Preferred Play Environment

No differences were found in the preferred play settings between the FSs. FS children showed significant differences from their traditional school peers in their preferred play settings. Untamed nature stood out as the favoured play settings of FS children (>70%), while preference for playing in nature and indoor multimedia games was similar in non-FS children (Table 3).

Discussion

There is growing advocacy for reconnecting people, especially children, with nature to promote environmental sustainability. FS– long-term outdoor learning settings- have gained recognition as a significant way to foster this connection. This study addresses a gap in the research concerning the influence of FS on children's connection-to-nature. To tap into the different psychological aspects of connection-to-nature, this study employed multiple visual and textual tools. Despite the limited sample size (reflecting small numbers of children in the participating schools), the findings highlight that FS children exhibit a deeper and more significant connection-to-nature than their traditional school counterparts. FS children demonstrate a stronger emotional bond and sense of belonging to the natural world (NCI). They include nature-in-self reflecting

that their connectedness encompasses care and commitment to nature (Schultz, 2002). They express more cognitive understanding of the importance of nature (Eco-Awareness) and greater intention for involvement in pro-environmental action (Eco-Affinity). These findings align with research indicating that connection-to-nature promotes pro-environmental behaviours in children (Otto & Pensini, 2017). Expectedly, both groups enjoy multimedia games, which are identified a key factor associated with declining nature-based outdoor time for youth (Larson et al., 2019), but FS children clearly prefer playing outdoors in wild nature to indoor multimedia entertainment. In conclusion, this study provides direct evidence that learning in a FS enhances children's connection-to-nature.

Table 3. Comparison of the distribution (%) of the participants' preferred play settings between children in FS and those in the traditional school.

Group	Digital game indoors	Urban street	Urban play-ground	Cultivated woodland	Natural woodland	Chi Square test		
						Chi value	df	significance
FSs	16.09	2.30	8.05	2.30	71.26	15.21	4	.004
Ref-school	38.46	2.88	11.54	2.88	44.23			

Acknowledgement

The authors thank the schools' administration and the students who participated in this study.

ESERA 2025 Copenhagen

Empowering Pupils To Explore Urban Environments. Identifying Contexts For Environmental Sensing Using Non-Functional Prototyping.

Gerfried Mikusch[1] and Monika Musilek[2]
[1]TU Wien, Austria
[2]PH Wien, Austria

When engaging in outdoor activities in public places, school pupils are exposed to environmental conditions such as heat and noise, as well as pollutants like particulate matter. This work investigates how school pupils can be made aware of these conditions, learn about their background, and reflect on the connection between outdoor activities and environmental conditions by enabling children to design non-functional, context-based environmental sensor artifacts in a three-stage workshop. A participatory workshop setting is introduced that identifies and describes the contexts of school pupils' outdoor activities as well as relevant measured variables in these contexts. Furthermore, school pupils design prototypes for environmental sensor artifacts using creative materials such as fabrics, cardboard, and dummy electronic components. Results from three workshops with 57 pupils reveal contexts in which environmental sensing can be applied, and environmental education can be connected to their personal interests and daily routines. The workshop results include non-functional prototypes as the basis for further design steps toward functional environmental sensor artifacts. Feedback from practitioners and experts provides valuable insights into enhancing the workshop setting and its materials. The study contributes a structured participatory design approach that bridges pupils' lived outdoor practices with environmental sensing concepts in lower secondary STEAM education. The outcome of our approach demonstrates how environmental education and the impact of environmental conditions on the realities faced by school pupils can be applied in STEAM education.

Keywords: Environmental Education, Classroom Research, STEM Education

Introduction

Climate change and its negative impacts on the environment are among the most significant challenges facing the world today. This particularly affects urban areas, where, for example, air pollution, higher anthropogenic waste, heat, and poor outdoor thermal comfort lead to overheating and poor air quality (IPCC, 2023). Children are directly exposed to these pollutants when being active in public spaces. This work investigates how pupils can be empowered to explore urban areas they frequently use by identifying contexts of outdoor activities and measured variables relevant to 10-14-year-old children. Therefore, non-functional environmental sensor artifacts are designed in participatory classroom workshops. The work is aligned with Austrian educational goals, where pupils learn to describe applications of technology in the environment and society using interdisciplinary examples and consider their relevance for social groups and cultural contexts (BGBl., 2022), the European sustainability competence framework GreenComp (Bianchi et al., 2022), as well as with the United Nations Sustainable Development Goal 13.3, which aims to improve education and awareness-raising on climate change mitigation (United Nations, 2016). The Austrian curriculum does not include subject-specific computer science teaching at this age. STEAM subjects provide the educational foundation for this work, as they combine science, technology, engineering, and the arts. Many educational materials, projects, products, and technologies have emerged in recent years to support pupils in learning to code (*Scratch - Imagine, Program, Share*, 2024), assemble robots (*Micro*, 2024), and experiment with

environmental sensors (*senseBox*, 2023). The focus of these solutions is on helping children understand complex technology. While numerous educational tools introduce pupils to environmental sensors, little is known about how pupils themselves contextualize environmental sensing within their everyday outdoor practices. This study addresses the gap by engaging pupils as active designers of environmental sensing artifacts grounded in their own outdoor activities. Through participatory, non-functional prototyping, pupils identify relevant contexts, environmental influences, and measurable variables connected to their everyday experiences in urban environments. To better understand how environmental sensing can be meaningfully embedded in pupils' lived experiences, this study investigates the following research questions:

RQ1: How do pupils conceptualize the relationship between their everyday outdoor activities, perceived environmental conditions, and measurable environmental variables within a participatory design process?

RQ2: How are these conceptualizations materialized in pupils' non-functional prototypes of environmental sensing artifacts?

Theoretical framework

Contextual Design (CD) integrates user-centred techniques into the development of software and hardware systems and, therefore, focuses on users and their practices (Beyer & Holtzblatt, 1997). CD aims to design "a new and better way for users to live their lives, achieve their intents, touch the people that matter to them, and perform their activities by introducing better tools and systems." (Holtzblatt & Beyer, 2015). While CD ensures that the resulting artifacts are aligned with the user's context, *Participatory Design* (PD) integrates users as contributors to the entire design process. The design process is realized as a partnership between implementers and users (Schuler & Namioka, 1993). Musaeus et al. (2024) apply PD to design learning tools involving teachers, researchers, and developers to overcome challenges in computing education in high schools. Morais et al. (2022) present a theoretical model for children's participation, including typologies and roles in a PD process. The model serves as a theoretical foundation, supporting the planning of activities and methods in the design process. Iivari et al. (2024) follow a PD approach that includes activism education to enable PD that matters, meaning the PD process must address significant societal issues that matter to people. *Participatory urbanism* describes the involvement of citizens in research activities and "promotes new styles and methods for individual citizens to become proactive in their involvement with their city, neighbourhood, and urban self-reflexivity" (Paulos et al., 2008). Participatory urbanism enables a better understanding of, e.g., air quality through the use of low-cost hardware and higher-resolution data for an area (Miskell et al., 2017). Benavides Lahnstein et al. (2022) investigated young people's participation in citizen science programs and called for enhancing their opportunities to participate and position themselves as actors in authentic scientific initiatives. The GreenComp framework defines sustainability as "prioritizing the needs of all life forms and of the planet by ensuring that human activity does not exceed planetary boundaries" and refers to sustainable development as processes to stimulate or achieve progress in sustainable ways (Bianchi et al., 2022). Henke & Elster (2022) introduce guiding principles to promote action competence in the context of education for sustainable development in schools, following a design-based research approach. Citizen participation in collecting environmental data is implemented in various ways. Helbig et al. (2021) provide a comprehensive overview of scientific projects that utilize wearable sensors, for example. From these approaches, we derive three guiding principles for a workshop design: contextual anchoring in everyday practices, shared control in design decisions, and materialized reflection through prototyping.

Method

The study follows a participatory design approach with children, drawing on cooperative inquiry and low-fidelity prototyping traditions (Druin, 1999, 2002). These approaches are particularly suited to exploring children's perspectives on technology and environmental phenomena, as they support expression beyond verbal articulation. Hagen et al. (2012) introduce a method matrix for designing with children and aligning them with specific activities in the design process, such as the "bags of stuff" method for low-tech prototyping. The bags of stuff represent a collection of materials, including paper, scissors, glue, markers, etc., used to create technology prototypes in response to specific questions, maintaining focus on the design task (Knudtzon et al., 2003). Based on these principles, a three-stage workshop was developed to elicit 10-14-year-old pupils' outdoor activity contexts, relevant environmental variables, and design ideas for environmental sensing artifacts.

Workshop Stage 1: The Context Of Outdoor Activities

The first stage of the workshop focuses on eliciting pupils' everyday outdoor activities and the contexts in which these activities take place. Using a structured template, participants describe their outdoor activities by outlining the activities themselves, required items, modes of mobility, and the social setting. This information provides insights into pupils' lived outdoor practices and the situational conditions under which environmental sensing could potentially be integrated. Pupils talk about their experiences and how they relate to their surroundings in the following phase. Based on their perceptions and observations, they identify specific environmental elements that caught their attention during these activities. To convey these observations, they employ evocative language. This step is intended to document their preliminary, experience-based comprehension of environmental conditions prior to delving into more formal methods of measurement. This initial phase lays the groundwork for later workshop sections by gathering qualitative data regarding the contexts of the pupils' activities and their sensory experiences.

Workshop Stage 2: Environmental Data And Measured Variables

The second stage of the workshop is all about linking what pupils notice in their environment to actual things that can be measured. Building on the sensory experiences from the first stage, pupils explore common environmental factors important in urban settings, such as temperature, noise, and air quality. In this part of the workshop, pupils acquire basic knowledge of the most common measured values and distinguish which can be experienced through their senses and which require a specific tool for detection. After this introduction, participants add measured variables to the ones they named earlier and generate a richer picture of possibilities for measuring relevant environmental data. To conclude this stage, participants reflect on possible effects caused by the identified environmental influences and formulate concrete ideas for reducing these effects.

Workshop Stage 3: Designing An Environmental Sensor For A Specific Context

In this stage, pupils design and create individual non-functional environmental sensor prototypes. The design of the artifacts is supposed to address the previously defined criteria of an outdoor activity and the identified environmental influences. Therefore, participants use dummies for electronic and sensor components, as shown in Figure 1. These components are intentionally aligned with real-world technical counterparts to introduce basic technical constraints without requiring functional implementation.

The prototyping process aims to support materialized reflection on how environmental data collection and feedback could be embedded in pupils' everyday outdoor practices. At the end of

the workshop, participants present their results, explain their design, and provide reasoning for their design decisions. This stage generates qualitative data on pupils' conceptualizations of environmental sensing and the role of material prototyping in linking everyday contexts with abstract measurement concepts.

Figure 1: 3D printed sensor dummies for technical components. (red = sensors, blue = microcontrollers and GPS module, yellow = output components, green = power supply).

Data Collection And Analysis

Data were collected through the templates participants used to describe their outdoor activities, note the environmental influences they experienced, document the actions they envisioned to mitigate negative effects, and through the resulting prototypes. The workshop's design stage was video-recorded. These records were used to analyse the design process the participants followed and the design decisions they made. This wide variety of collected data enabled data triangulation (Flick, 2011) to yield comprehensible insights into participants' conduct and resulting designs. Data were analysed thematically (Braun & Clarke, 2006), and the resulting themes are aligned with the stages of the workshop and the single tasks. The resulting prototypes, their functionality, and included measured variables were tracked back to the initial descriptions of outdoor activities, needed items, modes of transport, and relevant measured variables to identify how the results correspond with the initially described context and which new factors emerged during the design stage. The workshop design and its materials were discussed in semi-structured expert interviews (Meuser & Nagel, 1991), which included a teacher (IP1), a researcher in the field of learning technologies and eDidactics (IP2), and a researcher and teacher educator covering the fields of health and environmental education (IP3). The expert interviews were video recorded, transcribed, and analysed thematically.

Results

The results are based on data collected during three workshops with 57 participants across three different schools in Vienna, Austria. The participants are aged 10-14 years and have not received subject-specific computer science teaching. The analysis focuses on patterns across activity contexts, environmental perceptions, and design concepts.

Contexts of outdoor activities

Analysis of the activity descriptions revealed dominant themes in pupils' everyday outdoor practices. A large proportion of activities were related to sports and physically active leisure, including both organized sports and informal play. Swimming for leisure, ice skating, and various ball games were highly referenced by the participants. Other referenced activities reflect

participants' transitional and social activities, often including their friends and relatives, such as relaxing, going for a walk, sitting in the park, and shopping.

The referenced activities were associated with items participants regularly use during their outdoor activities. Various types of bags, backpacks, and other carrying aids were referenced, as well as drinking bottles and nutritional supplements. Leisure and sports equipment, such as balls, rackets, skates, specific clothing, and other sports gear, was assigned to the theme of physical activity. Money was highly referenced to be a relevant item for outdoor activities, as well as the (smart)phone for communicating with others. Skateparks, soccer goals, and other infrastructure were mentioned as relevant, as well as proper conditions such as nice weather. Regarding their mobility, participants identified walking, cycling, riding a scooter, being driven by car, and using public transportation as the most relevant options.

When asked about their perception through their physical senses, participants most frequently referenced their sports equipment and temperature in relation to their sense of touch. Regarding their sense of smell, nature was highly referenced, and for their auditory sense, they referenced various animals, people, and sports equipment, such as the sound of hitting a ball.

From Physical Senses To Measured Variables

In addition to phenomena participants perceived with their physical senses, they reflected on specific measured values relevant to their outdoor activity. Weather and air quality variables were identified, including temperature, wind speed, particulate matter, CO_2, and light intensity. Noise was mainly referenced as general noise, rather than noise from specific sources. In the theme of soil & water, soil moisture and water quality were referenced. Traffic-related references include vehicle count and vibrations caused by vehicles. Many references include values that do not address environmental measures in any sense, such as the velocity of a soccer ball or a bike ride, but are closely related to the outdoor activities of the participants.

Participants reflected on potential actions to improve the conditions of their outdoor activities. Requests for regulations include implementing threshold values for pollutants. Improvements of conditions require reducing noise and improving water quality. Regarding transport, having fewer cars and fewer cargo ships is desired. Ideas for enhancing public infrastructure include additional greenery and increased shading. Actions that describe individual behaviour address proper nutrition and hydration, as well as the use of earplugs to reduce noise exposure.

The second stage of the workshop demonstrates how environmental conditions can be measured using specific sensors and identifies the relevant measured variables. It clearly shows that, in addition to environmental measures, participants are highly interested in measures directly related to their outdoor activity, such as the speed of a soccer ball.

Context-Based Designs Of Environmental Sensing Devices

In the third stage of the workshop, participants were tasked with designing and creating a sensor prototype for an outdoor activity, working in groups of three to five pupils using the available materials and tools. This design and prototyping stage produced 24 non-functional prototypes for environmental sensors. Three distinct patterns were found, as illustrated in Figure 2.

The first design pattern features wearable sensors. Sensing technology is incorporated into clothing items such as hats, bracelets, and vests. These sensors continuously gather data on the wearer and provide quick feedback, linking their surroundings to their sensations. Another design pattern involves sensors embedded in activities. These sensors are incorporated into sports gear or equipment related to the activity, such as entertaining devices, bags, or training tools. This combines environmental data with activity information to illustrate how people move, their

performance levels, and their locations. The third pattern involves sensors in places or things around us. These are set up in parks, streets, or private gardens. They monitor the environment over time and are usually intended for group use rather than providing information to individuals. In every design, pupils typically combine information about the environment with their own activity. It appears that sensing the environment was more relevant in relation to people's preferences, daily activities, and social circles.

Figure 2: Examples of resulting designs: Cap with temperature sensor (wearable sensor), portable radio with temperature sensor (activity-related sensor), garden fairy lights (placed sensor).

Cross-Cutting Insights And Misalignments Across The Workshop Stage

During the three workshop stages, some recurring ideas and conflicts emerged. Many groups created sensor designs based on the activities and environmental factors they had previously identified. However, some groups started to focus more on activity or health information. In these cases, environmental sensing shifted to the background and became less closely tied to the original research. This difference highlights the conflict between allowing freedom in the design process and maintaining a strong focus on environmental sensing. The open prototyping phase encouraged creativity and engagement. However, sometimes pupils concentrated on aspects of their activities that were personally important to them rather than considering the environment in the first place. Nevertheless, these changes provide valuable insights into what motivates and interests pupils. The shift towards activity information suggests that environmental sensing is more meaningful to pupils when it relates to how they engage in activities, how they play, or what they care about. These results highlight the need for clearer transitions and reflection between workshop phases while allowing sufficient freedom. This would facilitate creative and relevant design processes.

Experts And Practitioners' Perspectives On The Workshop Design And Learning Potential

The results from the expert interviews reflect their perspectives on the *workshop setting*, its *materials*, the *resulting designs,* and *learning effects.* The experts emphasized the importance of seamless transitions between workshop stages, particularly when shifting from contextual analysis to prototype creation. They added that, without clear direction, pupils might lose focus on environmental issues and become more concerned with personal, activity-related actions. IP2 recommends using more structured templates to support transitions and maintain focus on the workshop goals. IP3 points out that gamification elements work well in this age group, and the templates could be designed like a gameboard where participants fill in information and develop ideas step by step. Regarding support, the experts noted that teachers should act as helpers, not co-designers, and that their role in the workshops should be clear. While some direction was considered beneficial for pupils' thinking and social needs, experts cautioned against teachers influencing pupils' design choices, as IP2 states: "They can supervise, and they can talk to children who are distracted doing other things and guide them back to the task, but not do the task for them. And you should try to write this down explicitly in your workshop setup." (IP2). The

experts also reviewed the workshop materials and noted that the information posters in the second part contained too much text for the targeted age group. IP3 suggests to "…simplify it. With more illustrations, I only keep the most necessary facts. […] I would insert legends." (IP3). Using more pictures and better-planned note-taking was suggested to help pupils engage with and understand the material more easily. At the same time, the use of non-working technical models was well received, as they facilitate thinking about real design without the need for functional parts, as IP1 emphasizes: "Even though they weren't real sensors, it still made it somehow realistic, or gave it a feeling of seriousness." IP1 addressed the learning effects and stated that: "I was just thinking about whether, for some children, this was perhaps the first time they had to deal with the fact that there are specific values for measurements. […] it was certainly an eye-opener for some people to learn that there are sensors for these different measured values and in which units they are measured." (IP1), but also mentioned "that for some people, this then also expired in their short-term memory" (IP1).

The feedback from experts shows that the workshop setting and its goals are well set for discussing environmental sensing and creating sensor designs in a participatory session. Additionally, the experts' perspectives reveal improvements in materials, transitions between stages, and the definition of the teachers' role.

Discussion

The findings in relation to the research questions are discussed in this section and are situated within the theoretical frameworks of context-based learning and participatory design.

Interpreted through the lens of Contextual Design (Beyer & Holtzblatt, 1997), the findings indicate that pupils conceptualize environmental sensing in close relation to their everyday contexts. Participants were not only able to name a wide range of outdoor activities, but also to identify relevant environmental factors and metrics. The environmental conditions became meaningful primarily when embedded in concrete activities such as sports, mobility, or social leisure, supporting the CD assumption that design is grounded in their lived contexts.

From a participatory design perspective, pupils' conceptualisations demonstrate how shared control shapes meaning-making processes. The workshops enabled pupils to express environmental sensing concepts through their own interests and experiences, positioning them as contributors throughout the design process. This aligns with Schuler and Namioka's (1993) understanding of participatory design processes as a partnership between designers and users.

Pupils' frequent integration of environmental and activity-related measurements can also be interpreted as participatory urbanism. Benavides Lahnstein et al. (2022) found that pupils positioned themselves as learners and actors engaged with environmental issues relevant to their immediate surroundings. Environmental sensing was therefore not viewed as a stand-alone data collection task, but rather as a means of understanding and potentially responding to environmental conditions in urban contexts.

Interesting in our research was that there were clear differences in the transition between the stages of the workshop: While stages one and two were well integrated in terms of content, the transfer of their findings to stage three was not always consistent. Several groups designed prototypes that were only partially based on the previously named activities or metrics. This suggests that additional structuring aids, such as connecting worksheets and templates, checklists, or a brief re-mapping of the previous stage, could strengthen the connection between the stages. Regarding RQ1, this indicates that the presented workshops support pupils in conceptualizing the relationship between outdoor activities and environmental conditions by facilitating structured reflection on this relationship through the workshop process and its materials. Nevertheless, there

is room for improvement regarding the transitions between stages. As well, the focus on creating environmental sensors must be maintained throughout the design phase.

In RQ2, we investigate how the relationship between outdoor activities and environmental sensing materializes in sensor designs. The non-functional prototypes demonstrate how the pupils' ideas about the relationship between outdoor activities and environmental sensing were realised through design. These artifacts serve as tangible examples of how pupils integrated environmental sensing into activity-specific contexts, rather than using it as a technical fix. This demonstrated that environmental measurements were considered important when they were directly related to pupils' daily activities.

The conversation now shifts to how pupils integrated environmental sensing ideas into their non-functional prototypes, building on these conceptualizations. The findings also highlight a fundamental conflict between developing contextually accurate and environmentally relevant sensing concepts and ensuring transparency in the participatory design process. While openness encouraged creative and varied designs, it also sometimes led to activity-related features taking precedence over environmental sensing. In a few instances, however, this focus on activities also resulted in hybrid designs that integrated activity-related and environmental measurements, demonstrating pupils' attempts to negotiate relevance within the design space.

From a participatory design perspective, this conflict reveals a key challenge: balancing personal preferences with broader societal concerns. According to the results, environmental relevance requires intentional support rather than assuming it will emerge naturally. This is consistent with Iivari et al.'s (2024) call for participatory design that addresses important issues. To facilitate design processes that reflect pupils' lived experiences and engage with relevant environmental issues, it is crucial to balance creative freedom with thematic alignment.

Limitations

Several limitations of this study need to be considered. The workshops took place in school settings with limited time and resources, and the sustainability of the learning outcomes was not systematically assessed. The results, therefore, capture their ideas and understandings at a specific moment rather than documenting lasting learning. Group dynamics, such as the presence of dominant individuals or unequal participation, may have influenced how environmental concepts were expressed in the prototypes' designs. Finally, the workshop used a predefined set of materials for non-functional prototyping. While this made the activity accessible for the age group, it may also have narrowed the range of possible designs. This reflects a common tension in participatory design: offering enough structure to support learners while allowing space for open-ended exploration.

Conclusion And Future Work

Climate change mitigation is a challenge that needs strong efforts from all parts of the global society. Education and awareness-raising on climate change and the reduction of pollutants are integrated into curricula to support children in identifying how they are affected within their cultural context. The introduced participatory workshop setting, along with its materials, enables participants to reflect on environmental conditions related to their outdoor activities by creating a context-specific environmental sensor. The resulting designs illustrate how children envision environmental sensor artifacts for their outdoor activities, and that certain combinations of measured variables, collecting data on environmental conditions and the activity itself, are a fruitful approach for supporting engagement and long-term use.

From a didactic perspective, two levels of impact can be distinguished: (1) research findings on the contextualization of environmental measurement in the everyday lives of young people, and (2) learning effects in terms of environmental awareness, interest in technology, and design competence. While methodological openness provides rich design ideas for research, a stronger connection to school subject contexts (e.g., physics, geography, biology) can be helpful for sustainable learning effects. The results suggest that measurable, sensory variables (temperature, noise level, wind) facilitate intuitive access, while more abstract variables (e.g., NO_x, ozone) require additional didactic preparation.

Overall, the study confirms the potential of participatory, context-based design workshops to promote both environmental education and technical design in lower secondary education. To optimize the workshops, it is particularly advisable to strengthen the common thread between stages in terms of content, make the materials more age-appropriate, and create opportunities for further in-depth work in the classroom. Additionally, in future work, the dummies representing technical components are to be replaced by functional parts, enabling children not only to design sensors but also to collect real-world data and draw conclusions about environmental conditions affecting their outdoor activities.

Acknowledgements

This work is conducted within the scope of the “STEAM - STEM - stART'em” doctoral program funded by OeAD (Austria's Agency for Education and Internationalisation). The workshops were supported by the grammar schools BG & BRG Rahlgasse (Vienna) and BRG Seestadt (Vienna), as well as by the middle school PMS Vienna.

Learning About The Menstrual Cycle Through The Use Of Narratives In Initial Teacher Education

Candelaria Manetti[1], María Madelaine Vieyra[1] and Leticia Garcia-Romano[1,2]
[1]Science and Technology Teaching Department, Faculty of Exact, Physical and Natural Sciences, National University of Córdoba, Córdoba, Argentina.
[2]National Scientific and Technical Research Council (CONICET), Córdoba, Argentina

Human biology and health education are extremely important topics in secondary school and, by extension, in teacher education. In particular, there are several misconceptions and reductionist ideas associated with teaching and learning about the menstrual cycle. Within this framework, we set out to develop a teaching sequence to foster a comprehensive understanding of the biological and functional concepts related to the menstrual cycle. The study used a design-based research approach. The activities were implemented in an initial teacher training course in Córdoba, Argentina, focusing on creating multiple narratives about the menstrual cycle and reflecting on the stories of different characters. The results show that the pre-service teachers constructed contextualised ideas about the menstrual cycle and that the pedagogical resources developed facilitated a practical visualisation of the theoretical content, promoting the expression and questioning of notions, taboos, emotions and experiences related to this process.

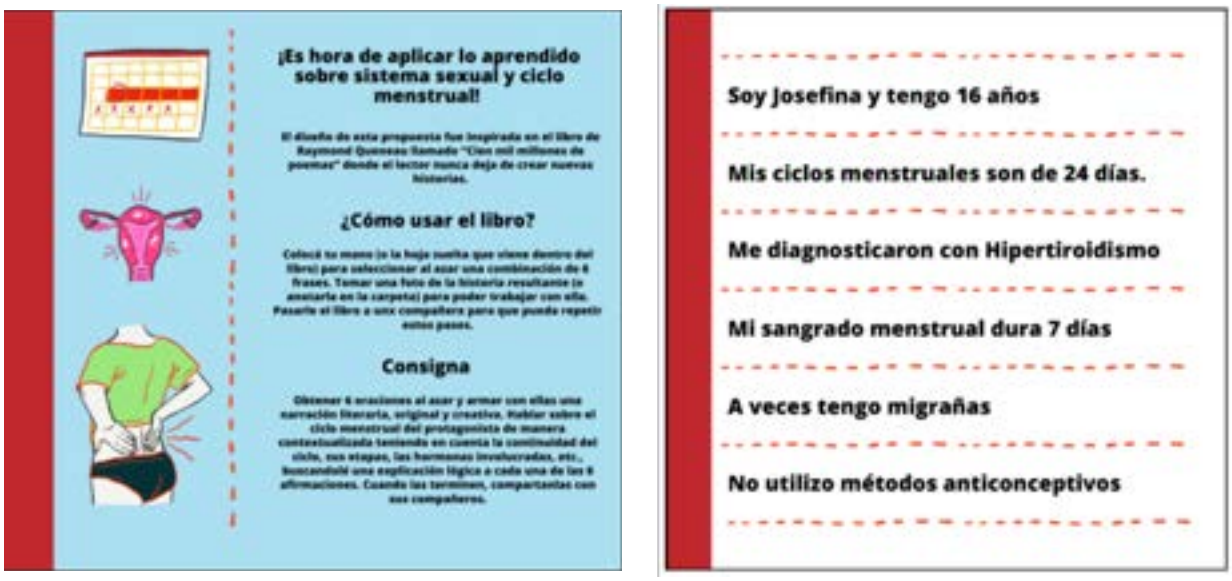
Keywords: Health Education, Teacher Education, Human Biology.

Introduction

In secondary schools in Córdoba (Argentina), the biology curriculum broadly covers Human Biology, including biological systems, organs and processes. However, much of this content is complex and abstract for students, which often leads to rote learning (Ariza & Navarro, 2021). In addition, many of these topics are closely linked to health education, which requires teaching oriented towards the analysis of information, the development of critical thinking skills, reflection, problem-solving and the ability to establish relationships (Jiménez-Aleixandre & Puig, 2022).

Regarding specifically the concept of the menstrual cycle, several authors highlight the variety of misconceptions and reductionist ideas linked to this process, including approaches that focus only on reproductive aspects, notions that emphasise the uniformity of bodies, and approaches that override emotions, experiences or cultural meanings about this process (Blázquez Rodríguez & Bolaños Gallardo, 2017; Kohen, 2018; Sirovina, 2022). This view makes it difficult for students to connect the menstrual cycle to their daily lives and understand its relevance to health and well-being. Droguett Muñoz and Camacho González (2021) assert that the teaching of the menstrual cycle reflects the shortcomings of the current education system, which is not adapted to students' needs. Learning about the menstrual cycle involves understanding complex biological processes that require in-depth preparation, making it a challenging subject. In this sense, it is necessary to improve teacher training in mastering these concepts so they can teach them more deeply, avoiding simplistic explanations.

The menstrual cycle is a multidimensional phenomenon in which biological, psychological, social and cultural aspects interact. This underlines the need to analyse the psychosocial aspects of the menstrual cycle, considering not only the biological functions but also the psychological, anthropological and cultural dimensions (Botello-Hermosa & Casado-Mejía, 2015). This integration requires rethinking the teaching of the menstrual cycle so that students not only



receive information but also understand its multidimensionality and apply it to specific contexts. In this sense, narratives offer the potential to convey the conceptual content of school science, contribute to meaningful understanding by relating central ideas in a plot, and positively impact student motivation, among other issues (Revel Chion & Adúriz-Bravo, 2022). This proposal seeks to stimulate student motivation and foster situated and contextualised understanding, recognising the diversity of emotions and bodies, each with unique personal experiences.

Method

The study was conducted within a design-based research approach, which aims to generate knowledge to improve teaching practices by preparing, implementing, and analysing didactic designs (Guisasola & Oliva, 2020). The didactic design aimed to promote a comprehensive understanding of the biological and functional concepts of the menstrual cycle from a holistic, multidimensional perspective. The theoretical goal was to produce evidence-based contributions to the teaching of human biology, specifically the menstrual cycle, through narratives. The proposal was carried out in collaboration with the professor responsible for the 'Human Biology' course in an initial teacher training program in Biology, with seven pre-service teachers participating in its implementation. The results were analysed qualitatively.

In this context, the didactic tool ‘One Hundred Billion Menstrual Cycles’ (Figure 1) was created (Manetti, 2023). This small book allows readers to create multiple narratives about the menstrual cycle, featuring different characters. This tool aims to promote a comprehensive understanding of the biological, social, and emotional aspects of this concept.

Figure 1. Two pages of the book designed for the development of the didactic sequence. The first page explains how to use this teaching tool. The second page represents an example of the six sentences that could be combined to create a narrative.

The first part of the intervention consisted of a theoretical introduction to the menstrual cycle, addressing its definition, duration and characteristics. The pedagogical approach prioritised critical dialogue in the classroom, supported by audiovisual tools and constant feedback. Then, the pre-service teachers created contextualised narratives with one of the book's characters as the protagonist. Finally, in a group dynamic, participants shared their stories, highlighted the common and unique points of the narratives and reflected on how to integrate this knowledge into their daily lives.

The narratives were collected to evaluate the teaching sequence and to assess the tools used. Each narrative was evaluated on four components: pragmatic, rhetorical, logical, and theoretical. Following Revel Chion et al. (2013), the pragmatic component refers to the appropriateness to

the context that gives meaning to the story, the rhetorical component implies the intention to persuade the reader or listener of the narrative, the logical component represents the complex syntactic structure of the text and the theoretical component alludes to the theoretical model of reference, in this case, the menstrual cycle.

To deepen the theoretical component, the categories of analysis proposed by Bahamonde and Gómez Galindo (2016) were restructured, and the ideas of continuity, interaction, transformation and integration present in the narratives were evaluated. The concept of continuity implies conceptualising the sexual system and folliculogenesis as the basis of the menstrual cycle. The notion of interaction emphasises that the menstrual cycle is not only dependent on the sexual system but also cuts across all systems of the organism. Transformation refers to the evolving nature of the follicle throughout the menstrual cycle. Integration involves understanding the connections between the sexual system, other bodily systems, and the emotional experiences that occur during the cycle, establishing a logical, biological and emotional explanation for the process.

Each category was assessed using a rubric developed by the researchers, with the following values assigned: excellent, satisfactory, needs improvement or insufficient. Additionally, two surveys were administered, one at the beginning and the other at the end of the development of the didactic sequence, to assess pre-service teachers' knowledge and opinions on the subject and the proposal developed.

Results

Most narratives demonstrated contextual appropriateness, structural coherence, and persuasive presentation. In terms of the theoretical component, the most prominent category was integration, with most narratives showing a clear understanding of the stages of the menstrual cycle, the hormones involved, the characteristics of different methods of contraception, and the development of a logical, biological and emotional explanation for the symptoms presented in the book (Table 1). Regarding the other three dimensions, while some narratives were auspicious, others showed insufficient development. The most challenging aspects in this regard were the following: 1) only three narratives presented the interaction between the ovarian cycle, the endometrial cycle and the hormones produced in the hypothalamus, and 2) the transformation of the follicle into an egg cell was not captured in the writings. However, during the oral exchange of the narratives, the participants demonstrated an understanding of these topics. This finding suggests that the narrative writing task could be enhanced to foster greater development in this area.

Table 1. Assessment of the theoretical component across the seven narratives, showing the distribution of qualitative ratings for continuity, interaction, transformation, and integration.

Narrative	Continuity	Interaction	Transformation	Integration
Narrative 1	Satisfactory	Needs improvement	Needs improvement	Insufficient
Narrative 2	Excellent	Needs improvement	Excellent	Excellent
Narrative 3	Needs improvement	Insufficient	Insufficient	Satisfactory
Narrative 4	Needs improvement	Excellent	Insufficient	Satisfactory
Narrative 5	Needs improvement	Excellent	Insufficient	Excellent
Narrative 6	Needs improvement	Excellent	Insufficient	Excellent
Narrative 7	Needs improvement	Insufficient	Excellent	Excellent

Beyond identifying biological elements, the analysis of the narratives revealed an integration of the menstrual cycle as a multidimensional phenomenon. Participants articulated biological processes in relation to emotional experiences, social contexts, and life trajectories of the characters they constructed. This integration was particularly evident in narratives that incorporated references to stress, identity, life stages, access to healthcare, and contraceptive decisions. Such narratives suggest that the use of contextualised storytelling facilitated a shift from a fragmented understanding of the menstrual cycle to a more situated conceptualisation.

An additional relevant outcome concerns the explicit emergence of emotions associated with the menstrual cycle. Many narratives incorporated emotional dimensions such as anxiety, relief, discomfort or ambivalence. These emotional references were not treated as mere anecdotes but were often linked to biological explanations or contextual factors, such as hormonal fluctuations, social expectations, or stressful life situations. This finding suggests that narrative-based activities may create pedagogical spaces that legitimise emotional expression and contribute to questioning socially rooted taboos surrounding menstruation.

The diversity of characters represented in the narratives constitutes another significant result. Participants constructed stories that represented individuals at different life stages and with diverse bodily and identity-related experiences, as well as individuals with irregular cycles, health conditions, or diverse reproductive choices. This diversity allowed pre-service teachers to problematise the idea of a "standard" menstrual cycle and to recognise variability as a central feature rather than an exception. In this sense, the narratives functioned as a didactic resource to challenge universalised and normative models commonly found in school biology teaching.

Regarding the surveys, most participants highlighted the usefulness of the book and the infographic for understanding the menstrual cycle. The pre-service teachers highlighted that the book "One Hundred Billion Menstrual Cycles" enables them to combine sentences to create stories, engaging in a creative and reflective exercise while applying theoretical concepts in a practical context. In addition, the comprehensive, contextualised and holistic approach enabled participants to incorporate social, cultural and emotional aspects into their narratives, enriching their understanding of the menstrual cycle as a complex and multidimensional phenomenon.

Conclusions

The results indicate that the activities proposed during the sequence, including the use of the book 'One Hundred Billion Menstrual Cycles', enriched the understanding of the menstrual cycle, providing a more comprehensive and contextualised perspective. These pedagogical resources facilitated a practical visualisation of the theoretical content, promoting the expression and questioning of notions, taboos, emotions and experiences related to the menstrual cycle and menstruating bodies. Thus, a multidimensional construction of the cycle has been promoted, encompassing physiological, social, emotional, cultural, economic and health aspects.

Besides, it is important to highlight that the book 'One Hundred Billion Menstrual Cycles' offers opportunities to explore various topics, such as sexual diversity, pregnancy, and endocrine disruptors, among others, issues that we will be able to address in new implementation cycles of our proposal within the framework of the design-based research approach.

Although the results were positive, opportunities for improvement were identified. It is suggested that the narrative task be reformulated to deepen the teacher's theoretical knowledge, thereby leading to more enriched stories. It is also proposed to include more pages in the book, as the first sentences were less frequently chosen by participants, leading to the same characters and stories being selected by different pre-service teachers. This modification aims to generate a greater variety of stories and avoid repetition of the same characters. In dialogue with the professor who

carried out the sequence, we assert that it is essential to implement the strategy across various institutions to evaluate its effectiveness in different contexts and educational levels, in order to adjust the proposal and apply it transversally throughout the education system.

Despite the promising results, this study is limited by the small number of participants and its implementation within a single institutional context. Future research could explore the use of this narrative-based approach in other teacher education settings and educational levels. Additionally, further studies could investigate how narrative work interacts with other scientific practices, such as modelling or argumentation, in the teaching of human biology.

ESERA 2025 Copenhagen

Exploring Adolescent Student's Knowledge and Beliefs about Menstruation and Understanding the Influence of Education on It.

Garima Rai[1], Shamin Padalkar[2] and Rafikh Shaikh[1]
[1]Tata Institute of Social Sciences, India
[2]Indian Institute of Science Education and Research, India

This study explores the knowledge, beliefs, and attitudes regarding menstruation among middle school students in an urban co-educational school in India. The research investigates how formal education influences students' understanding of menstruation, with a focus on dispelling myths and misconceptions. Data was collected through a survey administered to 62 students from Grades 7 and 8, with a focus on comfort levels, scientific knowledge, misconceptions, and information sources. Findings indicate that while Grade 8 students demonstrated improved awareness of menstruation compared to Grade 7 students, significant gaps remain in scientific understanding and there are persistent cultural misconceptions. Boys exhibited lower levels of knowledge, they also showed a higher tendency to believe in menstrual myths. Girls, in contrast, had better knowledge. The study underscores the importance of integrating boys into menstrual education to reduce stigma and promote gender inclusivity. It suggests that menstrual education should begin before Grade 7 to ensure accurate information is provided before misconceptions take hold. It also calls for teacher training and more open discussions in schools. The research highlights the critical role of health education in challenging menstrual taboos, improving understanding, and fostering empathy across genders, leading to a more inclusive and supportive school environment.

Key words: Health Education, science education, cultural context

Introduction

Menstruation remains a critical area of research, particularly in understanding how education shapes students' knowledge, beliefs, and attitudes. The stigma and misconceptions surrounding menstruation often create barriers to open discussions, reinforcing restrictive social norms. In India, menstruation is frequently associated with cultural taboos that portray it as impure, limiting the participation of menstruating individuals in religious and social activities. While education and media exposure have contributed to changing perceptions, misinformation persists, affecting adolescents' understanding and menstrual health practices. This study explores how middle school students in an urban co-educational school in India understand menstruation and examines whether formal education helps dispel myths and misconceptions.

This study is grounded in Social Constructivism Theory, emphasizing that knowledge is shaped through social interactions, cultural norms, and education. Vygotsky's perspective highlights how family, peers, media, and school influence students' perceptions of menstruation (Akpan et al., 2020). Findings inform curriculum development, teacher training, and gender-inclusive education to challenge misconceptions and foster awareness.

Related literature

Research highlights persistent gaps in menstrual awareness among adolescents. A UNICEF (WaterAid, 2018) study found that 52% of girls in India are unaware of menstruation before menarche, leading to confusion and anxiety. Lack of education contributes to school absenteeism, with 23% of girls dropping out due to stigma and inadequate support (Garg & Anand, 2015). A

review of menstrual health programs in India found that schools with structured education initiatives had lower absenteeism, particularly in model schools with NGO support (Sivakami et al., 2018). In 2014, the Ministry of Health and Family Welfare introduced the National Adolescent Health Programme, called Rashtriya Kishore Swasthya Karyakram (RKSK). This initiative outlined specific guidelines aimed at promoting education, awareness, and improved menstrual hygiene management (MHM) through a peer education approach. The program focused on strengthening protective factors among adolescents to foster resilience, using both community-level and school-based strategies. Although this program aims to address an important issue, we did not find any literature on the actual implementation strategies or on the effectiveness of this programme.

Global research reinforces these findings. In Uganda, students' menstrual knowledge significantly improved after targeted educational interventions, demonstrating the value of structured school-based programs (Kansiime et al., 2020). Studies from Ghana and Afghanistan emphasize the role of sociocultural norms in shaping menstrual beliefs and the importance of including boys in menstrual education to foster a more inclusive learning environment (Mohammed & Larsen-Reindorf, 2020). In India, a cross-sectional study revealed that 76.2% of schoolgirls believed menstruation involved the removal of impure blood, highlighting widespread misconceptions (Seenivasan et al., 2016).

Despite menstruation being part of school curricula, many teachers feel unprepared or uncomfortable discussing the topic (Mukerjee et al., 2023). The success of model schools, which integrate NGO-supported menstrual awareness programs, suggests that structured interventions significantly improve students' understanding and experiences.

Research Questions

This study examines the following:

1. What are the knowledge, beliefs, and attitudes regarding menstruation among 7th and 8th-grade students?
2. What are the sources of this knowledge?
3. How does menstrual knowledge differ between Grade 7 (before formal instruction) and Grade 8 (after formal instruction)?
4. Are there gender-based differences in menstrual knowledge and beliefs?

Research Methodology

This study employed a survey method to examine students' knowledge and beliefs about menstruation. Consent was obtained from the head teacher, and a paper-pencil questionnaire was administered separately to Grade 7 and Grade 8 students. The questionnaire included basic demographic questions followed by 15 menstruation-related questions—one open-ended and 14 multiple-choice or checkbox-based, 3 of these questions were based on the questions used by previous researchers, such as Sakhi et al. (2023). Data was anonymized and analysed using descriptive and inferential statistics.

Study Setting, Participants, And Instructional Context

The study involved 28 Grade 7 students (17 males and 11 females) and 34 Grade 8 students (23 males and 11 females) from a government school in a metropolitan city in India. The school serves underprivileged students, many from migrant families with low parental education. The average age of participants was 12 years (Grade 7) and 13.25 years (Grade 8).

Menstruation-related content at the study site was taught by a female teacher, 48 years old with 11 years of teaching experience. Instruction framed menstruation as a health and rights topic relevant to students of all genders, and the teacher reported encouraging early, curriculum-integrated coverage (e.g., from Grade 5) given earlier pubertal onset and students' exposure to potentially unreliable online information. The topic was introduced through lessons on puberty and adolescence (physical changes, diet/nutrition) and then extended to reproductive development and the menstrual process. Teaching was interactive and used government-authorized materials (e.g., NCERT/SCERT videos), QR-code-linked textbook resources, and project-based student presentations. In the co-ed classroom, the teacher anticipated discomfort (particularly among boys) and addressed it through explicit scientific explanation and structured discussion intended to normalize the topic and support respectful participation.

Findings

This section presents students' knowledge, beliefs, and attitudes regarding menstruation, followed by grade-wise and gender-based differences. The findings are structured around four key themes: comfort level, scientific knowledge, misconceptions and superstitions, and sources of information.

Students' Knowledge, Beliefs And Attitude Regarding Menstruation

Questions Related To Comfort Level

When asked "Do you know about menstruation?", 36% of Grade 7 and 76% of Grade 8 students responded 'Yes', suggesting increased awareness with age and curriculum exposure. 50% of Grade 7 and 15% of Grade 8 said 'A little bit'. 14% of Grade 7 and 9% of Grade 8 students did not know the term.

For "Do you feel embarrassed discussing menstruation?" 25% of Grade 7 and 9% of Grade 8 students said 'Yes', while 50% of Grade 7 and 26% of Grade 8 said 'Sometimes'. 21% of Grade 7 and 62% of Grade 8 students did not feel embarrassed, indicating, although most students did feel embarrassed, there is a decline in stigma with increased age and curricular exposure.

Questions Related To Scientific Knowledge

For "At what age do girls typically start menstruating?", 68% of Grade 7 and 88% of Grade 8 students correctly answered '10-16 years'. The remaining students either underestimated (6-9 years) or overestimated (16-20 years) the age.

For "At what age do women stop menstruating?", 39% of Grade 7 and 59% of Grade 8 students correctly answered '45-55 years', showing lower awareness than that of age of menarche, while the remaining underestimated (30-45 years) or overestimated (after 55 years) menopause age.

Responses for "Which hygiene products have you heard of?" are summarized in Table 1.

Sanitary pads were the most well-known product, likely due to advertisements and availability in general stores. Despite being eco-friendly and traditional, cloth napkins and folded cloth were less recognized.

For an open ended descriptive question, in Grade 7, 4% identified menstruation as a reproductive process, 11% as a periodic process, and 75% lacked scientific understanding. 11% mentioned superstitions such as *"women would be dirty"and "women shouldn't be touched"*.

In Grade 8, 26% identified menstruation as reproductive, 24% recognized it as periodic and 15% mentioned hormones. However, 53% did not understand the shedding of the uterine lining, and 47% lacked knowledge about its periodic nature, indicating gaps despite curriculum exposure.

Table 1: Percentage of students who knew about each of the different hygiene products.

	Sanitary pads	**Folded piece of cloth**	**Menstrual cup**	**Tampons**	**Others**	**Cloth napkin**
Grade 7	96%	11%	14%	11%	0%	0%
Grade 8	68%	15%	12%	15%	21%	9%
Combined	81%	13%	13%	13%	11%	5%

Misconceptions And Superstitions

Students reported commonly held beliefs about menstrual, including:

"Girls cannot go out during menstruation."

"Menstruation should be kept secret."

"Menstrual blood is impure."

In response to "Have you heard of any of the following superstitions?", results are given in Table 2.

Table 2: Percentage of students who are aware of different superstitions.

Superstition	**Grade 7**	**Grade 8**	**Combined**
Menstruating girls should not enter temples or religious places	82%	71%	76%
Menstruating girls should avoid physical activities	43%	47%	45%
Menstruating women and girls should not cook or touch certain food items	39%	47%	44%
Menstruating women and girls should sit separately	36%	44%	40%
Menstrual blood is impure	32%	41%	37%
Menstruation should be kept a secret	36%	35%	35%
We should not touch menstruating women and girls	21%	18%	19%

The belief that menstruating girls should not enter religious places was most widespread. Percentages were similar across grades, suggesting deep-rooted cultural influences.

For "Should dietary restrictions be followed during menstruation?", 46% of Grade 7 and 35% of Grade 8 students said 'Yes', while 43% of Grade 7 and 50% of Grade 8 were unsure.

For "Should girls/women attend school or work during menstruation?", responses were:

25% of Grade 7 and 18% of Grade 8 said 'Yes'.

46% of Grade 7 and 65% of Grade 8 said 'Only if physically fit'

21% of Grade 7 and 15% of Grade 8 said 'No'.

For “Should girls/women participate in physical activities during menstruation?” 36% of Grade 7 and 29% of Grade 8 responded affirmatively, while 44% of Grade 8 said ‘No’, reflecting strong beliefs in activity restrictions.

Differences Between Grade 7 And Grade 8 Students

In addition to qualitative analysis, we also calculated the total scores based on the questions related to knowledge about menstruation. Average score of Grade 8 students (M=63.89%, SD=18.3) was significantly higher than that of Grade 7 students (M=52.98%, SD=21.2) with a moderate effect size ($t(60) = 2.17$, $p = .03$, $d = 0.56$). This indicates that the inclusion of the topic in the textbook and the classroom instruction must have played some role in this improvement.

Table 3: Sources of information about menstruation according to their percentages.

Source	Grade 7	Grade 8	Combined
Teacher	21%	59%	42%
Textbook	4%	62%	35%
Mother	50%	15%	31%
Friends	29%	26%	27%
T.V. advertisement	32%	24%	27%
Internet	39%	9%	23%
A doctor or a health professional	7%	12%	10%
Someone else in the family (sister / grandmother / father etc.) Please specify	11%	3%	6%
Other books (If yes, name the books)	4%	3%	3%
Other sources. Please specify	0%	6%	3%

Sources Of Information

Students’ responses to the question “Where did you get information about menstruation? Tick on all that applies” are given in Table 3.

Teachers and textbooks were the most cited sources for Grade 8, while mothers, TV, and the internet were more common for Grade 7. Few students consulted doctors or health professionals.

For “Would you like to learn more about menstruation?”, 68% of Grade 7 and 59% of Grade 8 said ‘Yes’, while 38% of Grade 8 were uninterested.

For “Should schools play a larger role in menstrual education?”, 54% of Grade 7 and 62% of Grade 8 agreed, though 21% of Grade 8 students opposed it.

For “How would you prefer to learn?” students preferred health professionals (32%), books (29%), and videos (14%), which again suggests unwillingness to discuss the topic in public.

Differences Between Male And Female Students

Table 4 describes the gender-based differences (RQ4).

Table 4: Comparison of Male and Female Students' Knowledge of Menstruation

Category	Girls (%)	Boys (%)
Average Score	71.5% (SD = 15.0)*	52.1% (SD = 19.6)
Awareness of Menstruation	83%	43%
Correct Age of Menstruation	66.7%	33.3%
Correct Age of Menopause	61.1%	44.4%
Primary Source of Information	Mother (55%)	Internet (27%), Friends (28%)
Textbooks as a Source	23%	43%
Teacher as a Source	41%	43%
Friends as a Source	27%	28%
Doctors/Health Professionals	14%	8%
TV Advertisements	23%	30%
Correct Scientific Explanation	10-15%	10-15%
Belief in Myths	1%	25%
No Response on Scientific Info	8%	43%
Alternative Misconceptions	-	"Hormonal imbalance," "Puberty is menstruation"
Embarrassment in Discussing Menstruation	14%	18%
Belief in Dietary Restrictions	50%	35%

* An independent sample t-test revealed that the average score of girls (combining Grades 7 and 8) was significantly higher than that of boys ($t(60) = 4.36$, $p < 0.00$).

Conclusions

The findings indicate a significant improvement in students' understanding of and beliefs about menstruation following formal instruction in Grade 8, compared to Grade 7 students who had not yet covered the topic of reproduction. However, while students demonstrate a foundational awareness, significant lacunae remain in their scientific understanding of the menstrual cycle. Consequently, even after formal instruction, menstrual myths and misconceptions remain prevalent.

A pronounced gender gap was also evident; male students demonstrated significantly lower levels of awareness and understanding compared to their female peers. While female students provided more accurate and informed responses, both genders remained influenced by social taboos and expressed feelings of embarrassment, often subscribing to entrenched myths and superstitions. Although both boys and girls relied on informal sources of information such as mothers for girls

and internet and friends for boys, textbooks and teachers remain a prominent source of information for both genders.

Recommendations

This study demonstrates the necessity for early and comprehensive menstrual health education (MHE). Within the diverse educational landscape of India, levels of menstrual literacy vary significantly across cultural, social, and geographical contexts. Although schools have integrated menstruation into the curriculum, the effectiveness of its implementation remains inconsistent.

Current pedagogical approaches focus predominantly on physiological aspects, often neglecting the psychological and emotional dimensions of the topic. Therefore, a more holistic approach is required to foster a nuanced understanding among students. To enhance menstrual education in Indian government schools, there is a critical need for a curriculum that integrates biological facts with emotional well-being and gender sensitivity.

The study also indicates that textbook-based instruction is insufficient to dismantle long-standing misconceptions and deep-seated social attitudes. To address this, educational stakeholders must prioritize robust teacher-training programs and school-based interventions aimed at promoting menstrual health and hygiene (MHH). Such interventions are particularly vital in schools serving lower socio-economic strata, where misinformation and superstitious beliefs are often more entrenched due to limited educational access.

Furthermore, collaboration between schools, parents, and healthcare professionals is essential to ensure that education is both scientifically accurate and culturally sensitive. Normalizing discussions around menstruation is a prerequisite for fostering an inclusive environment that empowers students to challenge misinformation and advance gender equality.

Directions For Future Research

This study opens several avenues for future inquiry within science and health education. Future research should explore the long-term impact of early-grade menstrual education in mitigating social stigma and taboos. Longitudinal studies, in particular, would be valuable in tracking how students' understanding evolves over time and how formal instruction shapes their long-term perceptions and practices.

Additionally, comparative studies across diverse school settings—including rural, tribal, and private institutions—would provide deeper insight into how socio-economic and cultural variables influence menstrual literacy. Finally, there is a significant gap in literature regarding male students' perceptions of menstruation. Future research should focus on inclusive educational models that involve boys, as gender-segregated approaches often inadvertently perpetuate the very stigma and misconceptions that education seeks to eliminate.

Exploring Expert Conceptualizations Of Type-2 Diabetes Through Network Analysis: A Pilot Study

Julien-Pooya Weihs[1,2]
[1]Geophysical Institute, University of Bergen, Norway
[2]Bjerknes Centre for Climate Research, Norway

This pilot study explores the conceptual structures of expert knowledge on Type-2 Diabetes (T2D) by applying network analysis to natural language explanations. Ten expert sources including interviews, educational videos, and a reference textbook, were transcribed and transformed into conceptual graphs through an automated pipeline that identifies [concept–relation–concept] triples from sentences. Concepts were categorized into domains of a T2D explanation, and semantic relations were encoded as directed edges. Network analysis techniques, amongst others betweenness centrality and backbone filtering, revealed both consensus and diversity in expert representations. While causes like obesity and family history were widely shared across the sources, treatment strategies lacked convergence. Individual graphs showed variation in node density, thematic foci, and conceptual connectivity. This study demonstrates a novel methodological pipeline for converting unstructured spoken or written expert discourse into analysable knowledge networks. It also suggests that conceptual divergence, even among experts, may influence how T2D is communicated and taught. This approach may extend to other disciplines where understanding conceptualization is crucial for a larger range of applications.

Keywords: Medical Science Education; Conceptualizations; Network Analysis

Introduction

Type-2 Diabetes

Organisms are in constant need for energy to sustain basic functions that include muscle contraction and cell division; for humans, a main source of energy is supplied via ingested food, notably from the glucose contained in carbohydrates. Insulin is a hormone that promotes the absorption of glucose in the blood by the cells of the body, amongst others in the liver and muscles. The latter organs convert the glucose into glycogen or triglycerides, which are forms of energy storage for the body to use. In the pancreas, beta cells are sensitive to the levels of glucose in the blood and promote (to decrease) or inhibit (to increase) insulin production to regulate the blood sugar. Type-2 Diabetes (hereafter T2D) is a chronic disease characterized by the inability of the body to either use insulin properly, or to produce enough of it, leading to high blood sugar levels. People affected by T2D may require regular external doses of insulin, for instance through injection shots, to avoid hyperglycaemic events that can cause potentially serious health complications.

While the pathogenesis of T2D is not fully understood yet, the disease is accepted as a complex multifactorial condition that is influenced by a combination of genetic, metabolic and environmental factors (Goyal et al., 2020). With a doubling of the number of people affected by T2D worldwide over 30 years, from 7% (1990) to 14% (2020) of the population, the condition is linked to over 1 million deaths per year on the planet, making it the 9th leading cause of mortality worldwide (Abdul Basith Khan et al., 2020). Because of the fast spread of the condition to all kinds of populations, T2D research is under important stress to tackle various associated challenges for public and global healthcare. Significant variability still exists in expert conceptualizations of T2D development, consequences, and subsequent medical care (Chatterjee

et al., 2017; Haddad & Haddad, 2018; Nauck et al., 2021). It is therefore critical to establish where the consensus lies with regards to T2D causes, treatment, and prevention.

Medical Science Education

Medical science education responds to the needs to keep the teaching and learning of medical science grounded in the fundamental sciences that compose it, as well as in research-informed best practices (IAMSE, 2026). As such, it has become increasingly multidisciplinary and collaborative, fuelled by an access to digital technologies and greater communication tools, but also because of a need to address rapidly developing complex healthcare challenges (Patel et al., 2005). This context has led to a growing pressure on medical science education to foster better medical reasoning reflected in decision making (Bornstein & Emler, 2001) and problem solving (Groen & Patel, 1985), as well as in the ability to conceptualize the disciplinary fields structuring the medical sciences (Shin, 2019). As academic instruction is provided to students by medical experts with different research profiles, their conceptualizations can influence their teaching contents and methods.

This study investigating the case of T2D within the medical sciences therefore asks the following research question:

What are the common points and differences between expert conceptualizations of T2D?

Revealing and analysing the different modes of knowledge structure and conceptual understanding amongst T2D experts (and, by extension, instructors) could inform teaching and learning in T2D education.

Methodological Frameworks

Conceptualizations And Expertise

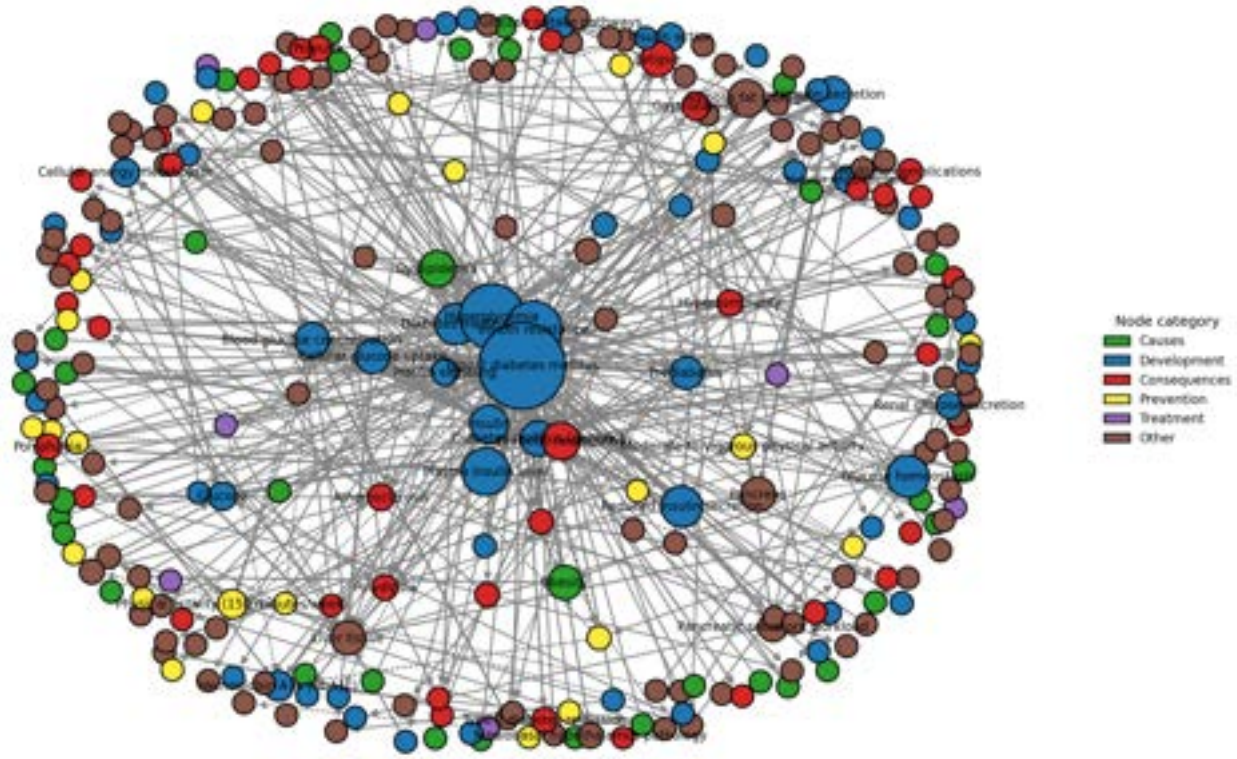
Different propositions stemming from the epistemology of science and cognitive sciences have debated how to characterize conceptualizations — also referred to as conceptual understanding — knowledge structures and means to distinguish expertise from less mature stages of experience in a discipline. Amongst these theoretical frameworks, conceptualizations are described as the combination of *content knowledge* and the appropriate judgement on how to *structure* it (Farrington-Darby & Wilson, 2006); the accurate [explanatory/logical/probabilistic] *relations* between *elements in a body of information* (Kvanvig, 2003); the grasp of '*together-hanging*' of *elements in a body of mutually supportive cognitive commitments* (Elgin, 2012); or the patterns of *relations* between *scientific concepts* (Goldwater & Schalk, 2016). A broader discussion on the common points and differences between these propositions is presented by Weihs (2026). All these representations however share a same dual nature, assimilating conceptualization to a set of concepts and the structure that connects them together. Through this lens, expertise is the mode of conceptualization reflected by disciplinary experts, amongst others in their explanation of a topic. Prior research has shown that expert explanations are denser, invoking a higher number of concepts and more relationships between them (Chi et al., 1981).

Network Analysis

The presented dual nature describing conceptualization motivates the use of network analysis as an analytical framework, supported by the suggestion by Siew (2020) that networks can be a plausible representation of knowledge structures. Stemming from mathematical graph theory and applying its algorithmic power in various domains, network analysis characterizes the properties of graph objects, composed of elements/nodes and the relationships/edges between them. Network analysis has recently shown great potential in educational research, revealing relationships between actors, institutions, or concepts in educational contexts, in ways that were

not visible before (Koponen & Mäntylä, 2020). Similarly, network analysis has been successful in studying concept maps used in both teaching and learning settings (de Ries et al., 2022; Kapuza et al., 2020), and recently to investigate scientific explanations (Koponen & Huttunen, 2013; Wagner & Priemer, 2023; Weihs et al., 2025). Particularly, Weihs et al. (2025) developed a methodology to represent and analyse conceptual understanding and knowledge using network analysis, for conceptualizations prompted via scientific explanations contained in concept maps drawn by study participants. In order to operationalize this methodology, one therefore has to have access to conceptual networks capturing the semantics and logics of a scientific explanation; either by collecting concept maps, or by transforming textual explanations into conceptual networks.

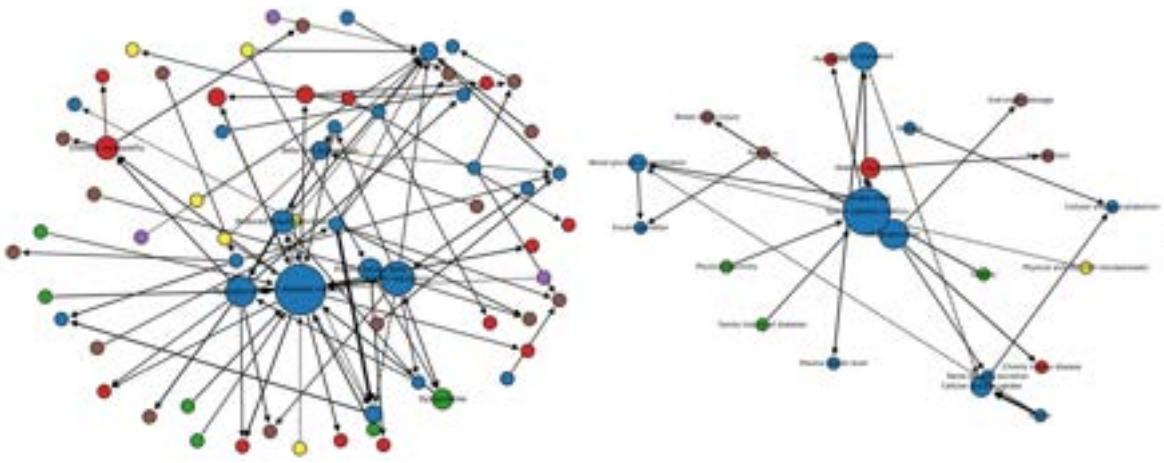
Research Design



In this study, conceptual networks are created from 10 expert sources on T2D chosen as a convenient sample for their common English language, free accessibility online, and recency: five interviews publicly available on YouTube with the T2D experts Matt Barton from Griffith University, Sarah Hallberg from Indiana University, Vassiliki Bravis from Imperial College Healthcare, Lisa Knust from Riverside Eagle Harbor Primary Care, and Erik Richardson from Ridgeview Family Health; four YouTube educational videos on the topic of T2D by the science education channel *SciShow*, the medical education channel *Understand*, and the diabetes education channels *Animated Diabetes Patient* and *Diabetes UK*; and an excerpt of the fifth chapter 'Epidemiology of Type 2 Diabetes' from a reference textbook on T2D titled 'Textbook of Diabetes' (Holt & Flyvbjerg, 2024). To do so, the nine video sources from YouTube were downloaded as audio files with a script using the *yt-dlp* library, and transcribed with a script using the *whisper* library. Through a Python-coded automated routine using natural language processing tools, the transcripts were then split into individual sentences, and in each sentence, statements with the canonical logic of *[concept A–relation–concept B]* triples were identified. Both concepts in each statement, as well as the relation between them, were coded using inductive thematic analysis (Clarke & Braun, 2017), which informed the creation of an iterative codebook. Each concept was then attributed only one of the six used categories: *Causes*, *Development*, *Consequences*, *Prevention*, *Treatment*, or *Other*. Positive relations such as '*increases*' or '*leads to*' were weighted as 1, while negative relations such as '*decreases*' or '*prevents*' were weighted as -1. For each source, the thematically coded statements were then encoded as nodes connected by a directed edge using the *networkx* library, creating conceptual graph structures for every expert source. These networks were then explored using some tools of network analysis.

Results and Discussions

Joint 'Map Of Type-2 Diabetes'



Compiling the information from the networks of all sources yields Figure 1. This joint network presents dense data that can however be regarded as the 'state of current knowledge' about T2D, according to the collected sources. It only shows the labels of the nodes with highest betweenness centrality, in other terms, the nodes most traversed by the paths between any two nodes of the graph network, which can be understood as the most essential concepts that connect the entirety of the knowledge contained in the structure. To improve readability, backbone graphs are created and presented in Figure 2.

Figure 3. Joint network aggregated from all 10 sources. The nodes are colored by category, the node size reflects their betweenness centrality, and the edge style encodes their sign (solid = positive, dotted = negative) with thickness proportional to their number of occurrences across all the sources.

The graph on the left in Figure 2 presents a weight-driven backbone network in which only edges repeated at least twice, even potentially by a same source, are chosen as a filtering criterion. In the right-hand graph, a consensus on edges mentioned by at least three sources is chosen as the filtering criterion. In the latter, three causes of T2D stand out: *obesity*, a *family history of diabetes*, and *physical inactivity*. Similarly, the consensual health consequences are *chronic kidney disease*, *diabetic neuropathy*, and *polydipsia* [an abnormally great thirst]. Such convergences in consensus answer the first part of this study's research question on the common points amongst expert conceptualizations of T2D. The only retained prevention method is *150min/week of physical activity*, and no treatment finds consensus on this graph. This could be due to the different foci of each source on the topic of T2D, which is explored in Figure 3.

Figure 2. Backbone networks filtering the joint network from Figure 1. The graphs are networks only displaying edges mentioned at least twice on the joint network (left), or mentioned at least by three sources (right). The encoding is the same as in Figure 1.

Individual Networks

Figure 3 presents the networks of each source separately. Amongst all sources, the textbook excerpt (bottom-right) particularly stands out, due both to its density in nodes and edges and to the variety of categories addressed. By contrast, some sources in the expert and YouTube channel groups focus significantly more on the prevention of the condition (in yellow), while other sources in both groups elaborate more on the consequences of the condition (in red). Likewise, certain sources present very coherent networks where almost all the nodes are interconnected, while others present two or more disjoint subgraphs, revealing a fragmented explanation where the transition from a topic to another could have been made more explicit. By comparing each individual network to the joint graph, it becomes possible to investigate which concepts and relations are unique to each source, as presented in Figure 4.

Figure 3. Individual networks for each source. The top panel presents the five expert sources (annotated with *E*), the bottom panel presents the four YouTube channel sources (*C*) and the textbook excerpt (*T*). The encoding is the same as in Figure 1.

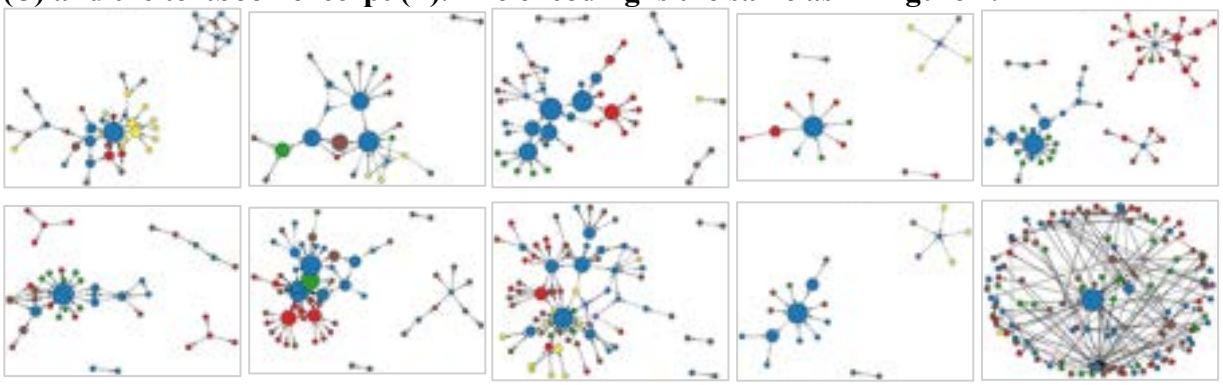


Figure 4. Uniqueness networks filtering the individual networks from Figure 3. The encoding is the same as in Figure 1; the order and annotations the same as in Figure 3.

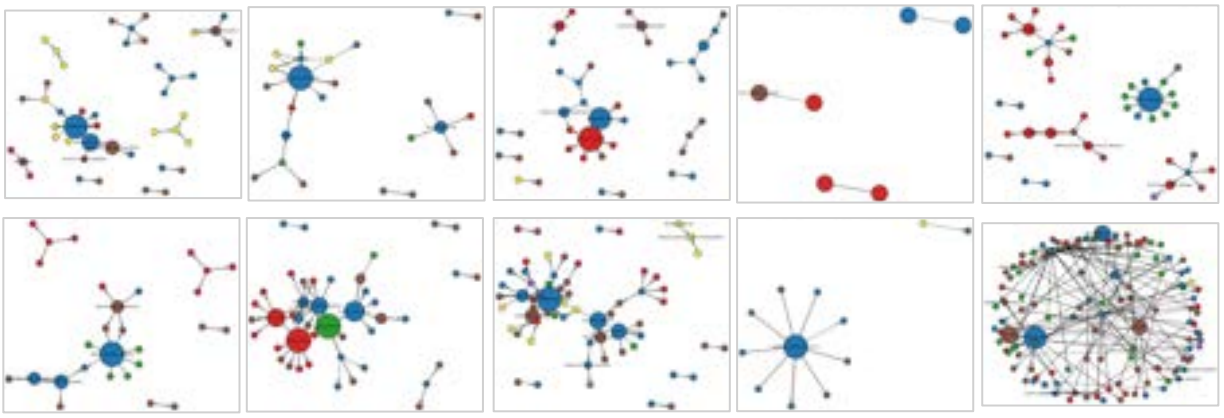

Figure 4 displays the nodes and edges that are specific to each source, and thereby shows what differences exist amongst them, answering this second part of this study's research question on the differences between expert conceptualizations of T2D. The expert source with highest focus on prevention (top-left) mentioned several unique concepts such as *dietary and physical activity monitoring*, *reduced fat, carbohydrate, and sugar intakes*, as well as *stairs climbing* and *more sustained housework and gardening activities* as overall *lifestyle modifications*. Sources focused on the causes (top-right and bottom-left) singularly mentioned *genetic predispositions and membership to high-risk ethnic groups*, but also *abdominal obesity*, *short sleep duration*, *smoking tobacco use* and *older age*, or even possible *medical therapy procedures* as factors elevating the risk of contracting T2D. Interestingly also, treatments are only mentioned exclusively across three sources, which, combined with an absence of consensus for the same category in Figure 2,

indicates possible ongoing debates in the T2D community about the remediation and interventions to cure the disease.

Conclusion

Preliminary Findings

This pilot study has investigated the conceptualizations of 10 expert sources on the topic of T2D, and shown that using automated coding routines enables to convert video into audio, then text, and finally into graph network data. This data can then be explored using network analysis tools, offering a new perspective on the knowledge structures and patterns of conceptual understanding of each source about their discussed topic. Common points as well as differences between sources were identified and helped supporting the idea that currently, there might only exist a partial consensus on the causes, consequences, development, prevention and treatment of T2D. At a time where the disease has become critical for public healthcare worldwide, more research building up on this pilot study could contribute to inform how to best teach the current and next generation of practitioners to most effectively address the global medical challenges associated with T2D.

Limitations

Despite its exploratory nature, this pilot study is subject to several limitations reducing its current scope and explanatory power. First, the small sample situates any claim outside of the realm of statistical significance, rendering the discussions mostly about first order patterns and tendencies. Then, only a triangulation of the used sources with commentary from other T2D experts — or another kind of admitted 'disciplinary truth' — about the results could help validate the findings and ensure that the discussion is grounded in contemporary T2D research, notably by confirming or rejecting statements from the sources. Also, as thematic analysis typically requires measuring an intercoder accuracy score, the analysis performed in this study has not been rigorously verified on a large enough sample to guarantee a maximal level of reliability. Finally, this study assumed that conceptualizations affect how experts teach when becoming educators but did not empirically address how these findings might impact educator training, teaching practices, or learning techniques. These important considerations are left open for follow-up work on the topic.

Implications

Beyond the complementary perspective that this pilot study presents on T2D conceptualization, the methodology it developed and used to convert natural spoken and written language in conceptual networks that capture the semantics and logics of a scientific explanation could have a larger impact on many other types of research. In fact, this method, also discussed amongst others by Wagner (2024), would enable a new type of data collection and subsequent analysis in many human and social sciences. Drawing on the power of network analysis to process this kind of network data could possibly expand the analytical treatment of both previously used and novel types of data sources. In addition, the presented methodology could be extended to the routines of reading and studying scholarly literature, enabling researchers to extract intersections with prior work and identify novel contributions in scientific articles automatically.

Informal, Non-formal And Out-Of-School Science Education

Co-editors: *Patricia Patrick & Lorenz Kampschulte*

Part 11 / Strand 11 Informal, Non-formal And Out-of-school Science Education

Teaching and learning theories and practices in informal, non-formal, and out-of-school settings such as museums, science centres, outdoor settings, community programs (including indigenous communities), communications media, after-school programs and clubs. Includes design, adoption, exchange, and evaluation of informal, non-formal, and out-of-school learning environments, especially those organised by institutions other than schools, as well as informal and non-formal approaches to the teaching/learning of science.

Sub-themes:

1) Science Learning in Museums and Science Centers
2) Community-based Science Education Programs
3) Outdoor and Field-based Science Learning
4) Evaluation of Informal Science Learning Experiences

Informal And Non-Formal Science Education: Learning In Vastly Different Settings

Strand 11 encompasses the design, evaluation, exchange, and implementation of informal and non-formal learning environments and recognizes diverse approaches to science teaching and learning across after-school initiatives, clubs, communication media, community programs, digital spaces, homes, Indigenous contexts, museums, outdoor environments, and science centers. These settings provide opportunities for science engagement, identity development, and inquiry. Science learning taking place outside the classroom complements formal schooling and broadens access to scientific learning (Braund & Reiss, 2006; Falk & Dierking, 2010; Rennie, 2014). Aligned with the ESERA 2025 conference theme, Transitions in Science Education: Sustainability and Digital Advances, *Strand 11 Informal, Non-formal and Out-of-school Science Education* highlights how science learning evolves across interconnected environments and educational landscapes, spanning a wide range of life domains, it creates new points of connection for science learning and thereby fosters sustainability. The Strand 11 papers illustrate how science learning occurs during interactions among educators, institutions, families, learners, and communities across informal settings. We grouped the articles based on their locations: school-linked, museum and science centers, home-based and remote, and game-based and designed learning. The paper subsets reflect distinct educational settings and illustrate the breadth of informal and non-formal science learning represented within the strand.

School-Linked Non-Formal Programs

School-linked non-formal programs connect student out-of-classroom science engagement with curriculum and educational goals. Science clubs, competitions, laboratories, and research experiences extend science connections and provide contexts where learners engage in experimentation, inquiry, and authentic scientific practices. These environments are important complements to formal schooling because they connect science to real contexts and experiences (Braund & Reiss, 2006; Dillon et al., 2006; Hofstein & Rosenfeld, 1996; Pfeiffer & Bradbury, 2023). School-linked non-formal programs extend learning across educational landscapes beyond classroom boundaries.

Museum And Science Center Partnerships

Museums and science centers are active learning spaces where visitors engage with collections, objects, educators, and scientific practices (Falk & Dierking, 2010; Patrick, 2023). Partnerships among citizen science initiatives, communities, museums, researchers, and schools encourage participation in science (Kampschulte & Hatcher, 2021). Museums and science centers promote public inquiry and engagement and direct interactions with objects that stimulate meaning making (Preston et al., 2026; Moussouri, 2002; Patrick & Moorman, 2021; Yeh, 2023), yet at the same time allow to broaden perspectives (Knabe et al, 2025). Citizen science initiatives further strengthen connections among museums, schools, and scientific communities (Bonney et al., 2016).

Home-Based And Remote Learning

Researchers recognize home as important sites for science learning because families connect science to everyday life. Family experiences influence science engagement and shape how learners encounter science during conversations, exploration, shared activities, and tinkering (Archer et al., 2015). Family contexts contribute to developing science interest (Tenenbaum et al., 2004). At-home science activities, family support, and virtual experiences support exploration and embed science in daily experiences. Moreover, the COVID driven push in technological developments dramatically extends the possibilities of science learning at home. Virtual experiences broaden access to informal settings and provide alternatives when face to face connections are limited (Radianti et al., 2020). The authors of the study highlight the growing relationships among families, technology, and science learning.

Game-Based And Designed Learning Environments

Designed learning environments boost science engagement and inquiry. Educational design, games, and differentiated learning experiences create structured opportunities for experimentation, problem solving, and interaction with scientific ideas. Game-based learning supports motivation and conceptual understanding (Arnab et al., 2015). Game-based approaches and structured laboratory experiences shape the design of learning aids and influence opportunities for participation and learning. Games provide spaces where learners negotiate ideas, collaborate, and interact with scientific concepts. Differentiated environments promote participation during intentional design choices. Out-of-school laboratories are adaptive learning environments that reinforce authentic learning experiences and structured inquiry (Scharfenberg & Bogner, 2010).

The papers in Strand 11 demonstrate the breadth, adaptability, and continued importance of informal, non-formal, and out-of-school science education across diverse educational landscapes. Spanning school-linked programs, museums and science centers, home-based and remote learning environments, and game-based and designed experiences, the studies illustrate how science learning occurs through interactions among learners, families, educators, communities, institutions, and technologies. The contributions highlight the capacity of informal science learning environments to foster engagement, inquiry, identity development, and participation while responding to local needs and emerging educational challenges. These papers show how science learning extends beyond classroom boundaries, creating meaningful opportunities for individuals and communities to connect with science in ways that support sustainability, inclusion, and lifelong learning. As science education continues to evolve in response to digital advances and societal transitions, the research presented in this strand underscores the vital role of informal and non-formal settings in expanding access to science and strengthening connections between science, people, and their communities.

Empowering Elementary School Teachers To Foster Students' Nature Connection: A Study Of Museum-School Collaboration For Horseshoe Crab Husbandry

Yeh, J. H. [1] and Chen, L. S.[2]
[1]National Museum of Natural Science, Taiwan
[2]National Museum of Marine Science & Technology, Taiwan

Biodiversity and species conservation are core missions of science museum education, yet engaging the public with uncharismatic endangered species remains a challenge. This case study examines a 2024 horseshoe crab care program launched by the National Museum of Marine Science and Technology (NMMST, Taiwan). The program aimed to empower elementary school teachers as catalysts for fostering students' nature connection. Through a collaborative model involving specialized workshops, husbandry kits, and regular expert consultations, the museum supported teachers in integrating live-animal care into the formal 3rd-grade curriculum. The findings indicate that this partnership significantly enhanced teachers' self-efficacy; the continuous technical backing from the museum converted potential pedagogical anxiety into a sense of professional mastery. Consequently, this empowerment trickled down to students, who not only mastered science process skills but also developed a profound sense of stewardship through the long-term "parenting" of horseshoe crabs. The study culminates in a release activity, demonstrating how empowering a single teacher can create a "ripple effect" that strengthens the connection between students, parents, and the natural world. This case provides a scalable model for science museums to move beyond one-time visits toward deep, curriculum-integrated partnerships.

Keywords: Teacher Empowerment, Nature Connection, Museum-School Collaboration

Research Background

Museum's Commitment For Education

National Museum of Marine Science and Technology (NMMST, Taiwan) has been committed to promoting public attention to issues such as Taiwan's maritime environmental protection and marine life conservation. Horseshoe crabs were once a common species along the coast of Taiwan. They have become an endangered species due to economic development in the area. The Industry-Academic Exchange Group of NMMST working with Taiwan Fisheries Research Institute to restore horseshoe crabs. Though Taiwan Fisheries Research Institute develops good horseshoe crab farming technology, to rebuild wild horseshoe crab population needs more social attention for coastal environment protection and no more over fishery. It is hard to track the life of a wild horseshoe crab. The NMMST looked for schools to participate in horseshoe crab breeding program. This program hopes that through the horseshoe crab breeding project, students will pay attention to the survival problems faced by horseshoe crabs through observing horseshoe crab's life cycle.

Conservation Context: The Crisis Of Horseshoe Crabs In Taiwan

Historically, the tri-spine horseshoe crab (Tachypleus tridentatus) was widely distributed along the western and northern coasts of Taiwan. However, this "living fossil" currently faces an existential threat due to anthropogenic pressures. Rapid coastal development for tourism has resulted in the fragmentation of nesting beaches, while the expansion of aquaculture ponds has further encroached upon essential nursery habitats for juveniles. Moreover, the discharge of urban wastewater and industrial pollutants has significantly degraded the water quality of estuarine

ecosystems. These cumulative factors have led to a drastic decline in wild populations, making the conservation of this species a matter of national ecological urgency.

The Pedagogical Power Of Uncharismatic Species

In environmental education, public attention is often disproportionately directed toward "charismatic megafauna" (e.g., pandas or dolphins). However, the horseshoe crab serves as a powerful uncharismatic species for transformative learning.

Challenging Aesthetic Biases: Integrating "alien-looking" species like the horseshoe crab into the curriculum encourages students to move beyond superficial aesthetic judgments. This process fosters a deeper, more inclusive ethical stance toward biodiversity, where the value of a species is recognized through its ecological role and evolutionary history rather than its "cuteness."

Facilitating Cognitive Conflict and Curiosity: The unique, prehistoric morphology of the horseshoe crab creates a "cognitive conflict" that stimulates curiosity and scientific inquiry. By caring for a species that initially appears unfamiliar or even "ugly," students undergo a profound shift in empathy—a process that Giusti et al. (2025) describe as shifting social and spatial relationships with nature.

From Alien to Kin: As students engage in the daily husbandry of these organisms, the horseshoe crab transitions from an "uncharismatic alien" to a "vulnerable dependent." This transformation is a critical driver for nature connection, proving that emotional stewardship can be successfully cultivated even for the most unconventional representatives of the natural world.

Integration Of Citizen Science In Science And Environmental Education

Citizen science (CS) serves as a robust framework for bridging formal science education with environmental stewardship. According to Bruckermann et al. (2021), participation in urban wildlife ecology projects significantly enhances participants' scientific knowledge and fosters positive attitudes toward science, which are foundational for environmental conservation. Okada (2024) expands this through the CARE-KNOW-DO model, asserting that "open schooling" approaches strengthen the connection between scientific learning and real-life sustainability challenges. Furthermore, Bruckermann et al. (2023) found that participants' scientific reasoning skills are strong predictors of topic-specific knowledge gain. This suggests that CS provides a high-level cognitive environment where students can internalize ecological literacy through authentic scientific inquiry Bruckermann et al., 2023.

Challenges In Implementing Citizen Science Within Elementary Curricula

Despite its potential, implementing CS in primary school settings presents significant pedagogical hurdles. First, cognitive and skill-based barriers are prominent; Bruckermann et al. (2023) highlight that scientific reasoning is a prerequisite for effective learning in CS. For younger students (Grades 3–6), the complexity of data collection and systematic observation may exceed their developmental stage. Second, Atias et al. (2025) warn of epistemic injustice in school-based CS. This occurs when students are relegated to the role of passive "data sensors" rather than active contributors to knowledge construction, potentially undermining their agency and interest in science. Finally, Okada (2024) emphasizes the logistical burden on teachers, noting that balancing core curriculum requirements with the time-intensive demands of CS projects requires significant teacher empowerment and resource reallocation.

From Scientific Data Collection To Embodied Nature Connection

The integration of science and environmental education in primary schools has traditionally leaned towards citizen science models, which emphasize data contribution and scientific reasoning. However, recent scholarship suggests a critical shift toward prioritizing nature

connectedness as a more developmentally appropriate and pedagogically effective goal for young learners.

The Primacy Of Emotional And Embodied Connection

According to Lau et al. (2025), a student's sense of nature connectedness is a more powerful predictor of positive attitudes toward biodiversity than the mere acquisition of factual knowledge. This is further elucidated by Schilhab (2021), who argues through the lens of embodied cognition that learning gains are maximized when children engage in sensory-rich, physical interactions with the natural world. Unlike abstract data-driven citizen science tasks, the long-term "parenting" of live organisms (such as the horseshoe crab) allows students to develop an intuitive, embodied understanding of life cycles, which reduces the cognitive cost of learning while increasing emotional investment.

Pedagogical Feasibility For Non-Science Teachers

A significant challenge in primary science education is the perceived barrier for non-science major teachers. Harris et al. (2025) highlight that fostering nature connectedness can be deliberately developed through pedagogical strategies that focus on "care" and "experience" rather than complex scientific protocols. This approach is more accessible for generalist teachers compared to rigorous citizen science projects, which often require specialized scientific reasoning skills that may exceed the developmental stage of 3rd to 9th-grade students (Bruckermann et al., 2023).

Transformative Space And Stewardship

Giusti et al. (2025) and Graf & Debrabant (2026) emphasize that schools should serve as transformative spaces for "green transition teaching." By shifting the educational objective from being "data sensors" for adult-led research to becoming "stewards of life," teachers can facilitate a deeper relationship with nature. This shift mitigates the risk of epistemic injustice (Atias et al., 2025) and empowers teachers to lead meaningful environmental education without the need for advanced scientific specialization. Consequently, establishing a nature connection provides a more inclusive and sustainable framework for basic school science curricula.

Integrating The Horseshoe Crab Program As A Solution To Epistemic Injustice

Atias et al. (2025) argue that school-based citizen science often suffers from epistemic injustice, where students are treated as mere tools for data collection rather than active epistemic agents. This marginalization can lead to a lack of ownership and a superficial understanding of the scientific process.

The horseshoe crab care program by NMMST provides a pedagogical alternative to mitigate this issue. Unlike traditional citizen science models that focus on data contribution, this program empowers students through a stewardship-based approach. By transitioning from passive observers to active "parents" responsible for the survival of an endangered species, students are positioned as primary knowledge-holders within their classroom ecosystem. This high level of pedagogical agency aligns with Okada’s (2024) CARE-KNOW-DO model, where the emotional commitment to "care" for the horseshoe crabs drives the motivation to "know" (scientific knowledge) and "do" (conservation action).

Furthermore, by addressing the cognitive barriers mentioned by Bruckermann et al. (2023), the museum’s collaborative support enables teachers to scaffold complex scientific reasoning through tangible, daily interactions with live organisms. This transformation shifts the focus from simply reporting data to fostering a deep nature connection, thereby ensuring that students’ voices and actions are epistemically valued in the broader context of biodiversity conservation.

Research Methods

Research Design

This study employs a qualitative case study design to explore how a museum-school collaborative program empowers teachers and fosters students' nature connection. By focusing on the "Horseshoe Crab Care Program," the research investigates the transformative process of integrating live-animal husbandry into the formal school curriculum.

Participants And Context

The program involved 14 schools (8 primary and 6 junior high schools) in Taiwan. The analysis specifically highlights the experiences of elementary school teachers who acted as primary facilitators. The collaboration was structured into two phases:

Professional Empowerment Phase:

Teachers participated in an intensive workshop covering horseshoe crab biology, aquarium ecosystem establishment, water quality monitoring, and egg incubation techniques. A collaborative lesson-planning session was conducted, where teachers co-designed and submitted pedagogical plans tailored to their classroom contexts.

Implementation And Support Phase:

The museum provided essential resources, including horseshoe crab eggs and water quality testing kits. Students closely monitored the biological progression as the eggs developed through four embryonic stages before successfully hatching into first-instar trilobite larvae. Under the teachers' guidance, the students continued the husbandry process until the crabs reached the second-instar stage. At this point, the teachers facilitated the transfer of the juvenile crabs to the Taiwan Fisheries Research Institute (TFRI) for specialized long-term care until they matured into fourth-instar juveniles.

To bridge classroom learning with real-world conservation, the National Museum of Marine Science and Technology (NMMST) collaborated with the TFRI to organize the "Bringing the Horseshoe Crabs Home" release event. Teachers and students who participated in the curriculum were invited to natural sandy beaches—specifically those with historical sighting reports of the species—to release the crabs into the wild. This final act transformed the rearing process into a tangible contribution to species restoration, reinforcing the participants' identity as conservationists. It also provided an emotional milestone for teachers to reward students' dedication, offering a sense of achievement as they completed this critical stage of their environmental mission.

Conservation Action And Reflection Phase:

To conclude the program, the museum organized a series of release activities, where teachers and students returned the juvenile horseshoe crabs they had raised to their natural coastal habitats. This hands-on conservation act transformed the classroom experience from a mere biological project into a meaningful participation in species restoration, deeply reinforcing the participants' identity as environmental stewards. For teachers, the release ceremony served as a vital emotional milestone, providing a sense of closure and fulfillment. It offered a structured opportunity to reward students’ long-term dedication with a profound emotional connection to the cycle of life, solidifying the pedagogical transition from scientific knowledge to active conservation commitment.

Data Collection

To ensure a holistic understanding of the program's impact, multiple qualitative data sources were collected:

Pedagogical Artifacts: 14 teaching plans submitted by participating teachers during the workshop, reflecting their initial instructional designs and goals.

Consultation Records: Detailed logs from regular consultation meetings, capturing teachers' real-time challenges, reflections, and anecdotal evidence of student engagement.

Teacher Narratives: Qualitative feedback regarding teachers' emotional shifts, perceived self-efficacy, and observations of students' behavioral changes (e.g., patience, persistence, and stewardship).

Data Analysis

The data were analyzed using thematic analysis. Following the transcribed consultation meetings and document review, codes were generated to identify patterns related to teacher empowerment, pedagogical adaptation, and the emergence of students' nature connectedness. These themes were then triangulated across the different data sources to ensure the validity and depth of the findings.

Findings

The preliminary findings from this case study reveal a distinct pattern of teacher empowerment and age-specific student engagement, categorized into two primary themes:

1. Age-Specific Pedagogical Adaptations And Teacher Empowerment

Teachers demonstrated significant pedagogical autonomy, adapting the program to align with grade-specific curriculum goals. This adaptability highlights a key aspect of teacher empowerment: the ability to contextualize external resources effectively.

Seventh-Grade Teachers (Junior High)

These educators primarily leveraged the program to facilitate inquiry-based learning and experimental design. The investigation of variables in raising horseshoe crabs was often integrated as a structured student project, aligning with a more advanced stage of scientific reasoning [Bruckermann et al., 2023]. Some teachers noted that the standard husbandry tasks were insufficient for the cognitive level of junior high students. For instance, Teacher 1 remarked:

I feel that simply having students observe the changes in the eggs every day and record temperature and water quality data is too simple for junior high school students; there isn't much to explore.

Consequently, these educators shifted the focus toward active experimentation. Teacher 2 described their approach to experimental design as follows:

Although the Fisheries Research Institute already has the best water quality composition, I want students to be able to adjust the pH within a certain range, such as adjusting it up or down by 0.5, and see how much the egg growth period will differ.

Consequently, a divergence in pedagogical perspectives emerged: junior high school teachers viewed the horseshoe crabs primarily as experimental subjects, aiming to have students manipulate growth-related variables through controlled experiments. However, the collaborating aquaculture experts opposed treating these sensitive organisms as experimental animals for middle school students, prioritizing animal welfare and conservation ethics. In response to this constraint, the junior high teachers pivoted their strategy. Instead of structured experiments, they

established classroom aquariums and shifted the focus to a voluntary participation model. Students who showed interest could volunteer to perform daily observation, photography, water quality monitoring, water changes, and feeding, thereby maintaining engagement through long-term husbandry and documentation rather than experimental manipulation.

Third-Grade Teachers (Primary School)

In contrast, primary teachers focused on foundational science concepts. They combined the theme of horseshoe crab husbandry with the broader study of aquatic animal movements and life histories, emphasizing descriptive observation and engagement over experimental manipulation.

This interdisciplinary approach was exemplified by Teacher 4, who coordinated with various subject teachers to integrate the horseshoe crab into the third-grade curriculum:

I first asked the science teacher to use the presentation provided by NMMST to introduce the concept of horseshoe crabs to the children. Then, in the language arts class, students read a text about animal tails using teaching aids; we paired this with the museum's dried horseshoe crab specimens. Watching the children touch the different tails while describing and speculating on their functions was brilliant. Since they were unfamiliar with horseshoe crabs, I also asked the computer teacher to let them search for videos or explanations regarding their movement. After attending the workshop, the art teacher even took the initiative to use the simple mobile phone microscopes provided by the museum to have students light and photograph the crabs. ... I am very grateful for the assistance of the science, art, and computer teachers during this period, bringing a bit of the horseshoe crab into different subjects. …At the end-of-term fair, students decorated their horseshoe crab photographs on the classroom windows facing the aisle, along with simple horseshoe crab informational posters to introduce the animal to students from other classes as they passed by. I'm so proud for them.

Interviews with other participating primary school teachers consistently echoed this model of multidisciplinary collaboration, involving joint planning across language arts, science, computer science, art, and even physical education. These educators frequently expressed admiration for their students' performance throughout the process. For primary teachers, raising horseshoe crabs functioned as a pedagogical intersection for diverse subject areas. From this common starting point, students were empowered to apply their existing skills in a real-world context, transforming classroom knowledge into a tangible sense of agency. This process allowed students to experience how their collective academic competencies could be directly channeled into the active conservation of an endangered species, fostering a deep connection between their learning and environmental responsibility.

2. Emotional Investment, Skill Application, And Nature Connection

The findings strongly support the hypothesis that prioritizing nature connection is highly effective at the primary level, addressing the emotional "CARE" component of the CARE-KNOW-DO model (Okada, 2024).

Emotional Connection

Primary school students exhibited a notably higher degree of emotional investment and affective response in observing the growth of the horseshoe crabs compared to seventh-grade students. This intense emotional engagement facilitates the development of a strong nature connection (Lau et al., 2025). The depth of this bond was vividly captured in the observations of Teacher 6, who noted how students took on a parental role and extended their engagement beyond the science curriculum:

The children in my class were very proud to call themselves 'Horseshoe Crab Dads' or 'Horseshoe Crab Moms.' During the process of caring for the eggs until they grew into first-instar larvae, the first thing they did upon entering the classroom every day was check the tasks marked on the husbandry duty roster. The computer teacher also mentioned that they would proactively look for photos or videos related to the crabs' natural habitats during class. ... For the end-of-semester school fair, they even took the initiative to suggest making horseshoe crab conservation bookmarks to the art teacher, printing their photographs to paste onto conservation slogans. I never expected them to be so invested for the entire semester; even after the young crabs were returned to the Taiwan Fisheries Research Institute, their interest persisted.

Through this model of interdisciplinary pedagogical collaboration, primary school teachers expressed significant satisfaction with the profound enthusiasm ignited within their students. The educators were particularly impressed by the sustained nature of this engagement, which remained high from the initial hatching phase until the end of the semester. Furthermore, teachers acknowledged that such a complex, cross-domain curriculum would have been unattainable without the National Museum of Marine Science and Technology (NMMST). The museum's provision of specialized biological knowledge and essential physical resources served as the critical foundation, empowering teachers to venture beyond their individual areas of expertise. This partnership effectively bridged the gap between specialized marine science and classroom practice, allowing teachers to facilitate a sophisticated Interdisciplinary Learning experience that was both scientifically rigorous and emotionally resonant for the students.

Practical Skill Application

The long-term, hands-on nature of the program provided a context for practical application of scientific skills. Primary school students perceived immediate utility in foundational science skills such as weight measurement, volume measurement, and water quality testing, reinforcing the link between abstract classroom knowledge and real-world utility (Schilhab, 2021). This shift in perceived competence was also observed by the educators. Teacher 8 reflected on their initial skepticism regarding the students' ability to maintain scientific rigor in a classroom setting:

Initially, I didn't think elementary students would be able to accurately perform so many scientific process skills, such as weighing, reagent volume adjustment, and interpreting test strip reactions. Especially since they had to do it themselves in the classroom after the initial lessons, I thought they wouldn't be able to stay precise and accurate. But the horseshoe crabs actually survived and hatched. This was the first time I felt so certain that the students had truly mastered the things we taught in science class.

This reflection underscores the profound impact of authentic learning. When the accuracy of scientific skills is directly tied to the survival of a living organism, students' actions transcend mere classroom exercises and evolve into a profound sense of moral responsibility. The "empirical feedback" provided by the successful hatching and survival of the horseshoe crabs not only validates the students' learning outcomes but also significantly bolsters teachers' confidence in implementing inquiry-based instruction within primary education. This alignment between rigorous scientific practice and ethical commitment demonstrates how real-world challenges can catalyze both academic mastery and personal growth.

These findings suggest that while older students can engage in data-driven citizen science, younger students benefit immensely from stewardship-based activities that foster embodied cognition and emotional connection to nature, offering a scalable model for inclusive environmental education.

Conclusions And Implications

This study highlights the pivotal role of museums as teacher empowerees. By providing scaffolded support, museums enable non-science major teachers to lead complex conservation projects. Furthermore, the program demonstrates that when students apply science process skills (e.g., microscopy, pH monitoring, digital micro-photography) to biological restoration, they develop a positive scientific self-concept. This "stewardship-based" model offers a scalable framework for inclusive environmental education that cultivates both scientific literacy and environmental empathy.

This program demonstrated significant potential beyond student learning outcomes, highlighting the museum-school partnership model as a powerful catalyst for teacher professional development (PD). Our findings suggest that the museum's provision of expert scientific knowledge and tangible resources was instrumental in empowering primary school teachers—even those outside the life sciences domain—to successfully implement sophisticated interdisciplinary curricula.

Nonetheless, the long-term impact of this specific collaborative model on sustained teacher professional growth remains a critical area for future investigation. Subsequent research should focus on the following three key domains:

Internalization And Transferability Of Pedagogical Skills:

Future studies should track whether the teachers, post-program, can internalize the acquired interdisciplinary planning skills and scientific inquiry guidance techniques. It is essential to determine if this growth in professional capacity remains dependent on ongoing museum support, or if it successfully transfers into the educators' long-term teaching repertoire across various environmental topics.

Formation And Sustainability Of Professional Learning Communities (Plcs):

The initial "Professional Empowerment Phase" fostered collaboration and co-design among educators. Subsequent research could investigate the longevity of these museum-initiated cross-school professional learning communities. Further study should explore how the museum's role evolves from a primary resource provider to a long-term knowledge partner supporting these sustained teacher networks.

Paradigm Shifts In Educational Beliefs

Our research identified clear differences in perspective between junior high and primary teachers regarding bioethics and experimental design. Longitudinal studies could explore if sustained museum-school collaborations alter teachers' perceptions of the balance between "scientific inquiry" and "biological conservation," thereby influencing their core environmental education values and teaching methodologies.

Acknowledgement

The authors would like to express their gratitude to Professor Marianne Achiam and the session audiences for their insightful suggestions. This work was supported by the National Science Council (NSTC, Taiwan) under grant numbers NSTC 113-2515-S-396-002 and NSTC 112-2515-S-396-002.

ESERA 2025 Copenhagen

Designing Materials Science Activities to Promote Student Engagement with Cutting-Edge Research

Maria Gavala[1], Eleni Botzaki[1], Argyris Nipyrakis[1], Dimitris Papazoglou[2] and Dimitris Stavrou[1]
[1]University of Crete, Department of Primary Education, Greece
[2]University of Crete, Department of Materials Science and Engineering, Greece

Formal education often cannot provide timely access to cutting-edge research in rapidly evolving fields like materials science, despite its relevance to urgent global challenges. Informal learning environments can bridge this gap, though challenges remain in effectively designing and integrating such experiences. This study investigates how materials science content can be educationally reconstructed and communicated through redesigned educational visits, using the Model of Educational Reconstruction (MER). Materials science researchers, science education researchers and secondary teachers collaboratively developed inquiry-based activities on biomaterials and hydrogels. Seven teachers implemented these materials, with data collected through observations and semi-structured interviews. Findings reveal that while interdisciplinary collaboration is essential, teachers serve as critical mediators due to their intimate knowledge of students' backgrounds and interests. Their reflections provided valuable insights into material effectiveness and visit design. This research demonstrates that successful communication of contemporary research requires both interdisciplinary collaboration and serious consideration of teachers' insights and recommendations.

Keywords: informal education, materials science, model or educational reconstruction

Introduction

Rapid advancements in materials science and their applications are poised to significantly impact future generations, presenting opportunities and challenges for society. These developments highlight ethical, sustainability, and educational issues that require interdisciplinary collaboration and public engagement, as seen with many emerging research topics (Ehrler, 2022). Simultaneously, advancements in materials science are revolutionizing real-world applications such as medical applications which lead to significant improvements in diagnostics, therapeutics, and regenerative medicine. Consequently, fostering scientific literacy among citizens appears essential to empower them to stay informed about scientific advancements but also to make well-informed decisions concerning their health, environment, and other critical aspects of life. In this direction, formal education in schools is expected to play an important role in shaping scientifically literate citizens. However, formal education's approach to scientific development is usually delayed, as it takes a long time before new knowledge is integrated into school curricula (Besley & Tanner, 2011).

In this context, the literature stresses the importance of informal learning spaces, such as research centers and science laboratories, which can complement formal education. These spaces are authentic environments, allowing students to come into direct contact with new knowledge, thus bridging the gap created in formal education (Berg et al., 2021). Communication strategies for cutting-edge research topics in informal learning spaces focus on the active participation of visitors, utilizing contemporary teaching approaches such as inquiry-based learning and interdisciplinary STEM approaches (Schwan, Grajal & Lewalter, 2014). Students' interaction with scientists in these settings helps to form a more realistic picture of scientific activities, while

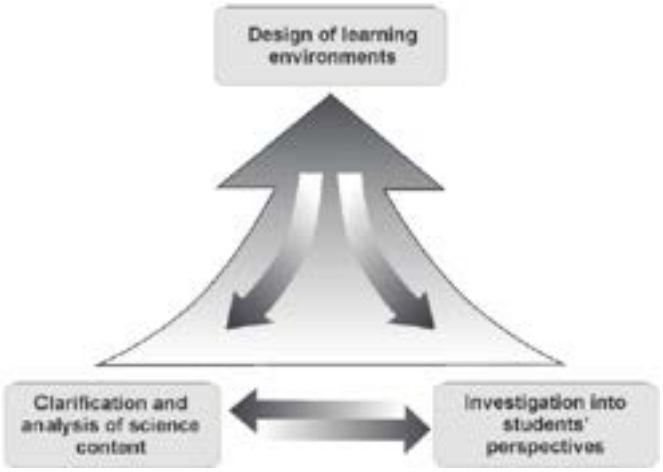
at the same time bringing them into contact with scientific practices, enhancing their interest in related careers (Woods-Townsend et al., 2016).

However, designing and implementing educational visits to informal learning spaces requires close collaboration among experts in science content, science knowledge transformation, and science communication (Giannakoudaki & Stavrou, 2022). This interdisciplinary teamwork highlights the value of integrating various skills and knowledge areas while ensuring the creation of learning experiences that promote understanding and active engagement of students in informal learning spaces (Achiam, 2013). Teachers play a central mediating role in translating educational materials and visit experiences into meaningful learning, as they create inclusive environments, guide scientific practices, and facilitate connections between informal learning experiences and curriculum goals (Cooper & Bolger, 2024). This mediating role is strengthened through collaboration with science center staff and through appropriate preparation of students via activities that link visit themes with the curriculum (Souza et al., 2023).

Based on the above, this paper aims to develop and evaluate a series of STEM activities for informal learning spaces that focus on communicating contemporary scientific developments in the field of materials science to students. Therefore, the research question that runs through this paper is, "How can contemporary scientific knowledge be educationally reconstructed and communicated to students in informal learning contexts?".

Methodology

Research Context



This study was carried out in the context of the MaSCot project, a 24-month cross-departmental project at the University of Crete that aimed to bring together science education researchers and materials science researchers to co-develop learning experiences in out-of-school environments to communicate contemporary scientific research topics to students. The research process was divided into three main phases. In the first phase, initial educational visits hosted in the Department of Materials Science and Engineering (DMSE) were observed to establish a baseline understanding of existing practices and identify areas for improvement. In the second phase, a learning community—consisting of experts in materials science, science education, and science communication—collaboratively developed two sets of inquiry-based STEM activities. These activities were designed to be implemented either before or after educational visits to the DMSE. In the third phase, the in-service teachers participating in the project implemented the developed materials to support educational visits to the DMSE, either as preparation before the visit or as extension activities following the visit.

Theoretical Framework

The Model Of Educational Reconstruction

The methodological framework used in this study is based on the Model of Educational Reconstruction, which consists of three components: (a) clarification and analysis of the scientific content, (b) research on teaching and learning, and (c) design and evaluation of the learning environment. These three components are not independent but dynamically interact continuously, providing reciprocal feedback (Duit et al., 2012).

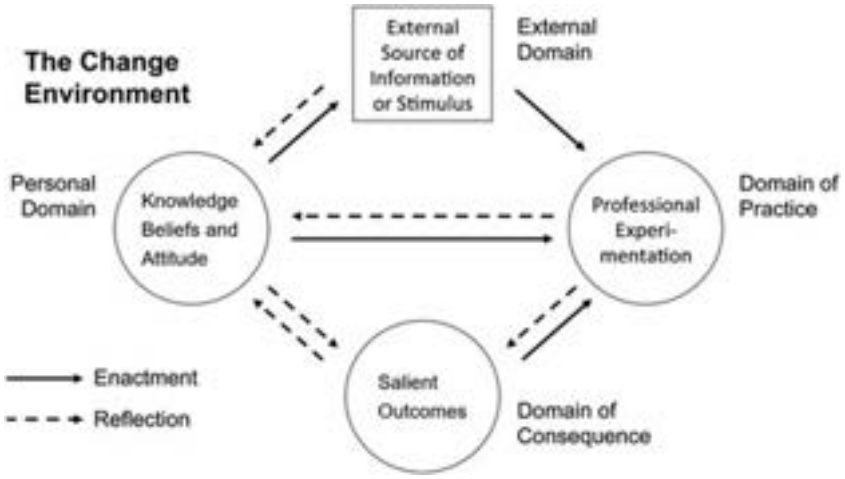
Figure 1. The Model of Educational Reconstruction.

Application of MER in this Study

For the clarification and analysis of the scientific concepts, group meetings among researchers of materials science and science education were held. They collaboratively identified and discussed the key concepts that are deemed as important to be taught/presented to students. For biomaterials the concepts of biocompatibility, mechanical properties and biodegradation were found as the most prominent. As for polymers and more specifically hydrogels, key concepts relate to their composition, such as cross-linked polymerization, their mechanical and chemical properties, e.g., elasticity or viscous behavior, and the breakdown of polymers, which depends on environmental conditions such as temperature or pH.

The second component of MER, investigation of the literature, revealed several key principles for teaching and learning interdisciplinary topics such as materials science: making connections between disciplinary fields explicit, approaching topics through real-world problems, linking content to everyday experiences, and integrating theoretical knowledge into contexts that simulate authentic research practice (Li et al., 2015; Acosta, 2023; Fagnani et al., 2020).

The third component—design and evaluation of the learning environment—emerges from the interaction between the first two, involving the educational reconstruction of identified concepts using contemporary approaches to science communication. In our study, the environment reconstructed is the designed educational material to be used to frame the educational visit (before/after).



The Interconnected Model Of Professional Growth (IMPG)

Professional development is characterized by dynamic interactions across multiple aspects of teacher practice, as conceptualized in the Interconnected Model of Professional Growth (IMPG, Clarke & Hollingsworth, 2002). This framework identifies four interconnected domains: the personal domain (K), encompassing teachers' professional knowledge, beliefs, and attitudes; the domain of practice (P), representing instructional experimentation and implementation; the domain of consequence (S), which captures notable outcomes emerging from instruction; and the external domain (E), comprising influences beyond the individual teacher, including institutional factors, curricular frameworks, and professional development experiences.

These domains are connected through two mediating mechanisms: enactment and reflection. Teachers enact practice by drawing upon their professional knowledge and pedagogical orientations to inform instructional decisions, while reflection enables them to recognize and

interpret how shifts in one domain generate changes—or consolidate existing approaches—across others.

Figure 2. The Interconnected Model of Professional Growth.

The choice of IMPG in this study is based on the model's effectiveness for studying teachers' professional learning concerning the development of teaching materials in cutting-edge topics (Sgouros & Stavrou, 2019). Particularly, for the purposes of this study, the IMPG framework serves as an analytical lens for examining how teachers engaged with and evaluated the designed materials. Teacher reflections on outcomes include their direct observations of student responses to the materials and activities, offering meaningful insights into the educational value of the designed materials. Given that teachers function as critical intermediaries between instructional materials and student learning, their professionally-grounded reflections—informed by authentic implementation contexts and direct observation—provide substantive evidence for assessing the quality and impact of the educational materials.

Table 1. Framework for the analysis of current educational visits.

Axes of analysis	Categories	Sub-categories
Structure	Guidance	- Introductory presentation - Guided tour
	Role of Scientists/Researchers	• Model experiments • Explain scientific concepts • Describe potential careers
	Role of Teachers	- Accompany students - Explain concepts
Content of the visit	Scientific Concepts	- Optics & Lasers - Magnetic materials - Optoelectronics
	Scientific Practices	- Demonstration of experiments - Demonstration of equipment

Data Collection And Analysis

Data were collected using an observational protocol based on key aspects of educational visits proposed by Sajons and Komorek (2018), including the purpose of the visit, students' prior knowledge, the orientation of activities, and the roles of staff and teachers. Additionally, data were collected through semi-structured interviews with seven of the participating teachers following their implementation of the redesigned visits.

Due to the exploratory nature of the research, qualitative content analysis methods (Mayring, 2015) were employed. Observational data from the educational visits were analyzed according to visit structure and content, with inductive categories and subcategories presented in Table 1. The interview data were analyzed using the IMPG framework to identify interactions among the four domains, with analytical criteria presented in Table 2.

Table 2. Description of criteria for categorising interactions among the domains of the IMPG model.

Mediating process	Criteria	Examples
External - Personal (reflection)	The teacher reflects on the teaching material or the visit and this reflection influences or reinforces their knowledge, attitudes, etc., related to science teaching.	"In the end, I realised it — I would have preferred if we had seen the main presentation and one laboratory."
Personal - External (enaction)	When a teacher's initial perception regarding educational visits affects what is done or said during the Community of Learners meetings or during the visits themselves.	-
External - Practice (enaction)	Stimuli from the material and the meetings lead to the application or adaptation of teaching practices.	"The material was implemented in the first year of upper secondary school."
Practice - Personal (reflection)	Experience gained from implementing teaching practices leads to reflection and possible change or reinforcement of beliefs, knowledge, or attitudes.	"Perhaps the preparation should have been done differently; we should have found a way to connect things."
Personal - Practice (enaction)	The teacher's personal perceptions or knowledge influence how they carry out their teaching and how they act during the visit.	"We had a discussion; I told them some general things that I had in mind from a previous visit."
Practice - Salient outcomes (reflection)	Something that occurs during the lesson or the visit produces specific outcomes regarding the benefits for the students.	"The students were excited, they participated, they wanted to respond."
Salient outcomes - Practice (enaction)	A specific outcome influences the teacher's practices.	"And because the students were motivated, we continued during the next class hour as well."
Salient outcomes - Personal (reflection)	Observing the outcomes for the students prompts the teacher to interpret the result or to reconsider an initial perception.	"[…] perhaps it is ultimately more beneficial for students to interact with university students rather than professors."
Personal - Salient outcomes (reflection)	How teachers themselves perceive the benefits for their students.	"I think they took a step further; their horizons widened."

Findings

Analysis of the Initial Educational Visits

The analysis of the initial school visits revealed that the visits primarily consisted of an introductory presentation providing general information about the department, its research areas (e.g., optoelectronics, magnetic materials, biomaterials), and key research highlights as well as potential career pathways. Subsequently, a guided tour of the university's laboratories took place, including a demonstration of experiments and equipment by the scientists, while also explaining scientific concepts. The role of teachers was found mostly to accompany the students and, in some cases, provide additional information to help students understand the topics being discussed. The presented experiments were neither linked to innovative research activities related to the field of materials science, nor to the school's curriculum. The students were not adequately prepared by their teachers and lacked background knowledge in such specific research topics; hence, they struggled to understand the content, find relevance in the subject matter, and establish meaningful connections with scientists and their roles. Consequently, the innovative nature of the research carried out at the university, the real-world relevance of these applications, and the social implications of these issues were not emphasized.

Redesigned Visits

The structure of the visit itself was identical to the initial visits, with the addition of demonstrative experiments. The selected experiments were chosen based on the meeting discussions and what was convenient for the university to offer. The topics were polymers (specifically hydrogels and thermoresponsive polymers) and hydrophilic/hydrophobic surfaces. The specific experiments varied across visits, reflecting the dynamic nature of ongoing research and teaching in university settings where educational outreach activities are supplementary to core research functions.

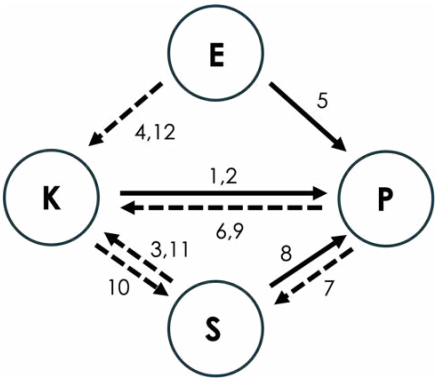
The Educationally Reconstructed Material

Two sets of inquiry-based STEM activities were developed for supporting use before/after the educational visit. One of them was focusing on biomaterials and one on polymers, specifically hydrogels. Both sets follow a common structure: an introductory engagement activity, exploration of fundamental material properties, application within an authentic research context, and finally, reflection on societal and environmental connections.

The biomaterials activities were framed within a research scenario where students assumed the role of research team members developing a bone implant like applications in the DMSE. The implant was designed to function as a "bridge," providing a substrate for new bone cell growth and eventually biodegrading completely so the patient develops unified, natural bone.

Activities include: (1) an introductory task on compatibility where students selected the correct charging cable for a mobile device; (2) biocompatibility testing by counting live and dead cells in microscopy images and calculating cytotoxicity using mathematical formulas; (3) evaluating mechanical properties by comparing strength values between the implant and natural bone to determine if modifications are needed; (4) calculating biodegradation rates from mass loss data, creating graphs, and interpreting results; and (5) a reflective discussion on the ethical implications of biomaterial development and use, including the progression from initial design to animal and human testing.

The hydrogel activities began with an orientation task where students identified common characteristics in images (flexibility and water retention capacity).



Activities included: (1) modeling polymer synthesis by connecting "macromolecules" to create networks and three-dimensional structures, then analyzing water retention mechanisms; (2)

studying absorption properties using synthetic hydrogel beads, measuring mass before and after water exposure; (3) comparing mechanical properties between natural (agar-agar) and synthetic hydrogels, observing elastic behavior under light pressure and plastic deformation under greater force; (4) examining polymer degradation under high temperature by placing both hydrogel types in boiling water and observing differences; (5) an authentic research scenario where students select appropriate hydrogel samples for different applications (wound dressings, bone implants, drug delivery systems) based on viscoelasticity measurements; and (6) a reflective activity on microplastics in various environments, prompting discussion about the environmental impact of extensive polymer use and the need for sustainable alternatives.

Teacher Case Study

To illustrate the application of the IMPG framework in evaluating the designed materials, we present a case study of one participating teacher (Figure 3). Teachers' professional reflections provide valuable evidence of material quality and effectiveness, as they possess direct knowledge of their students and observe firsthand how students engage with and respond to instructional materials in authentic learning contexts. The selected teacher taught first-grade high school students (ages 15-16) and implemented the biomaterials activity set as a follow-up activity after the educational visit to the DMSE.

Figure 3. IMPG Interactions of Case Study Teacher.

Because teachers' reflections emerged non-chronologically during the interviews, the analysis is organized by domain interactions rather than by sequence of events.

The interconnected nature of the IMPG domains is evident in the analysis above. The teacher's actions stemmed from multiple sources: external factors such as the provision of educational materials, personal beliefs and attitudes, and observations of student interest (interactions 5, 2, 8). Simultaneously, reflections on both student outcomes and on the designed materials or visit structure enhanced her attitudes toward certain practices—for example, implementing more hands-on activities—and generated new pedagogical insights, such as recognizing the value of undergraduate student facilitators with whom school students could more easily identify and connect. The impact of the designed materials is also apparent. The teacher noted that students wanted additional time to complete the biomaterials activities, as one hour proved insufficient, and highlighted the meaningful ethical discussions generated around biomaterials and science more broadly. She characterized the overall visit experience as highly successful, reporting both cognitive gains and positive shifts in students' attitudes toward science, and expressed her intention to continue such practices in the future.

Table 3. Examples of IMPG Interactions of Case Study Teacher.

Mediating process	Examples
External - Personal (reflection)	4 - The teacher chose the biomaterials activity set, citing its practical simplicity and fewer experimental requirements compared to the hydrogels set. 12- The teacher suggested increasing experimental demonstrations during the visit and allocating more time in each laboratory, noting that students expect hands-on experiences and that extended time would allow for on-site implementation of the designed activities
Personal - External (enaction)	-
External - Practice (enaction)	5- The teacher implements the biomaterials set as follow-up activity after the visit
Practice - Personal (reflection)	6- "It was very well adapted to the first year of upper secondary school and aligned particularly well with the topic of forces. For me, as a physics teacher, it integrated smoothly with the visit and provided a coherent framework." 9- The teacher reflected that a reorganisation of the programme would have facilitated the completion of the activities within one continuous session instead of two separate sessions
Personal - Practice (enaction)	1- The teacher provided general information to the students, drawing on prior experience from previous visits. 2- Regarding her actions during the visit, the teacher stated that her role was primarily learning-focused, while also ensuring smooth organisation and students' social well-being.
Practice - Salient outcomes (reflection)	7- The implementation of the material led to a discussion on the social dimensions of science and provided motivation for students to think more broadly about material properties (e.g., silicone strength).
Salient outcomes - Practice (enaction)	8- Due to students expressed interest, the teacher continued the activity in the following lesson.
Salient outcomes - Personal (reflection)	3- Students' references to biomaterials guided the discussion, leading the teacher to select the biomaterials set of activities 11- Positive student feedback, especially regarding interaction with an undergraduate student, prompted the teacher to refine her beliefs about effective mediation during visits, indicating that engagement with undergraduate students may be more impactful than interaction with academic staff.
Personal - Salient outcomes (reflection)	10- The teacher reflected that the activity, in combination with the visit, helped students make meaning of school science, allowing them to move beyond classroom learning and broaden their attitudes towards science.

Teacher Recommendations

Teachers, as key mediators between students and researchers, possess direct knowledge of their students' backgrounds, interests, and capabilities, making their recommendations essential for improving educational visits. In our study, participating teachers emphasized several priorities, as follows. Structural and procedural recommendations: i) ensuring coherence between preparatory materials and the visit itself by aligning worksheets, activities, and demonstrations with the laboratories students will encounter; ii) increasing visit duration to allow deeper engagement; iii) organizing visits around coherent scientific themes rather than broad departmental overviews; iv) ensuring early communication about which laboratories will be included to enable effective student preparation and the selection of laboratories that directly connect to classroom content. Materials and facilitation: i) providing dedicated worksheets for each laboratory station; ii) integrating authentic data and artifacts to strengthen inquiry; iii)

involving university students as near-peer facilitators; iv) ensuring that guides are familiar with teaching materials in advance.

Conclusions

The analysis of the initial school visits highlighted several key limitations, such as the weak connection between the presented experiments and cutting-edge research, as well as students' difficulties in relating the content to the curriculum due to limited preparation. As a result, the real-world relevance of materials science and its societal implications often remained underemphasized. At the same time, universities face structural constraints: they typically lack specialized staff in science communication and dedicated resources for educational outreach, while the ongoing and dynamic nature of research makes it difficult to standardize what can be presented to visiting school groups. Consequently, redesigning educational visits in a systematic and sustainable way remains challenging.

Part of the solution lies in the design of educational material to support such visits in informal learning spaces, which can act as a bridge between cutting-edge research and school science, while also helping students make explicit connections to the societal, ethical, and real-world implications of scientific research. In this context, collaboration among teachers, science education researchers, science communicators, and materials science experts is crucial for the effective design and appropriation of such interventions. Educational materials that are purposefully designed can mediate between advanced scientific content and students' prior knowledge, making contemporary research both accessible and meaningful.

As previously discussed, teachers play a central mediating role in educational visits to informal learning environments. However, introducing topics related to cutting-edge research can be demanding, particularly for less experienced teachers, who may feel uncertain or cautious when engaging with unfamiliar scientific content. This highlights the need for professional development programmes, that can strengthen teachers' confidence in these contexts. At the same time, teachers' recommendations, concerns, and experiential insights should be taken seriously, as they offer valuable perspectives for improving both the design and implementation of educational visits in informal learning environments.

Acknowledgments

The project is carried out within the context of the Interdisciplinary Research Programme – Category C2, funded by the Special Account for Research Funds of the University of Crete (Project number: 11516).

ESERA 2025 Copenhagen

Exploring Non-Formal Science Education: Growing Crystals, Growing Minds

Jorge Martín-García and María Eugenia Dies Álvarez
Instituto Universitario de Investigación en Ciencias Ambientales de Aragón, Universidad de Zaragoza, Spain

In the field of non-formal science education, there are still activities that remain under researched. This is the case for crystal growth contests for school students. To address this gap, a four-year longitudinal study was designed to explore the perceptions and experiences of 165 teachers and 559 students from Aragón (Spain), who participated in such a competition. Using qualitative methods with a descriptive and interpretative scope, pre- and post-competition questionnaires containing open-ended questions that allowed participants to elaborate their responses were distributed annually. The data were analysed through qualitative content analysis, identifying categories that provided a framework for interpreting the results. The findings provide an integrated perspective of the benefits that the contest provides to participants and highlights the potential of long-term non-formal activities to bridge formal and non-formal education. Teachers reported improved pedagogical practices and enhanced professional skills, and students gaining a deeper understanding of scientific processes and developing different skills. Students found the competition enjoyable and rewarding, which improved their knowledge and perception of science, provided them with some practical experience, and promoted their skills. Additionally, the relaxed setting fostered stronger teacher-student relationships, contributing to a more engaging and collaborative learning environment. These findings offer valuable insights for designing more effective educational initiatives and provide a foundation for future research on the role of long-term non-formal activities in science education.

Keywords: crystal-growing competition, student perceptions, teacher experiences

Introduction

Non-formal education in the field of science has experienced very strong development over the last decades, primarily because it is less constrained by limitations typically associated with traditional classroom settings. As a result, non-formal education has emerged as a means of extending and enriching both students' and teachers' experiences. These experiences support science learning in ways that traditional schooling cannot (Kisiel, 2014) and address aspects of science education that are often absent in formal education (Jarvis & Pell, 2005).

The literature (e.g., Affeldt et al., 2017; Burke & Navas Iannini, 2021; Nuora & Välisaari, 2018) shows how non-formal teaching is recognised as an element that contributes notably to lifelong learning (Woithe et al., 2022) and provides different types of benefits to participants that are mutually reinforcing, highlighting that such experiences offer various cognitive, procedural, affective-emotional, personal, and social benefits to participants. Indeed, research also demonstrates the positive impact of these activities on teachers in terms of professional development and training.

1. *Cognitive Benefits.* They allow students to be exposed to learning conditions that simply cannot be reproduced in the classroom (Nadelson & Jordan, 2012), thereby providing additional support for learning. Along the same lines, they act as a bridge between knowledge acquired at school and outside of it, promoting the acquisition of new content, concepts (Canovan, 2019; Domenici, 2022), and models (Bell et al., 2009) from a more interdisciplinary perspective (Yu & Yang, 2010). In this way, they not only foster a greater understanding of how scientific knowledge is generated and constructed but also have a

positive effect on academic performance (Miller et al., 2018). Finally, they offer opportunities for students to develop skills, attitudes, and values normally associated with science (Weinberg et al., 2011) and develop their cognitive abilities (Julien & Chalmeau, 2022).

2. *Affective Benefits*. They foster students' interest and curiosity in science (Weinberg et al., 2011) and increase their motivation towards both science itself (Markic et al., 2017; Tisza et al., 2020) and its learning (Affeldt et al., 2015; Raaijmakers et al., 2021). Furthermore, they promote, develop, or generate more positive attitudes and feelings (Nuora & Välisaari, 2018) towards science and its learning, thereby enhancing the appeal of science education and generating positive emotions towards the sciences (Canovan, 2019). Consequently, they have the capacity to induce changes in participants' attitudes towards science (Millar et al., 2019) and contribute to increasing the perception of the social relevance of science and students' commitment to science (DeWitt et al., 2018). Finally, they contribute to the generation of a scientific identity (Burke & Navas Iannini, 2021) and the promotion of scientific vocations (Jones et al., 2011; Wünschmann et al., 2017) and professional orientation towards science careers.

3. *Social Benefits*. They contribute to socialisation because they bring students with common interests into contact, which allows for the generation of a certain sense of community belonging (Millar et al., 2019) where they can be recognised by themselves and others as people of science, which also aids in the consolidation of a scientific identity (Burke & Navas Iannini, 2021).

4. *Benefits for Teachers*. They promote professional reflection and identity (Haatainen et al., 2024) and support teachers in their professional development (Gupta & Adams, 2012; Martín-García et al., 2024). In this sense, they provide an opportunity to broaden, enrich, and diversify teacher training by offering motivating structures for learning and opportunities to practise science teaching in "safe" environments (Avraamidou, 2014; Martín-García et al., 2024). This helps them develop greater confidence in their abilities as educators and improve their self-concept and self-efficacy when teaching science (Martín-García & Dies Álvarez, 2024). Therefore, they contribute to the development of both scientific-content knowledge (Jung & Tonso, 2006) and pedagogical-content knowledge (Kisiel, 2013). Finally, they also help them acquire a greater understanding of the characteristics of their students (Tang et al., 2017).

Knowing these benefits, educational research has long advocated bridging formal and non-formal education (Fallik et al., 2013; Molz et al., 2022; Watermeyer, 2015). However, much of the existing research has focused on short-term, non-formal activities, such as museum visits led by external educators (Avraamidou, 2015). In contrast, the present study centres on a long-term, academic-year-long activity coordinated and implemented by teachers themselves, without the intervention of external educators. This allows for a more direct link between formal and non-formal experiences and helps identify how these experiences relate to the curriculum content and how to integrate them effectively into their lessons

The Present Study

Non-formal education in science is an extraordinarily broad and heterogeneous reality that is difficult to categorise, encompassing highly diverse activities conducted in various contexts and with differing durations and developments. For instance, non-formal activities range from visits of a few hours to specific locations led by external educators, to projects lasting several months

where the work is carried out directly with the teacher, such as in science clubs (Martín-García et al., 2025).

Within this second category, we find the so-called crystal-growing competitions for schoolchildren (Whelan et al., 2018), which have been celebrated with great success worldwide (Perret et al., 2014; Van Meervelt, 2014). These are global events organised at a European and international level by the International Union of Crystallography. These events provide an opportunity for students to operate as 'scientific researchers', to investigate something they are curious about, design and implement experiments, collect data and extract meaning from them, draw evidence-based conclusions from the obtained results, and present and explain them to others. The one and only condition is that the projects must include some crystal-growing experiences.

Nevertheless, there is little research that provides empirical evidence concerning crystal growing competitions, as there have been no systematic studies of their implementation and outcomes. Furthermore, prior research seems to be scattered through isolated publications that are generally based on personal anecdotal opinions and subjective perceptions from the organisers rather than data and evidence gathered through research (Perret et al., 2014; Van Meervelt, 2014). This article aimed to fill that gap by providing evidence-based information derived from a four-year longitudinal investigation.

In Spain, crystal-growing competitions are now celebrated all over the country with several regional editions that culminate in a national final. Specifically, in the region of Aragón, where the study focused, the contest, named *Concurso de Cristalización en la Escuela de Arag*ón (CCEA), has held ten editions, reaching more than 10,000 students and over 140 schools from both urban and rural areas.

The contest is divided into three stages, covering almost the entire academic year: an initial stage where the competition, its organisation, development, and functioning are presented to the teachers; a second stage where the students work on their crystallisation projects supervised by their teachers; and a third stage in a congress format where representatives from each school defend their project before a jury of experts and the public attending the final. It is also mandatory for each team to elaborate a scientific poster summarising the project and its conclusions and to exhibit their laboratory diaries as well.

The contest's main objective is to raise students' awareness of science, increase their interest in it, encourage them to participate in scientific activities, and develop their scientific skills and abilities. The competition offers students an opportunity to immerse themselves in scientific investigations as if they were scientists, to design and conduct their own research projects, implement experiments, collect data, and make evidence-based decisions.

Method

Despite the crystal growing competitions have been held worldwide for years, there is a notable lack of empirical studies addressing their formative potential or their impact on teachers and students who participate in them (Van Meervelt, 2014). Consequently, this research was designed with an exploratory and descriptive nature, aiming to understand the experiences and perceptions of those involved in such competitions. Therefore, to align with this objective, a qualitative methodology with an interpretative focus was adopted to give participants a voice and allow their perceptions to be studied directly.

Previous studies (e.g., Garner et al., 2015; Karnezou et al., 2021) indicate that one of the objectives most frequently pursued by educators participating in non-formal activities, at least in

the field of science, is precisely to connect the activity with the school curriculum, often being the main reason for determining which activities or projects have potential interest. Building on this basis, the research also aims to analyse how the competition activities fit within the secondary curriculum framework, by analysing the secondary education curricula to determine which of their elements can be addressed within the scope of the contest activities.

In this way, the perspective "from within" offered by the participants' impressions and experiences is complemented by an analysis "from without", conducted using the official normative documents that regulate secondary education in the region of Aragón.

To analyse the participants' perspective, a longitudinal study was conducted between 2016 and 2020, involving 165 teachers and 559 students from various towns in Aragón. For data collection, two ad-hoc open-ended questionnaires were designed each year for the teachers and two for the students: one administered prior to the competition and one afterwards. These questionnaires included open-ended questions that required the participants to construct their own responses, and they were specifically developed for the research and adapted to the context. The first questionnaire was distributed before the experimental phase began. The second, in contrast, was administered once this second phase had concluded but always before the competition final. Both were administered via the Google Forms platform to facilitate the subsequent analysis process.

The textual information contained in the respondents' answers was analysed using content analysis procedures. Specifically, strategies typical of Qualitative Content Analysis (Mayring, 2022) were employed by applying a semantic approach that allowed the identification of codes based on explicit meanings in the data. That is to say, the object of the analysis was not so much the style, composition or the organisation of the discourse, but rather the meanings contained within the transmitted message. This process allowed for the inductive generation of sets of categories representative of the participants' perceptions, providing an explanatory framework from which to interpret participants' responses and comprehend the underlying background. This analysis process was carried out in duplicate: first by considering the responses from each year separately, and subsequently from a more general perspective, considering the responses from the different editions as a whole.

Finally, for the studies focusing on the curriculum, documentary analysis strategies were used (Wotring et al., 2021) on the orders that specify the curriculum. This was done to locate, fix, select, and give meaning to the data collected in these documents, thereby allowing the researchers to discover and describe the central axes and main themes of the curriculum.

Findings

The responses from the teaching staff describe the competition as a beneficial learning context for students, where they can have fun and enjoy themselves, while acquiring knowledge across various subjects and developing a range of skills. Similarly, they regard it as an opportunity to foster a deeper understanding of scientific phenomena and explore science, scientific work, and research. Additionally, the contest is considered beneficial for teachers themselves, as it provides a chance to enhance their professional competencies and improve their role as teachers.

On the other hand, students perceive the competition as an opportunity to gain new knowledge and engage in laboratory work alongside their peers. Many also acknowledge that it has improved their perception of science, as they have discovered it to be more appealing, interesting, less abstract, and more accessible. In terms of content, curriculum analyses indicated that the contest allows for the inclusion of both specific topics and complete blocks of content from various subjects.

Specifically, seven key aspects summarising their perceptions of how the CCEA can contribute to science education have been established from the participants' responses. In this regard, the participants perceive the competition as an opportunity to:

1. **Improve Students' Scientific Education**

Teachers described the competition as an effective tool to foster students' scientific education because it allows them to address content from different subjects and, at the same time, go a step further than the curriculum and work on topics not explicitly included in the normative documents. Similarly, the students acknowledge specific learning achievements, both in the field of crystallisation and in relation to the curriculum of various subjects. The systematic curriculum analysis not only corroborates these perceptions but also reveals how other curricular elements exist that can be worked on beyond those mentioned by the participants. Furthermore, teachers emphasise the competition's ability to integrate knowledge from different disciplines, which allows for offering students an image of scientific knowledge as something that is coherently interrelated. Finally, it also provides an opportunity to promote the development of students' competencies, particularly their scientific competence.

2. **Develop Students' Skills**

According to teachers, participation in the competition provides students with opportunities to develop skills that are challenging to cultivate in traditional classroom settings. These include scientific skills, such as analysing and interpreting data, as well as transferable skills such as teamwork, which are highly valued by both teachers and students. In the case of the students' responses, they highlight how they have not only learned to work as a team but also to plan and organise that work.

3. **Provide Students with A More Realistic Image of Science**

Students feel that participating in the competition provides them with more realistic insight into how experimental sciences operate. They have come to appreciate key aspects, such as the importance of methodology, the need for replicability, and the broader role of science in society. Teachers emphasised that the contest helps students develop a more accurate understanding of how scientific knowledge is created and validated. In this way, students can appreciate the sometimes tentative nature of science and move a little closer to understanding its nature.

4. **Offer Students an Enjoyable Experience in Science**

Many teachers participate in the competition to reward their students by offering them an enjoyable and engaging experience that can help reduce the feelings of stress or anxiety that science sometimes generates and substitute them with a more positive emotional bond that may make students more willing to engage with it. This approach seeks to create a positive emotional connection with science, foster improved attitudes towards the subject, and boost motivation. Students confirmed that they perceived the competition as both rewarding and fun.

5. **Promote Teacher Professional Development**

Teachers regard the competition as an opportunity to complement and extend their training and support their professional growth. Specifically, they acknowledge that the competition is a way to come into contact with new ideas and highlighted that the competition equips them with additional resources and teaching strategies to enrich their educational toolkit. In this sense, they consider that they have gained practical knowledge for their daily teaching practices as well as insights that broaden their scientific understanding especially, but not only, in the field of crystallisation. Moreover, teachers described how the experience has allowed them to better understand the students and become more aware of their abilities and needs, which is very useful

when planning and guiding classroom teaching. Finally, they acknowledge that participation in the contest serves as a source of motivation and personal satisfaction because they believe they are doing something beneficial for the students, which encourages them to become involved in other non-formal education activities.

6. Test New Science Teaching Strategies

Teachers view the contest as an opportunity to rethink their teaching practices, giving greater importance to practical laboratory work. They also see it as an opportunity to explore different teaching-learning contexts and situations and a platform for innovation, allowing them to experiment with new methodological approaches and to assess their effectiveness. Consequently, they feel more confident in applying these approaches in the classroom and feel more capable of teaching science.

7. Strengthen Personal Relationships

The findings revealed that the contest fosters a conducive environment for strengthening the bond between teachers and students. In this sense, there is an almost unanimous consensus among teachers in pointing out that the interactions established with students during the sessions dedicated to the contest differ significantly from those habitually generated in the classroom. The more relaxed atmosphere of the event, coupled with students' increased motivation, created a climate of trust and enhanced communication. This enables teachers to gain a better understanding of their students, contributing to a more enjoyable and fulfilling experience for everyone.

Discussion

The findings of this four-year longitudinal study emphasise the significant educational value of crystal growth contests for both teachers and students. The perceptions of participants reveal that the competition is a mutually beneficial experience for both of them alike. For students, it fosters engagement, skill development, and a deeper understanding of science. For example, they themselves highlight the effect of the contest on their image of science and science subjects, acknowledging that this has improved, in some cases because they have discovered a more appealing, entertaining, or interesting science, and in others because they have discovered a less abstract, less complicated, and more understandable science.

For the teachers, it supports professional growth and innovation in teaching practices while it contributes to promoting their content-knowledge, their pedagogical-knowledge, and their knowledge of the students, their characteristics, needs, and motivations. Finally, from the curricular perspective, it is clear that the contest allows for addressing specific content or knowledge in a simple and integrated manner, but also complete or practically complete blocks of the curriculum from different subjects belonging to different areas of knowledge.

However, the development of the contest is not free of problems or situations that must be confronted or resolved, which have led teachers to question certain aspects of it because they do not fully align with their vision of what the project should be. There are other aspects that, in the teachers' opinion, should be rethought or modified; these mainly refer to organisational aspects and not so much to how the contest is conceived or the effects it has on the participants, which are perhaps the most interesting aspects for the research. Thus, the results highlight the multifaceted benefits of participation that extend well beyond disciplinary knowledge to encompass broader educational and developmental outcomes.

These results broadly align with existing research (Affeldt et al., 2017; Burke & Navas Iannini, 2021; Karnezou et al., 2021; Molz et al., 2022; Raaijmakers et al., 2021), highlighting the critical

importance of integrating formal and non-formal education to enhance the teaching and learning of science and ensure equitable benefits for all students. However, this study introduces several distinctive contributions that enrich the current understanding of such educational experiences and deepen our understanding of their role in science education.

First, it addresses an activity that, despite its global implementation, has been largely overlooked in prior research. Second, the focus on long-term initiatives marks a departure from the predominantly short-term activities typically examined in the literature. Third, the study adopted a multi-perspective approach to explore the experiences of both teachers and students. This approach, although uncommon, is essential for providing a holistic understanding of educational impact. Finally, the longitudinal design is particularly noteworthy, as studies of this nature remain scarce in the context of non-formal science education activities.

Collectively, these results represent a valuable contribution to the field of non-formal science education, offering new insights into the potential of these activities to enrich both teaching and learning. It is notable that the results of such diverse research, conducted in such different contexts, present so many marked similarities regarding the benefits that non-formal activities offer. This convergence suggests that the elements that are repeatedly observed are crucial for understanding the true significance of participation in non-formal activities for both teachers and students and that these are the aspects that should be attempted to be transferred to the classroom as much as possible.

Conclusions

In synthesis, the School Crystallization Contest, due to its nature as a non-formal activity, its development, the mode of work it promotes, and the final congress format as the culmination of the research and experimentation processes, brings together the best of three worlds:

1. The broad spectrum of possibilities offered by non-formal education, as it involves fewer limitations than formal education.
2. The benefits of methodologies based on inquiry, laboratory work, collaboration with peers, autonomy, and motivation.
3. The complementary nature of public science communication experiences.

The project harmonises these three elements to achieve greater scientific literacy among students, a greater understanding of science and its knowledge, and to continue training science teachers by improving their professional performance. In this process, the experience contributes to fulfilling curricular objectives, to the development of the key competencies that structure the curriculum in Spain and facilitates the addressing of content from different subjects from a multidisciplinary perspective, which rightfully makes the contest an extremely comprehensive training tool.

Therefore, these findings serve as a basis for future research, but also for the development of non-formal education programmes that are more enriching and attractive for teachers, who ultimately decide whether or not to integrate them into their classroom practice. However, beyond their academic value, they also have practical value because they offer the community a clear example of what participation in non-formal education activities can entail in terms of training and personal and professional development.

Exploring Teachers' Objectives In Science Clubs And Beyond

Jorge Martín-García[1], Ana Sofía Afonso[2] and María Eugenia Dies Álvarez[1]
[1]Instituto Universitario de Investigación en Ciencias Ambientales de Aragón, Universidad de Zaragoza, Spain.
[2]Institute of Education/CIEd, Campus de Gualtar, University of Minho, Portugal

Despite the value that teachers place on non-formal activities, their goals and what they need from them remain underexplored, particularly in the context of long-term initiatives. In this work interviews with 19 teachers coordinating school science clubs in Portugal were conducted and their key objectives for the implementation of the club in the school were analysed. These include bringing science closer to students and communities, connecting activities with the curriculum, fostering scientific and interdisciplinary skills, and enhancing student motivation and engagement. In parallel, a literature review was conducted to identify studies examining teachers' goals for non-formal education activities. Thirty relevant studies were analysed, and their findings were compared to the objectives identified in the context of science clubs. The results revealed that teachers coordinating science clubs recognised all the goal types highlighted in the literature but placed greater emphasis on certain objectives which are less frequently mentioned in other types of non-formal activities. The findings underscore that science clubs enable meaningful experiences that complement traditional teaching, fostering interdisciplinary connections and promoting scientific literacy. The study concludes that understanding teachers' beliefs and requirements is crucial for designing activities that not only complement the curriculum but also address challenges within the formal education system. Greater integration between formal and non-formal education can generate synergies, bridging gaps and creating a seamless continuum of experiences that enrich science teaching and learning.

Keywords: non-formal education, science clubs, teachers' goals.

Introduction

There is growing evidence that students' knowledge and understanding of scientific concepts develop across a variety of settings, both within and beyond the classroom (Mujtaba et al., 2018). The benefits of non-formal learning environments for school students have been widely studied in many countries, showing that these activities make significant contributions to science teaching both in the conceptual-cognitive and affective-emotional domains (e.g. Aslan et al., 2023; Haatainen et al., 2024). As a consequence, it has been acknowledged that non-formal learning experiences can support science learning in ways that traditional schooling cannot overcome (Covert et al., 2019; Kisiel, 2014).

Nowadays, teachers increasingly recognise the value of non-formal learning spaces in providing educational experiences for their students (DeWitt and Osborne, 2007). Therefore, the effective integration and utilisation of these environments in science teaching represents an essential step toward fostering a more comprehensive and impactful approach to science education.

The role played by teachers in the integration of formal and non-formal education cannot be denied. Research firmly suggests that teachers and their approaches to non-formal learning play a crucial role in determining the effectiveness of such experiences (Luehmann and Markowitz, 2007; Uppin and Timoštšuk, 2022). Particularly critical is the value teachers attribute to these activities in enhancing their students' learning and abilities, as well as the goals they have for the experience, and the potential such activities offer to establish meaningful connections with the school curriculum (Karnezou et al., 2021). Despite their importance, these factors are often

overlooked and limited emphasis has been placed on understanding teachers' perceptions, particularly in the context of long-term scientific activities (Martín-García et al., 2024).

For this reason, understanding teachers' beliefs regarding non-formal activities, what they need, and what they are looking for when entering the world of non-formal education is essential for designing activities that are both effective and responsive to their demands. However, achieving such interrelations and complementarity is considerably more feasible when activities are designed and implemented by teachers themselves and extend throughout the academic year. Examples such as science clubs illustrate this point effectively, as they allow for frequent and meaningful connections between non-formal activities and classroom learning. In Portugal, there is an established network of science clubs known as the "Clube de Ciência Viva na Escola" (The Alive Science Club at School), initiated and supported by the Ministry of Education. Within this framework, science teachers working at participating schools are responsible for coordinating science clubs. Such activities enable a seamless transition from classroom knowledge to application in a non-formal setting, or vice versa, facilitating experiential learning and the construction of knowledge in both contexts (Martín-García, Afonso, et al., 2024; Martín-García, Dies Álvarez, et al., 2024).

The focus of this study is to explore the specific goals established in the context of science clubs, with their unique characteristics, and compare them to the goals set for other types of non-formal education activities. To complement this analysis and establish comparisons with other types of non-formal activities, we conducted a review of 39 studies that explored teachers' objectives and expectations regarding various non-formal education activities to identify the types of objectives typically mentioned by teachers and whether these differ between short-term and long-term activities.

Method

This study is part of a broader investigation examining science teachers' subjective perceptions and experiences with school science clubs in northern Portugal. Following the previously described objectives, the study comprised two main parts: a literature review and a qualitative study using semi-structured interviews. Firstly, a bibliographic search was conducted in the Web of Science database to identify articles addressing the objectives, intentions, and expectations of teachers regarding non-formal education activities. Following a review of the titles and abstracts of the retrieved references, studies explicitly outlining the specific objectives set by the teachers were selected. Finally, the studies were classified based on the type of activity they described, and whether they were short- or long-term initiatives.

In parallel, we were interested in the evaluation of the perspectives of the teachers who coordinate science clubs regarding their goals, expectations, or intentions towards non-formal education. The analysis of teachers' perspectives in the literature often relies on closed-ended questions, which do not allow for a detailed understanding of their views, thus limiting their validity (Jensen and Buckley, 2014). In contrast, in this case, we approached the study using semi-structured interviews with 19 teachers who coordinated school clubs in the northern region of Portugal. The interview script conformed to a set of open-ended questions to invite teachers to elaborate on their answers.

Both the literature findings and the interview transcriptions were analysed using inductive bottom-up content analysis from a semantic perspective. This meant that our codes were directly derived from the data rather than imposed based on an a priori framework (Mayring, 2022). We then grouped codes with similar meanings to generate categories until we had a set of categories that were representative of the types of goals mentioned by the teachers in each case. This set

provided an explanatory framework which allowed interpretation and comprehension of their responses.

Findings

The search yielded 30 studies that mentioned concrete objectives for participating in non-formal educational activities. Of these, 22 studies focused on short-term activities, while only 7 examined long-term projects. The study by Tisza et al. (2020) spans several types of activities with differing durations, making it unsuitable for classification under a single category. Specifically, the studies on short-term activities were primarily focused on the context of museums (18 studies), of which 16 were developed as school field trips. Works carried out in outreach laboratories (2 studies) and science festivals (2 studies) also appear. Finally, one of the studies discusses field trips in general, without specifying the type of location visited. Regarding long-term activities, science fairs predominate (3 studies), but there is also mention of projects conducted in aquariums (1 study), crystal growth competitions (1 study), and enrichment programmes (1 study), and even in a science club (1 study). The analysis of these studies allowed us to generate several categories, as summarised in Table 1, which describe the primary types of objectives identified in these studies.

Table 1: Types of objectives for non-formal education activities mentioned by teachers in the 30 selected studies from the literature review. Number of studies conducted in short-term and long-term activities that mention each of the objectives (percentage of the total number of studies conducted in short-term or long-term activities).

Code	Objective focused on	Number of articles	Short-term (n=22)	Long-term (n=6)
O1.	Increasing students' exposure to science	16	10 (45,5%)	5 (71,4%)
O2.	Science content-knowledge	18	12 (54,5%)	5 (71,4%)
O3.	Curriculum connection	14	12 (54,5%)	2 (28,6%)
O4.	Providing new learning experiences	17	14 (63,6%)	3 (42,9%)
O5.	Experimental work experience	10	7 (31,8%)	3 (42,9%)
O6.	Developing of students' skills	9	3 (13,6%)	5 (71,4%)
O7.	More effective teaching	12	7 (31,8%)	5 (71,4%)
O8.	Exposing the students to what the settings uniquely have to offer	9	8 (36,4%)	1 (14,3%)
O9.	Personal interest of the teacher or school demand	8	6 (27,3%)	2 (28,6%)
O10.	Motivation and interest	18	14 (63,6%)	3 (42,9%)
O11.	Enjoyment and engagement	13	12 (54,5%)	1 (14,3%)
O12.	Personal relationships and interactions.	9	7 (31,8%)	2 (28,6%)

Note: Cells shaded in purple indicate content-oriented goals, cells shaded in green indicate affective-oriented goals, and cells shaded in red refer to general education-oriented goals. The total number of objectives does not match for objectives O.1, O.2, O.6, and O.10 because these are the objectives mentioned in Tisza et al. (2020) study, which refers to all types of activities without specifying duration.

The review of the literature reveals a broad range of objectives, suggesting that non-formal activities can serve diverse purposes and address various educational needs. The revised studies include more cognitive objectives, focused on the acquisition of specific scientific knowledge, but also more affective objectives, centred on areas such as motivation, enjoyment, and interest in science. Furthermore, objectives more focused on the immediate educational context also feature, relating to the teaching and learning process, such as the curriculum, the teaching practice, and the type of educational experiences to which students are exposed.

The most commonly mentioned objectives include the acquisition of scientific knowledge and content, as well as the enhancement of student motivation and interest. Additionally, many studies have emphasised the provision of new learning opportunities and exposure to science in ways that allow students to engage more deeply. These findings underscore the teachers' emphasis on connecting non-formal activities with the classroom, whether as complements, extensions, reinforcements, or applications of classroom learning, targeting both subject-specific knowledge and the development of skills and attitudes.

Reviewing short-term and long-term activities separately reveals that all categories derived from the literature analysis are mentioned in both groups. However, there are differences in the types of objectives most frequently cited. For example, in long-term activities, the dominant objectives are "*To increase their exposure to science*", "*Science content-knowledge*", "*Development of students' skills*" and "*More effective teaching*", which appear in 5 out of the 7 articles contextualised in long-term activities (71.4%). In contrast, in short-term activities, the predominant objectives are "*Providing new learning experiences*" and "*Motivation and interest*", appearing in 14 out of the 22 studies found (63.6%). To a lesser extent, "*Science content-knowledge*", "*Curriculum connection*" and "*Enjoyment and engagement*" stand out, being mentioned in 12 studies (54.5%).

The qualitative findings derived from interviews with teachers who coordinated science clubs show that they set a wide variety of different goals for the clubs. The responses could be organised into seven categories, but within the majority of them, several different themes can be identified. Both the categories and the most relevant themes found within them are summarised in Table 2. It is important to note that these categories are not mutually exclusive. More often than not, teachers expressed several goals, and some of them may be classified in more than one category. In fact, all 17 interviewed teachers identified more than one category of objectives. Specifically, three teachers mentioned two categories, three mentioned three categories, nine mentioned four categories, and three mentioned all five categories. This demonstrates the multifaceted nature of these objectives.

Overall, teachers coordinating science clubs recognised all the types of objectives discussed in the 30 reviewed references. That is to say, the goals declared by the teachers are, for the most part, quite similar to those found in the literature. In both cases, objectives aimed at providing concrete benefits to students or improving their learning of science predominate. Table 2 illustrates how the categories constructed in the interview analysis relate to the types of objectives found in the literature review. However, differences are also observed, for example, in the relevance given to the learning of disciplinary content or science. For this reason, our interviews reveal some unique aspects that differentiate the clubs from what is typically reported in the broader literature.

Firstly, it became evident that teachers see the science club as an opportunity to integrate concepts in broader contexts and engage in interdisciplinary activities, a goal that appeared in only one of the 30 references analysed. Secondly, these teachers place strong emphasis on the opportunity to integrate concepts in broader contexts and engage in interdisciplinary activities. This was

particularly striking as this specific goal appeared in only one of the thirty analysed references. Finally, teachers placed greater emphasis on goals related to bringing science closer to the community and students—a key objective present in all interviews and thus fostering community and student appreciation of the club's role in promoting science education, an objective that was not captured in the 30 references.

Table 2: Types of objectives mentioned by teachers coordinating science clubs in the interviews: categories, subcategories, and number of teachers mentioning them. Relationships or associations with objectives derived from the literature review analysis (n=17).

Category	Subcategories	Number of teachers	Associated objectives from the literature review
To bring science closer to pupils or the community	Disseminate the study of science. Motivate students and engage them in scientific activities. Promote scientific literacy and scientific culture. Showing that science is important to society.	17	O1.; O2.; O3.; O4.; O10.; O11.
To promote other means of teaching and learning:	Providing interdisciplinary experiences. Connecting with the curriculum. Experience the experimental component of science.	14	O1.; O2.; O3.; O4.; O5.; O7.; O8.; O9.
To develop students' skills and abilities	Scientific skills. Cross-disciplinary skills.	13	O5.; O6.; O9.; O12.
To increase awareness about what the club offers	Supporting students with difficulties or high abilities.	6	O1.; O2.; O3.; O4.; O5.; O6.; O7.; O8.; O9.
To increase students' science content-knowledge		12	O2.; O3.
To promote or improve personal relationships and interactions.		2	O6.; O12.

Discussion

The main aim of this study was to examine the specific goals set within the context of science clubs and to compare them with those established for other types of non-formal education activities. Previous studies in this field seems to be somewhat contradictory. Some studies reveal that although schools and teachers attribute high value to the museum visit, the international literature indicates that teachers hardly define their goals for the museum visit (e.g. Cox-Petersen et al., 2003). For example, Tal et al., (2005) studied 30 teachers in four natural history museums in Israel. They found out that only one-third of these teachers provided specific purposes for

conducting the museum visit, explaining how the visit was connected to the school curriculum. Most of the teachers gave general answers about the purpose of the visit, while in many cases teachers stated that others had planned the visit and they were unaware of the purpose. On the other hand, other publications reported that teachers seem to have multiple objectives for activities such as fieldtrips which include both cognitive and affective elements (Anderson et al., 2006; Karnezou et al., 2021; Martín-García and Dies Álvarez, 2022). Other works have also shown how teachers articulated their goals around these two dimensions (e.g. Canovan, 2019; DeWitt and Storksdieck, 2008; Tisza et al., 2020).

The results obtained in this work, both in the literature review and in the teacher interviews, align more closely with these latter studies. Specifically, the analysis of the references found in the literature review evidences that teachers recognise the role such places can play in providing unique educational experiences for their students, both when dealing with short-term and long-term activities. Consequently, they generally establish certain objectives for the activities, although these may sometimes be very generic.

The interview results are generally consistent with the findings derived from the systematic analysis, although they do show certain slightly distinct elements that have not been recorded in the studies analysed in the literature. However, it has not yet been possible to determine whether these elements are inherent and exclusive to the science club as a non-formal education context or whether they are more related to the sustained, long-term nature of the activities carried out.

In any case, given the complexity and diversity of activities encompassed within the domain of non-formal education, teachers' objectives in out-of-classroom learning environments are far from uniform. However, although the activities and their contexts differ, there are some noteworthy similarities with regard to teachers' declared goals. It is notable that the results of such diverse research, conducted in such different contexts, present so many marked similarities. This convergence suggests that the elements that are repeatedly observed are crucial for understanding the true significance of participation in non-formal activities for teachers and that these are the aspects that should be attempted to be transferred to the classroom as far as possible.

There are no major differences between short-term and long-term studies regarding the types of objectives proposed by the teachers. In fact, as indicated, the reviewed studies, as a whole, mention all the categories emerging from the analysis, both when considering only the short-term activities and when considering only the long-term ones. However, our review revealed that much of the existing research has focused on short-term activities such as school field trips, where external educators often lead educational initiatives. In contrast, we identified only two studies that examined long-term activities, where teachers take on responsibility for leading the activities themselves (Longhi and Schroeder, 2012; Martín-García and Dies Álvarez, 2022).

There is growing evidence that students' knowledge and understanding of scientific concepts develop across a variety of settings, both within and beyond the classroom. Therefore, teaching science in the classroom environment should be supported with experiences gained outside the classroom (Aslan et al., 2023). Thus, the appropriate and effective use of non-formal activities in science teaching is very important and it should become a core practice rather than something that teachers do when they have extra time. For that reason, understanding how teachers' beliefs regarding non-formal activities are structured—what they need, seek, and value when engaging in non-formal education—is essential for designing activities that are both effective and responsive to their demands. Activities that truly align with teachers' expectations are more likely to be meaningful and impactful.

For this reason, we agree with authors such as Luehmann and Markowitz (2007) who declare that much can be learned about secondary science classrooms' needs by considering teachers' perspectives because by considering both educators' perspectives, we gain a clearer understanding of the practice. In other words, by considering these perspectives, we gained valuable insights into the perceived gaps in the formal education system. These reflections serve as informal diagnoses of the challenges in science teaching and offer a roadmap for improvement. Similarly, gaining insight into teachers' perspectives is essential not only for designing non-formal activities that effectively address the needs of educators and students but also for promoting stronger integration between formal and non-formal education. In this regard, some of the reviewed references indicate that students learn more and benefit more from non-formal education experiences when they are already familiar with the topics and content addressed, as their prior knowledge seems to condition the learning they can achieve (DeWitt and Storksdieck, 2008). Therefore, such integration between formal and non-formal opportunities can generate synergies that bridge the gap between these two domains, thus creating a seamless continuum of experiences that enriches science teaching and learning.

Furthermore, depending on factors such as teachers' personality traits or teaching styles, the same activity may serve a wide range of purposes, addressing both cognitive and affective goals, which are often interlinked rather than mutually exclusive. In this sense, considering these factors, the same non-formal education activity or context can serve different purposes depending on how it is developed, structured, sequenced, and connected with the work carried out in the classroom. In this context, it is the prioritisation of specific goals over others, rather than the initial establishment of certain objectives, that significantly influences the teachers' practice, the way they deal with the experience, and the overall outcomes of such activities (Karnezou et al., 2021). Nevertheless, even though teachers' agendas dominate the course and outcomes of non-formal experiences, there is always an element of unpredictability in learning in out-of-school environments (Uppin and Timoštšuk, 2022).

Finally, authors such as Garner et al. (2015) consider that it is also important that the students know exactly what is expected of them during the field trip. Nevertheless, they described how research shows that students are often unaware of the overall goals and thus they are unprepared for effective, goal-oriented learning during the activities. An implication of this is that teachers must therefore carefully inform their students about the goals pursued through participation, so that students can know what is expected of them during the activities.

Therefore, when researching within the framework of non-formal education, it is no longer sufficient to merely consider the general objectives of the activity proposed by the teacher, but also which ones are priorities for the teachers, in line with what this last author suggested. This is an aspect that we have not carried out throughout this study, but which would be interesting for future research to consider as a possible line of further investigation.

In conclusion, taking into account both the results of the systematic review and the perceptions shared by the teachers during the interviews conducted in the science clubs, it is evident that further analysis of teachers' perspectives within the specific framework of long-term activities is necessary, as a gap still exists in the literature given that far fewer studies focus on this type of activity.

In this way, we can come to understand the subtle differences that exist between short-term and long-term activities and be able to advise teachers in the best possible way regarding whether to opt for one, with what objectives or purposes, or to achieve what specific goals when choosing the other. It is clear that the characteristics and learning outcomes that can be derived from one and the other can be very different, and therefore, teachers approaching a short-term or long-term

activity with the same type of objectives, regardless of how it will be developed, could be a poor choice.

Therefore, it is necessary for us to know what benefits one provides, what achievements are attained, and what those of the other are, so we can better advise and support teachers when choosing what type of activity, they need to achieve their proposed goals, since they are the ones who truly control and know what they seek, what they need, and what options they should offer their students.

This study evaluates the educational potential of the board game PIXEL – Picture (of) the Universe, designed by the Italian National Institute for Astrophysics in collaboration with the Game Science Research Center. PIXEL, integrated within a Game-Based Learning framework, aims to enhance students' understanding of the Nature of Science, with a particular focus on the social and institutional dimensions of scientific research. The game's mechanics simulate astrophysics research, emphasizing collaboration, resource management, and inquiry associated with image resolution in astrophysics. Through gameplay and associated activities, students explored scientific processes in an engaging, risk-free environment. The study involved 32 high school students participating in a 40-hour program, which included gameplay, facilitation training, reflective diary writing, and feedback sessions. Using qualitative thematic analysis of students' diaries, the research identified significant shifts in perceptions of science and research. In the pre-activity, responses largely reflected formal, textbook-like views of science, emphasizing the scientific method as a rigid process. In the post-activity ones, students displayed a more nuanced understanding, highlighting collaboration, iterative research, and the human aspects of scientific inquiry and manifesting a personal point of view about science and researchers. The study confirmed PIXEL's effectiveness in promoting NOS understanding; it emphasized the importance of integrating games into well-designed educational frameworks, demonstrating the potential of GBL to help learners refine their ideas, increasing their complexity and aligning them more closely with the real practices of contemporary astrophysical research.

Keywords: Nature of Science, Game-Based Learning, Scientific Citizenship

Introduction

This study explores the educational potential of the board game PIXEL - Picture (of) the Universe (Figure 1), developed by the Italian National Institute for Astrophysics (INAF) in collaboration with the Game Science Research Center. PIXEL aims to promote understanding of the Nature of Science (NOS), particularly its social and institutional dimensions, through a Game-Based Learning (GBL) approach. By combining engaging gameplay with scientifically grounded content, PIXEL bridges students' experiences with the methodologies and dynamics of astrophysics research.

GBL is often used as an umbrella term for a wide range of educational practices that involve games. However, the mere use of games in educational settings does not, in itself, constitute GBL. A critical distinction concerns the role that the game plays in the learning process and, more specifically, the degree of agency afforded to learners.

Figure 1. PIXEL - Picture (of) the Universe; game set-up.

A first approach, which can be described as “game-as-tool” for learning, treats games primarily as vehicles for content delivery. In this case, disciplinary knowledge is embedded into gamified formats, such as quizzes or trivia-based games, with the main aim of increasing motivation or engagement. While these approaches may be effective forms of gamification, they do not fully align with the principles of Game-Based Learning, as gameplay remains largely instrumental and does not support deeper meaning-making processes.

A second approach conceptualizes the “game-as-model” of the expected learning outcomes. Here, game mechanics are intentionally designed to embody key processes, structures, or ideas in the domain of interest. Through interaction with the game system, learners can experience simplified or metaphorical representations of complex phenomena. In this case, GBL can occur when gameplay is accompanied by opportunities for reflection and sense-making, allowing learners to connect in-game actions with disciplinary concepts and practices.

A third perspective, which we refer to as “game-as-game”, positions the gameplay itself as the core learning practice. In this view, learning emerges from players’ autonomous decision-making, negotiation, and strategic action within the game system. Rather than serving as a means to transmit predefined or expected content, the game creates a space in which learners actively construct understanding through participation. From this perspective, the educational value of GBL depends strongly on the level of agency allowed by the game and on the role of facilitation in supporting reflection, discussion, and skills development. This perspective is often used in educational contexts to foster transversal competences, rather than focusing primarily on disciplinary learning.

PIXEL is intentionally designed to support both the game-as-model and the game-as-game perspectives. Its mechanics embody key features of scientific research, while gameplay itself constitutes a meaningful learning experience. When embedded within a structured Game-Based

Learning framework that includes facilitation and reflective practices, PIXEL enables students to explore and make sense of the Nature of Science not through explicit instruction, but through lived and negotiated experience.

Playfulness, Game Design And The Nature Of Science

Play is an inherent and universal aspect of learning across cultures and species, facilitating cognitive development, engagement, and social interaction (Huizinga, 1950; Smith, 2010). Neuroscience literature suggests that play activates brain regions involved in memory, problem-solving, and emotional regulation, fostering the foundations for lifelong learning (Puschmann et al., 2012). Grounded in these principles, PIXEL aims to create a meaningful and enjoyable learning experience that actively engages students in scientific practices and in reflecting on the Nature of Science.

PIXEL is a eurogame, a category of board games characterized by strategic mechanics and minimal reliance on chance. The game's central mechanic revolves around the resolution of astrophysical images, which represents the process of constructing detailed celestial images through observational data. During the observation phase, players must place tiles of different sizes that represent portions of the observed object at incremental resolutions. Players must use resources strategically to improve telescopes, to conduct observations, and to build an image collaboratively. The mechanics emphasize:

1. Iterative research. Lower-resolution tiles are larger and require fewer actions, mirroring the preliminary surveys astrophysicists conduct before focusing on detailed observations.
2. Collaboration and competition. Observational data is shared among players, representing the collaborative nature of scientific research, while maintaining competitive gameplay, representing competition in academia.
3. Scientific practices and professionalism. Winning the game requires players to build a coherent strategy, allocating limited resources to publications, facility improvements, staff growth, and multidisciplinary specialisation, thus reflecting the constraints and trade-offs of real-world scientific research.

PIXEL was designed to embody NOS principles, i.e., the values, practices and social dimensions of scientific knowledge. Among the different approaches addressing it, we chose to use the Reconceptualized Family Resemblance Approach (RFN), which encompasses both cognitive-epistemic and social-institutional aspects of science (Erduran & Dagher, 2014). These include practices, knowledge generation, social organization, and the reward systems of science. A key focus was to present scientific work as a human endeavour, offering students a holistic view of how research communities operate. The study evaluated PIXEL's educational impact through two research questions:

1. Can PIXEL, within a GBL experience, enhance students' understanding of the social and institutional dimensions of research in astrophysics and beyond?
2. Can this GBL experience foster a more personal and humanized perception of researchers and the research process?

Educational Design And Research Methodology

The study follows a qualitative case study design, aiming to validate the educational potential of PIXEL - Picture (of) the Universe in fostering students' understanding of the social and institutional dimensions of science. The board game was implemented within a structured GBL

intervention carried out in the context of the Italian PCTO (Pathways for Transversal Skills and Orientation) non-formal program, a national initiative for Italian high school students that requires them to complete a set number of hours of learning in collaboration with external educational or professional partners, in order to achieve a broader educational experience that extends beyond formal learning.

The 40-hour educational program – distributed over 5 to 6 months depending on the local schools – took place in 5 Italian cities and allowed participants to experience the game in multiple roles (as players, facilitators, and reflective learners). The intervention combined gameplay, structured debriefing, and reflective writing to promote NOS understanding. The design explicitly avoided direct instruction about NOS concepts or the social dimensions of science, so that any conceptual change could be attributed to the students' experience with the GBL process itself. Voluntary participation was emphasized to align with the principle of play as a voluntary attempt, fostering genuine engagement and motivation. In the following, we outline the structure of the educational design.

1. Training sessions. Students were introduced to basic GBL principles, to PIXEL's mechanics, and the scientific concepts underpinning the game, such as astrophysical image resolution. Importantly, social and institutional aspects of NOS were not explicitly addressed, allowing these to emerge organically during gameplay and debriefing.
2. Facilitation practice. Students practiced facilitating PIXEL sessions with peers, learning to guide gameplay and conduct debriefs, which are critical for metacognitive learning. To support this, a graphic debrief tool was provided to help analyse player interactions and themes.
3. Reflective diaries. Between interventions, students documented their experiences and reflections by answering open-ended questions in diaries, which served as key data sources for the study. This reflective practice aimed to enhance critical thinking and self-regulated learning.
4. Feedback sessions. Participants engaged with astrophysicists and game creators in two feedback sessions, discussing their progress, challenges, and insights, further deepening their understanding of the research world.

Qualitative Data Collection And Analysis

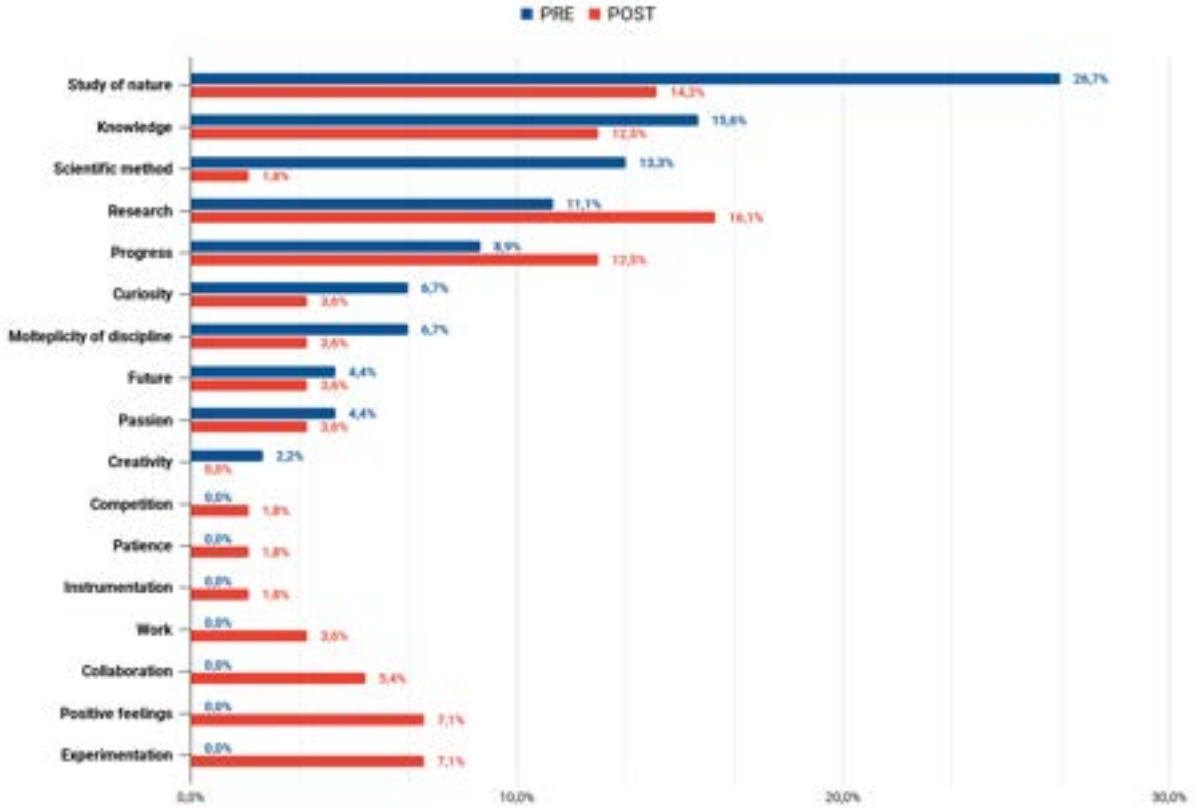
To explore students' evolving conceptions of science, data were collected through reflective diaries compiled after each session. The diary method was chosen to support a metacognitive, explicit-reflective approach to learning about NOS (Lederman et al., 2002; Abd-El-Khalick & Lederman, 2023). Each diary included 3-5 open-ended questions encouraging students to articulate their views on science, research, and scientists. The first and last sessions contained identical questions – "What is science to you?", "How does scientific research work?", and "How do researchers work?" – allowing for a pre/post comparison of conceptual change. For the purposes of this study, only these sessions are presented in the following sections, as the others were used to track students' progress in understanding and facilitating the game. This qualitative and reflective approach aligns with action research traditions (Lewin, 1948; Cunningham, 1976), in which the act of observation can itself promote transformation. In this sense, reflective diaries were both a learning tool and a data source.

We conducted two complementary analyses: a content-oriented analysis, focused on identifying recurring themes in students' reflection diaries, and an expressive register analysis, aimed at capturing shifts in students' style and tone.

The content-oriented analysis was inspired by the Reflexive Thematic Analysis framework (Braun & Clarke, 2006, 2019). We adopted a primarily inductive approach, allowing themes to emerge from the diaries while remaining attentive to our research questions. The analysis was conducted mainly at a semantic level, focusing on the explicit content of students' writings, though in some cases we drew on latent interpretations. Ten researchers, organised into five pairs, independently coded the data. Each pair identified emerging themes and assigned preliminary keywords to each data entry. A longitudinal perspective was then applied to trace the evolution of themes for each participant. Following these initial cycles, the groups compared results, synthesized the outcomes, and refined them through iterative discussions until a stable pool of themes was established. This process was iterative, involving multiple cycles of code creation, evaluation, and refinement.

In the analysis, we noted significant variation in the tone and style of student responses, ranging from formal, stereotypical formulations to more personal, elaborated accounts. To account for this, we also categorised entries into expressive registers using a latent thematic analysis. Well-structured and elaborate responses were coded either as bookish responses or personal elaboration, whereas superficial, incomplete, or nonsensical entries were tagged separately. This additional analysis provided insight into shifts in students' expressive registers, highlighting a move from bookish, stereotypical formulations to more personal, reflective engagements with science, research, and the role of scientists.

For each question of the first and last sessions, the number of occurrences of each tag was counted across the entire sample to determine how often specific themes were mentioned. The percentage frequency normalized over the number of tags in the pre (45, 35, 45 tags for each question, respectively) and in the post (56, 81, 54) was then calculated.



Finally, the tags were grouped within the two systems of the RFN: the cognitive-epistemic and the social-institutional systems.

Results

The findings presented hereafter highlight notable changes in students' perceptions, emphasizing a broader and more nuanced understanding of science and research. The results are introduced by discussing the three questions separately.

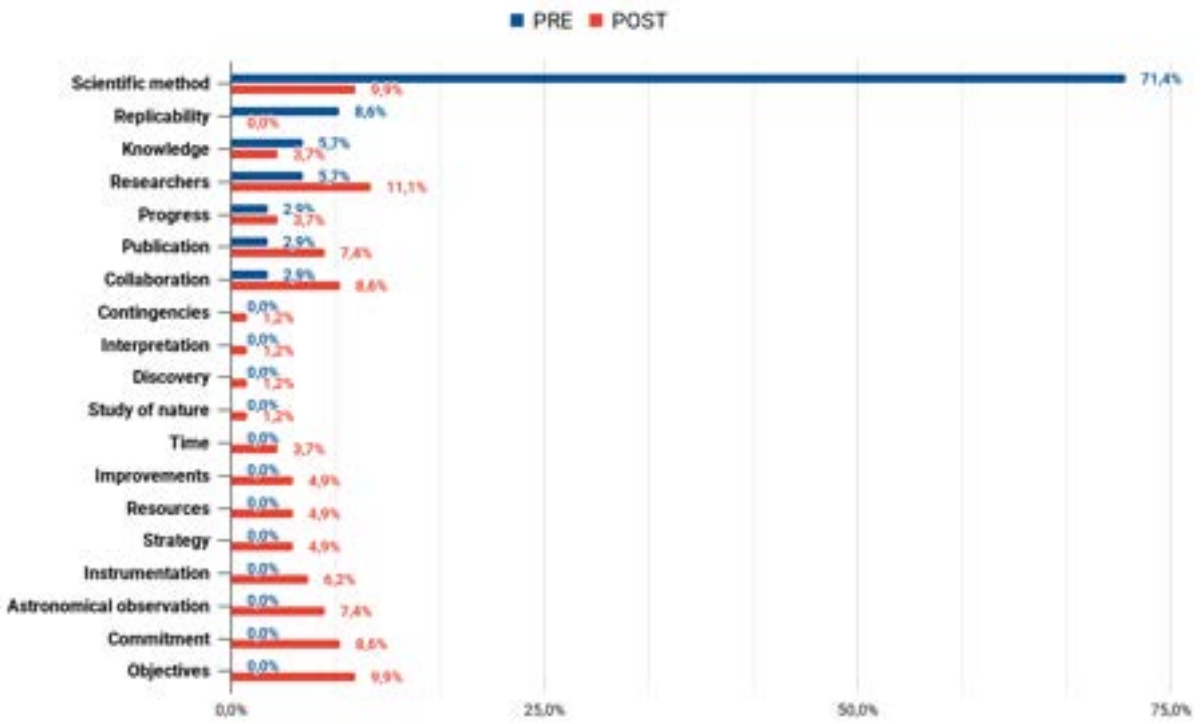
Perceptions of Science. Students' responses to the question, *"What is science for you?"*, initially clustered around ten themes, such as **Study of nature**, **Knowledge**, **Scientific method**, and **Research**. By the end, these expanded to 16 themes, reflecting a richer and more diverse understanding. Significant reductions occurred in the themes **Scientific method** (from 6 to 1 occurrences, -11.5%) and **Study of nature** (from 12 to 8, -12.4%), indicating a shift away from narrowly defining science through traditional concepts. Meanwhile, themes such as **Progress** (from 4 to 7, +3.6%) and **Research** (from 5 to 9, +5.0%) grew in prominence, alongside new themes like **Collaboration** (0 to 3, +5.4%), **Experimentation** (0 to 4, +7.1%) and **Positive feelings** (0 to 4, +7.1%), a theme we introduced to count the entries with an explicit sense of positive values associated to science. See the graphic of Figure 2 for the percentage frequency of each theme. These changes suggest that students began to view science as a multifaceted and collaborative endeavour, emphasising discovery and shared passion.

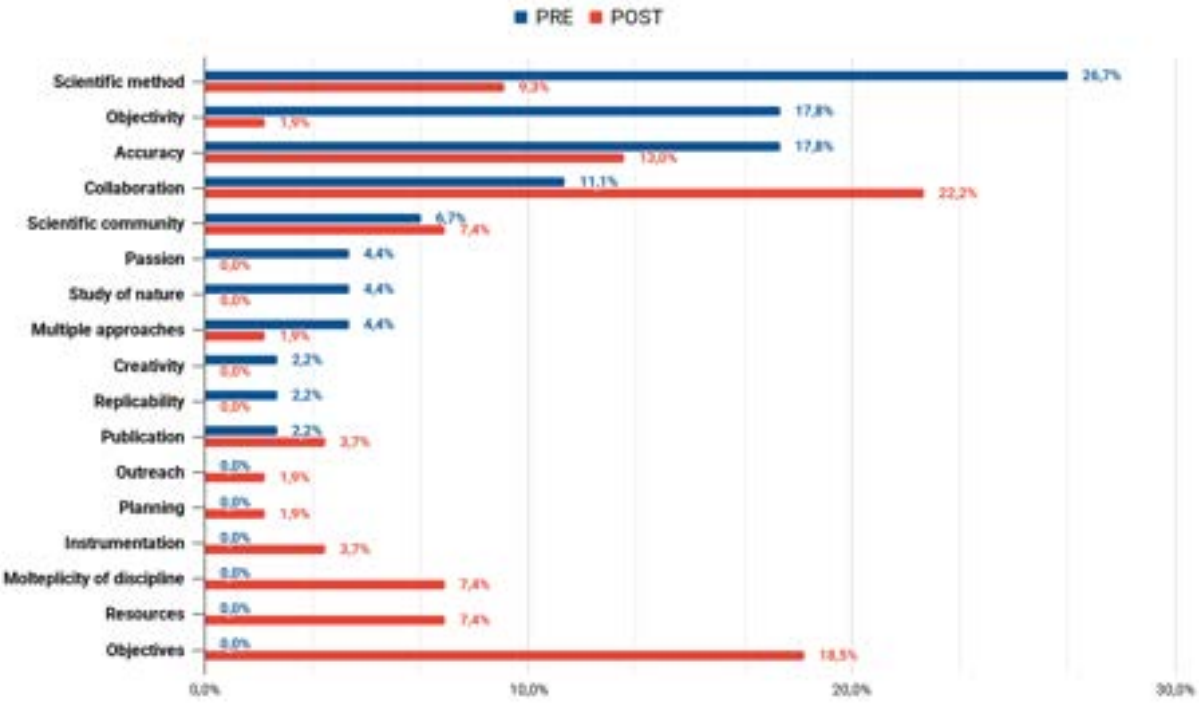
Figure 2. Frequencies of the themes emerged in the answers to the question "What is science for you?" asked at the beginning of the project (blue, pre) and at the end (red, post)

Understanding Scientific Research. The students' understanding of scientific research evolved from 7 themes in the pre-activity phase to 18 themes post-activity, as shown in Figure 3. The theme **Scientific method** dropped dramatically (from 25 to 8 occurrences, -61.5%), while new concepts, such as **Astronomical observation** (from 0 to 6, +7.4%), **Commitment** (0 to 7, +8.6%), emerged, often influenced by the game's design. For example, themes such as **Objectives** (0 to 8, +8.9%) and **Instrumentation** (0 to 5, +6.2%) can be traced back to the game mechanics, where players simulate research goals and resource management. The theme **Replicability**, which disappeared entirely (from 3 to 0, -8.6%), was deemed less relevant in the context of astrophysics, a field where transient and non-replicable phenomena are common. This shift illustrates the "efficiency" of GBL approach to reshape students' perceptions, broadening their understanding of the complexity and human dimensions of research, and in this case, wiping out a concept.

Perceptions of Researchers' Work. Responses to the question, *"How do researchers work?"*, also showed significant variations from pre- and post-activities (Figure 4). The **Scientific method** theme declined significantly (from 12 to 5 occurrences, -17.4%), while themes like **Collaboration** (from 5 to 12, +11.1%) and **Objectives** (0 to 10, +18.5%) grew substantially. The reduced focus on **Objectivity** (from 8 to 1, -15.9%) underscores the game's emphasis on the subjective, strategic, and collaborative aspects of research, challenging the perception of science as purely objective. Students began to view researchers as individuals navigating complex goals and balancing cooperation and competition, an insight that aligns with the educational objectives of the game.

Figure 3. Frequencies of the themes emerged in the answers to the question "How does scientific research work?" at the beginning of the project (blue, pre) and at the end (red, post)





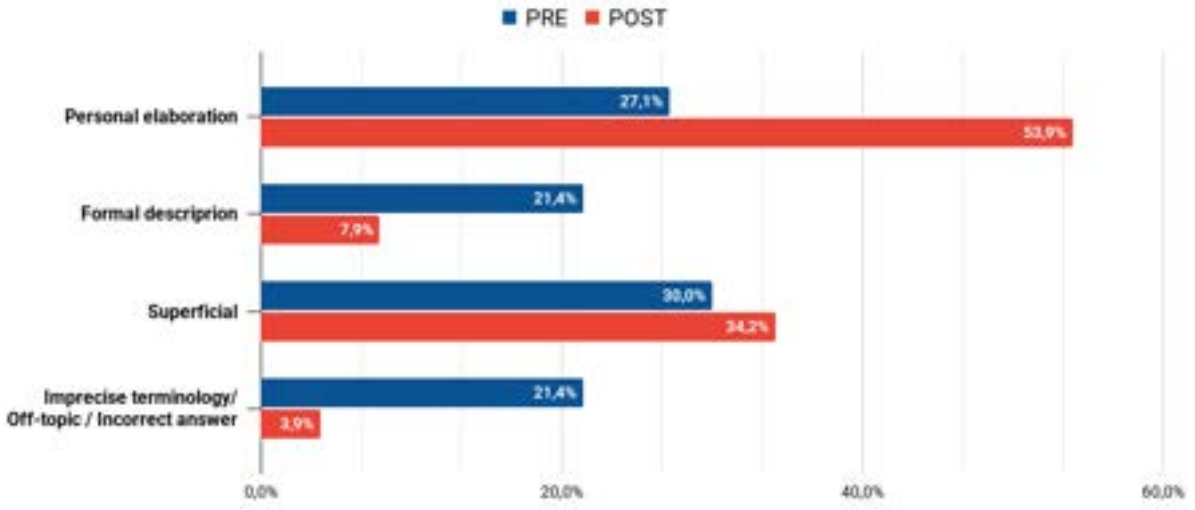


Figure 4. Frequencies of the themes emerged in the answers to the question "How do researchers work?" at the beginning of the project (blue, pre) and at the end (red, post)

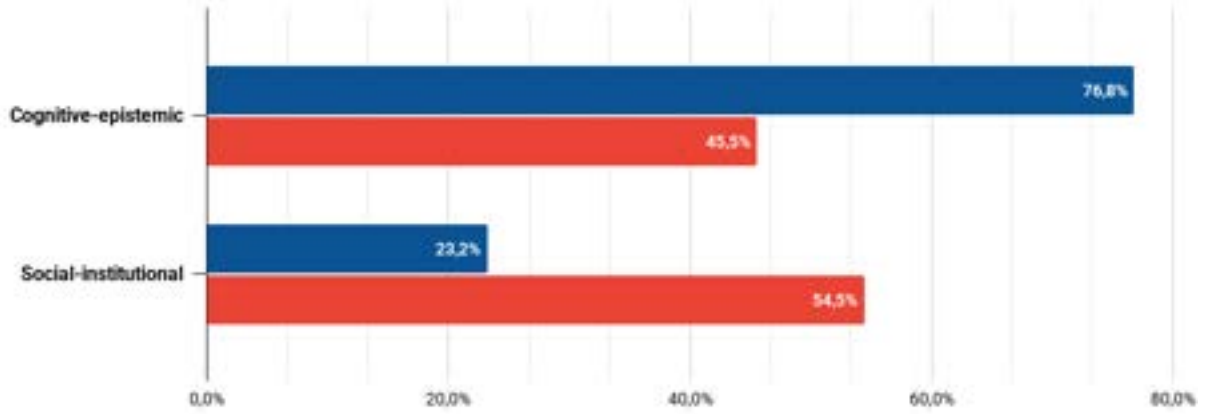

Modal Analysis. A comparative analysis (Figure 5) of response categories revealed a major shift from formal, textbook-like answers to personal elaborations, which increased by 26.8% (from 19 to 41 occurrences). Conversely, formal descriptions decreased by 13.5% (from 15 to 6). This transition reflects a deeper engagement with science, as students moved beyond memorized knowledge to expressing their own perspectives, enriched by the GBL experience. Incorrect or off-topic responses nearly disappeared, highlighting the game's effectiveness in fostering comprehension.

Figure 5. Tag for modal analysis for the three questions (pre-blue and post-red)

RFN mapping. To further examine how the GBL experience influenced students' understanding of the Nature of Science, the themes emerging from their responses were interpreted through the lens of the Reconceptualized Family Resemblance framework. Specifically, each theme was associated with either the cognitive-epistemic or the social-institutional system, and their relative presence was compared across the pre- and post-intervention phases. The resulting distribution is illustrated in Figure 6.

Figure 6. Frequency of the themes addressing the two RFN systems (pre-blue and post-red)

Before the intervention, students' representations of science were largely dominated by themes related to the cognitive-epistemic system, which accounted for 76.8% of all coded occurrences. After the GBL experience, this proportion decreased substantially to 45.5%. In contrast, themes associated with the social-institutional system increased markedly, from 23.2% in the pre-phase to 54.5% in the post-phase.

This redistribution highlights a significant shift in how students conceptualized science. While their initial views emphasized methods and procedural aspects, their later reflections increasingly foregrounded the human, social, and institutional dimensions of scientific work. Such a reorientation suggests that the GBL experience supported a more balanced and comprehensive understanding of science, in line with the integrated view of scientific practice articulated by the RFN framework.

Discussion and Conclusions: Games as an activator for NOS reflection

This study explored the educational potential of the board game PIXEL – Picture (of) the Universe when embedded within a structured GBL framework, with particular attention to

students' understanding of the NOS. Rather than focusing on the effectiveness of the game as an isolated artefact, the analysis highlights how the interplay between game design, educational orchestration, and reflective practices can foster more informed, nuanced and humanized views of scientific research.

The findings indicate a clear shift in students' perceptions of science and scientific research, particularly regarding the social and institutional dimensions of NOS. Prior to the intervention, students' responses largely reflected formal, textbook-like conceptions of science, often centred on the scientific method as a linear, rigid procedure. Such views are well documented in the literature and remain a persistent challenge in science education (Abd-El-Khalick & Lederman, 2023). Following the GBL experience, students' reflections became more diversified, articulated, and personal. The increased salience of socio-institutional themes suggests that students began to perceive science as a collective, situated human enterprise rather than an individual, abstract, and decontextualised process. This transformation aligns with previous studies (Buaraphan, 2012; Erduran et al., 2019), positioning GBL as a viable learning strategy for making epistemic and social processes of science visible and discussable. Importantly, these outcomes cannot be attributed solely to the game. As argued by Clark (1994), learning does not reside in the medium itself but in the instructional methods through which it is enacted. In this sense, PIXEL functioned as an epistemic artefact whose educational value emerged through its integration within a carefully designed GBL pathway.

Moreover, this study shows how specific game mechanics can be systematically mapped onto NOS dimensions through the Reconceptualized Family Resemblance Approach, effectively linking game design, gameplay dynamics, and students' reflections. Mechanics such as competing objectives and collective construction made core scientific practices experientially accessible, highlighting tensions between collaboration and competition, uncertainty and decision-making. The findings suggest that the effectiveness of GBL for NOS lies in the coherent alignment of game mechanics, facilitation, and reflective practices, fostering authentic and experience-based understandings of science.

Indeed, the results highlight a shift in students' expressive registers from formal descriptions to personal elaborations, indicating not only conceptual change but also increased agency and epistemic engagement with science. Reflective diaries played a key role in supporting this transformation, enabling students to connect their gameplay experiences with broader perspectives on scientific research and to develop a more confident, personal scientific voice.

In conclusion, the findings underline the potential of analogue board games as effective tools for addressing the epistemic and social dimensions of science, while emphasising that the impact of GBL depends on thoughtful educational design rather than on games as stand-alone solutions. For educational practice, this highlights the need for intentional facilitation, debriefing, and reflection, pointing to the importance of teacher education programs that frame GBL as a comprehensive pedagogical approach.

On the other hand, as a qualitative case study involving a small, self-selected group of students, the findings are not intended to be generalised statistically. While the study is situated within the specific domain of astrophysics, this choice represents a strength rather than a limitation. Astronomy is widely recognised as a "gateway science" (Salimpour et al., 2021), capable of engaging learners and fostering broader reflections on science as a human and epistemic enterprise that extends beyond the disciplinary context.

Overall, this study contributes to ongoing discussions within the ESERA community about how playful and experiential approaches can support learning about the Nature of Science. By

combining game design, the RFN framework, and reflective educational practices, the PIXEL GBL experience offers an example of how games can be used not merely to motivate learners but to foster deeper epistemic understanding and personal engagement with science.

Acknowledgement

The authors would like to acknowledge their INAF colleagues who contributed to the development and implementation of the project, Giovanni Contino, Giannandrea Inchingolo, Riccardo Leoni - and Fabrizio Villa for the game's pictures. They also wish to thank Andrea Ligabue (University of Modena—Reggio Emilia) for guiding the game design, as well as Tommaso Francesco Piccinon and Michele Masini, psychologists affiliated with the CeRG–Centro di Ricerca sul Gioco, University of Genoa, for their valuable contributions and insights. We want to acknowledge all the students involved in the project and recognise the precious collaboration of their teachers from Liceo Ginnasio Statale "Luigi Galvani" of Bologna, Liceo Scientifico Statale "Antonio Pacinotti" of Cagliari, Istituto Statale di Istruzione Superiore "Piero Gobetti - Alessandro Volta" of Florence, Istituto Superiore "Majorana" of Palermo, Liceo Scientifico "Ascanio Landi" of Rome.

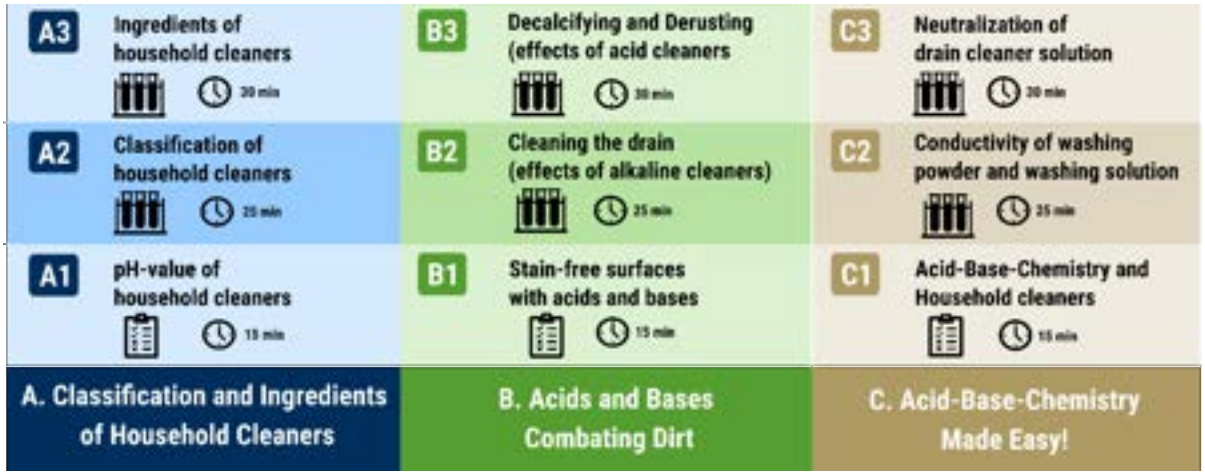
Complexity-Differentiated Learning To Support Students' Lab Work In Out-Of-School Student Laboratories

Nicolai ter Horst[1], Julia Dietrich[2] and Timm Wilke[3]
[1]Friedrich-Schiller-University Jena, Chemistry Education Department, Germany
[2] Catholic University of Eichstätt-Ingolstadt, Professorship for Empirical Educational Research, Germany
[3]Carl von Ossietzky University of Oldenburg, Chemistry Education Department, Germany

Out-of-school student laboratories (OSL) are often hosted by institutions of higher education like universities and aim to facilitate interest in science. A key component of these learning offers is the hands-on experience which for STEM-subjects mainly means conducting experiments. While research has shown that OSL are able to foster situational interest and knowledge acquisition, the effects are rather small and in general do not last over a longer period of time. The integration of digital media and the provision of complexity-differentiated tasks could help promote motivation and aid knowledge acquisition while still staying true to the hands-on approach of the OSL. Therefore, a new method for digital and complexity-differentiated learning in the OSL was developed, implemented and tested. Our recent study focused on the investigation of complexity-differentiation while using this method for lab work in the OSL. One group used complexity-differentiated material based on a differentiation matrix (DM), while the other group was not aware of the complexity-differentiation in the material and conducted station learning (SL). The study was conducted with thirteen 8th grade classes (N=280), evaluating the influence on emotions, expectancy value motivation and knowledge acquisition. In addition, the choice of fields or stations was recorded. The results will be presented in this proposal and possible consequences for the use of likewise methods in the OSL will be shown.

Keywords: out-of-school student laboratories, digital advances, differentiation



Introduction

Promoting interest in natural sciences is a primary goal of out-of-school student laboratories (OSL). By offering a stimulating and research-related program they aim to motivate students to engage with scientific content and pursue a career in STEM (Stamer et al., 2020). However, empirical studies on the promotion of interest in OSLs often show only short-term effects (Lewalter et al., 2021). One way to improve the effectiveness of OSL might be adapting the courses to different levels of complexity to appeal to more participants (Affeldt et al., 2015). This could be supported by using digital media while thereby increasing motivation and learning outcomes (Hillmayr et al., 2020). The following contribution presents a study that tests the effectiveness of a new method in the OSL combining these approaches: the use of digital and complexity-differentiated learning modules (DCDLM).

Theoretical Foundations

The basis of DCDLMs is a differentiation matrix (Sasse & Schulzeck, 2021), in which tasks are created according to thematic complexity in a horizontal direction and tasks according to cognitive complexity in a vertical direction. The supposedly easiest field is therefore at the bottom left of the matrix, the supposedly most difficult field at the top right. For our OSL we use a 3x3 matrix. In previous tests, this size has proven to be particularly suitable for a three-hour student lab, as a large part of the learning module can be viewed and worked on by students at this time (ter Horst et al., 2024). Two different types of tasks are used: experimental and theoretical fields (see Fig.1).

Figure 1. Differentiation matrix for the exemplary module "household detergents".

Multitouch Learning Books (Huwer et al., 2018) are used for our DCDLMs, which contain the differentiation matrix and the material used per field. The learning environment was designed according to principles of the Cognitive Theory of Multimedia Learning (Mayer & Fiorella, 2014) with the aim of minimising the extraneous cognitive load (Sweller et al., 2011). Learners receive feedback by comparing their answers with solutions and can determine their own approach in terms of content and time (Moreno & Mayer, 2007).

Theoretical Proposals

In addition to the implicit effects of the differentiation (e.g., learning aids) and digitalisation measures used (e.g., tablet as a learning companion), DCDLMs' primary intended effect is through transparent complexity differentiation. This enables students to make an initial assessment of the complexity of the task and, if desired, to adapt it to their self-perceived level of knowledge (Corbalan et al., 2011). The differentiation matrix also gives them an overview of all the tasks in the course, which can help them to bring structure to the topic. This should provide additional clues for the decision in favour of or against a task, potentially leading to better choices (Relan, 1995). By comparing them with solutions, they also receive feedback on their level of knowledge and can then adjust their learning path (Bennett, 2011). To analyse the effectiveness of the method, an exemplary module on the topic household detergents was evaluated.

Aims Of The Study

This study focuses on the complexity-differentiation of the DCDLMs and its potential effectiveness. Therefore, a distinction was made between two settings: one in which the learners are aware of the complexity- differentiation of the learning module (dDM) and one in which they were not (dSL). In a pre-post quasi-experiment, the effects of the learning design on emotions (joy, curiosity, boredom, frustration), expectancy value motivation (expectation of success, utility value) and influences on performance (subject-specific and topic-specific knowledge) were investigated, since we expected emotional-motivational and cognitive benefits from the described learning design. Finally, the choice of fields was exploratively analysed to draw conclusions about possible connections.

Hypothesis 1 (emotions): Both intervention groups show an increase in joy and curiosity (cur) from pre- to post-test and a decrease in boredom (bor) and frustration (fru). The intervention group dDM shows more positive changes in enjoyment and curiosity and more negative changes in boredom and frustration compared to the intervention group dSL.

Hypothesis 2 (expectancy value motivation): Both intervention groups show an increase in expectancy of success (ex) as well as utility value (uv) from pre- to post-test. The intervention group dDM shows a more positive change compared to the intervention group dSL.

Hypothesis 3 (performance): Performance increases in terms of subject-specific (ssk) and topic-specific knowledge (tsk) in both intervention groups. Compared to the dSL intervention group, the dDM intervention group shows a higher increase in knowledge from the pre-test to the post-test.

Research question: How does the choice of fields differ between the two intervention groups (dDM, dSL)?

Method

The study was conducted with thirteen school classes from five schools in Thuringia (N=280) from May to June 2023. In the following, for hypotheses H1-H3 (a), the results for changes across the student lab day are first reported using t-tests for dependent samples. Two complementary statistical methods were then used to test whether the changes in the groups differed from each other (H1-H3): (b) In the change score approach, the difference between pre- and post-scores (post minus pre) is predicted by group membership in a multiple regression (dDM=0 vs. dSL=1). (c) In the ANCOVA approach, the post-test value is predicted by the pre-test value and the group membership (dDM=0 vs. dSL=1). Parametric tests are used due to the respective group size. Table 1 lists the results for (a), (b) and (c). Finally, descriptive comparisons for the research question on field selection are presented.

Results

Looking at emotions, there was a significant increase in enjoyment and a decrease in boredom and frustration across both groups (a). However, the decrease in negative emotions was only significant for the dSL intervention group. Curiosity also only increased significantly in the dSL intervention group. Contrary to our hypothesis, the results for the direct group comparisons (b, c) consistently showed a significantly greater increase in curiosity in the dSL group.

When looking at expectancy value motivation, there was an increase in the expectation of success across both intervention groups, which was also significant for both. Contrary to our hypothesis, a significant decrease in utility value was observed across both groups, although this was only significant for the dDM intervention group (a). The results for the direct group comparisons (b, c) consistently showed, also contrary to our hypothesis, a significantly greater decrease in utility value in the dDM group.

The development of knowledge regarding acid-base chemistry (ssk) showed that it increased significantly both across both intervention groups and for each individual group. There was a significant increase in the development of knowledge regarding household detergents (tsk) across both intervention groups, although this was only significant for the dDM intervention group (a). The results for the direct group comparisons (analyses b and c) showed no group differences.

Differences between the two groups can also be described in the choice of fields. The number of fields selected in the dDM group is clearly shifted towards the easier fields. The choice of fields in the dSL group is more evenly distributed and shows a significantly higher proportion of the more difficult fields (Fig. 2).

Figure 2. Choice of fields for the dDM (right) and dSL group (left).

Discussion And Implications

The aim of the study was to test the complexity-differentiation of DCDLMs in the OSL for two varying settings. Despite positive results across both groups, the dSL group showed advantages over the dDM group, which is contrary to the hypotheses formulated at the beginning. The different field selection of the groups may offer an initial explanation for this.

The dSL group appears to benefit from the diversified choice of fields of varying complexity showing both affective and cognitive advantages. This may be due to a more interest-driven approach. Knowledge of the varying difficulty of the fields therefore seems to have a negative effect on the participants in the dDM group, as they generally choose unhelpful learning strategies (easier fields).

The reasons for this can be manifold: these include the reduction of effort costs (Flake et al., 2015), inadequate self-evaluations of the level of performance (e.g. due to a low ability self-concept) or difficulties in self-regulation, if the intention was to take the complexity into account. In the discussion at the conference the possibility of a higher cognitive load for the students with the new method was also discussed, due to their unfamiliarity with it.

Thus, there is a need to improve the choice of fields. More specifications could be made to encourage or obligate the students to include more difficult fields. Also, a more precise diagnosis of the level of knowledge could be made at the beginning. As positive results can be found in both intervention groups, the use of DCDLMs in the OSL appears to be potentially useful but requires adjustments to offer advantages over previous didactic concepts.

Acknowledgement

The project “digitalchemlab - digital and differentiated learning in the school laboratory” was funded by the Joachim Herz Foundation with €15,000. The authors would like to thank the foundation for their generous support.

[6]Università di Bologna, Italy
[7]CNR-ISMAR Milano, Italy

Citizen Science can represent an informal and engaging learning method for both students and teachers to explore scientific research. At INFN Frascati National Laboratory we organized, in collaboration with European Citizen Science Association (ECSA), the European Citizen Science Academy and Citizen Science Italia, a Citizen Science School addressed to high school students, teachers, University students and researchers focused on Rome Technopole's research macro areas. The School allowed participants to work on real research projects that provided concrete results and fostered collaborative reflections on the usage of citizen science as an educational strategy.

Keywords: Citizen Science, STEM education, Project-based learning

Introduction

Informal and non-formal learning experiences have been shown to exert a highly positive impact on students, particularly in the context of STEM subjects (Hussim et al. 2024). While formal learning is a well-structured activity within educational institutions, informal learning takes place outside the school environment (Ayar, 2015) and provides unique opportunities to all learners because of the flexibility and ease of access to learning specific knowledge or skills (Jenson et al., 2023). This is even more true for Project-Based Learning (PjBL), where students experience and indulge in complex, real-world tasks, resulting in an idea, a product, or prototypes (Santhosh et al., 2023).

In this context, citizen science approach could represent a very valid ally. Although citizen science (CS) encompasses a wide range of activities and practices (Haklay et al., 2020), making it difficult to define it broadly (Haklay et al., 2021), it can be delineated as the involvement at various levels of the public in scientific investigation and data collection (SEEDS project, 2025) that has a genuine scientific outcome, such as new knowledge, conservation actions, or policy changes (ECSA, 2025a). CS is in fact a way of doing scientific research, that revolutionize the relationship between scientific community and citizens and responds to an Open Science approach, indicated as a priority by the European Commission (European Commission, 2025); in Italy, it has recently become an integral part of the National Plan for Open Science (MUR, 2025) of the National Research Program (PNR) 2021-2027 of the Italian Ministry of University and Research. In addition, CS has great potential for schools. By its very nature, it is perfectly in line with a Project-Based Learning, as it facilitates students' active participation and strengthens the connection between scientific exploration and their personal experiences; in addition, its

methodology enhances critical thinking and experiential learning of the scientific method, while establishing meaningful ties with the research community through tangible projects. CS is also beneficial for teachers, who take a more engaged and rewarding role, moving away from the conventional model of knowledge transmission, and emerging as key drivers of change towards a contemporary and dynamic educational community (SEEDS project, 2025b)

For all these reasons, at INFN Frascati National Laboratory we decided to propose a citizen science initiative among the activities carried out by Rome Technopole project: a Citizen Science School addressed to high school students and teachers, university students and researchers. The school was designed to provide first-hand experience of citizen science, through the step-by-step development of real scientific research projects that exploit this methodology.

Methodology

Context And Setting

The Citizen Science School1 was organized at INFN Frascati National Laboratory within the Rome Technopole2 innovation ecosystem in collaboration with the European Citizen Science Association (ECSA), the European Citizen Science Academy and Citizen Science Italia (CSI).

As the largest Italian research center devoted to nuclear and subnuclear physics with accelerators and related applications, the Laboratory proved to be an ideal setting for the School. Its environment allowed participants to engage directly with a cutting-edge research hub that integrates a broad spectrum of disciplines—ranging from particle and theoretical physics to technological development and computational studies—and brings together professionals from both STEM and non-STEM backgrounds. Furthermore, the School drew significant advantage from the Laboratory's long-standing experience and recognized expertise in organizing educational and outreach initiatives aimed at schools and the broader public (Bertelli et al., 2023). The presence of dedicated rooms and facilities further contributed to creating an effective and welcoming learning atmosphere.

Rome Technopole is the Ecosystem of Innovation of Rome and the Lazio region, in central Italy, built among the NextGenerationEU plan and composed of territorial leaders of research and innovation and organized in a network of state and private universities, public research organizations, local authorities, highly qualified and internationally recognized private companies. Overall, it consists of 39 Founder Partners: 7 Universities in Lazio, 4 National Research Centers based in Lazio (CNR, ENEA, ISS, INFN), 2 small and medium-sized enterprises, 17 large companies and multinationals, 3 local institutions (Lazio Region, Municipality of Rome, Lazio Chambers of Commerce), 2 business associations that are members of Confindustria and INAIL, a nonprofit public entity. The core of the project is developed on three thematic areas: Energy Transition, Digital Transition and Health & Bio-Pharma.

Two additional organizations played a crucial role in the design and implementation of the School: the European Citizen Science Association (ECSA), whose primary objective is to support public participation in research across the natural sciences, social sciences, humanities, and the arts, and Citizen Science Italia (CSI), which is committed to ensuring that citizen science is recognized, promoted, and adequately funded and operates in Italy. Both organizations contributed with their expertise and experience in the field of citizen science to the realization of the School.

Participants And Research Groups

The School was addressed to a mixed group of 25 people including high school students (16 years and older, attending the last two years of high school) and teachers from across Europe, university students from European universities, and researchers from Rome Technopole. The choice to target a diverse audience was mainly motivated by the need to simulate as realistically as possible the real case scenario of the citizen science approach, but also by the aim of testing our innovative educational approach with schools and, at the same time, evaluating its effect on scientific community. Participants were randomly selected among those who had applied for registration, considering gender balance and geographical diversity. In total, we involved 20 non-experts participants from 4 different countries (Finland, Italy, Serbia, Turkey): 5 teachers, 8 university students and 7 high school students. These participants were then joined by 5 Italian researchers from the Rome Technopole project, engaged through an open call to all Rome Technopole organization, and 5 citizen science experts of ECSA and CSI who acted as facilitators. During the School, participants worked in 5 groups of 4 people each, comprising at least one university student, one teacher and one high school student, plus researchers. Each group worked separately on a research topic.

The School's Research Projects

Since one of the fundamental ideas behind the School was to provide participants with direct, practical involvement in citizen science, we chose to engage them in authentic, ongoing scientific projects. The selection of research topics was determined by researchers from the Rome Technopole who participated in the initiative, as they corresponded to the main projects they were currently working on. Given the breadth and multidisciplinary nature of the Rome Technopole project, the final research themes were highly diverse and included: Antibiotic resistance; VR/AR/MR environments; Dentistry; Digital and physical spaces in prisons; Physics, energy, and sustainability.

Once the research areas had been defined, the second—and most delicate—phase in the School's design was devoted to addressing these topics through a citizen science approach. To this end, the researchers were invited to reflect, with the support of citizen science experts, on which elements of their studies could benefit from citizen involvement. They were asked to consider whether there were data or observations that citizens could provide, whether citizens might help extend the project's impact or disseminate it within their communities, but also, more broadly, how collaboration with the public could enrich their research perspectives.

Subsequently, the researchers began to outline a preliminary draft of a research program to be carried out during the School. It is important to emphasize that, unlike other outreach activities to which they had previously contributed, they were not asked to define what the participants *should do*. Instead, they were invited to identify the areas in which participants could *meaningfully contribute*—without specifying the activities to be carried out in a prescriptive manner. The intent was to leave ample room for participants to contribute not only to defining the research results, but also to the methodological approach.

The Realization Of The School

The Citizen Science School Rome Technopole was held from February 3 to 7, 2025, with activities running from 9:30 am to 6:00 pm. Given the School's ambition to design and set in motion five citizen science projects within this limited timeframe, the introductory phase was deliberately kept concise: it consisted of a brief overview of citizen science and of the five research areas. Then, the working groups were formed, based on participants' preferences, if any. From that moment on, the groups continued their work independently during parallel sessions,

except for two scheduled plenary meetings held each day—one in the morning and one at the end of the day—to review the progress made, exchange reflections, and share emerging ideas, challenges, and experiences. As the days progressed and collective discussions unfolded, it became increasingly evident that the groups were encountering similar difficulties, regardless of their specific research focus. For example, all teams faced challenges in formulating their research question(s) and in defining an appropriate methodology to achieve their objectives. Equally clearly, it became apparent that these issues could be addressed with common solutions or approaches. Another aspect that emerged was that, just like in a real citizen science project, throughout the course of the School, all the actors involved were making different contributions and adopting different stances based on their individual needs, availability, personal dispositions, often stepping outside their typical professional role. Some teachers adopted a more passive role, allowing themselves to be guided; some students assumed leadership responsibilities and organized the work as if they were instructors; and some researchers collaborated closely with the groups, working alongside them throughout the activities and sometimes leaving their role as experts behind.

The final day of the week was devoted to the presentation of project outcomes by all groups, followed by a concluding discussion with the citizen science experts, who identified both the strengths of the work accomplished and areas with potential for further improvement. Each group succeeded in developing innovative strategies to initiate or enhance citizen engagement within their respective research contexts. In some cases, the proposed approaches focused on raising public awareness of specific issues or on collecting data of value to the researchers; in others, the groups formulated practical plans to guide the future evolution of their projects. In two cases, groups also managed to pilot their proposals with a small cohort of acquaintances, providing an initial test of feasibility.

Results

The specific outcomes achieved by each research group are presented in detail below, together with a brief description of the methodology used.

Research Line 1: Antibiotic Resistance

Lead Researcher: Silvia Cammarone, Department of Chemistry and Technologies of Drug, Sapienza University of Rome.

Aim. Raise public awareness and promote responsible antibiotic use by assessing citizens' knowledge, habits, and risk perceptions, and by creating pathways for sustained engagement.

Process and products. The group initially developed a survey aimed at evaluating citizens' knowledge of antibiotics and their use, as well as exploring their perceptions of the issue from both individual and collective perspectives. Then, the team expanded its vision into a larger engagement concept, "IGEA" (cItizen enGagement awarEness on Antibiotics) that included educational programs in schools, online seminars on correct antibiotic use, interactive games for children and a monitoring app concept that should allow users to record cases of infections, antibiotic use, and perceived treatment effectiveness, as well as send water samples to nearby laboratories to check for bacterial contamination.

Research Line 2: User Interfaces For VR/AR/MR Environments

Lead Researcher: Marco Raoul Marini, Department of Computer Science, Sapienza University of Rome.

Aim. Design innovative user-interface (UI) concepts for virtual, augmented, and mixed reality (VR/AR/MR) that enable intuitive, accessible interaction without traditional input devices.

Process and products. The group first analyzed the requirements of UIs in immersive environments and identified possible "hands-free" interaction strategies—such as voice commands, eye movements, gestures, and walking. They then developed prototypes illustrating how these interactions might function within a cooking scenario, with potential extensions to surgical and industrial contexts. As an additional product, the group drafted a survey to assess citizens' familiarity with VR/AR/MR technologies and to explore the situations in which users would be interested in adopting such interfaces.

Research Line 3: Dentistry

Lead Researcher: Lorenzo Arcuri, Department of Life Sciences, Health, and Health Professions, Link Campus University of Rome; Ilaria Cammarota, Department of Chemical Science and Technologies, University of Rome Tor Vergata.

Aim. Increase public awareness of proper home oral hygiene and assess the prevalence of effective practices.

Process and products. In the introductory phase, participants witnessed a self-inspection protocol demonstration for the oral cavity held by the researcher, who gave particular attention to identifying lesions or unusual characteristics of the oral mucosa. After familiarizing themselves with the procedure, they then collaborated on the development of clear informational materials—combining images and text—to make the protocol accessible to a broad audience. The group then designed an initial survey aimed at investigating individuals' habits and lifestyles related to oral hygiene, to be administered alongside the self-inspection instructions. A second questionnaire was subsequently drafted to evaluate the ease of performing the procedure and to record observations made by participants. Over the course of the week, the group also began collecting preliminary responses to the first questionnaire from their personal networks.

Research Line 4: Digital And Physical Spaces In Prisons

Lead Researcher: Serena Cataldo and Luca Mazzali, Department of History, Humanities and Society, University of Rome Tor Vergata.

Aim. Deepen the understanding of prison conditions and spatial organization, examine the transformative impact of educational programmes on prisoners, and develop innovative proposals to improve these environments.

Process and products. At the beginning of the week, the group had the exceptional opportunity to meet a former prisoner who underwent a profound personal transformation by obtaining a university degree while in prison. This meeting laid the groundwork for subsequent discussions with researchers, who shared their work on the functions and meanings of space within carceral environments. Based on these insights, the group decided to focus on designing a study space within prisons that could be used by prisoners and staff. To support this work, two complementary surveys were planned: a quantitative questionnaire for prisoners, to gather data on their study experiences, needs, and aspirations; and a qualitative questionnaire for prison police staff, in order to understand how to improve educational spaces without compromising security and surveillance requirements. As an additional outcome, the group also planned a follow-up phase involving university students to compare their experiences with those of prisoners and jointly design improved educational spaces in prisons.

Research Line 5: Physics, Energy And Sustainability

Lead Researcher: Giovanni Mazzitelli and Ruggero Ricci, INFN Frascati National Laboratory.

Aim. Reflect on the concept of sustainability, understand the physical and technological constraints underlying it, and explore its real-life applications.

Process and products. After an initial brainstorming session aimed at establishing a shared definition of sustainability and analyzing its environmental, social, and economic dimensions, the group examined the physical meaning of sustainability and energy, progressively developing a more technical vocabulary. The group therefore decided to focus on the 2030 Agenda for Sustainable Development and specifically on lighting in private and public spaces. To raise public awareness and collect real data, participants designed a prototype "sustainability calculator", a tool that compares the costs (energy consumption, monetary expense, and CO_2 emissions) of using incandescent or compact fluorescent lamps versus LEDs and includes estimates of production and disposal costs. As a further development, the group proposed targeted applications of the calculator by key stakeholders, such as teachers, students, and industries, alongside a study to assess its impact on these different groups.

Discussion And Conclusion

At the end of the School, the organizers implemented a simplified evaluation procedure aimed at gathering feedback and reflections. This process involved (a) informal discussions with participating students and researchers, (b) two structured questionnaires, one administered to researchers and one to participating students, and (c) a debriefing meeting within the organizing team to review the results and identify areas for improvement. From this evaluation process, several noteworthy aspects emerged.

Firstly, the School successfully achieved its primary goal of engaging participants in citizen science through an innovative and participatory approach to authentic scientific research projects. All participants, despite their varying levels of expertise and different perspectives, actively contributed to the development of the research and had the opportunity to experience first-hand every stage of the scientific process. Participants developed a clearer understanding of both the importance and complexity of dividing the scientific problem into sub-problems, defining research objectives and questions, selecting appropriate methodologies, and sharing tools and preliminary results. They also recognized that scientific inquiry is far from the linear and orderly process often described in textbooks. Instead, it unfolds as a non-linear and sometimes intricate trajectory, characterized by failed attempts, dead ends, and unexpected changes in direction. Within this process, unconventional or interdisciplinary approaches can occasionally lead to effective solutions. Furthermore, regarding citizen science, participants had the opportunity to develop and practice related skills in a stimulating environment that encouraged discussion and critical exchange. This context allowed them to explore firsthand the potential of citizen science both as an educational tool, particularly for teachers, and as a research methodology for the experts involved. Finally, in full accordance with the principles of citizen science, the School has also generated tangible benefits for the research projects themselves. In addition to increasing their visibility, the activities carried out during the School have led to the development of future-oriented roadmaps, some of which can be implemented immediately and have the potential to produce rapid and significant results.

Despite these highly positive elements, we are fully aware that the implementation of the school has also revealed several weaknesses, particularly regarding the lack of more quantitative measures of its impact. A future edition should therefore include a systematic investigation of how the School experience influences students' and teachers' understanding of science practice, as well as the extent to which teachers and researchers intend to integrate the citizen science approach into their teaching practices or research activities. Furthermore, an interesting direction for future development would be to establish mechanisms that ensure the continuity of projects initiated during the School, for example creating a lasting community of students, teachers, and researchers that could collaborate and promote further growth of the research projects.

Nevertheless, we believe that the Citizen Science School Rome Technopole represented an innovative and successful model, with a considerable potential for replication in a variety of other contexts.

ESERA 2025 Copenhagen

What Does It Take to "Use" a Museum? A Closer Look at Museum Literacy

Lorenz Kampschulte[1] and Gun-Brit Thoma[2]
[1]Deutsches Museum, Germany
[2]IPN Leibniz Institute for Science and Mathematics Education, Germany

In recent decades, museums have undergone a profound transformation from authoritative repositories of knowledge to participatory spaces of exchange, learning, and social engagement. Increasingly positioned as trusted institutions and as so-called "third places," museums now address complex societal challenges, contribute to democratic education, and foster dialogue across diverse communities. Despite these developments, museum audiences remain socially uneven, with educationally and economically disadvantaged groups still significantly underrepresented. This paper argues that improving accessibility and participation requires not only institutional change but also a clearer understanding of how museums can actively support and enable visitors to engage meaningfully with their offerings. To address this gap, the article revisits and expands the concept of museum literacy, originally introduced by Carol Stapp, and develops a differentiated, holistic framework. Drawing on established literacy models from fields such as digital, media, and scientific literacy, museum literacy is sketched as a three-level construct: (1) awareness and basic knowledge of museums and their affordances, (2) the practical application of skills within museums, including socio-cultural and emotional dimensions, and (3) the transfer of museum content to personal and societal contexts beyond the visit itself. Based on a small mixed-method study involving museum professionals, eight key dimensions of museum literacy are identified, ranging from curiosity and motivation to information processing, emotional competence, and appreciation of exhibits. The findings highlight which dimensions are considered particularly relevant and which are perceived as influenceable by museums. The paper concludes that fostering museum literacy is central to strengthening museums' social role, enhancing visitor engagement, and supporting inclusive, reflective, and democratic cultural participation.

Keywords: Lifelong learning, Out-of-school learning, Science Museums

Introduction

The social role of museums has changed significantly in recent decades. Moving away from the traditional image of the museum as a temple of information and knowledge, many museums are reorienting themselves towards becoming places of exchange and participation for all people in our society, increasingly developing into so-called "third places". This role extends far beyond the simple provision of information. Museums are now actively addressing major societal challenges. For instance, natural history and science museums engage with issues such as climate change, biodiversity and energy supply, while museums of cultural history, archaeology o art explore topics including cultural diversity and cultural influences on society, social developments and transformation processes. Ate the same time, they critically examine issues such as looted art, colonialism and the repatriation of objects. In this expanded role, museums function as mediators between different parts of society: they connect history with politics, the economy, and contemporary social issues. They promote exchange between different cultures and groups, as well as dialogue between art, culture and society at large. Particularly significant is the increasing attribution of a role in democratic education. By providing spaces for critical reflection, dialog, and participation, museums contribute to the strengthening of democratic social structures. As a result, their range of functions is expanding considerably beyond their traditional tasks.

As informal learning environments, museums address people of all ages. They act as an interface between leisure activities and education, providing low-threshold, flexible opportunities for learning and fostering dialogue on social issues. Another important aspect is the high level of trust museums enjoy among the public – not only in Germany, but internationally (Wilkening, 2021; Grotz & Rahemipour, 2024). Alongside changes in museums' self-conception, reflected in the revised ICOM definition of a museum (ICOM, 2022), museums are increasingly gaining importance for local communities as so-called third places (Dauschek, 2022). Nevertheless, despite these developments, many museums continue to primarily attract academically educated audiences, while educationally and economically disadvantaged groups remain significantly underrepresented (Hooper-Greenhill, 2006; Thoma et al., 2022; Wegener, 2016).

In order to enhance the accessibility of museums and facilitate more effective use, access, and understanding of their offerings, a multifaceted approach is necessary considering both institutional conditions and visitor-related factors. On the institutional side, museums must create environment that are welcoming and accessible to all segments of society. This includes measures such as reducing entrance fees, fostering inclusive and organizational cultures, implementing broad and effective communication strategies, and diversifying content by incorporating a wider range of knowledge, achievements, and perspectives that reflect societal diversity. Equally important is ensuring that museum staff more closely mirrors the diversity of society itself, thereby promoting representation within the institution. From the visitor's perspective, it is essential that individuals feel confident and prepared to engage with museums. This includes being aware of available content, activities, and learning opportunities, as well as possessing strategies to navigate and meaningfully use of what museums offer. Such preparedness enhances both the relevance and the depth of the museum experience.

There is little doubt that museums are intended to function as inclusive spaces for public engagement and, by definition, should be accessible to all individuals regardless of background or prior knowledge (BVMP, 2024). However, the concept of "accessibility without prerequisites" warrants critical examination. For example, extensive explanatory texts are of limited value to individuals who cannot read, even when written in simplified language. Conversely, oversimplifying information to accommodate broader audiences inherently diminishes the richness of content provided to visitors who possess foundational knowledge, owing to spatial and attentional constraints. The central challenge for museums therefore lies in developing differentiated offerings that address the needs of diverse audiences while enabling meaningful engagement across demographic groups. Layered communication strategies offer one possible approach to reaching the broadest possible audience.

In this context, a conceptual framework that highlights relevant dimensions of engagement may be helpful – both to support a greater inclusivity by minimizing unnecessary prerequisites while enhancing offerings, and to strengthen visitor competencies and foundational skills that enable deeper and more comprehensive use of museum resources.

The term museum literacy was first introduced in 1984 by Carol Stapp, who defined it by analogy to the more established concepts of "computer literacy" and "library literacy":

> By analogy, basic museum literacy means competence in reading objects (visual literacy), but bill museum literacy signifies competence in drawing upon the museum's holdings and services purposefully and independently. Museum literacy therefore implies genuine and full visitor access to the museum by virtue of mastery of the language of museum objects and familiarity with the museum as an institution. In a word, the museum literate visitor is empowered. (Stapp, 1984)

Stapp also pointed out that, while the use of libraries and computers is commonly taught within school curricula, the use of museums generally is not. However, her work does not provide a detailed description or operationalization of museum literacy. Although later initiatives – such as the EU project "museum literacy" (Gazzeri & Brown, 2010) - offer illustrative examples, a comprehensive and clearly defined conceptual framework remains lacking.

Adopting a holistic perspective, this article seeks to capture the various facets of the construct of "museum literacy". Specifically, it asks: What are its core components, and can these components be differentiated in ways that allow them to be systematically addressed, fostered, and measured?

Approach And Definition Of Museum Literacy

Current research demonstrates that literacy is fundamentally shaped by the cultural, political, and historical contexts of the communities in which it develops. Literacy is not only embedded in language and society, it also exists along a continuum across multiple levels that ultimately reflect an individual's cultural identity. Bélisle (2006) distinguishes three complementary approaches to literacy: an autonomous model, which conceptualizes reading and writing as technical skills; a sociocultural model, which emphasizes that literacy is always socially and ideologically embedded; and a "strong claim model", which represents the most far-reaching perspective and is based on the innovative potential of structured thought processes, thereby enabling the creation of something fundamentally new.

In a recent article (Kampschulte et al, 2025), we analyzed literacy models across various domains, including digital literacy (Martin & Gruziecki, 2006; Iordache, Mariën & Baelden, 2017), media literacy (Trültzsch-Wijnen, 2020; De Smedt et al., 2009), AI literacy (Long & Magerko, 2020) or scientific literacy (Gräber et al., 2013; Fischler, Gebhard & Rehm, 2018; Henriksen & Frøyland, 2000). Across all of these models, an elemental composition of literacy is always apparent, literacy consistently comprises a) a body of (subject-specific) basic knowledge, b) the abilities and skills required to use and apply this knowledge – typically in conjunction with tools – , and c) the application of this knowledge in private and/or social life contexts. Building on these discussions and with a view to the interpretation commonly used in English-speaking countries, this project adopts a concept of literacy that draws particularly on the digital literacy definitions proposed by Martin and Gruziecki (2006) as well as Iordache, Mariën, and Baelden (2017):

> Museum literacy consists of three components that build on each other: the basis is the organizational and content level, an awareness of the existence of museums, and basic knowledge about the affordances of museums and how they can be utilized. The second level is characterized by the ability to practically apply specific knowledge and skills in museums, including socio-cultural and emotional dimensions (e.g., being able to experience suitable emotions). The third level is the ability to apply the museum content in different life contexts – inside and outside the museum. This includes personal added value and, for example, the ability to engage in current discourses and thus participate in society.

Together, these three components increase the likelihood that individuals will use museums and benefit from them as spaces for personal development, social interaction, and participation.

The explicit inclusion of socio-cultural and emotional dimensions represents a specific feature of museum literacy. These aspects are far more central to museums than to other literacy concepts such as digital, or scientific, or computer literacy being used by Carol Stapp in the original definition. At this level, museums open up completely different channels of communication that run parallel to learning processes. In principle, these channels can support learning, they are also

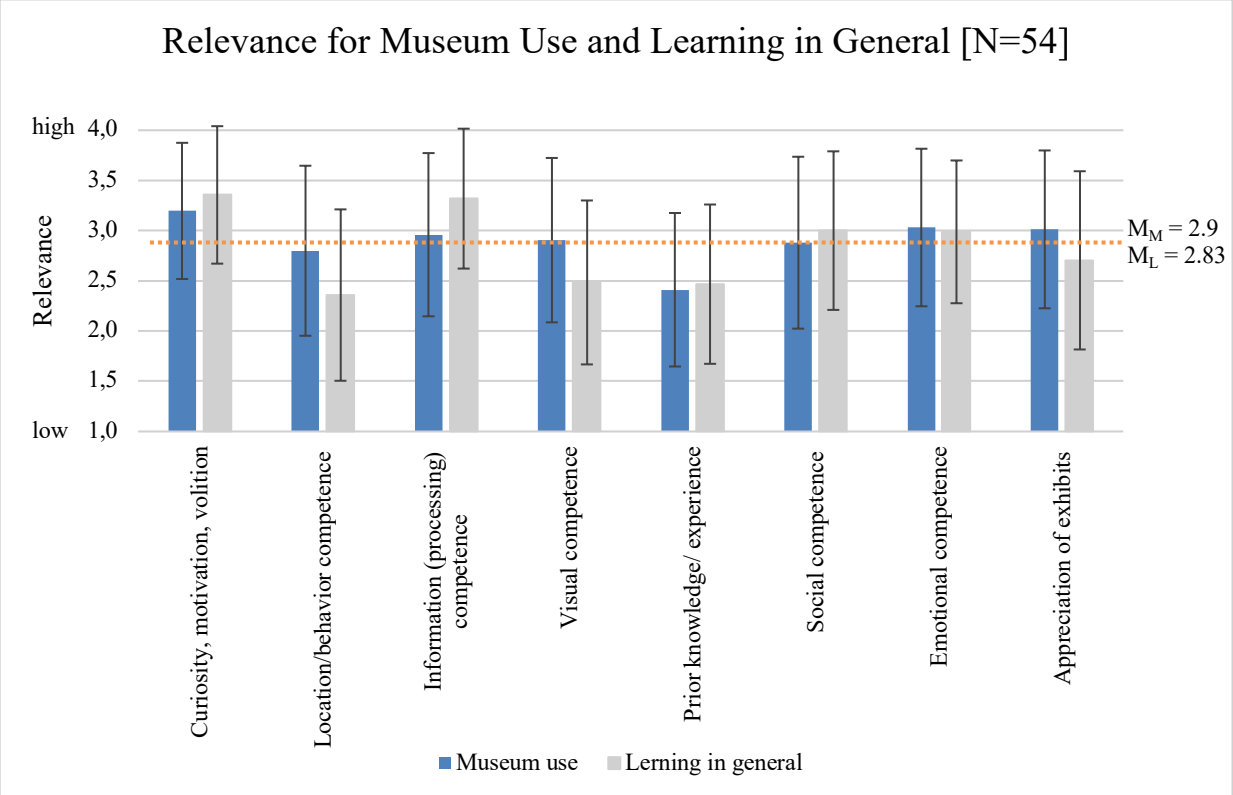
crucial for achieving other visit objectives, such as social interaction during group visits or intense emotional experiences, for example when visiting memorial sites.

Study On Museum Literacy From A Museum Perspective

Table 1. Eight dimensions of museum literacy as found in the study.

	Dimension	Description
1	Curiosity, motivation, volition	Curiosity, motivation and the will to do something in the museum at all are the central basis for using a museum. Curiosity, especially intrinsic curiosity, is the desire to learn new things and discover hidden things. Motivation summarizes all motives that lead to a willingness to act. The deliberate, purposeful transformation of goals and motives into actions - and therefore results - is known as Volition. All three facets are closely linked to emotions and control the behavior in a museum.
2	Location and behavioral competence	This dimension encompasses the knowledge and skills needed to orient oneself in a museum in terms of time and space, to structure the visit and to behave appropriately in the location.
3	Information (processing) competence	The ability to use the information provided in a self-determined, confident and targeted manner.
4	Visual competence	The ability to interpret, evaluate and use information in the form of an image, sign or visual medium. Visual literacy is based on the idea that images can be "read" and that meaning can be discovered through this process of reading.
5	Prior knowledge and experience	This dimension includes both subject-specific knowledge and general prior knowledge that is relevant to the classification and understanding of the content offered, or experience that facilitates understanding.
6	Social competence	The ability and willingness to communicate and interact with other visitors or museum staff as appropriate to the situation.
7	Emotional competence	The ability to (correctly) perceive, understand and influence one's own and others' feelings. This includes emotional self-regulation in particular, but also the ability to allow emotions in the museum.
8	Appreciation of exhibits	Objects of cultural heritage are the basis of museums. Appreciation for these exhibits can arise in different ways (an object was selected for the museum vs. I know about the historical significance of the object) and increases the relevance for users.

To gain a deeper understanding of the skills and prerequisites required of museum visitors for museum literacy, we conducted a study aimed to identifying the knowledge implicitly or



explicitly embedded in museums: In a first step, approximately 25 museum professionals and educational researchers participated in a round table discussion to identify what they considered to be the most important skills and prerequisites. These were grouped into seven overarching topics and further refined through an iterative, anonymized online survey process. In a second step, the experiences and perspectives of 15 purposively selected museum experts were collected for each of the seven topics, summarized, and analyzed using a qualitative online format.

Dimensions Of Museum Literacy

The results of the quantitative survey of museum experts revealed in the end eight dimensions that are relevant to the use of museums:

In the third phase of the study, these eight dimensions were evaluated by a larger group of museum professionals. A total of 54 participants were presented with the eight dimensions identified in the first phase and asked to assess their relevance. The aim was to distinguish whether the dimensions were perceived as more museum-specific or more general. The aim was to find out which factors could be particularly influenced by museums, either by improving e.g. their offers or communication, or with the aim to develop targeted opportunities to develop e.g. knowledge or skills.

Figure 1. Evaluation of the eight dimensions of museum literacy by museum experts in terms of their relevance to museums specifically or their relevance to learning in general.

Overall, the average relevance ratings for museums and for learning in general are very similar (MM = 2.9 for museums; ML = 2.83 on a 1–5 Likert scale). Museum professionals rated prior knowledge and experience as the least relevant dimension for both contexts. For a meaningful "use" of museums, curiosity, motivation, and volition were considered most important, followed by emotional competence and appreciation of exhibits. The largest differences between museums and learning in general – apart from location and behavioral competence – were found in the dimension of visual literacy. Visual literacy was rated as moderately important for museum use but considerably less important for learning in general. Information (processing) competence showed the opposite pattern: it was rated as slightly above average in importance for museums,

but as highly important for learning in general. These differences provide initial indications of which dimensions may be particularly promising starting points for further development on the museum side.

Discussion

Ultimately, all of these dimensions contribute to museum literacy and thus to a stimulating visitor experience. Of course, not all dimensions need to be fully developed in order to experience a good museum visit. Rather, they define a space of possibilities in which visitors can be situated. Which dimensions are activated, and to what extent, varies across museums, individuals, and visits. A six-year-old child, for example, will engage with different dimensions and with a different intensity than an adult who visits museums several times a month. Differences can also be observed within target groups: some visitors approach museums in a structured, knowledge-oriented manner, while others place greater emphasis on social or emotional dimensions.

Some of the dimensions outlined above are highly general in nature. Curiosity, motivation, and volition, for instance, play a role in most learning processes in everyday life. Other dimensions, by contrast, are highly museum-specific, such as location and behavioral skills. Given that the dimensions presented here were derived from a sample of museum professionals, they are strongly shaped by an institutional perspective. The next logical step is therefore to examine these dimensions from the visitors' perspective and to compare internal external viewpoints. Established evaluation models from other literacy domains can serve as a basis for this process and be adapted to the museum context.

In a changing social landscape, museums are widely regarded as trusted institutions, placings them in a strong position to act as independent and reliable sources of information. At the same time, this trust cannot be taken for granted, particularly as political influence on cultural institutions becomes increasingly visible. Museums therefore need to actively maintain and strengthen their credibility – by remaining spaces of enjoyment and inspiration, while also functioning as dependable sources of knowledge and as platforms for open dialogue and critical reflection.

The promotion of museum literacy plays a pivotal role in achieving these objectives. From an institutional perspective, it supports the development of more inclusive programs tailored to the needs of diverse audiences. From the visitors' perspective, individuals are supported in effectively accessing, understanding, and making use of the resources and experiences offered by museums. By bridging gaps in understanding and accessibility, museum literacy contributes to a more informed and interconnected society.

Acknowledgement

We would like to express our sincere thanks to the many discussion partners who have worked with us over the past few years to further develop and refine the concept of museum literacy, in particular, the members of the Leibniz Centre of Excellence Museum Education. We would also like to express our special thanks to our former research assistant Felix Müller from the IPN Leibniz Institute for Science and Mathematics Education for his comprehensive support in data analysis. The work was in part funded by the Leibniz Competition Fund within the project Leibniz-Platform for Advancing and Supporting Visitor Research in Museums (LePAS, T136/2022).

ESERA 2025 Copenhagen

A Scoping Review On Using Virtual Reality To Visit Informal Environments In Primary Science Education

Patricia Photo and Nonkanyiso Pamella Shabalala
University of South Africa, South Africa

Virtual reality (VR) is progressively being explored as a means of facilitating access to informal learning environments in primary science education. These environments, such as museums, science centres, and natural settings, are widely recognised for supporting engagement, inquiry, and meaningful science learning, yet remain inaccessible to many schools due to logistical and financial constraints. This study presents a scoping review of literature published between 2014 and 2024 to map patterns and developments in the use of VR for visiting informal learning environments in primary science education, as well as to identify emerging challenges and opportunities. Guided by the Informal Science Learning framework, 25 empirical studies were systematically analysed. The preliminary findings indicate a growing emphasis on immersive virtual field trips using technologies such as 360-degree video and head-mounted displays to enhance learner engagement and inquiry-based learning. The review also highlights persistent challenges related to cost, technical infrastructure, health concerns, and teacher preparedness, alongside opportunities for improving accessibility and inclusivity in science learning. By synthesising current research, this scoping review provides an overview of how VR is being used to extend informal science learning opportunities for primary learners and identifies key considerations for educators, researchers, and technology developers.

Keywords: Out-of-School Learning, Primary Science Instruction, Virtual Reality

Introduction and Conceptual Framework

Virtual reality (VR) is increasingly being integrated into educational contexts, offering immersive and interactive learning experiences that extend beyond the constraints of traditional classroom-based instruction (Lopes et al., 2024). In primary science education, VR has attracted growing scholarly attention for its potential to simulate access to informal learning environments such as virtual museums, science parks, zoos, and natural ecosystems (Han, 2021). Through these virtual experiences, learners can explore scientific phenomena and contexts that may be geographically distant, logistically inaccessible, or financially prohibitive, thereby addressing persistent barriers related to cost, safety, and time constraints in school-based science learning (Han, 2021; Lopes et al., 2024).

Research suggests that VR-supported learning can enhance learner engagement, conceptual understanding, and motivation by enabling experiential and inquiry-oriented approaches to science education (Won et al., 2023; Xie & Zhang, 2024). The affordances of VR allow learners to observe dynamic processes, manipulate variables, and interact with representations of complex scientific concepts that are difficult to visualise through textbooks or static media alone (Han, 2021). These features are particularly valuable when VR is used to replicate informal learning environments, where exploration, curiosity, and learner-driven inquiry are central to knowledge construction and the development of critical thinking skills (Won et al., 2023).

Considering its pedagogical potential, the integration of VR into primary science education is accompanied by notable challenges. Studies have reported barriers related to hardware costs, technical infrastructure, limited teacher training, and concerns about learner well-being, including cognitive overload and motion sickness (Barrett et al., 2023; Han, 2021; Mohale, 2024). At the same time, VR presents important opportunities to support inclusive and equitable learning by accommodating diverse learning needs, providing multimodal representations, and broadening

access to high-quality informal science experiences that may otherwise remain unavailable to many learners (Lampropoulos & Kinshuk, 2024; Lopes et al., 2024).

To synthesise and make sense of this growing body of literature, this scoping review is guided by the Informal Science Learning (ISL) framework as articulated by the National Research Council (2009). The ISL framework conceptualises learning as a socially mediated, interest-driven process that occurs across diverse contexts beyond formal classrooms, including museums, science centres, outdoor spaces, and digitally mediated environments (National Research Council, 2009). It emphasises key dimensions such as learner engagement, meaning-making, participation in scientific practices, and the role of learning environments and tools (Photo & Shabalala, 2025). Framing this review through the ISL lens enables a systematic mapping of how VR has been used to facilitate access to informal science learning environments in primary education, while also illuminating the patterns, developments, challenges, and opportunities that have emerged in this field between 2014 and 2024. Guided by the Informal Science Learning framework, this scoping review addresses the following research questions:

1. What patterns and developments are evident in the use of virtual reality to facilitate access to informal learning environments in primary science education between 2014 and 2024?
2. What challenges and opportunities have emerged in using virtual reality for informal learning environments in primary science education during this period?

Methods

This scoping review employed a systematic methodology to gain an in-depth understanding of previous research on the use of VR to facilitate access to informal learning environments in primary science education and to identify gaps for further exploration. Following the framework proposed by Gough (2017), the review was guided by clear research questions. It included systematic activities such as the identification of relevant research, study selection, screening, synthesis, and the formulation of evidence-based claims. The focus was on publications released between 1 January 2014 and 31 December 2024, providing perceptions on how the field has evolved over this period.

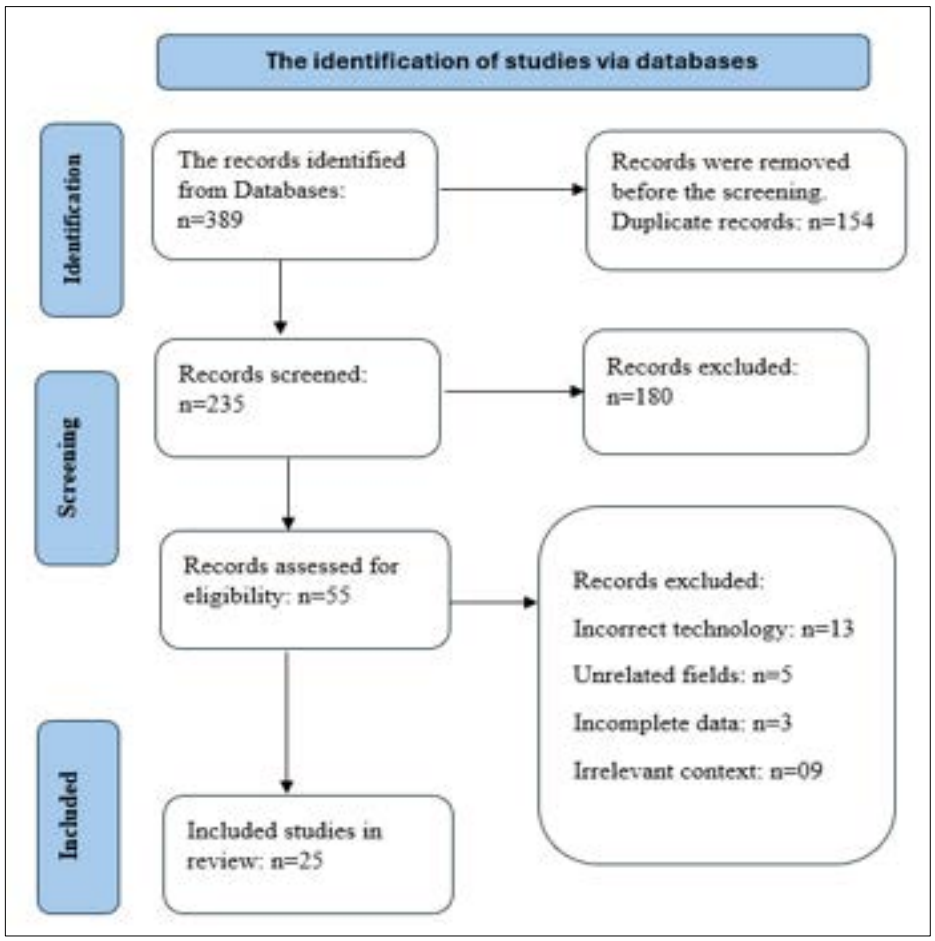
Study Selection And Screening

Study Identification

This scoping review followed PRISMA principles (Liberati et al., 2009). The initial search was conducted using EBSCOhost and included databases such as Academic Search Premier, Education Source, and Applied Science & Technology Source. The search terms incorporated variations of “virtual reality,” “informal environments,” “primary science education,” and related keywords such as “outdoor learning,” “field trip,” “nature reserve,” “science park,” and “natural environment” to capture the range of contexts in which virtual reality is implemented. The review focused on studies published between 2014 and 2024, reflecting recent advancements in VR technology and its applications in education. The initial search yielded 389 articles, and after the removal of 154 duplicates, 235 studies entered the screening phase for further evaluation (see Figure 1).

Manual Screening

Following the initial identification of 235 articles, a manual screening process was conducted. Articles were included if they (1) focused on virtual reality technologies in informal learning environments, (2) pertained to primary science education, and (3) were peer-reviewed empirical studies. Non-peer-reviewed articles, unrelated fields, and incomplete records were excluded.



Eligibility

The first author conducted the full-text screening of the remaining 55 studies. Only studies written in English, peer-reviewed, and published between 2014 and 2024 were included. Based on the eligibility criteria, 30 studies were excluded: 13 for incorrect technology (Calvert & Abadia, 2020), 5 for unrelated fields (Goff et al., 2018), 3 for incomplete data, and 9 for irrelevant context (Huang et al., 2019). After the full-text review, 25 studies were included in the final analysis.

Data Extraction

Study characteristics were extracted and coded to address the research questions. The coding process was conducted inductively by the first author and verified for consistency. Each study was analysed for its purpose, framework, participant population, type of VR used, informal learning environment context, methodology, setting, and reported challenges and opportunities.

Figure 1: PRISMA Flow Chart (Liberati et al., 2009)

Preliminary Results And Discussion

Following a systematic scoping review process, 25 studies examining the use of virtual reality (VR) to facilitate access to informal learning environments in primary science education were identified and analysed. These studies, published between 2014 and 2024, reflect a steady growth in scholarly interest in VR as a means of extending science learning beyond the formal classroom into digitally mediated informal contexts. Consistent with the aims of a scoping review, the findings focus on mapping key patterns, developments, challenges, and opportunities rather than evaluating the effectiveness of interventions.

RQ1: What Patterns And Developments Are Evident In The Use Of Virtual Reality To Facilitate Access To Informal Learning Environments In Primary Science Education Between 2014 And 2024?

Emergence Of Immersive Virtual Field Trips (Vfts)

A prominent development across the reviewed literature is the widespread adoption of immersive virtual field trips (VFTs) as a primary application of VR in informal science learning. Many studies reported the use of VR to simulate visits to museums, science centres, natural habitats, and geographically remote environments. Han (2020) demonstrated that VR-supported VFTs effectively addressed logistical and financial barriers associated with traditional field trips, while still providing learners with meaningful experiential learning opportunities. Technologies such as 360-degree videos and head-mounted displays (HMDs) were commonly employed to enhance learners' sense of presence and immersion, which studies associated with increased engagement and curiosity (Cheng, 2022; Garcia et al., 2023).

Beyond access, several studies indicated a shift towards designing VFTs that support exploration and inquiry, allowing learners to navigate environments, observe scientific phenomena, and interact with contextualised content. This trend reflects a broader movement toward experiential and learner-centred approaches in primary science education, aligning closely with the principles of informal science learning.

Addressing Accessibility And Inclusivity

Another notable pattern concerns the use of VR to promote accessibility and inclusivity in primary science education. Multiple studies highlighted VR as a practical alternative for schools facing financial, geographical, or safety-related constraints that limit participation in physical field trips. Garcia et al. (2023) reported that VFTs offered scalable solutions for under-resourced schools, while Cheng (2022) emphasised the value of localised and culturally relevant VR content in making science learning more meaningful for diverse learner populations. Collectively, these findings suggest that VR-mediated informal learning environments can contribute to more equitable access to high-quality science experiences.

RQ2: What Challenges And Opportunities Have Emerged In Using Virtual Reality For Informal Learning Environments In Primary Science Education During This Period?

Technical And Pedagogical Barriers

Regardless of the documented benefits, the reviewed studies consistently identified technical and pedagogical barriers to the effective use of VR. Health-related concerns, including motion sickness, eye strain, and physical discomfort, were frequently reported as limitations affecting sustained learner engagement (Han, 2020). In addition, the cost of VR hardware and supporting infrastructure remains a significant obstacle, particularly for schools with limited budgets (Liu et al., 2020). From a pedagogical perspective, several studies pointed to challenges related to curriculum alignment and insufficient teacher preparation. Ramsurrun et al. (2024) noted that teachers often lacked the confidence and professional support required to integrate VR meaningfully into science learning activities, highlighting the need for targeted professional development.

Fostering Engagement And Inquiry-Based Learning

At the same time, the literature reveals substantial opportunities for VR to enhance informal science learning through engagement and inquiry-based approaches. Klippel et al. (2020) demonstrated that relatively low-cost VR solutions, such as 360-degree environments, can still provide immersive and interactive experiences that support exploration and critical thinking.

Several studies emphasised that VR environments encourage learner curiosity, sustained attention, and active participation, particularly when aligned with inquiry-oriented tasks. These opportunities position VR as a promising tool for enriching informal science learning experiences in primary education when implementation challenges are adequately addressed. Table 1 provides a consolidated overview of the key patterns, challenges, and opportunities identified across the 25 studies included in this scoping review.

Table 1: Summary of Key Patterns, Challenges, and Opportunities Identified

Focus Area	Key Findings from Reviewed Studies
Dominant VR Application	Immersive virtual field trips simulating museums, natural environments, and science centres
Technologies Used	360-degree videos, head-mounted displays, and interactive VR environments
Educational Purpose	Enhancing access, engagement, exploration, and inquiry-based learning
Accessibility & Equity	Reduced logistical and financial barriers; scalable alternatives to physical field trips
Technical Challenges	Hardware costs, motion sickness, and infrastructure limitations
Pedagogical Challenges	Curriculum integration difficulties, limited teacher preparedness
Key Opportunities	Increased learner engagement, inquiry-based learning, and exposure to otherwise inaccessible environments

Practical Implications

The preliminary findings of this scoping review suggest that virtual reality has considerable potential to enhance learner engagement and support inquiry-based learning in primary science education by facilitating access to informal learning environments. For teachers, these initial insights indicate the value of incorporating VR-supported virtual field trips and exploratory activities into lesson design to stimulate curiosity, observation, and conceptual understanding, particularly in contexts where physical access to informal science settings is constrained. For researchers, the findings highlight the need for further empirical work that examines scalable and sustainable implementation models, with particular attention to challenges related to cost, infrastructure, and learner well-being. From a development and policy perspective, the preliminary evidence points to the importance of designing affordable, portable, and curriculum-aligned VR tools that are responsive to the realities of resource-limited school contexts, thereby supporting more equitable access to informal science learning opportunities.

Gaining Insight Into Rural, Underserved Students' Experiences Of At-Home, Justice-Centered STEM Kits And Books

Margaret Blanchard[1], Karen Collier[2] and Ana-Maria Topliceanu[2]
[1]NC State University, US
[2]Augusta University, US

Out-of-school activities have the potential to broaden participation in STEM, especially for groups with less access to school-based opportunities. In this exploratory, mixed-methods study, at-home STEM kits were mailed to rural middle school students to address inequities in STEM access. The kits included nonfiction trade books featuring the stories of underrepresented minority STEM professionals and content-aligned STEM kits. The quasi-experimental design used repeated measures over four sets of mailed-home STEM kits to gauge students' responses to generic prompts (control) compared to those that addressed social justice constructs (intervention). Morales-Doyle's justice-centered science pedagogy framework was adapted as Justice-centered STEM Framework (JCSF) and guided the data analyses. The research question was: How did students respond to the at-home intervention, and were there differences between the intervention group and the control group? Findings indicate that the at-home STEM kits led to similar responses between both student groups. Overall, the analyses revealed how these students operationalized salient aspects of the JCSF around critical consciousness, academic success, and cultural competence. Within these three elements, themes were coded that highlighted students' perceived reactions: STEM identity, self-efficacy, authentic STEM, enjoyable/engaging, learning, familial sharing, quality materials, learning, awareness, and inspiring. Implications and lessons learned are discussed.

Keywords: social justice, STEM kits, trade books

Introduction

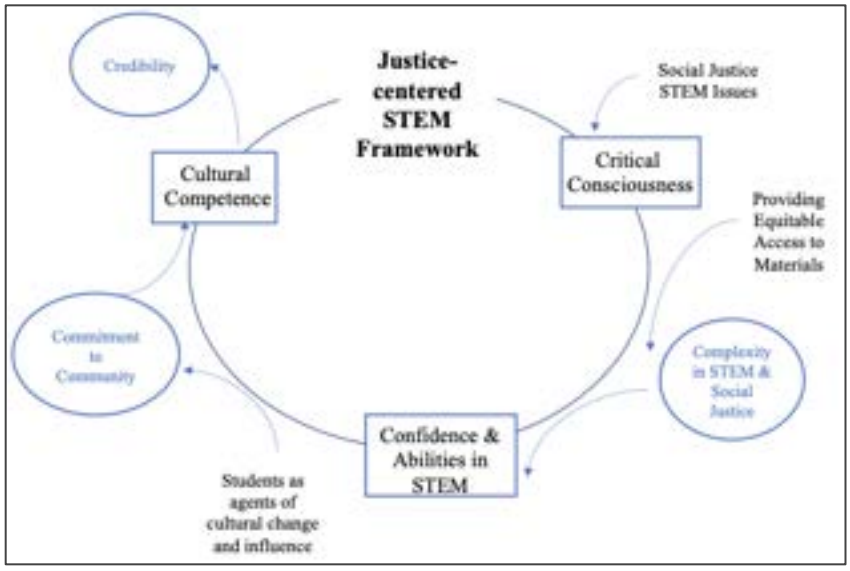
In the Spring of 2020, many teachers had to switch from in-person, synchronous teaching to remote, asynchronous classrooms overnight (Sun et al., 2020) as a result of the global pandemic. Many schools in the United States (U.S.) did not return to in-person instruction in the 2021-2022 school year following the initial impact of COVID. In addition to in-school impacts, the pandemic impacted after-school activities, which were suspended almost immediately (Moody, 2020) and were slow to return in many parts of the U.S.

One promising way to address this programming shortfall was through at-home interventions. In prior research, students and their family members had received high-quality STEM materials at home, which they completed with family members they found highly engaging (Gutierrez et al., 2025). However, sending home materials necessarily involves family members, who may be unclear about their role (Garcia-Reid, 2007; Hill & Torres, 2010; LaRocque et al., 2011). In addition, parents of children in educational systems that have underserved students, from lower socioeconomic (SES) homes, and who are racial/ethnic minorities are often distrustful of school systems (Hill, 2011). Multicultural literature can assist these students in their identity formation (Hseu & Hetzel, 2000), giving them a sense of belonging and acceptance in society. This study aimed to engage rural middle school students in the southeastern U.S. with an at-home intervention that included a hands-on STEM kit and a related trade book featuring multicultural characters, and to investigate whether social justice-oriented prompts affected their perceptions of these STEM materials.

Literature Review

Science Trade Books

Science trade books are important curriculum materials that can be used in K-12 science classrooms to strengthen students' literacy skills, assist students in learning science content, and ultimately increase participation in the STEM workforce (NSF, n.d.). In 1973, the National Science Teaching Association (NSTA), in cooperation with the Children's Book Council (CBC), created the Outstanding Science Trade Books for Children, a list of recommended trade books (NSTA, n.d.). Some criteria for selection include books that contain clear, up-to-date science content that is not oversimplified. Also, the books are free of gender, ethnic, and socio-economic biases; they are at the appropriate level for the audience and contain illustrations that are accurate in size, scale, and color (Texley, 2008). The science trade books provide opportunities for students to learn science practices (Texley & Ruud, 2017).



STEM Kits

Prior research has shown that students prefer learning science through activities with kits rather than just using textbooks (Houston et al., 2008). Analyzing qualitative and quantitative data from 588 elementary students (grades 3-5), Houston and colleagues discovered that using science kits was associated with more effective science instruction in terms of greater student satisfaction. In informal STEM settings, such as after-school programs and STEM camps, the use of STEM kits can broaden the participation in STEM of underrepresented groups (Newton et al., 2020).

Theoretical Framework

Justice-centered science pedagogy (Morales-Doyle, 2017; Figure 1) is a framework built on culturally relevant and critical pedagogy to address inequities in science education and potentially lead to social transformation. Drawing upon prior work (Ladson-Billings, 1995), culturally relevant pedagogy requires students to 1) experience academic success, 2) develop cultural competence, and 3) develop critical consciousness, challenging the current social order. The third criterion relates to Freire's work with critical pedagogy, emphasizing *conscientizacao*, a process by which people begin to view themselves as capable of eliminating oppression by transforming reality (Freire, 2020, 2021a, 2021b; Freire & Macedo, 2005). People develop a critical consciousness from education that elucidates the historical and political conditions that created inequitable social circumstances.

Figure 1. Justice-centered STEM Framework (modified from Morales-Doyle, 2017).

Research Design

This study used a convergent mixed methods design (Creswell & Plano Clark, 2018). The study collected repeated measures from students from five middle schools over six months to assess whether there would be differences in perceptions of justice-oriented constructs (e.g., critical consciousness, commitment to community) depending on whether they were responding to a neutral (control) or a justice-oriented prompt (intervention). Students received up to four STEM kits and justice-oriented trade books. Two of the five schools were randomly assigned to receive justice-oriented question prompts, while the remaining three schools received neutral question prompts for the STEM kits and trade books. Surveys included quantitative data from 6-point Likert-scale items and a qualitative open-ended question. The quantitative and qualitative data were collected simultaneously but analyzed separately, and the results were merged to address the third research question (Creswell & Plano Clark, 2018).

Research Questions

This study sought to understand how students participated in and responded to social justice-oriented trade books and STEM kits mailed to their homes during COVID-19.

1. How did the participation compare between students who received neutral (control) prompts and those who received social justice-oriented prompts (intervention)?

2. How did survey responses compare between students in the control and the intervention groups?

3. How did students describe what they gained from their experiences, and did they differ by group?

4. How do the qualitative themes map onto the justice-centered STEM framework?

Methods

Project Design

This project aimed to promote meaningful student and parent discussions around diversity, equity, and inclusion in STEM by increasing their awareness of, interest in, and positive perceptions of STEM professionals, fields, and careers. Built on pilot work conducted with rural middle school students (Blanchard et al., 2023; Gutierrez et al., 2025), this innovative project extended academic activities into the home by mailing home an interesting and challenging multicultural, nonfiction trade book with a STEM kit for at-home STEM-related investigations and reading.

Rationale For Materials Selected

The books were selected to highlight individuals who are traditionally underrepresented in STEM fields, to serve as role models (Table 1). The featured individuals revealed aspects of their lives, their character, and their choices, and highlighted adversities they may have faced. Two African American Females and Two Males (one African American and one Hispanic) were the subjects of the selected non-fiction historical trade books. For this study, all four books had these six common characteristics: 1) contained a simplified version of a story, 2) demonstrated a non-stereotypical appearance of a scientist, mathematician, or engineer, 3) were age-appropriate, 4) focused on the process of science, math, or engineering (struggles and perseverance) in contrast to science, math, or engineering as a miraculous event, 5) contained accurate information, and 6) had colorful illustrations (Delgado, 2021; Kibler & Chapman, 2019). Kiwi Crate Kits (Kiwico, 2022) were selected based on their quality, success, affordability, and ability to be mailed. As seen in Table 1, the book and STEM kits were paired on a related topic.

Table 1. Kit-book sets.

Kit	Book	STEM Kit
1	*Counting on Katherine* by Helaine Becker	Bottle Rocket
2	*The Boy Who Harnessed the Wind* by William Kamkwamb	Hand Crank Flashlight
3	*Seeds of Change* by Jen Cullerton Johnson	Drip Irrigation
4	*Esquivel! Space-Age Sound Artist* by Susan Wood	Light Up Speaker

Research Context

Five middle schools in the southeastern U.S. (partners in a STEM club project) agreed that kits could be mailed to their students' homes. All participating schools were classified as Title I, a U.S. federal education program that provides additional funding to schools with a majority of low-income students (Elementary and Secondary Education Act, 2015). The majority of the students (86% to 95%) identified as underrepresented minorities (URM), and 98% of the students at three of the participating schools qualified for free or reduced-price lunch (School Digger, 2022). Historically, end-of-grade test scores were significantly below those of their state (except for one school).

Participant Recruitment & Participation

The school's science teachers and academic coaches invited approximately 30 students from each of the five middle schools, grades 5th-8th, to participate in the project. Students received welcome letters with QR codes and a web link to a Qualtrics survey to sign up to participate in the project. Kits were mailed to the students' specified guardian, or (if requested) mailed to the student's school, to then be taken home by the student. A liaison teacher at each school encouraged students to participate.

Each kit and book had an associated survey that students could access through a web link or a QR code, to take after completing both the kit and the book. Once students completed both surveys, they were mailed the following kit and book. Students could receive up to four packages, each with a STEM kit and a related book. Due to lower-than-expected student enrollment, teachers at four schools received a classroom set of kits and books to share with their students approximately halfway through the Spring semester. One school incorporated the kits into its after-school STEM Club program and included a total of three kits in its club activities. A spike in survey responses on one date suggests that these kits and books were done during a club meeting, but otherwise, no data were collected that could verify the location of the reading and kit activities. Reminder postcards were mailed to students approximately two weeks after each kit/book mailing to encourage student participation.

Survey

The survey prompts were developed by the first and second authors, based on constructs of the modified Morales-Doyle framework (2017). Before distribution, the survey items were shared with other science educators (i.e., faculty, graduate students) and middle school students to provide face and content validity for the items (Sartori & Pasini, 2007). Through Qualtrics, survey questions utilized a 6-point Likert scale, with 1 represented *Completely disagree*, while 6 reflected *Completely agree*.

The students from two randomly selected schools received neutral survey prompts as a control group, reflecting activity completion and comprehension. As an intervention group, students from the other three schools received prompts informed by Morales-Doyle's justice-centered science pedagogy framework (2017; Table 2).

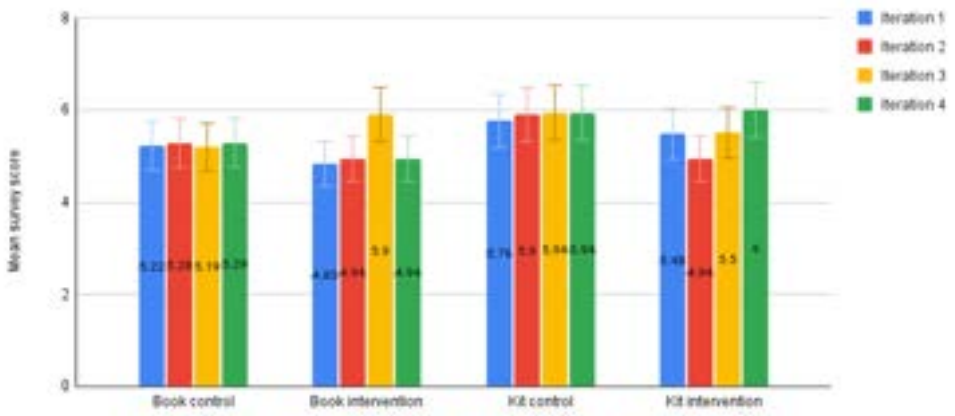
Table 2. Book and kit survey questions.

	Neutral Survey Items	Justice-Oriented Survey Items	Justice-Oriented Construct
Book 1	The main character faced opposition or challenges in the story.	Sometimes doing what is right, or ethical, is difficult.	Critical Consciousness
Book 2	The main character was very successful.	Others in the community were impacted by the abilities of the main character.	Commitment to Community
Book 3	The main character became well known.	The main character was committed to making their community a better place.	Commitment to Community
Book 4	This story made me think that the lead character was pretty special.	This story made me believe that if I wanted to, I could become a mathematician [varies by book].	Confidence & Ability in STEM
Book 5	People who impact the community are important.	This story made me believe I can impact my community in a positive way.	Commitment to Community
Book 6	I read all of the book.	I read all of the book.	Equitable Access to Materials
Book 7	I shared the book with a friend or a family member.	I shared the book with a friend or a family member.	Commitment to Community
Book 8	This was a biography, a story about someone's life.	This book is an example of how science [varies by book] can change the culture or habits of one's community.	Cultural Competence
Kit 1	I enjoyed working on the kit.	Working on the kit made me feel like I could overcome other challenges that I face.	Critical Consciousness
Kit 2	After doing this kit, I am looking forward to the next one.	After doing this kit, I gained confidence in my abilities in STEM.	Confidence & Abilities in STEM
Kit 3	This kit made me feel capable.	I think I could do some things in STEM that could improve my community.	Commitment to Community
Kit 4	I completed all of the kit.	I completed all of the kit.	Equitable Access to Materials

Open Response Coding

An inductive process was used to identify the themes from the open response items. Two coders read through all the comments and identified possible themes. Common themes that emerged from the statements about the kits included: STEM identity, self-efficacy, authentic STEM, enjoyable/engaging, learning, and familial sharing. Statements for the books repeated several previous themes, including enjoyment/engagement, learning, familial sharing, and self-efficacy. New themes also emerged, such as awareness, quality materials, and inspiring. After the codes were determined, one of the coders read through the statements and broke them into discrete units to delineate coding segments, a process referred to as unitization (Campbell et al., 2013). After the statements were segmented, the two coders independently assigned codes. After all items were coded, the codes were compared between the co-coders. A rate of 90% agreement was calculated for interrater reliability. Disagreements were then discussed until 100% agreement was reached for all statements (Patton, 2015).

Analyses and Findings



RQ1: Project Participation And Attrition

The project participants ($N = 110$) for both groups primarily self-identified as URM. The neutral group was more likely to be female (58%) and enrolled in 6th grade (44%). The justice-oriented group was more likely to be male (54%) and in 7th grade (71%). Comparing the survey completion rate of books to kits, students completed more kits across all interactions, except for the justice-oriented group in the fourth iteration, after the kits were mailed to teachers. The neutral group participated more throughout the project than the justice-oriented group, except for trade book 3 (*Seeds of Change*) and trade book 4 (*Esquivel! Space-Age Sound Artist*).

RQ2: Quantitative Analysis: Students' Responses To Justice-Oriented Survey Items

Kit scores were higher than trade book scores on the justice-centered survey constructs, except for Kit 2, Intervention. All scores were considered high as values represented *mostly agree (5)* or *completely agree (6).* Mean scores for the surveys increased across the iterations. Trade book means were lower than kit means. The justice-oriented means were lower than the neutral means for most data points, though the values differed only slightly in both conditions. The greatest difference between neutral (M =5.90) and justice-oriented ($M = 4.94$) survey means occurred with Kit 2, with a difference of 0.96 points. Statistical tests were conducted through t-tests, but no statistically significant relationships were found (Figure 2).

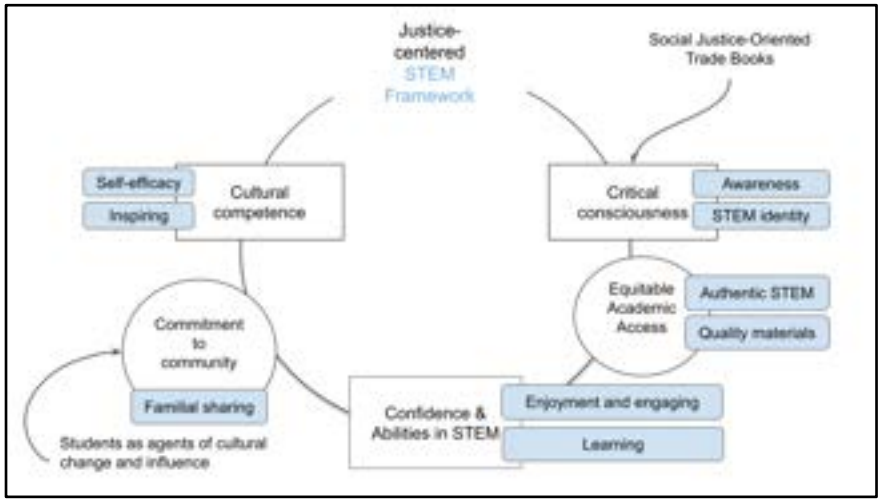
Figure 2. Book and Kit Survey Means.

RQ3: Qualitative Analysis: Themes From Open-Response Items

Both groups of students wrote positive comments toward the books and kits, and their responses aligned with the social justice concepts within the books, regardless of their group. The common themes that emerged from the statements included: STEM identity, self-efficacy, authentic STEM, enjoyable/engaging, learning, and familial sharing (Table 3). New themes that emerged with the book included awareness, quality materials, and inspiring.

Table 3. A Priori Codes in Open-response Analysis.

Code	Definition	Exemplar Statements
Learning	Learning new information or about STEM concepts.	***…****it tells about the environment and how we are hurting it.* (*Seeds of Change*, 8th grade, Hispanic Female)
Self-efficacy	Students expressed motivation to do something, take action, especially within their community.	*…the book was great…****to think how to make a change in the world.*** (*The Boy Who Harnessed the Wind*, 8th grade, Hispanic Female)
Enjoyable & Engaging	Fun or engaging experience in completing the activity/reading the book.	*Working on the STEM kit I thought it was very fun and creative.* (Bottle Rocket, 8th grade, Black Female)
Authentic STEM	When students spoke about experiencing STEM as it would occur in a lab, in contrast to a scripted experiment.	*My seeds grew a lot but when I took them out to the sun they died so I will plant more.* (Drip Irrigation, 6th grade, Hispanic Female)
STEM Identity	Positive beliefs toward their competence and performance in science, as well as believing others will recognize them as a scientist, engineer, or mathematician.	*It is bringing my dream of being able to build electronics true.* (Crank Flashlight, 6th grade Male, unknown race/ethnicity)
Familial Sharing	Students shared these experiences with their families.	*I also got to do it with my younger siblings, which was nice.* (Bottle Rocket Kit, 8th grade, Hispanic Female)
Quality Materials	Appreciation for the narrative and quality of materials.	*I think the book was really good* (*Esquivel Space Age Sound*, 6th grade, Hispanic Female)
Inspiring	Books gave rise to positive or creative feelings.	*I found this book inspiring because it showed that no matter what comes your way, you should never give up for what you believe in.* (*Counting on Katherine*, 8th grade, Black Female)
Awareness	Greater awareness toward critical issues with race, gender, and life situations.	*It helped [me] realize that everyone can do anything as long as you work hard.* (*The Boy Who Harnessed the Wind*, 6th Grade, Hispanic Female)



Themes Integration With A Justice-Centered STEM Framework

The fourth research question asked how the themes from the open-ended responses mapped onto the justice-centered STEM framework. The themes identified in the students' statements correlate

with the concepts of the JCSF (Figure 3). The themes of STEM identity and awareness are aspects of the component **critical consciousness**, as students could visualize themselves as real STEM professionals through the kits and relate to the social, racial/ethnic, and gender aspects of the characters in the stories. The themes of authentic STEM and quality materials reflected **equitable academic access** as students could complete real STEM experiences and learn about the challenges STEM professionals faced in the trade books. Prior research supports using quality STEM experiences in out-of-school activities as learning tools to reach underserved students (Blanchard et al., 2023).

The framework component **confidence and abilities in STEM** was reflected by two themes, learning and enjoyable/engaging. These components were critical in helping students persist in tasks and gain confidence in their abilities, as shown in prior research (Blanchard et al., 2023; Morales-Doyle, 2017). Familial sharing was the theme that related to **commitment to community**, as students wrote about sharing their experiences with their siblings and parents. In prior research, high school students reflected on this component when they presented their soil project at a family science night (Morales-Doyle, 2017). Lastly, **cultural competence** was reflected in students' sense of self-efficacy and inspiring themes as students wrote about how they could be agents of change and have critical roles in the future of STEM. This finding resonates with the effects of Laughter and Adams (2012) in their study of middle school teachers who used a short story, The Space Traders, to create classroom discussions about scientific bias and their larger societal contexts.

Figure 3. Components of the Justice-centered STEM Framework, with themes.

Note. The coded themes are included in rectangles shaded in blue. Blue font reflects changes from the original justice-centered science pedagogy model of Morales-Doyle (2017).

Limitations

A major limitation was the participation attrition, likely a result of an inability to communicate directly with parents or guardians, limited involvement of teachers, and the apathy that followed extended issues from COVID. Another limitation is the relatively small sample of students who participated in the study, all of whom were enrolled in rural middle schools in underserved communities.

Discussion

This at-home STEM intervention began as a response to COVID; none of the middle schools felt able to carry out STEM club activities when navigating the logistics of students returning to the classroom. Although it was anticipated that students would be excited about the kits and books and eagerly participate, student participation in the kits began slowly, and it took multiple

reminders via postcards mailed to homes to try to increase the level of participation. Of the students who began the project, a limited number continued past the second kit. These findings are similar to findings in another study, when students from an active STEM club carried home STEM kits (Gutierrez et al., 2025).

It was anticipated that the repeated measures of justice-oriented prompts might lead, over time, to increased student perception of their agency and involvement in their communities. However, findings revealed insignificant differences in participation, completion, and responses between the neutral and justice-oriented groups. The lack of difference in the findings between the two groups suggests that the project materials themselves - the STEM kits and the social justice-oriented trade books - were what led to students' perceptions, rather than the difference in the prompts (Blanchard et al., 2021; Smith, 1995; Steiner, 1998).

It also was anticipated that the students who received prompts that explicitly related to justice-oriented ideas would, over time, have responses that were more aligned with these constructs. The mean survey scores increased with iterations, potentially reflecting greater engagement and increased agreement with justice-oriented prompts as the project progressed. Yet, the analyses of the students did not reveal any statistically significant differences. It was hoped that students would share the trade book and/or kit with family members, yet they reported that they mostly did not. This was unlike the Gutierrez et al.'s (2025) study, in which students were explicitly asked to work with their family members and audio record the interactions.

Conclusions And Implications

The findings of this study lead to several conclusions and implications. First, students responded very positively to the at-home STEM kits and the social justice-oriented trade books. This suggests that the curriculum materials were of the right difficulty level and relevant or of sufficient interest for the students. Second, student participation fell off quickly. This was likely the result of a lack of strong ties to an active STEM Club or instructor support. Increased contact with the guardian and liaison teacher may have improved student participation. Third, although interest was quite positive, overall, interest seemed to vary based on the kit and book. It seems likely that the lack of choice related to perceived personal interest may have undermined completion. Fourth, despite the researchers' anticipation of the role of the social justice-oriented prompts, the differences in the prompts did not lead to differences in students' responses. This suggests that the social justice-oriented trade books, as well as the STEM kits, were more influential than the prompts; that they were able to stimulate elements of culturally relevant pedagogy (Ladson-Billings, 1995; Morales-Doyle, 2017), including students' cultural competence and critical consciousness. Finally, students gave positive and encouraging comments, reflecting that the intervention positively impacted students' sense of capability and future career aspirations in STEM. The role models from the trade books seemed to resonate for many of the students (Blanchard et al., 2023; Clark et al., 2024).

Acknowledgement

The authors would like to thank Dr. Donna Farland-Smith for her thoughtful feedback as the manuscript was being developed. This study was funded by Burroughs Wellcome Fund, #1017709.

Exploring the Perspectives of Families Following Their At-Home STEM Tinkering Experiences

Kylie J. Swanson[1], Kristie S. Gutierrez[2] and Margaret R. Blanchard[3]
[1]University of Colorado Colorado Springs, USA
[2]Old Dominion University, USA
[3]North Carolina State University, USA

This qualitative study explores the experiences and perceptions of nine families who participated in STEM Home Edition, a year-long at-home STEM learning program designed for middle school students and their families. The program aimed to foster STEM engagement and conceptual understanding through hands-on activities, including Circuit Scribe, Meccano robots, Germ Glo and Achoo! and Steve Spangler's Larry's Lab. Using the Learning Dimensions of Making & Tinkering framework (Bevan et al., 2017), this study analyzed family interactions across five dimensions, with a focus on Creativity & Self-Expression (LD4) and Social & Emotional Engagement (LD5). Data were collected from interviews and pre- and post-activity reflections with nine families. Findings revealed that Creativity & Self-Expression was the most often described Learning Dimension (45%), characterized by youth and adults expressing joy, constructing explanations, and setting personal goals. Social & Emotional Engagement followed (25%), emphasizing family members' perceptions of collaboration, confidence, and pride in the outcomes. Other Dimensions—Conceptual Understanding (15%), Initiative & Intentionality (12%), and Problem Solving & Critical Thinking (3%)—highlighted families' reflection on their ability to control variables, persist through challenges, and troubleshoot. The study also observed the demographic diversity of participants, with most families led by mothers and including a mix of racial/ethnic backgrounds and educational levels. These findings provide novel insights into at-home STEM engagement and underscore the potential of family-centered STEM programs to enhance learning, build confidence, and foster STEM identity. The study contributes to research on informal STEM education, offering practical insights for future program design and implementation.

Keywords: Out-of-school contexts, STEM education, Qualitative research

Importance Of Study

Engaging families in informal STEM learning fosters interest and participation in STEM fields (Dabney et al., 2016; Lin & Schunn, 2016; Roberts et al., 2018). Informal STEM activities, such as museum visits, zoo trips, and hands-on home experiments, enrich classroom learning and provide extended engagement opportunities (Roberts et al., 2018; Blanchard et al., 2020). Family involvement is also linked to improved academic outcomes for middle and high school students (Hill et al., 2018). However, parental engagement in STEM education presents challenges. Many parents face time constraints (Jeynes, 2006, 2010, 2012; Mapp et al., 2008) and barriers to school involvement (Bhargava & Witherspoon, 2015; Hill et al., 2018). As children enter adolescence, parents often step back to encourage independence (Hill et al., 2018). Yet, at-home STEM activities can increase students' motivation, confidence, and appreciation of STEM, similar to other informal learning experiences (Lin & Schunn, 2016). Encouraging parental participation in STEM at home can enhance students' engagement, knowledge acquisition, and career planning (Epstein, 1986).

Tinkering is commonly described in the literature as an interdisciplinary, inquiry-driven approach that integrates STEAM domains and emphasizes creativity, iteration, and problem solving, despite variation in how the term is defined. Vossoughi and Bevan (2014) characterize tinkering

as a mindset that spans making and engineering, highlighting experimentation, learning through failure, and iterative design. Tinkering often engages learners in open-ended exploration rather than predetermined outcomes and is most frequently studied in informal learning environments such as museums, camps, and afterschool programs.

Research demonstrates that tinkering can effectively support engagement with engineering concepts and practices. Marcus et al. (2021) found that family-based engineering design challenges fostered playful exploration and iterative testing, particularly when participants were provided with activity-specific guidance and access to testing stations. Similarly, Simpson et al. (2020) reported that elementary students in an informal afterschool STEM program demonstrated meaningful engagement with electricity and circuitry through hands-on tinkering projects. Although these activities aligned with NGSS expectations, the informal contexts afforded learners greater flexibility, time, and resources to enact science and engineering practices than is often possible in formal classroom settings. Together, these studies highlight tinkering's potential to support authentic STEM learning and family engagement in informal educational spaces.

This qualitative study examines the experiences of nine families participating in the STEM Home Edition program over ten months. This work extends previous work (Gutierrez et al., 2025) by detailing how these families interacted during STEM at-home activities. By exploring family reflections through interviews about their engagement in at-home STEM activities, this study provides insight into how informal STEM learning contributed to families' STEM engagement and development.

Conceptual Framework

The *Learning Dimensions of Making & Tinkering* framework (Bevan et al., 2017) served as a guide to document how families reflected on their participation in STEM activities at home. This framework consists of five key Learning Dimensions, as illustrated in Table 1. Multiple dimensions were often referenced simultaneously during family interviews, reflecting their interconnected and overlapping nature rather than existing as isolated or distinct categories. Initiative and Intentionality (LD1) captures evidence of self-directed learning, goal setting, and persistence. For this study, "organization of materials" was added to represent at-home activity contexts better. Problem Solving and Critical Thinking (LD2) includes experimenting with strategies, seeking assistance, and refining approaches; "building and assembly" was added to reflect hands-on construction practices. Conceptual Understanding (LD3) focuses on how participants generate explanations and use material properties to meet design goals. Creativity and Self-Expression (LD4) encompasses aesthetic responses, playful exploration, and novel uses of materials; "expressing negative emotions" was incorporated to capture affective responses observed in the data. Social and Emotional Engagement (LD5) reflects collaboration, mutual support, confidence building, and expressions of ownership.

Research Design And Research Question

This study used a qualitative study design (Creswell, 2013) to investigate the experiences of nine families who participated in at least three of the four at-home STEM activities. The after-school STEM Club students attended one of two rural, Title I middle schools in the southeastern US, and participated in a STEM Club at their school (Blanchard et al., 2023).

The research question for this study is: *How did families reflect on their tinkering experiences after an at-home STEM intervention?*

Table 1. The Learning Dimensions of Making & Tinkering (adapted from Bevan et al., 2017)

Dimension	Indicators
LD1: Initiative & Intentionality	a. Setting one's own goal b. Taking intellectual and creative risks c. Complexifying over time d. Persisting through failure e. Adjusting goals based on feedback f. Organizing materials*
LD2: Problem Solving & Critical Thinking	a. Troubleshooting through iterations b. Moving from trial-and-error to inquiry-focused refinement c. Developing work-arounds d. Seeking ideas, help, and expertise e. Building and/or assembly*
LD3: Conceptual Understanding	a. Controlling variables as projects complexify b. Constructing explanations c. Using analogies and metaphors d. Applying material properties to design
LD4: Creativity & Self-Expression	a. Responding aesthetically to materials b. Connecting projects to personal interests c. Playful exploration d. Expressing joy and delight e. Using materials in novel ways f. Expressing negative emotions*
LD5: Social & Emotional Engagement	a. Remixing or building on others' ideas b. Teaching and helping one another c. Collaborating in teams d. Developing confidence e. Expressing pride and ownership

Note: Indicators added by the authors are designated with an asterisk.

Methods

STEM Home Edition Program

The *STEM Home Edition program* (pseudonym) was implemented in the homes of students who were members of an ongoing after-school club and took place over one academic year. Each student began by bringing home a STEM kit to share with their family. Kits included STEM materials, snacks, activity instructions, career and post-secondary information, and pre/post-activity reflection prompts (Gutierrez, K. S. & Blanchard, M. R., 2018). The four activities were: 1) Circuit Scribe kit, 2) Meccano robot, 3) Germ Glo and *Achoo! The Most Interesting Book You'll Ever Read About Germs*, and 4) Steve Spangler's *Larry's Lab* (water-soluble polymers). Families kept the materials and received the next activity after submitting data. Up to four activities could be completed sequentially. At the program's end, families participated in interviews. Transcribed interview data totaled 82 pages and were coded using a priori categories

from the *Learning Dimensions of Making & Tinkering* framework in Atlas.ti, with additional codes for family context, such as "Family Dynamics" and "Family Relationship."

Participants

The demographic data reflect the diversity of families in the STEM Home Edition program. Most participants were White (5 families), followed by Black (3) and Multi-Racial (1). Slightly more were female (5) than male (4), with ages ranging from 11 to 13, and most (5) were 11 years old.

Mothers were the primary participants in eight families, with two families involving fathers and one with both parents actively engaged. Educational backgrounds varied: three adults held graduate degrees, three had undergraduate degrees, three had some college, and one had a high school diploma. Most families had one or two children involved, though one had four and another had three. This overview highlights the varied family contexts in the program.

Findings

Through the family interviews, the analysis of activity learning dimensions that was guided by the Learning Dimensions of Making & Tinkering framework, highlights the diverse ways participants engaged with STEM activities (see Table 2). *Creativity & Self-Expression* (LD4) was the most frequently observed dimension, accounting for 45% of codes (114 instances). For example, reflecting on the Circuit Scribe activity, the daughter from the Murphy family expressed, "*Well, it was very entertaining, and it - I thought it was really cool how, like, the electricity would flow through the little, like, parts where you draw on the paper. I thought that was really interesting.*" Reflecting on the Germ Glo activity, the mom from the Brown family said "I liked the germs one because I was amazed to see what was on our hands [...] it was amazing." This dimension reflects participants' joy, aesthetic responses, and creative use of materials. Key indicators included both youth and adults expressing joy (44 and 32 instances, respectively), youth constructing explanations (18 instances), and youth setting goals (13 instances).

Table 2. Percentages (and Frequencies) of the Learning Dimensions [and Indicators] of Making & Tinkering Reflected on During Family Interviews.

Activity	**Learning Dimensions**		**Most frequent indicators**
Family Interview	LD4: Creativity & Self Expression (114)	45%	Youth Expressing joy and delight (44)
	LD5: Social & Emotional Engagement (63)	25%	Adult Expressing joy and delight (32)
	LD2: Problem Solving & Critical Thinking (8)	3%	Youth constructing explanations (18)
	LD1: Initiative & Intentionality (31)	12%	Adult constructing explanations (16)
	LD3: Conceptual Understanding (38)	15%	Youth setting own goal (13)

Social & Emotional Engagement (LD5) was the second most prevalent dimension, comprising 25% of codes (63 instances). The dad from the Jones family reflected on the program saying, "*It enhanced my team-building skills, so that's what I can use later in life, more or less… that, and working with my son.*" This dimension highlights building confidence, teamwork, and pride in outcomes.

Other dimensions were less frequently observed but still enriched the learning experience. *Conceptual Understanding* (LD3), accounting for 15% of codes (38 instances), focused on controlling variables, constructing explanations, and connecting materials to achieve design goals. The mom from the Mueller family shared "*I had never heard the word polymer before, even though we had had the Orbeez, I didn't, again, read the directions that came with the Orbeez. I did not realize they were called polymers.*"

Initiative & Intentionality (LD1), representing 12% of codes (31 instances), highlighted goal-setting, persistence, and adapting plans. The son in the Wilson family noted, *"I learned a bit more about the jobs I'm interested in and a bit more about some of the jobs I'd rather not go for and still see how they're interesting to me sometimes too.*"

Problem Solving & Critical Thinking (LD2), the least observed dimension at 3% (8 instances), emphasized troubleshooting and creative workarounds. Reflecting on troubleshooting, the mom and daughter from the Baker family shared:

Daughter: *Circuits didn't really work.*

Mom: *Well, it took a little working with it and making sure to get it - to do things appropriately.*

These findings demonstrate how multiple dimensions often overlap, creating a rich, multifaceted learning environment where each dimension was evidenced at varying degrees of frequency.

Discussion

This study highlights the impact of family-centered STEM programs like STEM Home Edition in fostering engagement, learning, and confidence. Using the Learning Dimensions of Making & Tinkering framework (Bevan et al., 2017), findings reveal diverse family interactions with STEM activities. *Creativity & Self-Expression* emerged as the most prominent dimension, reflecting the joy and curiosity sparked by hands-on exploration. At-home STEM activities can enhance intrinsic motivation and creative problem-solving. *Social & Emotional Engagement*, the second most observed dimension, emphasizes collaboration, confidence-building, and emotional investment in STEM learning.

Less frequent but still significant, *Conceptual Understanding* and *Initiative & Intentionality* highlight the value of applying scientific concepts and persisting through challenges. The limited presence of *Problem Solving & Critical Thinking* suggests a need for more complex, iterative tasks within at-home programs.

Conclusions And Recommendations

These findings suggest several practical recommendations. Program designers should prioritize activities that integrate creativity, collaboration, and conceptual understanding to enhance engagement and learning. Providing resources to guide goal-setting and problem-solving may strengthen Initiative & Problem Solving. The program's demographic diversity underscores the need for culturally responsive design to ensure relevance across backgrounds. Lastly, involving families in STEM education fosters STEM identity and long-term interest. Schools and community organizations should adopt family-centered STEM models to connect informal and formal learning.

Acknowledgement

The authors acknowledge the STEM Career Clubs project team for their work on both the STEM Club initiative and the accompanying STEM Home Edition project that informed this study. Special appreciation is extended to the middle school teacher-coaches involved in the STEM Club

program, as well as to the students and families who participated in the at-home STEM activities and shared their experiences with the research team.

Bridging Educational Landscapes – Out-of-School Learning in Biology and Its Complementarity with Formal Curricula

Nina Janßen[1] and Michael Ewig[2]
[1]Leuphana University Lueneburg, Germany
[2]University of Vechta, Germany

Out-of-school education is considered to play a major role in teaching biological content and the acquisition of corresponding competencies. Still, the educational goals of out- of-school learning settings and their complementarity to those of school-based biology learning are almost unidentified. This research project is concerned with identifying the educational objectives used by out-of-school learning environments. In a qualitative case study, the out-of-school learning environments of a national STEM-cluster (N = 34) were analysed regarding their educational objectives concerning biology education. These objectives were ascertained through guided interviews with staff members of the environments and through the systematic collection and analysis of the educational materials of the learning environments. In addition, the similarities and differences between these and the educational objectives of school-based biology learning were identified. For this purpose, the collected educational objectives of out-of-school learning were compared with the educational objectives described in the national educational standards in biology by content analysis. The results of this study indicate that a common ground already exist between school-based and out-of-school biology learning within the STEM-cluster, particularly in developing competencies related to 'content knowledge' and 'decision-making'. However, the study also reveals untapped potential for further integration of school-based and out-of-school learning environments, which could enrich the biological education.

Keywords: Out-of-School Learning; Competencies; Complementarity

Theoretical Background

From the perspective of biology education, out-of-school learning environments are associated with numerous characteristics that support learning biology: Children and young people learn in diverse places, through various activities, and in different (social) constellations. They experience a real, practical connection to the subject matter and learn in an activity-based, independent way (Sauerborn & Brühne, 2020). The development of networked thinking and learning through multiple sensory channels is also at the core of out-of-school learning environments (Sauerborn & Brühne, 2020). According to Sauerborn and Brühne (2020), these aspects contribute to the long-term retention of acquired skills. They also prevent diminishing interest in scientific topics: Numerous studies on the effectiveness of out-of-school learning environments have shown that they can positively influence motivation and interest in science (overview in Bell et al., 2009). However, in the public's perception, schools are at the center of education. This perspective is also reflected in the research landscape, where school-based learning is studied far more frequently than out-of-school learning environments and is often clearly separated from learning outside of school. However, Birmingham and Calabrese Barton (2014) outlined the lack of a clear distinction between school and out-of-school learning: learners constantly cross the boundaries between learning in the context of school and situations of learning experienced in everyday life or out-of-school contexts – regardless of the place they are in.

For this reason, the consensus on a sharp differentiation of learning sites is shifting to a discourse on learning in which the boundaries between formal and informal education and between different educational institutions are blurred (Dierking & Tal, 2014). Bell and colleagues (2009) postulate that most people build their understanding of science throughout their lives by gathering and

processing information from many places and contexts for a variety of reasons. Learning in general, and science learning in particular, according to this view, occurs over time through a person's countless experiences, including learning opportunities within the context of school or at out-of-school learning environments (Dierking & Tal, 2014).

Approaches to conceptualise school-based and out-of-school biology learning in a complementary way remain largely superficial (e.g., Favre & Metzger, 2019). This is partly due to the fact that the design of out-of-school learning environments often lacks a deliberate connection between the educational objectives of these environments and those of formal school-based learning, preventing the full potential of these visits from being realized (Eshach, 2007). Furthermore, the integration of both learning environments could be hindered by a lack of clarity regarding the educational goals of out-of-school learning environments, which – unlike school-based educational institutions – do not have curricular guidelines.

Key Objectives

Based on the state of research, this study aims at giving a frame for a common perspective of school-based and out-of-school biology learning. Therefore, the study focuses on the comparison of the educational objectives of school-based learning with the educational objectives of didactically designed out-of-school learning environments. Since out-of-school learning environments do not follow curricular guidelines, their educational goals must first be identified. For this purpose, out-of-school learning environments of a national STEM-cluster are examined. Only learning sites that stated to teach biological contents and competencies are included in the study. Through a content-analytical comparison of the surveyed out-of-school educational objectives with those of school-based biology learning, already existing correlations as well as 'white spots' regarding complementarity and thus opportunities for stronger interconnections can be identified. This comparison is made against the background of the following questions:

1. What are the similarities and differences between the educational objectives of out-of-school and school-based biology learning?
2. To what extent do possible differences result in synergistic potential in the sense of a stronger interconnection of the learning environments?

Research Design

In the region of the STEM-cluster, 34 out-of-school learning environments were identified that (among other things) aim to address biological competencies. They can be assigned to the learning environment categories defined by Möller and colleagues (2023) (see Table 1), i.e., the learning environments can be distinguished in various settings – from nature parks to organic farms to environmental education centres – where biological topics are addressed in an engaging and experiential way.

The educational goals of the learning environments were elicited through guided interviews (Helfferich, 2011) with one site staff each. The interviews included five guiding questions that focused on the framework, the content, and the educational objectives of the environments. Each guiding question was further divided into two to six sub-questions to gain deeper insights. To gain a comprehensive understanding of the educational objectives of the learning sites, the guiding questions were formulated as narrative prompts. The interview questions had been piloted in spring 2023. Data collection for the main study was conducted from April 2023 to July 2024. The N=34 interviews ranged in duration from 28 to 46 minutes. In addition to the interviews, a systematic screening of existing educational materials (e.g., exhibition materials)

from the out-of-school learning environments was conducted to further identify and analyse their educational objectives.

Table 1. Learning environment categories with corresponding sample sizes.

Categories of learning environments	Number of environments in the sample
Zoos/Wildlife Parks	3
Nature Parks/Gardens and Protected Areas	6
Museums	5
Environmental Education and Experience Centres	7
(Agricultural) Farms	10
Youth Centres or Clubs	3

The content analysis of the interviews and materials of the learning environments is based on the qualitative content analysis method according to Kuckartz and Rädiker (2023). Therefore, a deductive category system was established based on the educational objectives outlined in the national educational standards for school-based biology education (Sekretariat der KMK, 2005). These objectives are divided into four competence-areas: 'content knowledge', 'procedural and epistemic knowledge', 'communication and interaction' and 'decision-making', which also represent the main categories of the deductive category system. The educational goals of the out-of-school learning environments – those identified through interviews as well as those obtained through the systematic screening of educational materials – were classified within the deductive category system. Educational goals of the out-of-school learning environments that could not be assigned to the category system are included in the analysis as inductive categories. As a result, the deductive and inductive categories contain the educational goals of school-based and out-of-school learning in the region under study.

The similarities and differences between educational objectives of out-of-school and school-based learning can then be taken from the category system: Filled deductive categories indicate a pre-existing match of the two types of learning sites. Unfilled deductive categories and categories inductively generated from the material of the out-of-school learning environments show where the educational goals of both environments (so far) diverge. Against the backdrop of a common perspective, these differences will be discussed in terms of the potential for greater intertwining.

Findings

Results show that the educational objectives of school-based and out-of-school learning in the region predominantly overlap in terms of 'content knowledge' and 'decision-making' competencies. Regarding other competence-areas, the fit is less pronounced: the learning environments pursue different learning objectives, particularly when it comes to developing skills for acquiring 'procedural and epistemic knowledge'. Many out-of-school learning environments focus on original encounters and general experiences of nature, for example through criteria-based observation of living nature. These competencies are not pursued by the governmental educational standards of school-based learning. The competence-area 'communication' also

shows less overlap. This is due to the fact that only a small proportion of communication-related competencies of school-based biology learning and also a small proportion of own communication-related competencies are pursued by the out-of-school learning environments. This area of competence is underrepresented at out-of-school learning environments in the region studied. In addition to competencies that can be assigned to the competence-areas of biology learning at school, the out-of-school learning environments also address competencies that cannot be assigned to any of the competence-areas of school-based biology learning. These include

- taking responsibility for living organisms,
- establishing connections between biological phenomena and other (scientific) disciplines,
- perceiving biological phenomena with all senses,
- gaining a (practical) understanding of biological phenomena through learning in real-world contexts,
- articulating the relevance of biological phenomena for one's own personal life context, and
- developing environmental awareness and sensitivity.

These additional competencies therefore mark a further point of divergence from school-based biology learning.

Conclusion

At its core, this study challenges the dichotomy between school-based and out-of-school education and argues for a more integrated approach. The limited overlaps between school-based and out-of-school learning regarding the competence areas 'procedural and epistemic knowledge' and 'communication' open up potential for synergies, as different approaches to develop competencies can be combined.

Beyond these partially shared competence areas, the study highlights that out-of-school learning environments address a range of independent competencies that are not explicitly covered by the competence framework of school-based biology education. These competencies, which often emerge from experiential, context-based, and sensory-rich learning situations, represent an additional potential for synergy. Integrating such competencies into school-based learning processes could contribute to a broader understanding of biology education that extends beyond curricular knowledge acquisition and supports more holistic learning processes.

By recognizing and leveraging the multiple strengths of both school-based and especially out-of-school learning, educators can provide a more comprehensive and engaging educational experience. In doing so, they can foster a generation of learners who not only have a deep understanding of biological concepts but also develop a profound connection to the natural world. As we move forward, it is essential to recognize the similarities and differences and explore their potential for collaboration to shape a truly effective and impactful biology learning.

Equity, Diversity And Identity In Science Education

Co-editors: *Wonyong Park & Katerina Pia Günter*

Part 12 / Strand 12 Equity, Diversity And Identity In Science Education

Socio-political, sociocultural, multicultural, multilingual, multi-modal, intersectional, racial/ethnic, equity, critical, feminist, and gender studies, as well as special needs in science education. Proposals that include theories, methods, and practices related to ways-of-being and ways-of-knowing in science education and through an array of onto-epistemological perspectives, ideas, theoretical, and methodological approaches build on and perhaps exceed identity in inter-, multi- and transdisciplinary ways. Inviting critical examination of identities as multiple and situated in various systems of power and privilege to afford complex understandings of educational opportunities related to access and achievement.

Sub-themes:

1) Addressing Gender and Racial Equity in Science Education
2) Multicultural and Multilingual Approaches in Science Teaching
3) Inclusive Practices for Students with Special Needs in Science
4) Intersectionality and Identity in Science Education
5) Critical Pedagogy and Social Justice in Science Education

Strand 12: Equity, Diversity And Identity In Science Education

Katerina Pia Günter[1] and Wonyong Park[2]
[1]Umeå University, Sweden
[2]University of Southampton, UK

Equity, diversity and identity are central to science education, shaping who is recognized as a legitimate participant in science, whose knowledge is valued, and who can imagine scientific futures. Research on science identity, recognition and Science Capital shows that participation is mediated not only by attainment or interest, but also by social relations, institutional cultures and wider systemic inequalities (Archer et al., 2015; Carlone & Johnson, 2007; Hughes et al., 2021; Danielsson et al., 2023; Dou & Cian, 2022). At the same time, expanding work on science identities has highlighted the importance of recognizing the complex, dynamic and socially situated nature of identity formation across contexts and over time (MacLeod & Avraamidou, 2025), foregrounding how identities are continuously negotiated within educational systems and broader sociocultural structures. An identity-focused perspective therefore invites science educators in Europe and across the world to examine how curricula, pedagogies, assessments and learning environments can (re)produce exclusion, but also how they can open more just and meaningful forms of participation (Avraamidou, 2020).

The ESERA 2025 proceedings in Strand 12 (Equity, Diversity and Identity in Science Education) explore contemporary issues in science and STEM education across diverse contexts, disciplines, and educational levels. Covering Indigenous knowledge systems, STEM, physics, science education research, and teacher education, the works address learners from middle elementary to higher education, as well as pre-service teachers, in-service teachers, and teacher educators. Together, the proceedings highlight science education as a culturally and socially embedded practice and emphasize the need for inclusive, context sensitive approaches that connect learners' experiences with scientific knowledge. The works reflect a broad international scope across multiple continents, including authors affiliated with institutions in Europe with Austria (1), Denmark (1), Germany (7), Greece (1), the Netherlands (1), Spain (2), Switzerland (1), and the United Kingdom (1), Asia with Israel (1), Singapore (1), and Taiwan (1), North America with the United States (1), and South America with Brazil (4).

The contributions in this strand address science and STEM education through three closely connected perspectives: 1) STEM and science identity formation, 2) equity and intersectionality, and 3) sociocultural influences. Across the papers, identity emerges as a dynamic process shaped by subject experiences, gender, Science Capital, and broader epistemological positions, while persistent inequities highlight how access, participation, and belonging are unevenly distributed. Learning is shown to be deeply embedded in sociocultural contexts, including family practices, language use, and Indigenous knowledge systems, which often remain underrecognized in formal science and STEM education. These perspectives converge in a shared concern with transforming educational practices, as studies on inquiry and teaching highlight the need to move beyond deficit views and address systemic and structural barriers. Together, the three themes point to a common pattern: participation in science is co-constructed through the interplay of identity, culture, and educational structures, calling for more inclusive, context-sensitive approaches to science education. However, they also display the diversification of perspectives on Equity, Diversity and Identity in Science Education.

STEM/Science Identity Formation and Trajectories

These contributions collectively frame science and STEM identities as contextually situated, evolving and unevenly supported across educational settings. Rather than treating participation as a matter of stable preference or ability, they show how learners negotiate subject-specific identifications, broader STEM self-concepts, environmental orientations, digital practices, and ideas about science in relation to school biography, gender, Science Capital and cultural knowledge systems (Bochert et al., 574; Manassero-Mas & Vázquez-Alonso, 1601; Birner et al., 716; Lisa-Marie Christ et al., 659; Bub et al., 830). Across the submissions, identity formation appears as a dynamic process shaped by institutional structures and epistemic norms: students may move towards or away from physics, chemistry or STEM more broadly as they encounter particular classroom experiences, disciplinary images and recognition opportunities. Several papers also point to the need for more inclusive and longitudinal approaches, both methodologically and pedagogically, including validated identity measures, narrative and interview-based work, and decolonial models that challenge the marginalization of Indigenous knowledge in science education (Raupp & Vanuchi, 901).

Equity, Diversity, Inclusion, and Intersectionality

These contributions collectively examine how inequality and inclusion in science education are produced through intersecting social, institutional, spatial and epistemic conditions. Rather than treating disadvantage as a single-axis problem, they show how race, gender, class, geography, disability, sexuality, gender identity and Science Capital shape learners' participation, recognition and sense of belonging in STEM. Submissions highlight the need for more intersectional and context-sensitive analyses, including work on how inequality is represented in science education research, how teacher educators and pre-service teachers understand gender equality, and how students' STEM motivations differ across social and geographic contexts (Pontes Silva & Franco dos Santos, 84; García-Ruiz et al., 40; Duek et al., 512; Silva, Teixeira, & Santos, 474).

Across the studies, inclusion is framed not only as a matter of access, but as a question of embodied participation, institutional responsiveness and everyday classroom practice. Contributions on physical ability, open inquiry, transgender students' experiences, and trans trajectories in chemical engineering show that barriers often arise from taken-for-granted norms about bodies, methods, identities and belonging, rather than from learners' deficits (Müller et al., 551; Abels et al., 1749; Cordeiro Lopes Fonte & Mendes da Silva, 239; Marosi et al., 784). Others caution that ostensibly inclusive spaces, such as out-of-school STEM laboratories, may reproduce gendered hierarchies through implicit pedagogical assumptions and differential forms of address (Gross & Abels, 194). Taken together, these submissions suggest that meaningful inclusion requires coordinated work across curriculum, pedagogy, teacher education, institutional culture and policy, particularly because teachers may support inclusive principles while still feeling underprepared to enact them in practice (Pannullo et al., 1751).

Sociocultural and Community Influences on STEM Learning

These contributions foreground sociocultural, linguistic and familial resources as central to science learning, challenging narrow views of what counts as legitimate scientific knowledge and participation. Across multicultural, multilingual and family contexts, they show that learners' sense-making is shaped by culturally embedded classification practices, translanguaging and everyday experiences that often sit outside formal school science. Indigenous Tao learners' biological classifications, for example, combine increasing taxonomic precision with ecological and cultural knowledge, challenging deficit views of Indigenous learners (Ge et al., 617).

Similarly, translanguaging among English learners appears as a collaborative resource for scientific reasoning and meaning making rather than a barrier to instruction (Barron et al., 788). Family activities also generate rich forms of Science Capital, but these sensory and meaningful experiences are not always recognized by schools (Nielsen et al., 1428). Together, the submissions argue for science education that connects disciplinary learning with students' cultural, linguistic and everyday lives.

The contributions in this strand offer rich and multifaceted insights into science identity, equity, diversity, and in particular the sociocultural dimensions of learning. Further, they point directly and indirectly to areas that remain less developed within current research and/or its communication in the proceedings of ESERA Strand 12. Much of the work continues to focus on how learners navigate participation within existing structures of science education, while fewer contributions explicitly interrogate how those structures themselves define the boundaries of legitimate knowledge, identity, and participation. Questions of epistemic justice, whose knowledge systems shape science education, how scientific norms are historically and culturally constituted, and how dominant epistemologies might be re-imagined, remain comparatively invisible. While intersectional and sociocultural perspectives are increasingly present, there are potentials and openings to more fully engage with science education as part of broader socio-political and historical formations, including colonial and global knowledge hierarchies that continue to shape what counts as science. Moving forward, we suggest the value of expanding science identity research beyond questions of access and recognition towards inquiries that also consider transformation and possible futures: not only how diverse learners come to see themselves as scientists, but how science education itself might be reconfigured when multiple ways of knowing, being, and valuing are taken as constitutive rather than supplementary, transgressing narrow and often deficit-oriented and neoliberal ideas of equity and diversity towards collaborative, collective, and community-oriented social and environmental justice.

In the changing world in which we find ourselves, there is a need to form a citizenry with a background in STEM (Science, Technology, Engineering, and Mathematics) related areas, who develop skills and competencies needed to make reasoned, well-founded decisions about problems that have not yet arisen. However, despite the emphasis on promoting curricular integrated STEM education, a gender gap persists, with women underrepresented in STEM fields. This imbalance, which has significant implications for equity and progress, limits innovation and social development, perpetuates labour inequality, and generates biased technological solutions by excluding diverse perspectives, resulting in less female representation that hinders equity and progress. It begins to manifest itself in Early Childhood Education, being therefore essential to prepare teachers at different educational levels in this regard, by understanding their initial perceptions of teaching science and technology from a gender perspective and delving into the stereotypes they hold based on their previous experiences. Consequently, this study describes the validation by experts of a structured questionnaire designed to examine teacher trainers' and pre-service teachers' perceptions concerning promoting gender equality in STEM areas. The validation was carried out through a panel of experts in science education, guaranteeing the relevance and reliability of the instrument, composed of 15 items distributed in four main categories related to perception and awareness of gender equality in STEM, practices and initiatives for the promotion of equity, identification and impact of female references in STEM and experiences and improvement proposals. Implementing the validated questionnaire will contribute to understanding current practices in STEM education, providing a comprehensive view of how teachers address the gender perspective in their teaching, their knowledge of leading women in the field, and the strategies they consider to promote gender equality.

Keywords: Pre-service teachers, Gender Awareness, STEM education

Theoretical Framework

International organisations have increasingly prioritised educational equity within STEM (Science, Technology, Engineering and Mathematics) disciplines, with gender-responsive pedagogy emerging as a critical policy concern (European Commission, 2020; OECD, 2022), aiming to deconstruct gender-normative assumptions in developing inclusive STEM education systems. However, there is a persistent STEM gender-bias strongly influenced by internalised gender stereotypes, social expectations, and a lack of scientific references (Hughes et al., 2020), that culminates in an imbalance in shaping professional trajectories, with overrepresentation of women in health-related and well-being areas, as opposed to underrepresentation in the STEM areas (World Economic Forum, 2023).

Research has continuously demonstrated that such disparity originates from the early stages of compulsory education (Brussino and McBrient, 2022), with female students developing a gender-based self-perception and competency-related doubts that affect their motivation, expectations,

intellectual aptitudes, and ultimately, their education and professional career choices towards strong social orientation careers (Cimpian et al., 2020; Evagorou et al., 2024).

Within this scenario, schools and educational actors emerged as key agents in the socialisation process of youth, developing an active role in disrupting gender stereotypes reproduction, as defined within the objectives of the STEM Alliance for Female Talent (Grañeras et al., 2022), which proposes goals such as making women visible in scientific-technological fields. This emphasis on the school's role should make educators, researchers, and policymakers feel the importance of their work in challenging gender stereotypes (Brussino and McBrient, 2022).

Multiple publications demonstrate that exposure to inspiring role models is crucial for fostering student commitment to STEM disciplines, an effect that is especially pronounced among women exposed to role models of the same gender. However, this representation is far from being adequately gender inclusive (González-Pérez et al. 2020). The need for more gender-inclusive role models is urgent, and it is crucial that pre-service teachers develop an adequate understanding of science and technology to challenge the stereotypes that persist in curricula and within the teaching community.

Aims And Research Questions

Considering the relevance of the exposure to women role models in STEM fields throughout the different education stages, we understand that it is necessary to research and analyse the perception that pre-service teachers and their teacher trainers of the degrees of Early Childhood Education, Primary Education and the scientific-technical specialities of the Master in Education have about the visibility of women in STEM areas. We hypothesise that the teacher's reflection on the gender gap in STEM areas will increase knowledge across all educational strata, fostering a concept of inclusive science, and an appreciation of female talent from an early age. Consequently, we aimed to design a questionnaire to address the following research question:

- How do we design and validate an instrument that evaluates teacher trainers' and pre-service teachers' perceptions and practices about promoting gender equality in STEM disciplines?

Methodology

Questionnaire Design

We designed the WOUMAP questionnaire following a thorough review of the relevant literature and discussions with the co-authors of this research. The first draft consisted of 15 items, which combined open-ended and 5-point Likert-type scale questions. The items were organised into four main categories: perception and awareness of gender equality in STEM (items I1, I2, I4 and I9), practices and initiatives for the promotion of equity (items I5-I9), identification and impact of female references in STEM (items I10-I15) and experiences and improvement proposals (items I3 and I11). Given our target participants, we elaborated two equivalent versions of the questionnaire, one for teacher trainers and another for pre-service teachers.

Validation Process

We proceeded with instrument validation using a digital form in *Google Forms*. Since participation in the validation process required the identification of experts, thereby implying the processing of personal data, we followed the guidelines on the Protection of Personal Data and Guarantee of Digital Rights and obtained with the approval of the Ethics Committee of the University of Málaga (reference no. 96-2023-H).

The form briefly introduced the objectives and context of the research, establishing the guidelines for completing the review. The first block included some demographic questions to characterise the expert. Next, the second block presented the 15 items, along with an explanation of the associated research objective. For review, we asked the panel to indicate the degree of adequacy of each item to the corresponding objective on a four-point Likert-type scale (1: very low, 2: low, 3: high and 4: very high), as well as the justification of the item's degree of adequacy chosen and possible comments and suggestions for improvement to the item.

Data Analysis

We carried out the analysis in accordance with the nature of the data collected with the validation questionnaire. Hence, we used the R-based software JAMOVI (version 2.3.21) to analyse the quantitative data, examining the distribution of scores for each question and providing the frequency percentages, the mean (*M*) and standard deviation (*SD*) as interpretive values. We also calculated the Content Validity Index (CVI) for each item (I-CVI) and for the scale as a whole (S-CVI), as well as the exact binomial test (*p*), which represents the probability of obtaining the observed level of agreement or higher by chance. The I-CVI was calculated as the number of experts who gave a rating with a high degree of agreement (values of 3 and 4 on the 4-point Likert scale) divided by the total number of panel members, considering acceptable values equal or greater than 0.80 and as statistically significant results, coefficient p values less than 0.05. The S-CVI was calculated as the average, calculated as the sum of all the I-CVI of the scale divided by the number of items (S-CVI/Ave), with a threshold of 0.90 or higher being considered excellent.

At the same time, we assessed the consistency and reliability of the ratings given by each evaluator on the panel by calculating the Fleiss' *kappa* statistic, which analyses the agreement between the evaluations of the different people on the panel and, unlike the CVI, considers the agreement that is produced by chance (Fleiss et al., 2003). As in the calculation of the CVI, given that the interest was in distinguishing between the degree of general agreement and disagreement, the analysis was simplified by dichotomising the data, treating values of 3 and 4 as "agreement" and values of 1 and 2 as "disagreement".

On the other hand, the comments recorded as qualitative data were pooled for evaluation of modifications or deletions to the valued item.

Findings

The S-CVI/Ave for the entire questionnaire was 0.94 in the teacher trainers' version. The I-CVI scores ranged from 0.78 to 1.00 (Table 1). Except for I2, the I-CVI scores ranged between 0.89 and 1.00 (Table 1), and 8 of the 15 items reached the maximum level, with statistically significant *p*-values in all cases ($p < 0.05$). Item I2, which had the lowest threshold (0.78), was carefully reviewed, modified, or eliminated in accordance with the panel's comments. In addition, the Fleiss' *kappa* statistic was calculated, obtaining a value of $K = 0.89$ (standard error = 0.04, 95% CI = 0.82 - 0.96, $p < 0.01$), which represents a degree of substantial agreement of the instrument (values between 0.81 and 1.00) (Fleiss et al., 2003). We observed similar results for the pre-service teachers' version, with an S-CVI/Ave of 0.95 and the same I-CVI scores distribution. Only item I3 presented an unacceptable value (0.78), which was also reviewed. Fleiss' *kappa* statistic value was $K = 0.91$ (standard error = 0.08, 95% CI = 0.75 – 1.00, $p < 0.01$).

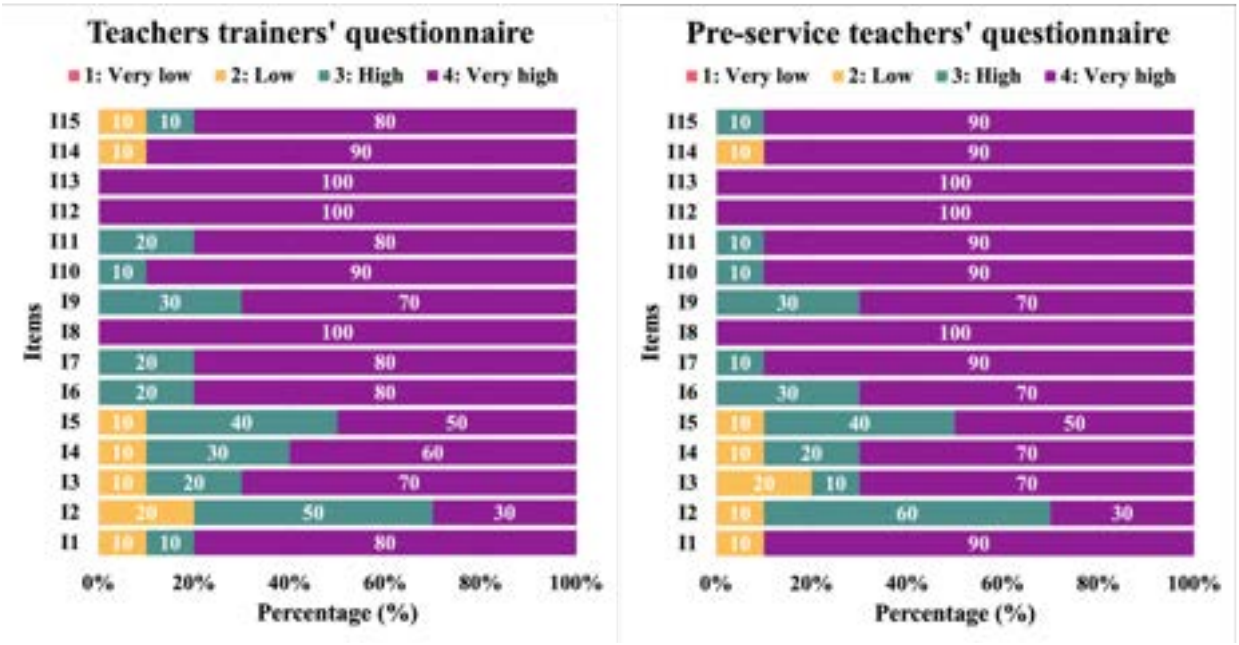

Figure 1 shows the results of the percentage of frequency obtained for items I1-I15 on teacher trainers' and pre-service teachers' versions. We observed a favourable assessment in all cases, with the sum of "high" and "very high" percentages exceeding 80% and mean values above 3.1 across all items. As indicated, I2 and I3 in the teachers' and students' questionnaires, respectively, which had the lowest mean and I-CVI values, were revised based on the qualitative assessment.

Table 1. Code, Content Validity Index (I-CVI), Mean (M), and Standard Deviation (SD) for each Item.

	Teacher trainers' version				Pre-service teachers' version			
Item	**I-VCI**	***p***	***M***	***SD***	**I-VCI**	***p***	***M***	***SD***

I-CVI: Item content validity index; *p:* exact binomial test

Figure 1. Results of the Quantitative Validation on the Items I1-I15 for Teacher Trainers' and Pre-service Teachers' Questionnaire.

Thus, the final validated questionnaire consisted of 15 items, including questions on a 5-point Likert scale and open-ended responses, with summarised and general statements for the teacher trainers' and pre-service teachers' versions shown in Figure 2.

Conclusions And Implications

This work presents an *ad hoc* research instrument designed for teacher trainers and pre-service teachers in Early Childhood Education, Primary Education, and the scientific-technical areas of Secondary Education. The WOUMAP questionnaire would allow us to investigate these teachers' perceptions about the visibility of women in STEM areas and the gender gap they identify in their teaching practice.

Figure 2. Simplified Statements of the WOUMAP Questionnaire Items.

PERCEPTION AND AWARENESS OF GENDER EQUALITY IN STEM	EXPERIENCES AND IMPROVEMENT PROPOSALS
I1. To what extent do you think there are stereotypes and barriers that can hinder the interest of students in STEM careers (related to science, technology, engineering and mathematics? What do you consider those stereotypes and barriers to be? **I2.** To what degree do you think dedication to a career in STEM areas is compatible with personal balance and/or familiar balance? **I4.** To what degree do you consider that the gender perspective is adequately represented in the training of STEM areas? **I9.** To what extent do you think women are adequately represented in STEM fields?	**I3.** Could you describe if you have experienced support, empowerment or an increase in confidence during your development in teaching-learning in STEM areas? If so, what has this support been like, from whom, and how do you think it can or has had an impact on your professional career? **I11.** What actions or changes would you propose to increase the presence and visibility of leading women in STEM education?
PRACTICES AND INITIATIVE FOR THE PROMOTION OF EQUITY	**FEMALE REFERENCES IN STEM: IDENTIFICATION AND IMPACT**
I5. In the subjects of the degree or master's degree that you are teaching/ studying, to what degree is a gender perspective incorporated or is gender equality explicitly promoted in the teaching of STEM subjects? **I6.** In the subjects of the degree or master's degree that you teach/study what type of activities are carried out to promote the visibility of women in STEM disciplines (Activities aimed at emphasizing the achievements of women in my area/Mentoring programs/Inclusive curriculum/Others) **I7.** What type of initiatives or programs aimed at promoting the visibility of women in STEM disciplines do you know of? **I8.** Indicate how frequently the following actions are shown or discussed in the subjects of the degree or master's degree that you teach/study: • Science/Engineering as a human product built jointly by men and women • Poor representation of women in science/engineering • Current and relevant women close to science/engineering • Contributions from women relevant to science/engineering • Social and personal context of women relevant to science/engineering • Scientists/engineers invited to give a talk on the subject • Reflection that it is not necessary to have extraordinary abilities to dedicate yourself to science/engineering • Physical and geographic diversity of people who do science/engineering	**I10.** Could you mention three qualities or characteristics that you consider essential for a female scientist and/or engineer to become a reference or role model in these disciplines? **I12.** Make a list of three women scientists or engineers you know, identifying any particular discovery or contribution to their field. **I13.** How did you find out about these three women? **I14.** To what extent has knowledge about any of the women you have referenced influenced your interest in STEM areas? **I15.** Describe how that influence has been on your professional career.

After a rigorous validation process by a panel of experts in Science Education, statistics were calculated to assess the validity of the content (CVI) and the agreement among the panel's evaluations (Fleiss' *kappa*), yielding satisfactory results in both cases. These results, supported by the analysis of the qualitative responses provided by the evaluators concerning each item analysed, have generated a final questionnaire comprised of 15 items of combined typology (Likert scale and open response), offering an efficient tool to deepen the vision and commitment that teacher trainers and pre-service teachers have with respect to the practice of inclusive teaching, and thus being able to identify successful strategies for addressing the gender perspective at all levels of education.

The Debate on the Race-Gender-Class Triad at The Main Science Education Research Event in Brazil, from 1997 to 2023

Carolina Pontes Silva[1,2] and Paulo Gabriel Franco dos Santos[2]
[1]Secretaria de Estado de Educação do Distrito Federal (SEEDF), Brazil
[2]Universidade de Brasília (UnB), Brazil

The history of science education in Brazil is permeated by domination and exploitation based on class, race, and gender. Thus, aiming to present an analysis of how the race-gender-class triad has been debated in science education in Brazil, we conducted a text search in the proceedings of the main science education research event in the country, the National Science Education Meeting (ENPEC), and analysed the theoretical frameworks underlying the articulation between these three categories in the works found. The debate involving race-gender-class in this field of research still treats the elements of this triad separately, as if they were independent of one another and not as part of the Brazilian socio-historical structure. This result reveals a deficiency in the way the Brazilian context of science education is treated in academia, an issue that must be overcome so that we can develop a fully emancipatory science education.

Keywords: race, gender, social justice

Introduction

Comprehending the historical development of science education in Brazil must involve understanding racism, class struggle and gender issues in the country, which permeate the entire history of Latin America. That is because it was the unit colonialism-capitalism-racism that structured all the development of Brazilian society (Santos, 2024), including science education. As Delizoicov (2004) points out, it is necessary to do the "historical recovery of science teaching" (p. 148) in Brazil, in a broad and multidisciplinary way.

Before entering science education history, it is important to remember the racist history of science, which used its social prestige to justify the inferiorisation and exploitation of black people, through craniology and phrenology, for example (Santos, 2024). Science, as a social product, has also been utilized to discriminate against women and, in some areas, still presents sexist views of the "feminine", associating it with hysteria, weakness and inability to use logic and reason, as it was in the beginning of hysteria history (Schmitz, 2021).

According to Santos and Galletti (2023), science education in Brazil began in the 16th century with Jesuit education developed from a scholastic perspective with the purpose of catechizing, indoctrinating and acculturating the native peoples of the "New World". In the 19th century, intending to educate the bourgeoisie children of the Brazilian landowning oligarchy, scientific education gained new nuances and a place of importance (Santos & Galletti, 2023). However, it was only from 1950 onwards, following a global trend, that scientific education became institutionalized and was officially included in the country's educational legislation, albeit of a professionalizing nature, seeking to respond to historical demands for industrialization and the enhancement of study and research centers (Santos & Galletti, 2023). Since the 1970s, during the military dictatorship in Brazil, questions about the neutrality of science, technological determinism, and scientific production risks arose and discussions have included not only what or how to teach, but also the subjects (who) and the purposes (for what). In this sense, since the political reopening and the efforts of organized political movements, issues of class, race, and gender have occupied the research and practice agenda in science education.

Thus, this paper's objective is to present an analysis of how the race-gender-class triad has been debated in science education in Brazil. We intend to answer the following question: how has the debate on the race-gender-class triad been treated in the field of science education in Brazil? We hope the answer can help us identify how these three categories are present in this area of education, how they are articulated, and how they indicate paths for developing a fully emancipatory education.

Theoretical Frame Of Reference

Considering that Brazilian science education was developed based on a society that excludes people who do not fit the universal subject model, the white man (Souza, 2020), it is necessary to understand the categories of race, class and gender as a unit in science education research. Addressing this triad requires a complex analysis, which comprehends the implications of these three elements together and, in this case, within the specificities of the concrete Brazilian reality. According to Kosik (1976), concrete reality takes in consideration what is beyond appearance, beyond the superficial and the immediate, a reality dependent on its socio-historical processes.

The dissociation of the three categories is reflected in science teaching, from the incipient representation of black women as members of the scientific class in textbooks (Silvério & Verrangia, 2021; Skumra et al., 2020) to the apparent difficulty (or resistance) that science teachers might have in complying with current educational legislation, including the teaching of Afro-Brazilian and Indigenous history and culture (*Lei [Law] 10.639*, 2003; *Lei [Law] 11.645*, 2008) in their pedagogical activities.

In this sense, we turn to Lélia Gonzalez (1984), who, when dealing with race, class and gender in Brazil, uses the dialectic between consciousness and memory. For the author, making a social analysis based solely on the class struggle, excluding gender and race, is the same as insisting on forgetting these categories and it is the same as denying the subject condition to black women.

It is important to mention that, differently from other perspectives that seek to establish intersections based on identity or other individual and group experiences in a society marked by different types of violence, Gonzalez (2020) articulates race, gender and class based on the social division of labor. A prominent intellectual during an internationalist period of the Brazilian Black Movement and with socialist interlocutors (Domingues, 2024), Gonzalez understands that the classic division of labor, broadly discussed in Marxist tradition, reproduces itself in the Latin-American and Caribbean context as a racial and gendered division of labor. From the centrality of the work category, the education role for the hegemonic reproduction of the productive model is questioned. Thus, the question remains: what is the education for the Brazilian working class constrained by dependency (Bambirra, 2013), by racism (Moura, 1983) and by misogyny (González, 2020; Saffioti, 1978)? Or, as Santos (2024) states, “what is the scientific education for the Brazilian working class today, considering its contradictions and the historicity of its material conformation, in a way of: potentializing the working class resistant forms, organizations and intellectuality; guaranteeing the solid general basic education in attention to the historical and contextual particularities of black people; adjusting itself to the objective contexts of the margins, peripheries and neglected peoples” (p. 12).

The memory erasure that Gonzalez (1984) refers to, also called *memoricide*, demeans non-white people and denies the influence of gender on social inequalities (Costa, 2005), contributing to the reaffirmation of the white man as a universal subject (Souza, 2020). Another author, Nancy Fraser (1997), would categorize these social inequalities as cultural injustice, which must be corrected by recognition policies. A second category of inequalities created by Fraser (1997) is socioeconomic injustice, which must be corrected by redistribution policies. Fraser (1997) also

admits reconciling these two types of policies – recognition and distribution – might be challenging, considering that sometimes they seem to represent opposite interests: individuality and community, respectively. Thus, initiatives that involve these two kinds of policies such as i) the publication of *Lei [Law] 10.639* (2003), which includes in the official curriculum of the Brazilian Education Network the mandatory teaching of the theme "Afro-Brazilian History and Culture"; ii) government actions and the strengthening of public policies for women (Ministério das Mulheres [Ministry of Women], 2023), as a result of the articulations of feminist movements (Costa, 2005), present themselves as a reaction to this memoricide.

Hence, assuming race-gender-class as a thematic and political unit in science teaching can contribute to critical scientific education, adapted to the concrete Brazilian reality. It was from this scenario that we conducted the research described in the following section and proposed an analysis of how the field of science education has conducted the debate on the race-gender-class triad.

In this perspective, we highlight some practical and epistemological consequences arising from the adoption of this unity within the context of science education:

- Recognition of the inseparability of race, gender, education and work categories in the historical processes analysis, safeguarded the particularities and contradictions (unity in diversity), promoting the inclusion/exclusion of scientific and historical themes, debates and contents, thus producing conditions for thematization and problematization of the reality engaged in the anti-racist and anti-sexist struggles, and in the class struggle itself.
- Search for unifying or overcoming exclusive or profoundly particularized approaches, in order to broaden the perception of phenomena and of reality itself, focused on reading society's historical and concrete movement and its effects in the scope of natural sciences production and education.
- Highlight the potential of educational processes, especially, of natural sciences education, in undertaking emancipatory projects with analytic, critical and interruption-transformation capacity.
- All the elements dialectally link themselves to the political dimension of science education which highlights and assumes the historical disputes in terms of contents, methods and axiological aspects of the educational phenomenon.

Methodology

To answer the question posed in the introduction section (how has the debate on the race-gender-class triad been treated in the field of science education in Brazil?), we conducted a text search in all available[1] proceedings of the National Meeting of Research in Science Education (Encontro Nacional de Pesquisa em Educação em Ciências - ENPEC), since 1997, totaling 13 editions. The search terms were: "race" ["*raça*"], "rac", "ethn" ["*etn*"], "negr", "class" ["*classe*"], "gender" ["*gênero*"], "sex"[2]. The papers that presented a connection with at least one of the elements of the aforementioned triad, expressed in their title, abstract and/or keywords[3], were counted in table 1 below.

[1] The proceedings of the II ENPEC, from 1999, were not available on the website https://abrapec.com/enpec-edicoes-anteriores/ and it was not possible to obtain them until the conclusion of this work.

[2] The word search was in Portuguese, because this is the main language at Enpec's proceedings. Also, incomplete words were used to encompass similar terms and those that were not related to the research were excluded.

[3] In most of the available proceedings, it was only possible to use the search tool considering the title of the papers. In these cases, we did not count the search terms that may appear in the abstracts and keywords.

Analysis and Discussion

Table 1 shows that, until the eighth event (2011), there were at most two papers that addressed race or class in their titles. A similar situation occurred with the gender category, but until the seventh event (2009). The number of papers with the race category in the title soared from 1 in 2011 to 5 in 2013. This increase may be related to the spirit of the times, since in the previous year, 2012, *Lei [Law] 12.711* (2012) was enacted, establishing the reservation of places in federal higher education institutions, such as universities, for students from public schools, as well as for black, brown and indigenous people.

Table 1. Number of ENPEC works that mention race, class and/or gender.

ENPEC edition	Race	Class	Gender	Triad
1997	0	1	0	0
1999	-	-	-	-
2001	1	0	1	0
2003	0	0	0	0
2005	2	2	3	1
2007	2	0	3	0
2009	0	1	2	0
2011	1	1	7	0
2013	5	0	13	0
2015	5	1	8	0
2017	6	1	15	0
2019	11	0	30	0
2021	6	0	14	0
2023	15	0	19	0

Subsequently, we read the only paper that presented the three elements (Cabral & Bazzo, 2005) to analyse how this debate was carried out.

The gender category, despite having oscillated in the number of appearances at each event, has maintained its constant presence since 2005. What is noteworthy is that this category has always been more present in ENPEC proceedings than the other two. Although we observed papers that mentioned race and gender, in our textual search, only one cited the three categories – race, gender and class – in its abstract. A possible issue in our research design, that we identified *a posteriori*, was not including search terms as "afr*", "woman*" or "women*" [*mulher**], "girl*" ["*menina**"] and others that, even in a peripheral way, could present an articulated debate involving gender.

This paper (Cabral & Bazzo, 2005), despite considering the race-gender-class triad, does not actually address it. In the introduction section, the authors present statistical data on the gender of researchers in different areas of science and technology (ST) to characterize the background of the investigated group:

> In the field of science and technology education, I conduct a qualitative investigation of socio-historical and epistemological aspects of a group of female professors and

> researchers in engineering and computer science at the Technological Center of the Federal University of Santa Catarina [*Centro Tecnológico da Universidade Federal de Santa Catarina*] (CTC-UFSC). Their accounts, collected as life stories, have revealed a trajectory often marked by inequalities and discrimination in the academic field in which they work, the adoption of strategies to overcome these hostilities, and the work efforts made beyond the efforts of their male colleagues (CABRAL, 2005).
>
> A greater presence of women in this area – I suggest in my work – is strengthened by transformations that involve awareness-raising processes, towards a critical awareness of scientific and technological practice and of gender.
>
> ...
>
> At CTC-UFSC, the average number of female professors and/or researchers is only 15%. Life stories of the investigated group confirm the existence of discrimination and micro-inequalities in the area, requiring them, among other strategies, an "extra effort" in attitude and work, and the delay or renunciation of personal desires. At times distanced/drifted away from research, they shift their interests solely to teaching.[4] (Cabral & Bazzo, 2005, pp. 2-3)

However, there is no mention of ethnic-racial data of researchers, which could contribute to a more qualified discussion about gender and race in the analysed field. As in relation to class, there is no consideration about its implications in work activities in ST, for example. Race and class are mentioned in the abstract referring to the non-neutrality of ST: "The science and technology way under de neutrality myth repelled gender issues, as well as race and social class, for example." (Cabral & Bazzo, 2005, p. 1). Along the paper, the authors write about class to explain the non-neutrality of ST, but there is no in-depth discussion.

> Cerezo and Luján (2001), when discussing the need for a new social contract for science, state that this challenge requires consideration of the cultural, ethical-political, economic, and academic dimensions, as well as the risks with which societies coexist.
>
> According to these authors, these risks would be associated with the "universalization of technology and its negative consequences for the abolition of national, social class, or generational barriers" (Ibid., 2001). In contemporary society, both goods and risks would be distributed – it would be a "society of risk". (Cabral & Bazzo, 2005, p. 3)

As in relation to race, it only appears again in a quote of another author, along with gender, also referring to the non-neutrality of ST. There is a predominance of the gender category and almost no articulation of it with the other two categories, they are not addressed as a triad. Beyond identifying representations, presences or absences of gender, race and class, the main issue we identify is the lack of an articulated analysis of how these dimensions are fundamental to read Brazil's historical problems, along with dependencies, territory and imperialism issues.

In general, although there is acknowledgement of the historical predominance of white men in the field of science to the detriment of black and indigenous people and women in general (Conselho Nacional de Desenvolvimento Científico e Tecnológico [CNPq], 2024), especially in studies on ethnic-racial relations and gender issues, little importance is given to the connection between race, gender and class in science education research. This scenario indicates that the view of white men as universal subjects and the limited space for black and indigenous people, especially women, still exert great influence in the field of science education.

[4] Translated from the original text in Portuguese.

Although socially relevant topics such as race and gender are present in science education research, the lack of articulation between them both and class may indicate a difficulty in recognizing that racism, sexism, and class exploitation are part of the same social structure in which science education is inserted. Finally, resistance to the class debate may be related to the elitist, historically based nature that still permeates science education and academia, neglecting historical research and the deeper problems of our society that require investigative shifts from the micro to the macro and vice versa.

It is worth mentioning a Brazilian author who theorizes about class and race, Clóvis Moura (1983), and states that these two categories are connected dialectically, as components of a productive unity: race and class orient work relations in Brazil (as well as in other countries with a history stained by slavery and segregation based on race). Thus, addressing class and race separately is a way of turning concrete reality invisible. Addressing class-race-gender issues more deeply is important to promote justice in science education, because this way, we can propose remedies, proper to our field, for both socioeconomic and cultural injustices that affect our students and the whole community. As Fraser (1997) states, there is a difficulty in connecting recognition to redistribution, but if we invest in one (often recognition) without the other (often redistribution), injustice will persist.

Conclusion

Affirmative action policies established in legislations such as *Lei 10,639* (2003), *Lei 11,645* (2008) and *Lei 12,711* (2012), as well as government initiatives in gender area, were and are important for the development of an emancipatory scientific education. However, the discussion of the race-gender-class triad, necessary for overcoming social inequalities, is still timid in the field of science education research.

The low number of papers addressing this triad at the main science education research event in Brazil demonstrates a significant gap in academic production and social appreciation of this topic by the community that thinks about science teaching in the country, which struggles with so many inequalities, including both cultural and socioeconomic injustices. Therefore, the results of this research point to the need for studies that address the concrete problems of this field, with the aim of promoting contextualized scientific knowledge, that thinks about scientific practice and questions the history of science, especially in Brazil.

If we want to develop a truly equitable science education, we must first acknowledge its racist, sexist and class-based history. The necessary communication between education, sociology and economic politics poses a challenge to science education researchers, a challenge we have decided to accept and we expect other researchers to do the same. Understanding the constant contradictions in the development of our field of work and study, we can overcome them through other proposals, truly emancipatory, developing policies of recognition and redistribution specific for science education.

Addressing Girls In Out-Of-School STEM Labs

Janne Gross and Simone Abels
Leuphana University Lueneburg, Germany

Out-of-school labs have been implemented to inspire and inform youth about STEM, to broaden participation, and to counteract the growing lack of STEM professionals. Despite their potential to address persistent inequities in STEM, recent research has shown that pedagogical approaches rather maintain than reduce gendered hierarchies. How girls are addressed in STEM partly depends on the educators and their workshop-related actions, which is affected by their teaching expertise and personal characteristics, such as related values, implicit beliefs or orientations. This study was conducted in cooperation with an out-of-school lab in northern Germany, that faces a decreasing number of girls attending workshops in their spare time. This challenge has led to the following research question: How are girls (not) addressed by the out-of-school STEM lab educators? To answer this question, episodic interviews with N=7 staff members were conducted to gain insights into impressions, experiences and observations during their workshop-related actions. To reconstruct the educators' (possible) gender-related orientations, which result in their workshop-related actions, five interviews were analysed so far using Documentary Method. Relevant topics emerge from the formulating interpretation: organisational design of the workshops, girls' and boys' behaviour and the educators' expertise. Through the reflective interpretation, different reconstructed modi operandi as narrated practices of action could be assigned to three areas: standardisation of a male-connoted STEM culture, gender-differentiated workshop-actions and attribution. By giving an in-depth insight into several orientations about girls in STEM behind the modi operandi, this study outlines the need for out-of-school research being redirected to the role of educators and their gender beliefs.

Keywords: Out-of-School Learning Environments, Science Education, Gender Issues

Theoretical Background

For years, STEM subjects have been accused of gender blindness and structures that continue promoting gender stereotypical education and career choices (Onnen, 2015; Stich, 2024). Traditional gender roles, stereotypes or the lack of role models can be identified as barriers for young women to pursue a career in STEM (European Commission, 2024). The variety of out-of-school STEM labs have the potential to overcome these barriers by making STEM subjects experienceable in an environment without traditional gender role models and the pressure to perform (Baar & Schönknecht, 2018). However, pedagogical approaches, which were originally implemented to provide access to STEM education *for all*, rather maintain than reduce gender-specific hierarchies (Archer et al., 2021).

Within the context of out-of-school STEM learning, researchers have strongly focused on the need to change young people's motivation, identity, or interest regarding STEM through lab interventions (Archer et al., 2021). However, recent findings have shown that research should rather focus on changing the (teaching) offers instead of learners to fulfil its potential for widening participation as well as disrupting gender hierarchies in STEM (Archer et al., 2021; Rodéhn, 2019; Silfver, 2018).

Numerous studies have shown that schoolteachers' performance is partly influenced by their explicit knowledge, pedagogical orientations and subjective values (Elsen, 2020; Hand et al., 2017; Helmke, 2017). This includes implicit knowledge, such as gender-related orientation patterns, which are reflected in their teaching actions, including body language, facial expressions or voice (Elsen, 2020). While there is a broad database on teachers' gender-stereotypical influence in schools (overview in Elsen, 2020), there are hardly results available about educators

in STEM learning contexts outside school (Archer et al., 2021; Rodéhn, 2019; Silfver, 2018). Especially in labs without a link to an educational institution, educators hold a wide range of credentials from formal teaching certificates to no educational practice (Tran, 2008). Research-based findings and developments from the school sector can therefore not simply be transferred here. In addition, it is questionable whether the educators are experienced or qualified in dealing with gender in STEM at all. Hence, it is "necessary to start exploring issues pertaining to educators [and] (…) their understanding of gender" (Rodéhn 2019, p. 163f).

Aim Of The Study

Current research findings show the necessity of adapting the offer on site to promote the participation of young people in STEM and to reduce gender hierarchies (Archer et al., 2021; Rodéhn, 2019; Silfver, 2018). Educators' implicit orientations in out-of-school STEM labs are crucial, because they shape their workshop-related actions. Aiming to investigate educators' implicit orientations about girls in STEM, this exploratory case study was conducted in cooperation with an out-of-school STEM lab in northern Germany without a connection to an educational institution. According to the educators, the number of girls participating in workshops in their spare time is steadily decreasing. This background leads to the following research question:

How are girls (not) addressed by out-of-school STEM lab educators?

Note: Although a gradual opening towards gender diversity in STEM can be observed, research results are still based on a binary gender perspective. These circumstances as well as the fact that the interviewees commonly referred to girls and boys as dichotomous gender characteristics lead to classifying results according to a binary gender definition, which does not represent the perspective of the authors.

Design & Methods

To answer the research question, episodic interviews (Flick, 2000) with full-time educators (N=5) and the management (N=2) in an out-of-school STEM lab were conducted. In contrast to narrative interviews, episodic interviews are characterised by the combination of two methodological approaches: narration and questioning (Flick, 2000, 2011). Accordingly, information about the educators' implicit orientations on girls in STEM are collected through narrative prompts regarding workshop-related situations as well as (feedback) questions based on the narratives that aim for subjective explanations, argumentations or definitions (Flick, 2000, 2011). Beyond obtaining this qualitative data, that method-internal triangulation is suitable for reducing the social desirability bias, which has an influence on responses referring to sensitive topic of "gender" (Wolter, 2022). The educators' professional qualifications differ widely (e.g., apprenticeship in carpentry, a degree in mechanical engineering with a specialisation in aerospace engineering or a doctorate in geology). Among the educators and the management, four people identified themselves as female, two as male and one as human. At the time of data collection, the interviewees were between 27 and 74 years old.

The episodic interviews were analysed by using Documentary Method according to Nohl (2010, 2017). This reconstructive analysing method is particularly suitable for gaining a profound insight into implicit, possibly gender related orientations, as the analysis focuses not only on the narrated practice of action (modi operandi), but also on how it was said as well as its context (Nohl, 2017; Rabe et al., 2023). For this purpose, the Documentary Method involves three core analytical steps: In the formulating interpretation, sections relevant to the research question are identified, thereby capturing the explicit content level of what was said in terms of topics. In the subsequent reflecting interpretation, underlying orientations about girls in STEM are elaborated behind the

narrated practice of action (Nohl, 2017). The third core element, the comparative sequence analysis, enables the contrast of relevant interview sections within and across cases to identify internal linguistic and/or (workshop-related) action logics or breaks. Regularly participating in research- and interpretation-colloquia serve to ensure the scientific quality of one's own interpretation and to continuously reflect on one's own location-boundness (Rabe et al., 2023).

Insight Into Preliminary Results

The analysis of five interviews, including the core steps described above, has been fully completed. The following relevant topics emerged from the formulating interpretation: organizational design of the workshops, the girls', boys' and educators' behaviour in the workshops as well as the educators' expertise.

During the reflective interpretation, a range of internal action logics could be reconstructed, which can be divided into three areas: standardization of a male-connoted STEM culture, gender-differentiated actions in the STEM workshops, and attribution. The educators' narrated action practices (modi operandi) show that they implicitly associate math, physics, computer science, and technology with masculinity. This is evident, for example, in the choice of workshop topics (programming car racing games) or the standardization of boys' (dominant) and girls' (cautious) behaviour. This implicit standardization results in specific gender-differentiated workshop actions, such as addressing girls by topics based on gender-specific stereotypes (natural cosmetics or jewellery soldering), encouraging girls ("you can do it"), working in gender-homogeneous groups, or concealing male-connoted STEM disciplines by avoiding "provocative" words (e.g., "graphs"). It was also mentioned that girls in the workshops need to be protected from dominant boys who devalued their work. Finally, all educators draw conclusions referring to the youth's interest based on the behaviour the educators observe: for example, the dominance of boys is attributed to a high level of interest, while the girls' restraint is implicitly assumed to indicate little or no interest.

The reconstructed logic behind the educators' modi operandi is based on their collectively shared belief that "STEM is male". This leads them to implicitly characterize girls as a target group that deviates from the norm in STEM, meaning that alternative approaches are needed to address them in STEM. These alternative approaches result in an implicit need for girls' own topics, own language, and own treatment in STEM workshops. Thus, in terms of their narrated practice actions, educators implicitly assume that addressing girls in STEM requires additional effort.

Discussion

The preliminary results clearly show that a variety of gender-specific orientations can be reconstructed, which make educators implicitly reproduce gender hierarchies and prevent girls from feeling a sense of belonging in STEM (Archer et al., 2021; Çolakoğlu, 2024). It is questionable why these orientations are so powerful, even though the decreasing participation of girls is regularly discussed within the team. Further studies are needed to investigate possible reasons. Educators implicitly believe that they are addressing girls by means of the gender-specific actions outlined above. However, their (explicit) narratives made clear that girls do not feel addressed, but rather that their feeling of "not belonging" is implicitly reinforced by the additional effort that was made (Çolakoğlu, 2024). With reference to Çolakoğlu (2024), working in gender-homogeneous groups initially seems to be a sensitive short-term solution to strengthen girls' sense of belonging against the backdrop of a male-dominated environment. In the long term, however, these groups are very exclusive in nature, reproducing gender and subject-related stereotypes and confirming implicit assumptions about the need to make extra effort for

addressing girls. Due to the lack of a sense of belonging, girls' participation in voluntary activities at the out-of-school STEM lab would probably remain low (Çolakoğlu, 2024).

Implications

As initial results from the project already indicated, there is not only an urgent need for action to minimise the impact of educators' implicit, gender-stereotypical orientations, but also to shift research's focus on the role of educators and their competencies regarding gender in STEM. Referring to the enormous diversity of out-of-school STEM settings in Germany, considerations about suitable interventions cannot (and should not) result in an overarching "recipe" for qualifying all out-of-school educators working in STEM labs. Even more, this study indicates providing support for educators to regularly reflect on their implicit, gender-stereotypical orientations. Additionally, it is conceivable to formulate corresponding competencies as recruitment requirements or to anchor the topic of gender in STEM as a fixed component of continuous professionalization opportunities for educators in out-of-school STEM labs.

Outlook

The Documentary Method will be further conducted to first analyse the last two interviews and secondly further contrast them with the (already) reconstructed modi operandi as well as those underlying orientation patterns. Additionally, episodic interviews with other STEM educators are planned to further contrast between the reconstructed gender-specific orientations, which result in the educators' workshop-related actions. A criteria-based selection of suitable STEM labs is already made.

ESERA 2025 Copenhagen

The Influence Of School Experiences In The Construction Of A Scientific Identity – A Case Study With Brazilian Transgender Persons

Yasmim Cordeiro Lopes Fonte and Joaquim Fernando Mendes da Silva
Laboratory of Didactics of Chemistry (LADQUIM), Institute of Chemistry, Federal University of Rio de Janeiro, Brazil

This qualitative case study investigates the influence of school and science classroom experiences on the construction of a scientific identity among transgender individuals in Brazil. Drawing on Foucauldian theories of disciplinary power and on the concept of Science Capital, the research analysed the narratives of eight transgender participants collected via online questionnaires. The findings reveal a dichotomous influence: profoundly negative experiences — characterized by systemic bullying, discrimination, spatial precarity, and institutional neglect — actively dismantle Science Capital and divert individuals from scientific paths. Conversely, affirmative experiences, particularly through supportive and gender-sensitive science teachers who provide recognition and mentorship, can foster resilience, build Science Capital, and catalyse the pursuit of scientific careers, often as an act of social resistance. The study concludes that the school environment functions as a critical filter, either reinforcing exclusion or enabling inclusion. It underscores the pivotal role of educators and institutional policies in shaping trajectories and calls for urgent structural reforms—including teacher training, curriculum revision, anti-bullying programs, and affirmative actions in higher education—to transform educational spaces into equitable foundations for scientific identity development among transgender students.

Keywords: Equity in Education; Gender Equity; Science Identities

Introduction

Gender identity and sexuality play a crucial role in shaping social interactions and career choices, deeply tied to one's sense of belonging. In Western societies, the male/female binary is a foundational element of capitalist and colonial structures, dictating social roles and labor opportunities—particularly in peripheral regions such as Latin America, where heteronormative authority continues to subordinate women and gender-diverse minorities.

This structural inequality is starkly evident in Brazil, which records the world's highest rates of murders and suicides among transgender and non-binary people. Widespread transphobia permeates all spheres of life, including education and future professional prospects. Although transgender and non-binary individuals represent 2% of the population, they account for only 0.3% of university students, with most abandoning school between ages 14 and 18 (Observatory of LGBTI+ Deaths and Violence in Brazil, 2025).

Prejudice is especially severe for trans women, reflecting socio-historical processes that silence femininity (Junqueira, 2016). The formation of gender and sexual identities is intrinsically linked to power relations (Seffner, 2011), and transgender people face systematic human rights violations worldwide, intensified by their visibility and the inability to conceal their gender identity (Rodrigues, 2011).

Foucault (1988) studied power relations and how they manifest themselves in social institutions. He argues that modern society is structured around complex networks of power that exert control over the bodies and identities of individuals, exercised through norms, discourses and practices that define what is considered normal. In the context of transsexuality, Foucault's insight can be applied to understand how educational institutions perpetuate gender norms that marginalize

those who do not conform to binary gender expectations. Foucault suggests that power is not only repressive, but also productive, in that it creates categories of identity and regulates behaviours through mechanisms of discipline and surveillance.

For Foucault, school is one of the main institutions that contribute to the formation of subjectivities, using a series of disciplinary techniques to shape behaviours and identities. These techniques include constant surveillance, ongoing assessment and normalization, which together work to reinforce prevailing gender norms. Transgender individuals who challenge these norms often face discrimination and exclusion, which can have a significant impact on their educational experience and psychological well-being.

Furthermore, Foucault highlights the importance of discourse in constructing identities and maintaining power relations. Medical discourse, for example, has historically pathologized transsexuality, classifying it as a disorder or abnormality. At school, this pathologization can manifest itself through discriminatory practices and the lack of inclusive policies that recognize and respect the diversity of gender identities.

For transgender people, the need for authenticity in expressing their identity often collides with social and institutional expectations, generating conflicts that harm concentration, active participation and knowledge acquisition. Thus, addressing the school experiences of transgender people is crucial for the creation of a more democratic and inclusive environment at schools and to promote equity and social justice.

Besides, few studies have addressed the formation of scientific identity of transgender students. Recently, Datta (2024) reported the results of an investigation about how transgender people negotiate identity and community questions in Indian science institutions, showing that the lack of social capital strongly determines their professional trajectories. Archer and coworkers (2019) had already delt with the relations between gender and the development of scientific identity when analysing groups of British students at high school, showing that Science teachers tend to endorse their male students' discourses.

Thus, investigating school experiences of transgender people is crucial for the development of a more inclusive environment, where they can build confidence on their abilities to pursue a scientific career. Thus, the objective of this paper is to describe our research on the experiences of a group of transgender people in Science classes and how they influenced in their professional choices. Our research question can be pointed out as: how Science class experiences influence in the adhesion of Brazilian transgender people to a scientific identity/career?

Theoretical background

Historical analysis reveals that transgender phenomena and gender diversity are not modern constructs but have ancient roots. Furthermore, many non-Western societies have historically treated gender variance as a sacred or mystical experience, distinct from the rigid Western binary (Correa, 2020). In Brazil, evidence of trans existence dates to the 16th century, with figures who resisted imposed gender norms despite persecution and derogatory descriptions in colonial records (Mott, 2005). The 20th century witnessed both severe repression — such as the targeting of trans people during the Military Dictatorship under accusations of subversion — and gradual medical and legal recognition.

The pathologization of transgender identities has been progressively challenged; homosexuality was declassified as a mental disorder by the APA in 1973 (and fully removed from the DSM-III in 1980) and by the WHO in 1990, while transgender identity was initially categorized as Gender Identity Disorder in the DSM (1980), later renamed Gender Dysphoria (2013), and more recently

defined as gender incongruence in the ICD-11 (2018), moving away from a pathological framework (Coacci, 2020). This historical trajectory underscores the long-standing presence of trans identities and the shifting socio-medical discourses surrounding them.

Human sexuality transcends mere biological differences, enabling research to incorporate the social dimension of gender (Melo & Sobreira, 2018). A fundamental distinction lies between sex (biological attributes) and gender (a sociohistorical construct), a conceptual advance that challenges the historical conflation of the two, which naturalized behaviours and social roles based solely on biology (Jesus, 2012). Gender is thus understood as a normative construction that assigns characteristics as masculine or feminine (Oka & Laurenti, 2018). Central to this framework is gender identity—an individual's subjective sense of self, which may be cisgender (aligned with sex assigned at birth), transgender (non-aligned), or non-binary (Jesus, 2012). This must be distinguished from sexual orientation, which pertains to affective-sexual attraction toward certain genders (Siqueira & Klidzio, 2021), illustrating the broad spectrum of human relations (Jesus, 2012).

Drawing on Michel Foucault's seminal work, schools can be understood as quintessential disciplinary institutions that actively produce and regulate normative gender identities. Through mechanisms of constant surveillance, evaluation, and the normalization of behaviours, educational environments reinforce a rigid gender binarism (Foucault, 1987). This disciplinary power operates not merely through repression but productively, shaping subjects by defining what constitutes a "normal" boy or girl, thereby marginalizing those who deviate from these cisheteronormative expectations. The historical pathologization of transsexuality within medical discourse, as analysed by Foucault (1988), finds its parallel in school practices that, often through omission or discriminatory behaviour, treat transgender identities as anomalies to be corrected or silenced. This framework illuminates how institutional structures systematically enforce gender norms, rendering transgender students vulnerable to exclusion and psychological harm as they challenge the established binary order.

However, this Foucauldian analysis also reveals the potential for resistance and transformation within the educational field. If power is diffuse and productive, it also creates spaces for counter-discourses and practices. The very institution that disciplines can be reimagined as a site of emancipation (Frigotto, 2001). Moving beyond a pathologizing view requires recognizing transgender existence as a legitimate form of subjective experience and social being, as emphasized by theorists like Arán, Murta, and Lionço (2009) and Butler (2009). From this perspective, education transforms into a tool for challenging the norms it has historically upheld. This entails actively deconstructing the heteronormative matrix (Louro, 2013) and cisnormative pedagogies (Junqueira, 2016) embedded in curricula and daily interactions.

Therefore, the potential for schools to become inclusive spaces hinges on a deliberate shift from disciplinary normalization to the affirmation of diversity. This requires implementing concrete policies that protect and respect gender identity, coupled with continuous teacher training to foster sensitive and informed approaches. By critically engaging with and disrupting the power relations that sustain gender binarism, education can fulfil its emancipatory promise. It can become a space where diverse gender identities are not only recognized but valued, allowing all students, especially those from marginalized groups, to fully access knowledge and build their futures without having to renounce their authentic selves.

The construction of a scientific identity is deeply intertwined with issues of access, representation, and social validation. Drawing on the work of Archer and colleagues, the concept of "Science Capital" is crucial here; it posits that the aspiration to pursue science is not merely an individual choice but is significantly shaped by one's access to a composite of economic, social, and cultural

resources specifically related to science. This framework helps explain how systemic inequalities — such as those based on gender, class, and race — can limit the development of a scientific identity from an early age, as historically seen in the exclusion of women, particularly poor and Black women, from exact and natural sciences. For transgender individuals, these barriers are compounded by a profound lack of representation and institutional recognition, which directly impacts their sense of belonging and possibility within scientific fields.

This marginalization is mirrored and reinforced by a prominent academic void. As highlighted by Moura and Zibetti (2023), there is a severe scarcity of research focusing on the schooling of transgender people in Brazil. Their systematic review, which filtered thousands of records down to only 28 relevant studies, reveals a field that is incipient, fragmented, and geographically concentrated in the South and Southeast regions. This research gap is not neutral; it reflects and perpetuates the structural invisibility of trans experiences in educational policy and discourse. The lack of interdisciplinary studies, especially from fields like Psychology that could illuminate subjective and psychosocial dimensions, means the specific challenges transgender students face in forming a scientific identity remain largely unexamined and unaddressed, thereby allowing cycles of exclusion in science education to persist unchallenged.

Methodology

This study is characterized as an applied, qualitative research, configured as an exploratory case study (Yin, 2001). The qualitative approach was chosen as it aims to investigate how individuals perceive and attribute meaning to their experiences, ideas, and events (Câmara, 2013), allowing for an in-depth understanding of the participants lived educational trajectories. The case study design was appropriate for obtaining insights from the detailed experiences of a specific group within their real-life context (Creswell, 2010).

The research involved eight transgender individuals (including both trans men and trans women), aged between 19 and 36, from different Brazilian states (Rio de Janeiro, São Paulo, and Pernambuco). Participants were recruited virtually through a non-probabilistic sampling technique, where invitations were directed to individuals who self-identified as transgender in their Instagram biographies. To ensure privacy, comfort, and an environment conducive to authentic sharing, all data were collected anonymously, with no request for identifying information such as names.

Data collection was conducted via an online questionnaire on the Google Forms platform, enabling access to participants from various regions. The instrument contained both open and closed questions, structured into three thematic blocks: (i) sociodemographic data, (ii) school and academic experiences, and (iii) professional experiences in teaching (where applicable). The questionnaire covered topics such as experiences of respect or discrimination in school, relationships with science teachers, access to higher education, and perceptions of the work environment.

For data analysis, documentary analysis and content analysis were employed, following the principles proposed by Bardin (2016). The process followed three fundamental stages: pre-analysis, material exploration, and treatment of results. From the responses, four core analytical categories were established based on the recurrence of themes and the research objectives: 1) School Experiences (encompassing bullying, discrimination, and sense of belonging), 2) Relationship with Science Teachers, 3) Experiences in Higher Education, and 4) Professional Trajectory and Teaching. These categories guided the interpretive analysis, allowing the participants' narratives to be critically examined considering the theoretical framework on education, diversity, and the inclusion of transgender people.

Results And Discussion

Guided by the dual theoretical lenses of disciplinary power (Foucault) and Science Capital (Archer et al.), this section analyses participants' narratives to address the central research question: how do Science class experiences influence the adhesion of Brazilian transgender people to a scientific identity or career? The analysis examines these accounts as lived experiences where the theoretical mechanisms of normalization and exclusion materialize concretely, while also highlighting moments of affirmation and resistance that directly shaped their relationship with science. This approach allows us to understand how specific interactions in the science classroom impacted their sense of belonging, access to scientific resources, and ultimately, their trajectory toward or away from a scientific career.

The school environment emerged from the narratives as a primary site of disciplinary power, where violence and exclusion enforce gender binarism. All interviewees reported severe bullying, from verbal harassment to sexual abuse. Interviewee H recounted: "Physical education classes were terrifying... they made my life hell, assaulted me physically, mentally, sexually, turning me into the class joke." This multiform violence targets non-normative bodies, seeking to render them docile (Foucault, 1987), and initiates a cycle of psychological suffering that corrodes self-worth and belonging (Aran et al., 2008). Exclusion was perpetuated not only by peers but through institutional neglect. Interviewee D noted a dissonance: "The teachers listened to my proposals... but often my gender identity was not respected," reflecting a form of symbolic violence born from a lack of understanding and inclusive policies (Bronzo, 2010).

The consequences were directly academic and aspirational. The relentless bullying described by Interviewee H led to plummeting grades and the abandonment of her medical career aspirations after a cruel incident in Grade 9: "The damage was already done, they broke me." This trauma hit her nascent Science Capital (Archer et al., 2015), depleting the resources necessary to sustain scientific identity formation. This illustrates how exclusionary environments actively dismantle, rather than build, the professional trajectories of transgender students.

The Foucauldian analysis is further concretized in the issue of spatial control, such as the acute anxiety around bathroom use mentioned by Interviewee E. This fear is a manifestation of spatial discipline and surveillance (Foucault, 1987). Bathrooms, as rigidly gendered binary spaces, become sites of normalization and potential confrontation, placing transgender students in a state of spatial precarity. This daily practice reinforces binary norms, invalidates their identity, and consumes cognitive energy that could be directed toward learning, creating a tangible barrier to educational engagement and academic belonging.

While the school environment emerged as a pervasive system of disciplinary power that actively eroded belonging and dismantled Science Capital, the participants' narratives revealed that specific actors within this system could function as decisive counterweights. This dynamic between structural exclusion and potential affirmation brings into sharp focus the pivotal role of educators. The following analysis examines the agency of science teachers, exploring how their pedagogical stance — ranging from conscious inclusion to passive neglect — directly mediated the impact of the hostile school climate. Their actions crucially determined whether initial student interest in science was validated and nurtured into tangible Science Capital or whether it was extinguished by the broader culture of exclusion.

Within the often-hostile school environment, Science teachers emerged as pivotal figures capable of acting as counterweights to disciplinary exclusion, directly influencing the participants' relationship with scientific knowledge. Positive reports highlighted teachers who respected

gender identity and actively engaged students' interests. Interviewee H recalled, "I always liked sciences, especially natural sciences. My teachers were very open and treated me equally, which made me consider the area as a career option when I was younger." This respectful and equitable treatment, as Oka and Laurenti (2018) argue, is fundamental for creating an inclusive pedagogical practice that can foster sustained interest in science among marginalized groups. Similarly, Interviewee D received significant support from her teacher, who encouraged her participation in national science and biology olympiads. This active mentorship provided her with specific forms of Science Capital (Archer et al., 2015) — such as access to special knowledge (Olympiad preparation), institutional recognition, and a network of support — that validated her scientific competence and belonging.

However, these affirming experiences contrasted with a broader institutional failure. Four interviewees stated they received no encouragement from teachers or schools to pursue science. This widespread lack of formal support reveals a systemic gap where personal interest was not translated into concrete aspirational identity due to absent mentorship, career information, or validation of scientific potential.

The analysis of these contrasting experiences underscores the teacher's dual role as both a potential agent of inclusion and an unwitting accomplice to systemic neglect. The positive cases demonstrate that when educators consciously adopt a gender-sensitive approach, they do more than transmit content; they perform an act of identity affirmation. By treating a transgender student with equality and actively promoting their participation, these teachers directly combat the pathologizing discourse and social exclusion their students face elsewhere. They become facilitators of Science Capital accumulation, building the social and cultural resources necessary for scientific identity formation. Conversely, the more common absence of active encouragement, even amidst otherwise respectful treatment, reflects a pedagogical shortcoming.

The influence of science teachers proved to be a critical variable, either facilitating a connection to scientific knowledge or reinforcing a sense of alienation from it. However, the translation of this school-based Science Capital into sustained scientific trajectories hinges on the subsequent gateway of higher education. The journey into and through university represents a contested stage where earlier experiences of support or exclusion are recontextualized within new structures of power and recognition. It is marked by profound structural inequalities. As evidenced by the interviews, access is not guaranteed, with financial and social barriers acting as significant gatekeepers. Interviewee B’s situation, who "could not attend college due to a lack of financial resources and opportunities," exemplifies the social vulnerability described by Filgueiras (2004), where systematic marginalization deprives groups of essential resources like education. The empirical reality of these barriers underscores the theoretical point that exclusion is not merely incidental but a structured outcome, preventing many from even entering university space.

Once within academia, the experiences diverge sharply, revealing the university as a deeply contradictory space. For some, it becomes a transformative environment for self-knowledge and affirmation, what resonates with Bento's (2014) conception of the university as a conducive context for the dynamic and non-linear process of gender reinvention, offering the freedom to reconnect with one’s identity. Conversely, others confront persistent invisibility and new challenges. Interviewee C, despite some growth, felt "constantly invisible," while Interviewee H’s earlier engineering studies were marked by intense depression and isolation, leading to severe mental health struggles. This contrast illustrates the dual potential of the university: it can be a site of emancipation for some while perpetuating normative exclusion for others.

This duality exposes the university as an arena where both liberation and normative control are negotiated. The positive accounts of Interviewees E and F, who found in university an opportunity

to "liberate themselves in relation to their own body" and experience a "process of self-construction," align with Bento's (2014) view of academia as a space for personal emancipation from previous social restrictions. However, the "invisibility" reported by Interviewee C and the pathologizing marginalization discussed by Marreiros e Silva (2015) reveal how institutional spaces often maintain a binary gender logic that silences trans presences.

Ultimately, the empirical data compels a critical synthesis: the university is a microcosm of broader social tensions regarding gender. True transformation, as theorized by Bento (2014) and Perelson (2011), requires actively dismantling the normative frameworks that render trans identities secondary.

The ambivalent nature of higher education — as both a site of liberation and of continued normative exclusion — frames the ultimate stage in the pathway toward a scientific identity: the professional career. The analysis of the experiences described by the interviewees reveals how a scientific identity, when achieved, is often enacted as a form of social resistance. It directly answers how adverse school experiences can ultimately lead not only to withdrawal from science but also to a resilient, politically charged commitment to transforming scientific and educational spaces for future generations.

Six of the interviewees opted for a degree in Education. The choice to enter the teaching profession emerges from the interviews as a deliberate act of social resistance and transformation. Interviewee D's trajectory is paradigmatic; she explicitly pursued a teaching career "with the aim of deconstructing the stigma that transgender people are not socially or intellectually capable." This motivation is deeply rooted in her own positive schooling experience, where supportive science teachers encouraged her participation in competitions and emphasized pursuing higher education. Her decision to become a Biology teacher, therefore, transcends mere career choice, embodying what Frigotto (2006) conceptualizes as education mobilized for the construction of a more just society. By seeking to "destigmatize gender prejudice" through pedagogy, she positions teaching not as the neutral transmission of knowledge, but as a critical practice that challenges oppressive norms and aims to transform social reality. This aligns with the resistance movement described by Frigotto and Ciavatta (2012), where education becomes a tool to contest the very structures of discrimination.

The reported current work experiences of the trans educators reveal a professional environment that is both affirming and demanding of constant resilience. Empirically, the accounts are "profoundly positive and inspiring," with Interviewee C describing his teaching experience as "incredible" and feeling like a "potency inside the classroom." Similarly, Interviewee F shares being "incredibly respected" during teaching internships, particularly regarding discussions on gender and transness. These positive experiences reflect Perelson's (2011) notion of recognition, where professional respect becomes foundational for affirmed identities and suggests that educational spaces can indeed become sites of empowerment. However, this affirmation coexists with the need for persistent self-assertion. As Interviewee C notes, the requirement to constantly impose himself to avoid delegitimization highlights the ongoing structural prejudice that necessitates a resilient and proactive stance. Thus, while their teaching practice is transformative for themselves and potentially for their students, it is continuously enacted within a context that still requires them to navigate and resist marginalizing forces.

In synthesis, the professional trajectories of these interviewees exemplify teaching as a transformative practice in a dual sense. First, it serves as a personal and political vehicle for resisting stigma and reclaiming social legitimacy, as theorized by Frigotto. Second, their active presence in classrooms performs a transformative social function, potentially altering the educational environment for future generations. The empirical data demonstrates that their

pedagogy is intrinsically linked to a project of social change. Their generally positive workplace experiences indicate progress, yet the undercurrent of needed resilience confirms that their transformative work occurs not in a void of acceptance, but through continuous engagement with and resistance to persistent normative structures.

Conclusions

This study concludes that experiences in science classes and school environments are decisive in shaping the scientific identity and career trajectories of transgender individuals. The empirical data reveals a sharp dichotomy: profoundly negative experiences, marked by discrimination, abuse, and exclusion, can cause deep trauma and divert individuals from scientific paths, as exemplified by Interviewee H who abandoned a medical career after feeling she "would never be accepted." Conversely, positive and inclusive experiences, centered on respectful and encouraging relationships with teachers, can foster a strong scientific identity and resilience. The testimony of Interviewee D, who received "consistent support from her teachers" leading her to become a Biology teacher, underscores how affirmative pedagogical relationships can empower trans students to pursue and thrive in scientific careers.

In direct answer to the research question — how Science class experiences influence the adhesion of Brazilian transgender people to a scientific identity/career — the findings demonstrate that these experiences function as a critical filter. They can either act as a mechanism of exclusion, reinforcing societal stigma and severing the connection between trans students and scientific fields, or as a catalyst for inclusion, providing the recognition and support necessary to build a scientific identity and a trajectory of resistance through education.

Based on these conclusions, urgent and multidimensional actions are recommended. At the policy level, this includes revising educational policies to incorporate specific guidelines for gender equity and the protection of transgender students. Institutionally, mandatory pre- and in-service teacher training on gender diversity and inclusive pedagogies is essential. Within Science education, a reformulation of curricula is needed to critically address concepts of sex and gender, thereby incorporating human diversity and deconstructing cisnormative biases. Schools must implement robust anti-bullying programs and establish integrated psychological and social support networks. Furthermore, to address barriers in higher education, affirmative actions for transgender access and permanence must be promoted. This study acknowledges its primary limitation as a qualitative case study with a small sample. Future research should expand on these insights through larger-scale, quantitative or mixed-method studies with more diverse demographic samples, as well as longitudinal designs that follow the educational and professional trajectories of trans individuals over time.

Science Capital Of Brazilian Students From The Periphery Of Rio De Janeiro: Correlations Between Gender, Ethnicity And Parents' Educational Level

Joaquim Silva, Viviane Teixeira and William Santos
Laboratory of Didactics of Chemistry (LADQUIM), Institute of Chemistry,
Federal University of Rio de Janeiro, Brazil

Science Capital, introduced by Archer and coworkers, is based on Bourdieu's concept of capital and how students' cultural, social and economic capitals influence the formation of a scientific identity and future career engagement. Higher Science Capital is linked to families with strong ties to science, with gender and ethnicity also playing a role. A key outcome of their research was a questionnaire assessing three dimensions—scientific cultural capital, science-related behaviours, and scientific social capital—generating a score from 0 to 105, classified as low, medium, or high. Since 2018, our group has been studying the Science Capital of public school students, who represent over 80% of Brazilian students mainly from lower-income backgrounds, with the aim of investigating the factors that promote inequalities in engagement with science. In this context, public schools both reflect social inequalities and provide opportunities for equity and social justice. Our research involved 936 high school students (ages 14-20) from six public schools in the metropolitan region of Rio de Janeiro, using a Portuguese-adapted Science Capital questionnaire. Results indicated a predominance of medium Science Capital levels, with the mother's educational level being the primary influencing factor. More male students were in the medium level, while gender non-normative students had a higher proportion in the high level. These findings emphasize the role of gender in Science identity formation and the need for policies promoting gender equity in education to ensure more inclusive access to scientific careers in Brazilian public schools.

Keywords: Educational equity, Equity in Science, Science Identities

Introduction

Science Capital is a concept developed by Archer and coworkers (2015) based on the Bourdieusian concept of capital and taking into consideration the school educational field. The concept was developed from their participation in the ASPIRES project (King's College, 2013), aimed to reflect the reduction in the interest of following scientific careers by young people.

The authors suggest that the legitimization of resources related to science is an important form of contemporary capital as they play a significant role in producing social relations of advantages and disadvantages, not only due to their high symbolic and exchange value in contemporary society, but also because science is conceived, in various international contexts, as a national priority within government policies (Archer et al, 2015). Thus, as we live in a society that continuously uses science and values it as important, the authors aimed to add new contributions to Bourdieu's theory of capital, specifically regarding scientific matters, which could contribute to a more democratic society.

After the initial study, other researchers have used this approach to evaluate the Science Capital in different countries, such as Finland (Kaakinen et al., 2023) and Singapore (Teo et al., 2018). In Brazil, our group has been developing research on the Science Capital of students since 2018, with a major interest in investigating the factors that influence the choice of a scientific career by female students from low income, peripheral neighbourhoods (Silva, Teixeira & Silva, 2023). Our investigation with ten students from five public schools from the Metropolitan region of Rio de Janeiro has shown that participating in science projects was the only way they could interact

with science professionals and science-related professions. We could also observe that those students had their mothers as professional inspirations and, so, they have a crucial role in their future professional choices. The girls that foresaw Science as a professional possibility pointed out that social media, TV shows and their teachers played a pivotal role in this choice. As a result of this research, we developed an e-book with orientations for teachers who wish to promote the development of the Science Capital of their students.

Our research group has recently published a paper (Mileo Jr & Silva, 2025) describing the results of research on the scientific aspirations of two groups of Brazilian students from different educational systems, using data collected with Archer's Science Capital questionnaire. The first group, composed of students from a Federal public school, displayed higher levels of cultural and social capitals than those of the other, composed by students of public schools ruled by the State of Rio de Janeiro local government. These results are reflected in a greater adherence of the former group to a scientific identity. Scientific aspirations are strongly influenced by social inequities within the groups and thus educational policies related to Science education are necessary to promote equity and social justice among these schools.

The research described in this paper deals with an investigation of students from six schools located in the metropolitan region of Rio de Janeiro, the second largest city of Brazil, aiming to answer the following questions: how the students at the analysed public schools are distributed in the three levels of Science Capital? In which extension can the sociodemographic data of these students explain this distribution? Are there relationships between our data and those found by Archer and coworkers (Archer et al., 2015)?

Theoretical Background

According to Archer (Archer et al, 2015), Science Capital is not a different kind of capital, but a way of grouping aspects of the social, cultural and economic capitals that are more related to creation and value exchanges that leads to a higher participation or adhesion to a scientific identity or career. The concept is related to the theory of social reproduction (Bourdieu, 1983) and, consequently, the values attributed to what is established as scientific capital are a function of the social context (field), and the strategies for obtaining this capital are directly linked to individuals' nonconscious perception of their position within this context (*habitus*). Thus, Archer synthesizes the relationship between the values and logics that shape students' engagement with science. In her view, Science Capital is a function of all the ways students relate to scientific knowledge, which can be understood through the following main dimensions: scientific literacy; attitudes and values related to science; scientific behaviours outside of school; and contact with people who work in science (Godec et al., 2017).

Considering these dimensions, the first results of Archer group's research showed that a higher Science Capital was associated with students who belong to a family with higher social and cultural capital associated with science. Other factors that influence the levels of Science Capital are gender and ethnicity, with higher levels being more likely to be found among white male students from high cultural capital families, in which at least one member has a Science related career. On the other hand, female students and black students suffer numerous experiences throughout their lives that lead them to believe that Science is not for them at all (see also Archer et al., 2019).

From measuring Science Capital, it becomes possible to develop diagnostic processes regarding students' relationships with elements of the different dimensions and to propose guidelines to increase their engagement with science. One of the key achievements of Archer research was the development of a questionnaire that can be used to quantitatively measure Science Capital

(Archer et al, 2015). The questions are divided in three dimensions (scientific forms of cultural capital, behaviours and practices related to science, scientific forms of social capital) from which 14 specific items were used to calculate the Science Capital, that can vary from 0 to 105. These values can be ranked in three different levels: low (0-34.5), medium (35-69.5) and high (above 70).

Methodology

We are particularly interested in the levels of Science Capital of young people studying at public schools, since they are frequented by more than 80% of the Brazilian students, especially those from the lowest economic income fraction of the society. This makes the public schools a scenario for the reproduction of the social inequities of Brazilian society, as well as a field to provide experiences that can promote equity and social justice. Understanding the distribution of the students in the three Science Capital levels and its relationship with their sociodemographic data may open opportunities to develop activities which can potentially enhance their social and cultural capital related to science.

The research was then conducted with 936 high school students from six public schools from the metropolitan region of Rio de Janeiro, Brazil. All of these schools are in peripheric, low-income districts and with limited financial support from the local government, which restricts the pedagogical opportunities available to teachers to overcome educational inequities. There is an important index of school evasion during the first year of High School, when boys are required to find an occupation to improve their family income. On the other hand, girls can leave school or reduce their time of dedication to their studies to take care of domestic affairs or due to an early pregnancy.

The students, ranging from 14 to 20 years old, answered a version of the Science Capital questionnaire (Archer et al. 2015) translated to Portuguese, with minor adaptations necessary to adjust the questions to the cultural and institutional realities of the schools. The answers were collected and treated using Excel. One-factor ANOVA tests were performed at $p < 0.01$. The answers were submitted to Cronbach's alpha test, which verified the internal consistency of the data collected (Table 1). After that, the Science Capital was calculated following Archer's methodology, and the students were grouped in the three levels (low, medium and high Science Capital) as described before. Then, correlations between these levels and the sociodemographic data collected in the same survey were drawn to find how these factors are associated with the construction of the students' Science Capital.

Table 1. Cronbach's alpha for the subdimensions of the Science Capital questionnaire.

Component	Cronbach's alpha*
Future science job affinity (aspirations)	0.66
Valuing science and scientists	0.69
Family attitudes (including attitudes to science)	0.74
Utility of science qualifications	0.76
'Informal' science activities	0.63
Science media engagement	0.75
Valuing museums/ museum experiences	0.79
Science teachers and lessons	0.77
Self-efficacy in science	0.66

* Cronbach's alpha values above 0.6 were considered satisfactory (Wartha & Santana, 2020).

Results And Discussion

Sociodemographic (gender, ethnicity and parents schooling) data of the analysed population are resumed in Table 2. It was composed equitably by male and female students. Most of them declared to be Black, which is consistent with Brazilian demographic (Brasil, 2025) data and with the fact that most of the lowest income families are composed of this ethnic group as a consequence of the strong marks of African slavery and the way its abolition was unfairly conducted in Brazil.

Table 2. Sociodemographic data of the students.

	Gender			Ethnicity		
	Male	Female	Other*	White	Black	Other*
n (%)	447 (47.8)	443 (47.3)	46 (4.9)	220 (23.5)	630 (67.3)	86 (9.2)

* Other response/Preferred to not answer

The percentual distribution of the students in the three levels of Science Capital is depicted in Table 3, together with data related to their family's cultural capital. Most of them are in the medium stratum and less than 1% was ranked with high Science Capital, while Archer's initial study pointed to a percentage of 5% at this level among British students.

Table 3. Science Capital and Parents' Educational Level (n = 936).

	Low (%)	Medium (%)	High (%)
Science Capital	45.7	53.5	0.7
Mother left the school before 16 y.o.	23.8	27.7	0
Mother frequented a university	7.2	13	28.6
Father left the school before 16 y.o.	25.2	28.3	28.6
Father frequented a university	6.3	12.4	14.3

The data highlights that the mother's educational level is a more significant predictor for achieving a high Science Capital score than the father's educational level, which exhibits a weaker influence. Feijó, França, and Pinho Neto (2022) studied the influence of mothers on the academic performance of Brazilian high school students. Using a national government database on student scores in the ENEM (the national university entrance exam), the authors found that a mother's level of education has a greater impact on her children's academic performance than the father's level of education — an effect that is stronger among daughters, particularly when the mother holds a university degree. This influence was independent of the traditional channels of educational transmission — the identifiable means through which higher parental education typically improves children's school performance, such as higher family income, fewer children, better household infrastructure, and the ability to choose higher-quality schools. The authors suggest that these effects may be related to the transmission of cultural values, parental involvement, and the communication of maternal expectations and future aspirations regarding their children's educational achievement.

Our results corroborate the findings of Feijó, França and Pinho Neto (2022) and can be related to the social role usually attributed to mothers as the parent responsible for taking care of their children's educational development and to encourage them to complete their studies. Another important fact is that, in Brazil, more than 50% of the families are headed by the mothers, which highlights their role in the constitution of their children's Science Capital. In addition, it is important to highlight the homogeneity in the rates of parents who left school before the age of

16 across all levels of Science Capital, which points to the critical issue of school dropout among men—especially Black men—as previously reported by Ratusniak (2024).

Table 4 describes how the different genders are distributed among the three Science Capital levels. There are no significantly differences between the means of male and female students at $p < 0.01$ (low level: 24.9 (male), 25.1 (female); $F(10.988) = 0.087$; medium level: 45.5 (male), 45.3 (female); $F(10.963) = 0.039$). It was not possible to perform the statistical analysis at the high Science Capital level due to the small number of students at this stratum.

Table 4. Science Capital and gender (n = 936).

	Low (%)	Medium (%)	High (%)
Male	43.2	56.6	0.2
Female	48.1	51.2	0.2
Other*	47.8	45.7	6.5

* Other response/Preferred to not answer

It is noteworthy that a higher percentage of students with high levels of Science Capital did not identify themselves as male or female. However, further studies are needed to explore this finding, particularly given the small number of respondents in this group.

We have also analysed gender distribution in each Science Capital level (Figure 1). The result reinforces the small, non-statistically significant differences between the gender distribution at low and medium levels of Science Capital.

Figure 1. Distribution of the population by gender in each Science Capital level.

The influence of ethnicity on the Science Capital scores were also analysed and the results are described at Table 5.

Table 5. Science Capital and Ethnicity (n = 936).

	Low (%)	Medium (%)	High (%)
White	45.5	54.1	0.5
Black	45.7	53.5	0.8
Other*	46.5	52.3	1.2

* Other response/Preferred to not answer

The data show similar distributions of White and Black students at the low and medium levels. At the low level, the means are not significantly different at $p < 0.01$ (25.3 (White), 25.0 (Black);

F(10.995) = 0.118) and the same is observed at the medium level at $p < 0.01$ (46.9 (White), 45.1 (Black); F(10.970) = 4.734). These data contrast with those obtained by Archer and colleagues (2015), in which ethnicity played an important role, a difference that may be associated with the different sample sizes of students in each ethnic group. On the other hand, we can infer the influence of low socioeconomic status, which, in these regions, does not differ greatly between these groups. These results are reinforced by the results depicted in Figure 2, showing that the ethnic distribution in each Science Capital level is similar to the ethnic distribution of the research population, as shown in Table 2.

Figure 2. Distribution of the population by ethnicity in each Science Capital level.

* Other response/Preferred to not answer

Conclusions

This study investigated the distribution of Science Capital among 936 high school students from public schools in the periphery of Rio de Janeiro and its correlation with sociodemographic variables. The results align with the international literature in one key aspect: the majority of students (53.5%) were concentrated at the medium level of Science Capital. However, our findings also reveal distinctive characteristics of the Brazilian context studied.

The most prominent factor associated with higher Science Capital was the mother's educational level, corroborating national research on the outsized influence of mothers on academic trajectories (Feijó et al., 2022). This underscores the crucial role of maternal cultural capital and involvement in fostering a scientific identity, especially in a social context where mothers are frequently the heads of households and primary educational guides.

Regarding gender, no statistically significant difference was found between the mean scores of male and female students. The higher percentage of gender non-normative students in the *high* Science Capital category demands deeper qualitative investigation to understand the specific trajectories and strategies of this group. Contrary to findings from Archer et al. (2015), ethnicity has not shown to be a statistically significant differentiating factor in this sample, suggesting that in these specific peripheral school contexts, with a high proportion of Black students, socioeconomic may override ethnic and gender distinctions in the formation of Science Capital.

These conclusions carry important implications for educational policy and practice: they reinforce the need for socioeconomic equity policies in science education, as this is strongly associated with gender and ethnicity in Brazil. Furthermore, they point to the potential of school-based interventions, such as science projects, to act as compensatory mechanisms for low familial Science Capital, particularly by connecting students with science professionals and career visions.

A primary limitation of this study is the extremely low percentage (0.7%) of students classified with high Science Capital, which restricts robust statistical analysis for this group. Future research should employ mixed methods, combining quantitative surveys with in-depth interviews and ethnographic observations. This approach would allow for a richer understanding of how Science Capital is mobilized, negotiated, and potentially resisted by students within their families and school environments, guiding the development of more effective and contextualized pedagogical actions.

ESERA 2025 Copenhagen

Inclusive Movement: Rethinking Physical Engagement In Science Classrooms

Charlotte H. Müller[1], Ipek Paksoy[1], Fan Wang[1], Julia Chatain[1], Manu Kapur[1,2] and Martina A. Rau[1]
[1]ETH Zurich, Switzerland
[2]Singapore-ETH Centre, Singapore

Science education includes many physical learning activities designed to support learning. Students inevitably move when they participate in laboratory experiments, excursions, or if they are animated to move in a certain way that is supposed to promote learning. However, most research focuses on normative physical bodies and interpersonal relationships and thus unintentionally or implicitly excludes many students who are unwilling to perform certain actions as they may feel uncomfortable doing so. For instance, one may be an introvert and/or afraid of being observed. Some learners may have body-related trauma that makes them deeply distressed with certain activities, and others might simply be less athletic or less confident in taking up space than their peers. Finally, some bodies may be prohibited from performing certain actions due to physical disabilities. In this exploratory seminar, we invite researchers and educators who design physical activities of any form for students. Together, we explored what we need to know about students, and their bodies, for the design process, and what we can offer to students who might not be comfortable with the designed activity without isolating them.

Keywords: Embodiment, Inclusive Education, Science Education

Introduction

Physical engagement such as movement, gesture, and interaction is an integral part of science education. Students perform lab activities, they learn on excursions outside the classroom, or educators animate them to move in a way that promotes learning (e.g. Choudhary et al., 2019). Many scholars understand learning today as situated, active, and context-dependent (Nathan, 2021; Wilson & Clark, 2001), meaning that how students move and interact will affect learning.

Concurrently, science education aims to promote inclusion. Inclusion here denotes the "process of addressing and responding to the diversity of needs of all learners through increasing participation [...] and reducing exclusion within and from education" (UNESCO, 2005, p. 13). While studying the general effectiveness of interventions for the average student is crucial, scholars further ask for who under what conditions interventions may fail or even be harmful.

This seminar explored how scholars and educators may design physical activity inclusively. Specifically, we asked for whom a certain activity might create more stress as well as with whose bodies this activity is aligned and with whose not. For example, asking students to act as atoms and run faster when the temperature is higher is aligned with the bodies of students who can run (well), enjoy it, and feel comfortable about being perceived by others as well as interacting with them. We thereby build on work by Vickery and colleagues (2024) who found that students were aware of how their own and other students' bodies differ from a normative body and how this may affect learning experiences that involve physical activity.

In the following, we first pose the problem that this seminar aimed to address. Second, we provide a set of illustrative examples of empirical studies, which specifically target physical activity. Finally, we present the objectives and results of the seminar.

Learning And Physical Engagement

Conceptual Framework

Traditionally, separating body and mind was the common way to approach learning and educational practices. Fundamental learning theories like cognitivism by Piaget and behaviourism by Skinner overlooked their interconnectedness (Shapiro & Stolz, 2019). Later, Dewey suggested that students learn by interacting with the world (Dewey, 1986). Likewise, embodied cognition theories suggest that (inter)action influences cognition; therefore, meaning-making, problem-solving, and other cognitive activities are influenced by the learner's interactions with the world (Wilson, 2002).

In science education specifically, experimentation activities are a prominent example where students investigate phenomena by manipulating objects or materials while moving in a specific way (Hardahl et al., 2019). Furthermore, research shows that physical movement enhances science learning under the right conditions: for example, moving according to a predicted asteroid trajectory improved understanding of gravity and planetary motion (Lindgren et al., 2016), mixed-reality environments aided retention of centripetal force concepts (Johnson-Glenberg et al., 2016), and dance increased engagement with the periodic table (Solomon et al., 2022).

However, not all students are equally capable of or comfortable with physical and social activity (Spiel, 2021). Vickery and colleagues (2024) recently analysed fifth-grade students' reflections on their embodied modelling experiences. They found that the students saw tension between their non-normative bodies (e.g. physical dis/ability, or athleticism) and the normative expectations (e.g. moving around). The authors thereby pointed towards questions that we targeted in this seminar: for which participants might a certain activity create additional stress, with whose bodies is this activity aligned and with whose they are not? Are there other options for the latter?

Illustrative Examples: Interventions And Concerns Related To Physical And Social Engagement

Currently, research involving deliberate engagement of students' bodily movements primarily focuses on the effect of the interventions on learning and motivation, while students' willingness or concerns are seldom mentioned. In the following, we illustrate how such interventions might potentially intimidate or disadvantage certain groups of students by examining four studies, which involve social dynamics, educational technology, or direct embodiment. Importantly, note that we do not intend to criticize the study designs but to shed light on overlooked practical implications.

First, immersive tools and interactive platforms, while engaging, can pose challenges related to students' sensorimotor abilities. For example, in a study where students learned chemical concepts by using a haptic device providing force feedback (Müller et al., 2024), successfully navigating the device and interacting with virtual molecules was critical to learning. Furthermore, anecdotally, not all students experienced the force feedback from the haptic system equally. These differences might have had an impact on the effectiveness of the embodied activity. Similarly, in another study where students learned about derivatives in a VR environment, results showed that students with higher bodily awareness benefited more from the activity (Chatain et al., 2024). This discovery points to the need of designing for interactions that accommodate diverse bodily abilities.

Second, the social pressure inherent in classroom settings might put students into dilemmas when participating in embodied activities. For example, in the Energy Theater study (Scherr et al.,

2013), each student was “a unit of energy” and was required to use hand signs or move with their peers to a certain region to indicate the energy flow. In these activities, students may feel that their explicit movements are being observed by the group. They may then hesitate to participate in such learning activities due to a lack of confidence in their movements yet feel unable to opt out for fear of disrupting the group dynamic or being perceived as uncooperative. Therefore, educators and researchers might need to seek students’ consent in advance and implement facilitation strategies that acknowledge and address these social pressures.

Finally, direct embodiment helps students form a bodily representation of the concept but can also implicitly establish normative body shapes. For example, in a study where students learned about robot anatomy, teachers prompted them to dance alongside robots and think about the similarities between human and robot body structures (Zhang et al., 2024). This activity may be uncomfortable for some students, as it involves comparing their bodies to a normative ideal, represented by the robot’s form. We conjecture that students with physical disabilities might feel excluded. Other students who perceive their bodies as bigger, smaller, or simply different than the normative expectation may also feel self-conscious under constant comparison. Thus, these differences between the expected norm (in the case of this study represented by the robots) and the students' bodies need to be framed in a supportive and sensitive way.

Objectives

Immediate Outcomes

The primary aim of this exploratory seminar was for participants of this seminar to leave with heightened awareness of which parts of certain activities might create additional stress for which students and whose bodies certain activities are aligned with and whose are not. Furthermore, the participants should get ideas for alternative solutions for these students.

Together, we reflected on current design choices in science education that engage students' physical bodies and explore potential design guidelines to facilitate these choices. For example, how may we design alternative versions of an educational activity to include students with different bodies without alienating them? How can we build a trusting environment for students to be physically active? This seminar aimed to critically discuss such questions in the context of science education.

We created a short summary from two data sources. First, from group discussions, we gathered the physical mind maps that the groups created. Second, we took detailed notes during the whole-group discussion. From this, we identified three recurring themes:

First, a frequently suggested idea was designing **alternative options** inclusively for students who are unable or prefer not to participate in a certain activity. We can either co-design and negotiate alternative options with the students, or instructors can offer equally meaningful and important options (e.g., assigning the role of the observer but reframing it as an important part of an experiment).

Second, we discussed how to design **space and material** inclusively. We can avoid exclusion by communicating a certain activity ahead of time and thereby allowing students to prepare, e.g., by choosing appropriate/comfortable clothing. Furthermore, the use of manipulatives could replace body-based activities (e.g., using a fake hand instead of a physical one). Generally, creating a safe space (i.e., the physical learning space) in which students can also explore activities out of their comfort zone is important. However, we need to elaborate more on what a safe space fully entails and how to create it.

Finally, some participants stressed the importance of fostering a positive **attitude** towards new experiences. Specifically, we should encourage students to try activities that they may initially not be comfortable with. In other words, it is necessary to foster an open mindset towards new experiences. In this context, we can even further teach students how to deal with discomfort to a certain extent.

Expected Long-Term Outcomes

Since we were aware that a 45-minute session is not sufficient to conceive complete design guidelines, we facilitated the formation of research relationships among participants to further discuss science education research in the context of inclusive movement. We have since continued the discussion virtually with interested participants. Currently, as a group, we developed a leading question: what actions can teachers take to ensure inclusive scientific experimentation and how does this depend on context? We are preparing more contributions to the scientific discussion on inclusive science education by building on the outcomes of this seminar. This is a first step towards a more inclusive movement in science education, starting with a highly prominent form of movement – experimentation. Interested scholars and practitioners are invited to contact any of the authors.

Conclusion

This exploratory seminar highlighted the importance of inclusive alternatives, thoughtfully designed spaces and materials, and fostering an open mindset that supports students in engaging with new and potentially uncomfortable learning experiences. We hope that participants have left this exploratory seminar with heightened awareness of the diversity of human bodies in classrooms and empirical studies, and how they might stand in tension with the normative expectations of certain activities. We invite interested participants, graduate students, educators, and researchers to join our newly formed group by contacting any of the authors.

ESERA 2025 Copenhagen

Validation Of A Professional Science Identity Scale For Higher Education Students Of Chemistry

Cornelia E. Borchert, Josia Hoppmann, Merlin Beaujean and Emine Büşra Kansizoglu
Bielefeld University, Germany

Although wide-spread internationally, science identity is just recently gaining importance in higher education in Germany as a possible factor impacting retention rates in science study programmes. Since German language instruments for surveying higher education students' science identity are lacking, this study validated a scale for use in chemistry-related programmes. Areas of science identity negotiations were drawn from science identity theory following Carlone and Johnson (2007) and Hazari et al. (2010). From a review of existing English language scales, a science identity scale with references to science identity theory and professional aspirations was chosen and translated. Hypotheses concerning validity were formulated and tested. Evidence of face validity and content validity was collected by means of discussion with science education experts and in qualitative think alouds with Bachelor students in chemistry-related courses. A quantitative survey of Bachelor students in chemistry and primary science was used to examine convergent and differential evidence of validity. The study generated evidence for the validity of the scale for use with higher education students in chemistry-related programmes. In future studies with German-speaking students, the scale can be used as an indicator of professional science identity and its utility as a predictor of retention and completion of chemistry-related higher education courses can be examined.

Keywords: identity negotiation, measurement instrument

Introduction

Both numbers of enrolment in chemistry programmes and successful completions have been declining over the last decade (GDCh, 2024). While attrition and drop-out from higher education and their interplay with study-related variables have been studied extensively in the German context (e.g. Fischer et al., 2020), science identity has not yet been considered a possible predictor in chemistry. Even though developing a science identity is important for professional aspirations of science learners (Archer et al., 2015) and success in higher education (Carlone & Johnson, 2007), science identity is rarely studied in higher education in Germany (Borchert & Schwedler, 2024; Danielsson et al., 2023; Günter et al., 2023; Schmid, 2023).

Identity is often described as "[b]eing recognized as a certain 'kind of person' in a given context" (Gee, 2000, p. 99). These recognition processes are based on shared, normative expectations about what constitutes that kind of person (cf. virtual social identity, Goffman, 1963). Areas of negotiation of those identity norms in science are competence, performance, recognition and interest (Carlone & Johnson, 2007; Hazari et al., 2010). A science identity scale should therefore be able capture identity negotiations along these norms.

There are several English language measurement instruments for science identity, some focusing on specific subjects, e.g. chemistry (Wolfe, 2013; Hosbein & Barbera, 2020) or physics (Hazari et al., 2010; Wulff, 2019). Often a single-item indicator of seeing oneself or being seen as a science person is used, together with related scales for the areas of science identity negotiation (Archer et al., 2015; Hazari et al., 2010; Hosbein & Barbera, 2020; Schmid, 2023). Shorter scales combine the areas of negotiation (e.g. Wolfe, 2013), survey belonging to the community of scientists (Byars-Winston et al., 2016) or professional aspirations (Lockhart et al., 2022; Williams et al., 2018). However, there are no short instruments in German for professional science identity

in higher education. This study therefore validated a German translation of the scale by Williams et al. (2018) for use in chemistry-related courses.

Research Questions And Hypotheses

The science identity scale by Williams et al. (2018) addresses the areas of negotiation of science identity norms and professional aspirations by relating science identity to a professional future self. This focus is of interest to our intended use of the scale with higher education students as a predictor for attainment or drop-out (Beaujean, et al., 2025).

Validation of the German translation followed the research question: To what extent can the translated scale be used as an indicator of professional science identity (PSI) when administered to Bachelor students in chemistry-related study programmes with the aim to assess interindividual differences in the extent of PSI?

The validation process (Hartig et al., 2020) was guided by the following hypotheses:

H1: The score on the PSI scale is linked to the areas of science identity negotiation.

H2: Differences in scores on the PSI scale can in part be traced back to difference in the enrolment in a study programme.

Methodology

Translation And Think Aloud

The science identity scale by Williams et al. (2018; cf. Supplement 2) was chosen for translation to German. Its nine items each consist of a statement about the participants and their relation to science (e.g. Item 1: “I am the kind of person who can succeed in science”; German translation: “Ich bin so eine Person, die in den Naturwissenschaften erfolgreich sein kann”). Experts in chemistry education assessed whether the translation was idiomatic and consistent with the aims of the scale.

After revision of the translation, five Bachelor students in chemistry-related study programmes answered the items and commented on the scale in a think aloud study (Kansizoglu, 2024). Qualitative content analysis (Kuckartz & Rädiker, 2023) was used to analyse transcriptions of the audio recordings. The areas of science identity negotiation, “Competence”, “Performance”, “Recognition” and “Interest” (Carlone & Johnson, 2007; Hazari et al., 2010) were used as deductive categories for coding. The remaining data was coded inductively as fitting in with science (“Fit”) and job and career negotiations (“Aspirations”).

Collection Of Quantitative Data

In an online survey, the scale was administered to students in two chemistry-related Bachelor programmes (Chemistry and Primary School Science) during the summer terms of 2024 and 2025 at a German full university. The survey also contained established German language scales on interest in chemistry, chemistry self-efficacy and chemistry self-concept (van Vorst, 2013; cf. Schmid, 2023) for comparison to areas of science identity negotiations. All instruments were scored on a 4-point rating scale. Demographic data comprised age, gender identity, study programme, semester, academic generation, grade of school-leaving certificate and course profiles for chemistry.

Analysis Of Quantitative Data

Internal structure of the PSI scale was determined using exploratory factor analysis (EFA) with principal axis factoring and promax rotation (Weiber & Sarstedt, 2021). Parallel analysis was run

to determine factor structure (Weiber & Sarstedt, 2021) and reliability was calculated using Cronbach's Alpha.

In order to examine evidence for convergent validity (H1), the mean score on the PID scale was correlated with the mean scores on the scales for interest, self-efficacy and self-concept using Pearson correlation coefficient.

Differential evidence (Kline, 2016; H2) was examined by testing mean scores of PSI for differences between study programmes with the two groups of chemistry students and primary teacher students. The latter group studies general concepts of chemistry among other natural and social sciences in their education courses but does not participate in courses such as physical or organic chemistry. Therefore, lower scores on the PSI scale were expected for the primary science students than for the chemistry students. Since Shapiro-Wilk test indicated that data in the chemistry group were not normally distributed, differences were tested using Mann-Whitney U test.

Description Of Sample

The sample consisted of 133 participants. 36 were chemistry students and 97 primary teacher students. On average, the students were 22 years old and in their third semester. 94 students identified as women, 36 as men and 3 reported a non-binary gender identification. 71 students were first generation academics, 61 were at least second-generation academics.

Mean grade of school-leaving certificate ("Abitur", the grading system ranges from 1.0 (highest) to 4.0 (lowest passing grade)) was 2.2 ± 0.57. Regarding the course profiles for their school-leaving certificate, 23 students had studied advanced level chemistry, 46 basic level chemistry and 62 students had had no chemistry classes.

Results

Evidence Of Content Validity (H1)

In the think aloud study the students reported on their thoughts when reading and answering the PSI items. Evidence was found for all four areas of science identity negotiations. There were 16 codings addressing aspects of competence and 5 codings about performance in science. In 8 codings, recognition as a science person was expressed and 11 codings reported on student interest in science. The remaining data was coded inductively. There were 30 codings in which the students negotiated fitting in with science biographically and currently, while 21 codings dealt with their future job and career aspirations of becoming a science professional.

EFA with parallel analysis indicated an 8-item scale with one-factorial structure. Following EFA, item 9 was eliminated from the scale. Cronbach's Alpha of the 8-item scale was 0.895, indicating high reliability.

Convergent (H1) And Differential (H2) Evidence

Mean PSI score was found to correlate significantly and with a large effect size with interest in chemistry ($r = 0.667$; $p = .000$) and chemical self-concept ($r = 0.561$; $p = .000$) and with a medium effect size with chemical self-efficacy ($r = 0.423$; $p = .000$).

Chemistry students (MD = 3.6; IQR = 0.7; $n = 36$) scored higher on the PSI scale than primary teacher students (MD = 2.9; IQR = 0.6; $n = 97$) with a large effect size ($U = 555.550$; $p < .001$; $r = 0.52$).

Discussion And Conclusion

The study provides evidence of validity and reliability of the PSI scale for use with students in chemistry-related study programmes. Both hypotheses were supported by data analysis. Think aloud data further underpins that participants negotiate their identities against the norms of science identity and a professional self in science when answering the items.

Chemistry students score higher on the PSI scale than students of primary school science, indicating that the scale can distinguish students in degree programmes with varying importance of chemistry.

As sample sizes of the sub-groups differed, more data from students of chemistry need to be collected and confirmatory factor analysis needs to be run to assess factor structure in order to complete the validation process.

The PSI scale can be used as an indicator of professional science identity negotiations in higher education students. Its utility as a predictor of retention and completion of higher education chemistry programmes can be examined.

ESERA 2025 Copenhagen

Examining Cultural Influences On The Development Of Classification Among Indigenous Students

Yun-Ping Ge, Andrew Jackson Manier, Erica Sandy Lin and James Ian Juan Espina
National Taipei University of Education, Taiwan

In multicultural science education, classification is often treated as a neutral cognitive skill aligned with scientific taxonomy, while culturally embedded ways of organizing knowledge receive limited attention. Grounded in epistemological pluralism, a worldview perspective, and developmental psychology, this study examines how classification develops among Indigenous Tao learners and how cultural and experiential factors shape classification practices across age groups. Participants included Tao middle and upper elementary students and community elders. They completed a two-phase classification task involving living organisms, followed by semi-structured interviews. Data were analysed using an iterative coding scheme integrating theoretically informed categories with participants' sorting rationales and verbal explanations. Three interrelated patterns were identified. First, developmental shifts were observed in students' classification criteria, with upper elementary students demonstrating more stable use of biologically defined attributes and greater linguistic precision than younger students. Second, cultural influences on classification increased with age: elders consistently emphasized relational and ecological criteria grounded in lived experience, such as habitat and food chains, reflecting culturally embedded ways of knowing rather than less advanced reasoning. Third, instances of misunderstanding decreased over development and were primarily associated with early linguistic and conceptual instability, rather than cultural differences. These findings challenge deficit-oriented interpretations of Indigenous learners' scientific reasoning and reconceptualize classification as a developmental and culturally mediated practice. The study highlights the interaction of cognitive development, language, and worldview in shaping classification, and underscores the value of integrating Indigenous ecological knowledge within more inclusive approaches to science education.

Keywords: classification, developmental psychology, indigenous knowledge, epistemological pluralism, world view

Introduction

The Indigenous Tao people are a minority Austronesian group who migrated from Taiwan to the Philippines and later returned to a small island due to famine. Their culture, particularly fish taxonomy and dietary practices, differs significantly from scientific classification systems. However, this traditional knowledge is increasingly endangered, as modernization continues to replace indigenous ways of living. In formal schooling contexts, scientific taxonomy is often prioritized, while culturally embedded classification systems receive limited attention.

Previous empirical research in indigenous science education has demonstrated that learners' understanding of nature is not shaped solely by formal schooling, but is deeply intertwined with language practices, lived ecological experience, and culturally embedded knowledge systems. Evidence from longitudinal research involving Tao learners across age groups suggests that reasoning about living organisms consistently reflects relational and experience-based orientations, particularly in contexts where ecological interaction forms part of everyday life (Ge, 2022; Ge, 2023). At the same time, both local culture and school education play crucial roles in shaping students' understanding of scientific classification (Aikenhead & Jegede, 1999). In response to concerns about cultural erosion, the Taiwanese Ministry of Education has recently promoted culturally responsive curricula aimed at revitalizing indigenous knowledge. However,

how such cultural restoration efforts interact with formal science education remains insufficiently understood, raising important questions about how these frameworks coexist—or potentially conflict—in shaping students' learning experiences.

Classification is a fundamental and essential component of the Taiwanese elementary science curriculum at both middle and upper levels. Recent scholarship has emphasized that classification systems, like ethical judgments in science, are culturally mediated rather than universal, reflecting historically and socially situated ways of knowing (Castagno et al., 2023). From a worldview perspective, classification can be understood as reflecting underlying cognitive and cultural frameworks that organize how learners make sense of nature, rather than as an isolated cognitive skill detached from experience (Aikenhead, 2001). Although a small number of studies have explored how indigenous traditions and ways of thinking influence pupils' learning of taxonomy (Fu, 2004; Ge, 2023; Lee, Yen, & Aikenhead, 2012), classification as a developmental and culturally situated practice remains underexplored. In particular, empirical research examining how cultural influences shape the development of classification among Tao children is still limited. Greater attention to this issue may offer valuable insights for both science education research and policy initiatives within the Ministry of Education.

Research Questions

Accordingly, this study aims to explore the development of classification among Tao children across middle and upper elementary school levels, while also examining the extent to which cultural influences shape their classification processes. To address these aims, the study was guided by the following research questions:

1. How do Tao children at different elementary school levels classify living organisms in a sorting task?
2. What developmental shifts can be identified in Tao children's classification criteria across middle and upper elementary school levels?
3. How do cultural and ecological experiences influence Tao children's classification reasoning?

By situating classification within a worldview-oriented and epistemologically plural framework, this study seeks to contribute to a more nuanced understanding of how indigenous knowledge and formal science education interact in shaping children's scientific reasoning.

Theoretical Framework

In contemporary multicultural contexts, epistemological pluralism has increasingly been advocated as a way to challenge the exclusive representation of scientific knowledge in science education (Cobern & Loving, 2001; Sjöström, 2025). Grounded in theories from cultural anthropology and developmental psychology, this study examines the mechanisms underlying classification reasoning. From a worldview perspective, classification is not merely a technical or cognitive activity but reflects an organized framework of assumptions about reality. According to worldview theory (Kearney, 1984), people's ways of classifying the natural world are shaped not only by internal cognitive coherence, but also by ongoing interactions with, and adaptations to, their surrounding environments.

From a developmental psychology perspective (Bjorklund, 1995; Inhelder & Piaget, 1964; Vygotsky, 1962), although different theoretical traditions employ varying terminologies to describe cognitive developmental stages, they share the assumption that cognitive development unfolds over time. Early classification tends to rely on arbitrary or perceptual groupings, followed by organization based on relationships or associations, and eventually by categorization based on

shared attributes. While Inhelder and Piaget (1964) emphasized a relatively sequential progression aligned with cognitive maturation, Bjorklund (1995) and Vygotsky (1962) proposed more flexible developmental models that allow for variability across contexts and individuals. Importantly, Vygotsky (1962) argued that the development of classification is closely intertwined with language use, social interaction, and cultural participation, highlighting classification as a socioculturally mediated process rather than a purely logical operation.

Cultural influences on classification have been empirically demonstrated in cross-cultural psychology. For example, Ji, Zhang, and Nisbett (2004) found that Chinese participants tended to categorize objects based on relationships, whereas Western participants more frequently relied on shared attributes, suggesting that classification strategies are shaped by culturally patterned modes of reasoning and environmental affordances. More recent scholarship has extended this perspective by questioning the assumption that scientific knowledge—and the ethical judgments embedded within it—is epistemically neutral or culturally universal. Instead, ethics and knowledge practices are increasingly understood as culturally mediated, shaped by histories, epistemologies, and community practices (Castagno et al., 2023). From this viewpoint, tensions between Indigenous traditions and scientific knowledge are not merely ideological differences, but reflect encounters between distinct epistemological systems. Similarly, science learning has been conceptualized as relational, value-laden, and culturally situated, with knowledge produced through relationships among people, environments, histories, and purposes (Sjöström, 2025).

Research Method And Design

To investigate Tao children's classification patterns, this study employed a task adapted from Ji, Zhang, and Nisbett (2004). The task consisted of six sets of photo cards, each representing three common living organisms found on the island.

Phase I: Categorization Task

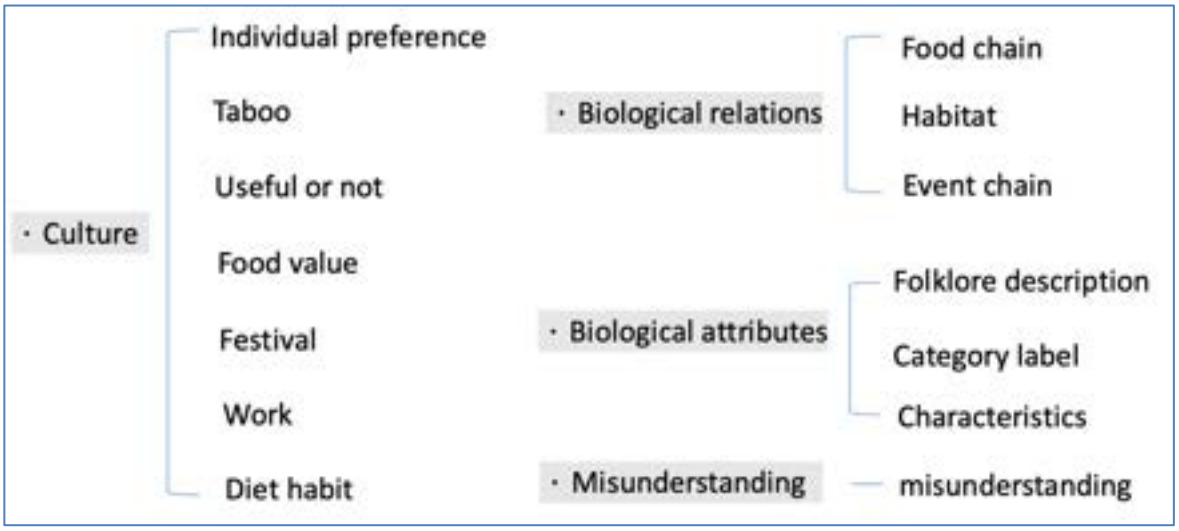
In the first phase, participants were asked to group two out of the three organisms together and explain the reasoning behind their choice. For example, if a participant grouped a pig and a monkey together while excluding a tree, stating that "both are animals," the response was coded as "characteristics" under the theme of "biological attributes" (as illustrated in Figure 1). Conversely, if a participant grouped a monkey and a tree together because "the monkey lives in the tree," the response was coded as "habitat" under the theme of "biological relations."

Phase II: Free Sorting Task

In the second phase, participants were instructed to freely sort all six sets of living organisms into groups based on their own criteria. To minimize linguistic influence, the selected organisms did not share any suffixes, affixes, or word roots in the Tao language.

Semi-Structured Interviews

In addition to the categorization task, participants took part in a semi-structured interview to assess their understanding of classification. At the beginning of the interview, they were asked whether they recognized the concept of classification. After completing the task, they were asked to reflect on whether their grouping decisions represented a form of classification



Data Analysis

Data analysis was guided by the study’s theoretical framework and research questions, drawing on perspectives from worldview theory and developmental psychology. The analysis aimed to examine how participants’ classification practices reflected both developmental patterns and culturally situated ways of reasoning. Rather than treating classification as a single outcome, the

analysis focused on the criteria and rationales participants used when grouping living organisms, as these were understood to index underlying cognitive, linguistic, and cultural orientations.

Participants' sorting decisions and verbal explanations were analysed iteratively. Initial coding focused on identifying the primary criteria used in classification, such as biological attributes and biological relations. These preliminary categories were informed by prior research on classification development and cross-cultural reasoning, providing an initial analytic lens for examining participants' responses. Comparisons were then conducted across middle elementary, upper elementary, and senior participants to identify developmental shifts and variations associated with age and lived ecological experience.

Figure 1. Coding scheme of classification criteria with 4 themes and 14 codes.

The coding scheme presented in Figure 1 was developed through an iterative process integrating theoretical perspectives and empirical data. As analysis progressed, participants' verbal explanations were closely examined to capture how classification criteria were articulated in practice. This process led to the refinement and expansion of coding categories, including the identification of culturally embedded reasoning, such as references to ecological practices, subsistence activities, and everyday experiences. Instances in which participants' explanations reflected ambiguous or inconsistent use of classification concepts were coded separately as misunderstandings, allowing analytic distinction between alternative epistemic orientations and conceptual confusion.

Consistent with a sociocultural perspective, participants' verbal explanations were treated as essential analytic data rather than supplementary comments. Attention was given to how language use, experiential references, and culturally grounded knowledge informed classification reasoning. Through this combined analytic process, the final coding scheme represents a synthesis of theoretical expectations and empirical regularities, providing a structured yet context-sensitive framework for interpreting classification as a developmental and culturally mediated practice within indigenous science learning contexts.

Participants

The study recruited both Tao elementary students and seniors as participants. Among the students, those in grades 3 and 4 were categorized as the middle school level group, while those in grades 5 and 6 were classified as the upper school level group. Table 1 presents the basic demographic information of the participants. Most of the senior participants had received a junior school education, while two had earned a bachelor's degree.

According to Table 1, the result that many students defined classification as waste sorting is related to Taiwanese waste management. Waste sorting has to be done before garbage disposal.

The data of seniors was drawn on previous study as reference so that the definition of classification and identification if their work is a kind of classification were not available in Table 1. Data analysis is based on the interview transcription and criteria of categorization. A coding scheme of 4 themes and 14 codes, shown as Figure 1, is developed for further comparison and analysis.

Table 1. Basic information about participants.

	number	gender	define classification	Is the work classification?
Middle elementary students	23	7 females 16 males	65% (n=15) waste sorting 13% (n=3) organize things 22% (n=5) sorting by common attributes	All confirmed
Upper elementary students	16	6 females 10 males	6% (n=1) unknown 44% (n=7) waste sorting 50% (n=8) sorting by common attributes	All confirmed
Seniors	24	12 females 12 males		

Findings And Discussion

The findings are presented with respect to three interrelated themes: developmental shifts in classification criteria, the increasing salience of cultural influences with age, and the reduction of conceptual misunderstanding over development.

I - Developmental Shift In Classification Criteria

Students' classification performances revealed clear developmental patterns that align with, but also extend, perspectives from developmental psychology. As shown in Table 2, upper elementary students were more likely to classify living organisms based on biological attributes (61.5%) than middle elementary students (49.4%) in Phase I. This pattern is consistent with developmental accounts suggesting that increasing cognitive maturity supports more stable use of attribute-based categorization. At the same time, the frequent misuse of terminology among middle-level students—for example, using "living things" to refer specifically to "animals"—indicates that younger students' classification reasoning is closely intertwined with ongoing language development. Classification at this stage appears to rely not only on perceptual features, but also on emerging linguistic resources that constrain how biological categories are expressed and differentiated.

In contrast to students' predominant reliance on biological attributes, seniors consistently classified organisms based on biological relations, such as habitat, food chains, and ecological interactions, across both Phase I and Phase II (Tables 2 and 3). Interview data revealed that many seniors explicitly drew on lived experiences of survival on the island, including fishing practices and long-term interactions with local organisms, when explaining their sorting decisions. Rather than indicating a less advanced form of classification, this relational pattern reflects an experience-driven mode of reasoning grounded in sustained engagement with the external environment. From a worldview perspective, seniors' classifications can be understood as the outcome of accumulated ecological knowledge, in which relationships among organisms are more salient than abstract categorical boundaries. This finding challenges a strictly linear interpretation of classification development and supports sociocultural models that emphasize variability in developmental trajectories shaped by experience and environmental adaptation.

Results from Phase II further illuminate the interaction between development, language, and classification. When participants were provided with a wider range of biological vocabulary, such as reptile categories, upper-level students demonstrated improved linguistic precision in their explanations. However, the overall reliance on biological attributes remained relatively consistent between middle and upper elementary students (Table 3). This suggests that while language development enhances students' ability to articulate classification decisions, it does not necessarily shift their underlying classification orientation. Developmental change in classification thus involves not only cognitive maturation, but also the expanding availability of linguistic and experiential resources that shape how classification criteria are selected and justified.

Table 2. Criteria of classification-the themes appear in Phase I.

Theme	Middle level students	Upper level students	Seniors
Culture	4.0%	6.3%	23.1%
Biological relations	25.0%	31.3%	63.9%
Biological attributes	49.4%	61.5%	9.5%
Misunderstanding	21.6%	1.0%	3.4%

Table 3. Criteria of classification -the themes appear in Phase II.

themes	Middle level students	Upper level students	Seniors
Culture	5.0%	11.2%	24.5%
Biological relations	31.5%	32.2%	55.0%
Biological attributes	50.8%	50.0%	19.9%
Misunderstanding	12.6%	6.6%	0.7%

Importantly, evidence beyond the sorting tasks further supports this interpretation. Interview data from a parallel longitudinal project (MOST 111–MY2) revealed convergent reasoning patterns, in which Tao participants across age groups consistently framed living organisms through relational, ecological, and culturally embedded explanations. This cross-task consistency indicates that the observed classification patterns reflect relatively stable epistemic orientations rather than task-specific strategies. Taken together, these findings suggest that differences between students' attribute-based classifications and seniors' relational classifications are best understood not as developmental deficits, but as distinct ways of organizing biological knowledge shaped by language development, lived experience, and culturally grounded worldviews.

II-Cultural Influence Increases With Age

Beyond developmental shifts in classification criteria, the findings indicate that cultural influences on classification become increasingly salient with age. As shown in Tables 2 and 3, seniors demonstrated the highest proportion of culturally grounded classification, frequently drawing on traditional ecological knowledge, subsistence practices, and culturally meaningful relationships among living organisms. In contrast, cultural references were comparatively rare among middle and upper elementary students, whose classifications were more strongly anchored in biologically defined attributes. This age-related pattern suggests that cultural knowledge does not merely coexist with scientific classification but progressively shapes how classification criteria are selected and prioritized over time.

From a worldview perspective, this pattern aligns with Kearney's (1984) assertion that classification systems reflect organized cognitive frameworks shaped through ongoing

interaction between individuals and their environments. Seniors' reliance on cultural reasoning indicates that classification is not simply a cognitive operation applied to biological entities, but a practice embedded within socio-cultural histories and lived ecological experiences. Cultural knowledge in this context functions as an interpretive framework that foregrounds relationships, purposes, and ecological interdependence, rather than abstract taxonomic boundaries.

These findings also resonate with research in cultural psychology demonstrating systematic differences in categorization strategies across cultural contexts. Ji, Zhang, and Nisbett (2004), for example, found that individuals from East Asian cultural backgrounds tend to emphasize relational classification, whereas Western participants more often rely on categorical attributes. The Tao seniors' classification practices extend this line of research by illustrating how relational and culturally embedded reasoning is not only culturally patterned, but also developmentally reinforced through long-term participation in local ecological and social practices. Taken together, the results suggest that indigenous classification systems represent integrated ways of knowing that connect biological understanding with cultural meaning, rather than deviations from scientific classification norms.

III-Reduction In Misunderstanding Over Development

In addition to developmental shifts and increasing cultural influence, the findings reveal a clear reduction in misunderstanding across age groups. As shown in Tables 2 and 3, instances coded as misunderstanding were more prevalent among middle elementary students and decreased substantially among upper elementary students and seniors. This pattern suggests that conceptual confusion in classification is not a stable characteristic of indigenous learners' reasoning, but rather a transitional phenomenon associated with early stages of cognitive and linguistic development.

Closer examination of students' explanations indicates that misunderstandings among younger participants often stemmed from limited linguistic resources and incomplete differentiation of biological categories, rather than from culturally grounded ways of knowing. For example, the use of overly general terms or inconsistent category labels reflected difficulties in articulating classification criteria, rather than alternative epistemic orientations. As students gained greater linguistic precision and conceptual stability, such ambiguities diminished, even as cultural or relational reasoning did not necessarily increase in the same way. This distinction is analytically important, as it underscores the need to differentiate between misunderstanding as conceptual instability and culturally embedded reasoning as a coherent way of organizing knowledge.

From a sociocultural and worldview perspective, the reduction of misunderstanding over development further supports the interpretation that indigenous learners' classification practices are shaped by expanding linguistic, cognitive, and experiential resources. Seniors' near absence of misunderstanding, alongside their strong reliance on relational and ecological criteria, indicates that culturally grounded classification is not a less developed form of scientific reasoning, but a stabilized epistemic orientation supported by extensive lived experience. Taken together, these findings suggest that effective science education in indigenous contexts should not aim to replace cultural ways of knowing, but to support learners in developing the linguistic and conceptual resources needed to navigate and articulate multiple classification frameworks.

Conclusion

This study examined the development of classification among Tao learners across middle and upper elementary school levels, with particular attention to how developmental, linguistic, and cultural factors shape classification practices. By integrating perspectives from developmental psychology, worldview theory, and epistemological pluralism, the findings offer a nuanced

account of classification as a culturally mediated and developmentally situated practice rather than a purely technical cognitive skill.

Across the findings, three interrelated patterns emerged. First, developmental shifts in classification criteria revealed that students increasingly relied on biologically defined attributes as cognitive and linguistic resources expanded, while seniors predominantly emphasized relational and ecological criteria grounded in lived experience. These patterns align with developmental theories yet also extend them by demonstrating that relational classification among elders reflects stabilized ecological knowledge rather than a less advanced stage of reasoning. Second, cultural influences on classification became more salient with age, as seniors' classifications drew extensively on traditional ecological knowledge and culturally meaningful relationships among organisms. From a worldview perspective, these findings highlight how classification functions as an epistemic practice shaped by sustained interaction with specific environments and cultural histories. Third, the reduction of misunderstanding over development underscores the importance of distinguishing conceptual instability associated with early language development from culturally embedded ways of knowing. As linguistic precision and experiential grounding increased, misunderstandings diminished, while culturally grounded classification orientations remained coherent and stable.

Taken together, these findings challenge deficit-oriented interpretations of indigenous learners' scientific reasoning and instead support a view of classification as a practice that emerges through the dynamic interplay of cognitive development, language use, and cultural participation. For science education, particularly in multicultural and indigenous contexts, this study suggests the value of pedagogical approaches that do not seek to replace indigenous ways of knowing, but rather support learners in navigating and articulating multiple classification frameworks. By recognizing relational and ecological reasoning as legitimate forms of scientific sense-making, science education can move toward more inclusive and contextually responsive practices.

Limitations And Future Research

Several limitations of this study should be acknowledged. First, the classification tasks employed in this research focused on living organisms within a specific ecological and cultural context. While this design was intentional and theoretically grounded, the findings may not be directly generalizable to other indigenous groups or scientific domains without further investigation. Second, although the study incorporated multiple data sources, including sorting tasks and interviews, the analysis relied primarily on qualitative coding of participants' explanations. Future research could complement this approach with longitudinal designs or mixed-method analyses to examine how classification practices evolve over time within individuals.

Future research could also explore how instructional interventions explicitly designed to bridge indigenous and scientific classification systems influence students' reasoning and language use. Comparative studies across different indigenous communities would further illuminate how diverse ecological contexts shape classification practices and worldview orientations. Finally, extending this line of inquiry to classroom-based interactions could provide deeper insight into how teachers and students negotiate multiple epistemic frameworks during science learning. Such research would contribute to ongoing efforts in science education to develop culturally responsive pedagogies that respect epistemological diversity while supporting students' scientific understanding.

Positioning Towards Science From An Identity Perspective: Results Of An Interview Study With Pupils In Their Initial Science Lessons

Lisa-Marie Christ[1], Olaf Krey[1], Frederik Bub[2] and Thorid Rabe[2]
[1]University of Augsburg, Germany
[2]Martin Luther University Halle-Wittenberg, Germany

The identity perspective is one way to better understand educational choices. Against this background, pupils' perceived approaches to science and their first institutionalised encounters with science, for example in subject lessons, can provide initial indications of their educational decisions throughout their educational careers. The aim of this research project is to gain a better understanding of how grammar school pupils perceive and position themselves in relation to science and science lessons, particularly in physics and chemistry during their first two years of science education. Guided and narrative-based individual interviews were conducted in two German federal states and 15 different grammar schools. The interview study comprises two waves of data collection, with all learners having experienced at least one school year of physics lessons at the time of the first interview. In a first step we focus our analysis on understanding which aspects students use to position themselves in relation to science and physics in their first interview. The qualitative content analysis of 30 interviews led to the development of a category system with four main categories: personal characteristics, school biography, science (subjects) and physics (lessons). The analysis reveals that students primarily position themselves on the basis of the science lessons they have experienced. The four main categories also correspond to core areas of students' (science) identity development.

Keywords: Early Science Education, Qualitative Research, Science Identities

Introduction

According to international science education research, educational choices, such as the decision to engage with or distance oneself from science, or the experience of feeling included in or excluded from scientific communities, can be understood in relation to identity (Archer et al., 2010; Carlone & Johnson, 2007). A preliminary understanding of identity can be drawn from socio-psychological and sociological perspectives: identity formation involves both self-knowledge and self-image, as well as the perceptions and ideas developed through interactions with others (Morf, 2023; Shanahan, 2009). Therefore, identity construction can be seen as a negotiation process influenced by an individual's social context and embedded within broader societal frameworks (Regan & DeWitt, 2015).

Theoretical Background

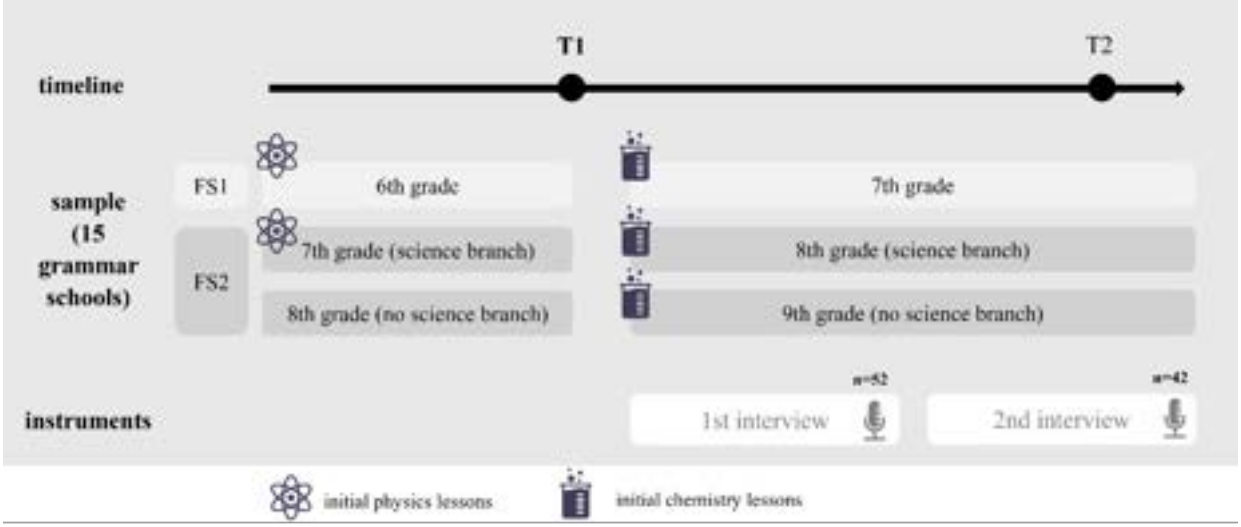
In the research project IdentMINT the construct of identity is employed as a multi-perspective framework to analyse students' engagement with and positioning towards science. Our identity framework focuses on students as whole persons, rather than isolating individual educational constructs (Avraamidou, 2020; Rabe & Krey, 2018), thereby placing their self-perception and relevance systems at the center of the inquiry.

Numerous studies have explored science identities and found that gender, ethnicity, and socio-economic background significantly influence educational trajectories (e.g., Archer & DeWitt, 2015; Hazari et al., 2022; Holmegaard et al., 2014; Kessels et al., 2006). However, there remains a research gap regarding how introductory physics and chemistry education shapes identity negotiation (Rabe & Krey, 2018). This is especially important given that, in many countries, including Germany, institutional encounters with science coincide with adolescence, a critical

phase of identity development. A developing physics identity may conflict with other identities, such as a students' gender identity (Brickhouse et al., 2000).

Positioning is regarded as a relational construct and constitutes an integral part of human communication and understanding (e.g. through actions, speech acts or social interaction). It assigns a relational position to both persons and objects in social space, either explicitly or implicitly (Davies & Harré, 1990; Harré & Van Langenhove, 1991). In the research project IdentMINT, positionings are reconstructed from linguistic expressions, i.e. statements made by learners about an object, and are regarded as indicators of identities. This understanding aligns with Harré and Van Langenhove (1991), who emphasise that narratives in which people talk about themselves differ according to how the individuals wish to present themselves.

Research Interest



In Germany, science education is based on subject-specific lessons like physics, chemistry and biology, rather than an integrated subject "science". The goal of IdentMINT is to deepen our understanding of how grammar school students perceive and relate to science, particularly in physics and chemistry, during the initial years of their formal science education. The central research question is: How do young learners position themselves towards science, particularly physics and chemistry, when talking about it?

Study Design And Interview Sample

The research project employs a mixed-methods approach, combining the interview study presented in this article with a longitudinal questionnaire survey.

Narratives, in which students shed light on their own experiences, offer valuable opportunities for identity formation (Lucius-Hoene & Deppermann, 2002). Accordingly, guided, narrative-based individual interviews were conducted with students from fifteen different grammar schools across two federal states of Germany (FS1: Saxony Anhalt, FS2: Bavaria). The interview study comprises two data collection points (T1 and T2). By T1, all participants had completed at least one year of physics education and by T2, they had additionally completed one year of chemistry (see Figure 1). However, the present article reports only findings from interviews conducted at T1.

Figure 1. Overview of the longitudinal interview study design.

The interview sample was selected to be as heterogeneous as possible with respect to gender, ethnic background and migration history, interest in science, and Science Capital. The relevant school authorities have approved the data collection from an ethical and legal perspective. The sole requirement for participation was voluntary consent, authorized by the participants' legal

guardians. At T1, the sample comprised 52 students from grades 6 and 7 (FS1) or 7 to 9 (FS2), 42 of whom also participated at T2.

Data Analysis And Findings

To answer the research question, the interviews were analysed using qualitative content analysis (Kuckartz, 2018). The category system was developed on the basis of a reduced sub-sample of 30 learners, selected to ensure broad coverage of the aforementioned characteristics. The category development followed a combined deductive-inductive approach: initial categories were derived deductively from the interview guideline and the theoretical and empirical literature in the field. The categories were subsequently refined and specified inductively based on the interview transcripts. Throughout the analysis process, intercoder agreement is regularly assessed; so far, a 'substantial' level of agreement has been achieved with k_n= 0.73 (Brennan & Prediger, 1981). The developed category system will be applied to the remaining 22 interview transcripts and revised if necessary. Below, we will provide an illustrative insight into the category system, including selected illustrative examples.

Insight Into The Category System

As a first result, we identified four main categories, along with their respective subcategories, which highlight key aspects that students use to position themselves in relation to science:

- *Personal Characteristics* (e.g., self-attributed qualities, hobbies, career aspirations, role models, health-related aspects)
- *School Biography* (e.g., favourite subjects, influential people at school, transition from elementary to grammar school, school choice, selection of subject focus)
- *Science (Subjects)* (e.g., associations with science (subjects), general interest in science, extracurricular engagement with science, science-related activities at home)
- *Physics (Lessons)* (e.g., engagement with physics (lessons), comparisons with other subjects, attribution of ability, significant others in relation to physics (lessons), gender stereotypes in physics, factors leading to rejection)

Revealing information about oneself – such as discussing hobbies or career aspirations – can involve an explicit or implicit act of positioning in relation to science. Statements that provide such information have been assigned to the *Personal Characteristics* category.

Similarly, discussion of one's own school biography was identified as a form of positioning. Narratives about favourite subjects or the choice of grammar school often reflect positionings towards science that were therefore assigned to the *School Biography* category.

It is also noticeable that the learners tend to express themselves in a more vague and distant manner when referring to science in general compared to physics, chemistry, and biology. In their narratives, they predominantly draw on experiences from subject-specific lessons. To illustrate these subject-specific modes of positioning, we present examples from the following subcategories of *Physics (Lessons)* category:

- *Physics in Comparison with Other Subjects*,
- *Significant Others in Relation to Physics and Belonging*, and
- *Attribution of Ability*.

One common form of positioning is comparing physics with other subjects. Students typically identify a characteristic of physics and relate this characteristic to themselves. The following

excerpt from the interview with Ajala (pseudonyms are used) illustrates such a comparison, in this case between the subject of physics and German:

> "Physics also has its grammar, or something like that. In other words, [also in physics] there are things you must be able to do or know ways how you should approach it. In German, however, one can talk […]. German also has a gut feeling. You can answer something with a gut feeling, but in science it's just facts and you must be able to justify them and so on." (Ajala, grade 8; Pos. 167)

A second subcategory captures forms of positioning through significant others and a sense of belonging. Students position themselves in relation to physics by referring to people associated with this subject. For example, Latif emphasises his passion for physics to set himself apart from his classmates:

> "I would like to talk about physics, but I don't exchange ideas much, actually not at all, because I don't think my classmates are very interested in it. Or they just don't care or don't want to talk about class. Maybe it's boring for them." (Latif, grade 7; Pos. 155)

Finally, pupils also position themselves in relation to science by means of ability attributions. They describe their perceived skills, challenges in physics and strategies for handling physics tasks. Elza, for example, talks about her confidence when experimenting in physics:

> "Yes, I really like experimenting because you can somehow better understand the whole thing working, so much better than when someone describes how the experiment should have gone or when the teacher demonstrates it in front of you. So, when you experiment yourself, it's just somehow cooler and more practical." (Elza, grade 9; Pos. 105)

Case Analysis – An Example

A second finding is that positioning is highly individual, particularly within these subject-specific modes of positioning. To illustrate this, we present several examples from a single student, Laila.

At the time of the first interview, Laila was in grade 8 and had chosen the science profile at her grammar school. With the start of the new school year, she was placed in a new class, which was challenging for her because she had to make new friends. All her previous friends selected the language branch and are therefore in other classes. When asked why she chose the science branch, Laila expressed a generally positive view of science, presenting herself as a student interested in chemistry and capable of meeting the performance expectations in both chemistry and physics. However, in retrospect, it is evident that she had not anticipated experiencing difficulties with physics:

> "So, for me, it was clear that I would take the science branch. Because I simply wanted to have chemistry lessons as soon as possible, and I find it difficult to learn languages, so the idea of writing school assignments in chemistry and physics, that wouldn't bother me so much (laughing). Except that I already have a few problems with physics. But otherwise, it was an easy decision for me to choose science." (Laila, grade 8; Pos. 47)

When asked about her experiences in physics, she positions herself as 'not a big fan':

> "Oh, (laughing) physics. So, I'm not a big fan. So, at first, when we started, I think last year, I really tried to have fun and so on. So, the topic of light, I had some fun, because there were lots of activities and experiments and doing, and observations. But NOW there are just formulas, and lots of mathematics. And I don't like maths at all. For me, so to speak, physics is now a second maths." (Laila, grade 8; Pos. 67)

Her explanation highlights her conflict with physics: although she enjoys certain topics and scientific activities such as experimentation and observation, the mathematical nature of physics poses a challenge for her. As a result of her experiences in physics lessons, the subject feels like a second mathematics class, which is particularly significant because she dislikes mathematics. Nonetheless, her belief that physics should be enjoyable remains evident.

Her favourite subject at school is a science subject: biology. In the following interview excerpt, she emphasizes the personal relevance and her interest in biological topics, particularly in plants:

> "I like those [biological] topics, they are very interesting. It's fascinating to observe other living beings and see what they do. This is a new world, and I think that's really, really nice. Also taking care. Even if it's just breathing or something, or like plants, just standing (laughing) there. They are also very interesting, because they are simply different. Taking a closer look, has always appealed to me, so to speak." (Laila, grade 8; Pos. 59)

Lailas mother, a geriatric nurse, supports her interest in plants by sharing her knowledge and providing books. In her leisure time, Laila also watches documentations about animals and enjoys drawing characters and stories. After school, Laila spends most of her time at home and rarely meets with friends. She lives with her parents and younger sister, and she considers her mother a role model. Her parents encouraged her to go to grammar school after primary school to ensure she received the best possible education. At the beginning of the interview Laila expressed her desire to become a plant or animal researcher, conducting experiments or observe whether animals can think independently.

Summary And Implications

The category system indicates that students primarily position themselves based on their experiences in science lessons, alongside personal and school-linked factors. While some students reflect on more general scientific experiences, they often illustrate their positioning with concrete subject-specific encounters. The question of why certain aspects are addressed by the interviewees will be explored in an exemplary, reconstructive, in-depth case study.

Main Categories As Core Areas Of (Science) Identities

When learners discuss physics, they refer not only to physics aspects but also to personal and school-related factors, such as being a good student, friendships, or engaging in hobbies. Our analyses suggest, consistent with previous research, that identity negotiations in physics are intertwined with broader identity processes and cannot be considered in isolation (Calabrese Barton et al., 2013; Hazari et al., 2010). Accordingly, the four main categories represent core areas of students' (science) identity development.

In the interview example with Ajala, she identifies structure and rules, or as she calls it a specific "grammar", in both German and physics. However, she values rational justification in physics more than an intuitive approach she experiences in German. By comparing the two subjects, Ajala reveals a facet of her identity through her positioning. Latif faces the challenge of wanting to discuss physics but is struggling to find like-minded peers, as his classmates are less interested in the subject. This sense of uniqueness shapes his positioning. Elza, in contrast, demonstrates self-confidence in experimenting and trusts her ability to acquire knowledge through hands-on activities. The influence of significant others and the importance of group affiliation (illustrated by Latif's experience) align with previous research, which emphasize the role of these factors in identity formation (DeWitt & Archer, 2015). Furthermore, the data suggest that access to science education plays a crucial role in shaping students' engagement with science (subjects) and in the negotiation of their identities.

Science Identities?

Furthermore, students differ considerably in whether they perceive science as a cohesive whole or as a collection of distinct disciplines. References to chemistry are particularly notable, given that, at the time of the first interview, the students had attended no or only a few weeks of chemistry instruction. It should be noted at this point that at the participating schools there is no subject called "science", which complicates discussions of a general science identity. Future research could investigate the validity of assuming the existence of a general science identity versus distinct identities for physics, chemistry, or biology, especially for specific educational purposes. This is particularly evident in Laila's interview. While she demonstrates an ambitious and open-minded stance towards science in general and biology in particular, she struggles with physics at grammar school. Although she initially looked forward to physics with high expectations and continues to enjoy scientific activities, she has distanced herself from physics due to its mathematical emphasis. This case raises a larger question: How does the development of subject-specific identities might align with or conflict with the development of broader scientific identities? It is crucial to empirically investigate the impact of integrated science teaching versus discipline-specific instruction on students' identity development.

ESERA 2025 Copenhagen

Identifying And Understanding Factors Influencing Students' Decisions Regarding STEM Education Pathways – First Findings

Agnes Birner, Florian Frank, Markus Elsholz and Thomas Trefzger
University of Würzburg, Germany

The research project DynaMINT (Dynamics of STEM-related educational and vocational decisions of children and adolescents) investigates how the self-positioning of children and adolescents towards science, technology, engineering and mathematics (STEM) develops during adolescence (age 13 to 16). This longitudinal study surveys participants over a period of 18 months.

The qualitative study aims to identify factors shaping students' decisions for or against STEM educational pathways, particularly in grade nine and ten. The study examines negotiation processes connected to STEM identity development and how co-curricular and informal STEM activities influence these processes with the goal of a clearer understanding of students' educational decision-making in STEM contexts.

By incorporating longitudinal data collection methods, including interviews and short surveys, the research will provide valuable insights into how students' perceptions of STEM evolve over time. This article presents the theoretical framework, the methodological approach, and first findings with a focus on two case studies.

Keywords: Science Identity, Qualitative Research, Educational Pathways

Introduction

Due to its crucial role in driving innovation, economic development, and addressing complex societal challenges, there has been an increasing global emphasis on STEM education (OECD, 2018). However, participation in STEM subjects remains lower than desired, especially among certain demographic groups, including women, students from lower socioeconomic backgrounds, and those from underrepresented minorities (Anger et al., 2024). At the end of secondary school, German students are at a crossroad in their educational journey, making decisions that will shape their academic and professional futures (Kultusministerkonferenz, 2022). Understanding the factors that influence these decisions can provide valuable insights into how to encourage more students to pursue STEM pathways.

Students' Decisions On Educational Pathways

Educational pathway decisions are shaped by a complex interplay of social, cultural, and institutional factors (Rabe und Krey, 2018). In Germany, early educational tracking requires students to choose between different types of secondary schools, which structure subsequent subject choices and educational opportunities (Kultusministerkonferenz, 2022). Within those school-types students have the possibility to decide on different subjects or different foci (e.g. science-focused or focused on foreign languages).

Besides these institutional aspects, the socioeconomic status and the parents' educational level still play a significant role in the students' decision-making process in Germany. Adolescents whose parents attained a lower educational status are less likely to finish their school career with a certificate that allows them to go to university than children of parents with a higher educational status (Autor:innengruppe Bildungsberichterstattung, 2024). Additionally, socioeconomically disadvantaged students are on average seven times less likely to reach the basic level of

competence in mathematics and science than socioeconomically advantaged students (OECD, 2023).

As can be inferred from the complex interplay of the factors mentioned above, the choice of educational pathways is a process that has no defined beginning or end. „Who one is and who one desires to be […] is always under negotiation and is contingent upon the resources one has access to and the social, cultural, and historical context in which one seeks to author oneself with and against the expectations of others" (Calabrese Barton et al., 2013). In other words, every decision for or against an educational pathway is a negotiation process, that is formed by and in turn forms the student's identity.

Negotiation Processes Within The Framework Of STEM-Identity Development

As the focus of the study lies on negotiation processes regarding STEM in general and on STEM subjects, the research is based on the science identity construct. Science identity research constitutes a broad international field (Danielsson et al, 2023) and provides a suitable framework for integrating multiple perspectives on educational decision-making in STEM. Kang et al. (2019) address how young people come to perceive both their present selves and possible future selves in STEM. Furthermore, the focus can be directed away from the individual towards social, political or even cultural perspectives. For example, what makes a promising STEM learner? Do these factors apply to all learners in this environment? Which factors inhibit or promote learners? (Carlone, 2023; Van Tuijl, 2016)

We focus on two models within this context: 'Framework of students' identification with physics' by Hazari et al. (2010) and 'A model of factors shaping young people's science aspirations and identities age 10-19' by Archer et al. (2020) To use these models in our research, we adapted them to the broader field of STEM-identity.

Hazari et al. (2010) who based their 'Framework for students' identification with physics' on the Model of Carlone and Johnson (2007), define identity as an interplay between three aspects: the personal, the social and the role identity. All those aspects influence each other and affect the student's view on physics. A student's development of their physics identity, which is one role-identity, is shaped by their personal and social sense of self, along with their physics-related perceptions. Four indicators for this perception are: interest (desire to learn and engage with physics), competence (belief in understanding physics), performance (belief in completing physics tasks), and recognition (acknowledgment as a physics person) (Hazari et al., 2010).

Archer et al. (2020) describe the influences on science identity and aspiration in an encompassing model which considers the overall influence of structural inequalities of gender, ethnicity and social class. Further, they name capital related inequalities (e.g. Science Capital or specific risks like mental health issues), educational factors and practices (e.g. careers education, the role of teachers or educational gatekeeping) and the representations of science (e.g. portrayal of science as masculine and clever).

Further aspects shown to influence science identity development are Significant Persons (parents, guardians, friends, teachers, siblings and well-known personalities from the media (Sjaastad (2012)), Critical Moments (events, that are retrospectively mentioned by students to have had a high impact on their decision towards STEM (Lykkegaard & Ulriksen, 2019)) and co-curricular STEM-activities (Mohr, 2022).

Co-curricular STEM Activities, Informal STEM Activities And Career Education

Co-curricular STEM activities are understood in this research as school-organized activities conducted outside regular lessons and facilitated by non-teaching staff (e.g. out-of-school

laboratories, factory tours, visits to a museum). Studies show that a visit to out-of-school laboratories has a positive effect on the motivational and affective characteristics of the students, but the picture is inconsistent regarding the persistence of these positive influences because the effects are short-term (Tillmann & Wenger, 2021).

Research on informal STEM activities indicates that such spaces provide opportunities for identity development that are often unavailable in formal classroom settings. These spaces allow students to pursue personal interests, develop skills in unique ways, engage with diverse cultures, involve their communities (such as family and friends), and exercise greater agency by directing their own scientific practices. This fosters empowerment and a more inclusive approach to science learning (Hazari et al. 2022).

Overall, co-curricular and informal STEM activities can contribute to students' motivational development, identity formation and agency, thereby supporting processes relevant to long-term career orientation and decision making. The Standing Conference of the Ministers of Education and Cultural Affairs (KMK) (2017) states that career education must be part of the school's curriculum and should be based on the students' interests, skills, and potential. The students should be enabled in a long-term process to make a reflected, self-responsible, cliché-free and active decision for their further education and career path.

Research Questions

Based on the theories and models presented so far, the study focuses on how students decide on their future educational pathways, particularly regarding STEM subjects and aims to answer the following questions:

1. What factors do students perceive as influential on their educational choices regarding STEM?
2. How do students develop their STEM identity (further) during grade nine and ten of schooling?
3. How do co-curricular and informal STEM activities influence students' decisions for or against STEM?

Methodology

To capture the diversity of the negotiation processes pertaining to identity development and educational pathway decisions, this study adopts an individual-centered research approach that foregrounds students' motivations and underlying meaning-making processes. Semi-structured interviews enable an in-depth reconstruction of students' self-perceptions and reasoning processes regarding STEM.

Context And Participants

To account for differences in curricula across German federal states and to reflect varied educational trajectories, students from two federal states and multiple school types are included. Except for Gymnasium students, participants are in their final two years of schooling and are facing imminent decisions about their future educational or vocational pathways; Gymnasium students may either leave after grade 10 or continue for three additional years.

Twenty-four students from six schools were selected by their teachers based on gender and STEM affinity (high/low), indicated by grades, classroom participation, and known extracurricular engagement.

Data Collection And Analysis

Data collection combines two instruments: semi-structured interviews and short written surveys. Interviews focus on students' experiences with STEM subjects, co-curricular STEM activities, informal STEM activities, the development of their STEM identities, and planned and made educational pathway decisions, while surveys capture planned educational pathways and co-curricular STEM experiences. Interviews took place in January/February and June/July of 2025 and will take place in January/February and June/July of 2026, with surveys administered in between to track changes over time and inform follow-up interviews. Due to organizational reasons, in the first interview-wave it was only twelve 9th grade students (seven female and five male) from three different schools. The interviews were transcribed using MAXQDA-Software and then manually corrected and anonymized (locations, names, etc.) in a second and third round.

The collected data is evaluated using qualitative content analysis according to Kuckartz and Rädiker (2022). A multi-stage process of category formation and coding was used. In the first coding phase the coding was carried out along the main categories that were also used in the guideline for the interviews and the STEM subjects were coded separately Within the next coding phase, the categories were developed further into the following categories: social and personal identity, significant persons, perception of STEM subjects, perceived relevance of STEM subjects, perception of STEM outside of school, STEM activities (co-curricular and informal), educational pathway decisions specified by aspired career, already chosen school subjects and career orientation. Before going into the analysis, case-specific thematic summaries were created for the individual students using the coded text passages.

In the cross-sectional analysis, the aim is to identify common patterns and themes (Kuckartz & Rädiker, 2022) based on similarities and differences between the students' narratives with respect to the aspects surveyed. These insights can contribute to sharpening the concept of STEM identity. They will also shed light on the influence of co-curricular STEM activities, informal STEM activities, especially in terms of identifying and describing key success factors.

In the planned longitudinal analysis, the changes in students' perceptions of STEM, STEM lessons and STEM identity as well as their retrospective attribution of meaning to educational pathway decisions are described. The comparison of statements on the same topic at different points in time provides information on how students are influenced by their experiences and evaluations (Rieker et al., 2024). On the one hand, the aspects described in the theoretical model are used, on the other hand it is also possible to identify new aspects and incorporate them into the model. For each student, an individual educational biography can be created and the relevant explanatory patterns for or against STEM (in the context of studies, profession, subject) can be identified.

In this article the findings of the first interviews (February 2025) will be described and discussed focusing on two students who were selected by their teachers because of their high affinity to STEM-subjects.

Findings

STEM Is Not A Unit

Before starting to go deeper into the description of the two students, it is important to note that throughout the twelve interviews the students were asked to describe and explain the term "STEM". Eight of the students didn't know the acronym while the other four said that they had heard about it but couldn't describe or explain it in detail. The interviewer gave all students a

verbal and written explanation of the acronym after the question to build a common understanding of the term STEM for the further interview.

Besides the unfamiliarity with the term STEM, what stood out within the students' answers was, that – even as the teachers who selected them were supposed to do so amongst other things by the affinity towards STEM, there was no student who liked all STEM subjects and in contrast, there also were no students who did not like all STEM subjects.

Mathematics, for example, was on the one hand characterized as easy to understand and to get good grades while time passed by fast and on the other hand the wish for a slower pace and skipping of unimportant topics were mentioned. The understanding of the content depends on the teacher's explanation. Also, students reported blackouts in tests. What stood out in comparison to other STEM subjects was that some students see their difficulties with mathematics as within themselves rather than by the lack of explanation or time. Also, the students perceived it as interesting and important for their everyday life, especially calculating e.g. the change you get in a shop and for diverse vocational fields (electrician, confectioner, insurance and banking sector).

In physics, the dislike and difficulties during class were mentioned. Besides that, it was characterized as boring and too theoretical which leads to difficulties processing the content. Special topics, e.g. electricity, gravity, and optics were described as interesting. Experiments stood out to be especially memorable. The teachers' influence on the liking of physics was rated differently. As in mathematics, the utility for the students' everyday life and their future vocation was mentioned.

Student Profiles And Influential Factors in STEM Positioning and Educational Pathways

In the following paragraphs two students (Julia and David[5]), who were interviewed in February 2025, will be described in detail regarding their positioning towards their STEM subjects, educational pathway decisions and further factors which turned out as influential for them.

"STEM Subjects [..] Run In The Family"

Julia is a 9th grade student who expresses a strong affinity for several STEM subjects, particularly mathematics, physics, chemistry, and the interdisciplinary subject 'computer science, mathematics, and physics'. Biology occupies a more neutral position in her subject preferences. She describes herself as someone who enjoys logical thinking and is able to establish connections quickly, framing these abilities as core aspects of her self-concept.

Family background plays a relevant role in Julia's positioning towards STEM. She reports that "STEM subjects in general run in the family"[6], as close family members have traditionally perceived themselves as competent especially in mathematics, even though none of them pursued a STEM-related profession. Familial recognition appears to contribute to the stabilization of her competence beliefs.

When asked about her perception of STEM, she identifies general competencies attributed to STEM professionals, including rapid comprehension, problem-solving abilities, strong intrinsic motivation, and comparatively weaker language-related skills such as vocabulary learning and memorization. Additionally, she differentiates STEM professionals' appearances across disciplines: biology and chemistry are associated with women in lab coats conducting investigations at laboratory benches, whereas mathematics was represented by a teacher carrying a brown briefcase and wearing a plaid shirt, jeans, and leather shoes.

[5] Names were selected randomly
[6] Direct quotes are translated from German to English.

Julia achieves good to very good grades in her STEM subjects and attributes her success primarily to internal factors such as logical reasoning, rapid comprehension, and sustained interest. She frequently compares her performance to that of her peers and is recognized by classmates as a source of academic support, particularly in mathematics. While this occasionally leads to social tension, it does not undermine her self-confidence; instead, it reinforces her self-positioning as competent in STEM.

Her subject choices reflect a strategic consideration of her perceived abilities, interest, and the anticipated relevance of subjects for future educational and occupational opportunities. Julia emphasizes the everyday relevance of mathematics and computer science, as well as their importance for a broader range of professional fields. Although she is uncertain about specific STEM career paths, she clearly envisions her future self within a STEM-related domain, particularly mathematics or computer science.

Co-curricular STEM activities play a comparatively minor role in Julia's narrative. She does not recall school-organized STEM activities but reports informal engagement, such as watching documentaries or visiting science exhibitions with her family. Time constraints due to multiple non-STEM hobbies limit her participation in additional STEM-related activities.

Overall, Julia's case is characterized by strong and stable competence beliefs, consistent recognition from significant others, and a future-oriented STEM-identity that extends beyond individual school subjects.

"It Just Happened"

David is also a ninth-grade student and expresses a differentiated but more ambivalent relationship with STEM subjects. He reports a strong liking of mathematics and chemistry, while physics, biology, and computer science are described as neutral. David characterizes himself as a rather quiet person when he is around people who he does not know very well and emphasizes everyday activities and social interactions outside of school.

Despite his positive experiences in some STEM subjects, David does not aspire to a STEM-related career. Instead, he envisions his future in the catering sector or in caregiving professions. These career aspirations are closely linked to professions from his family environment.

He expresses clear, stereotypical images of various STEM professionals: mathematicians are described as wearing glasses, jeans, plaid shirts, and carrying leather briefcases; computer scientists as quietly working at a computer, dressed in jeans and a pullover; natural scientists as wearing white lab coats and gloves; and technicians as performing physical labor in black shirts and work trousers.

David's competence beliefs in STEM subjects are inconsistent. While his performance in mathematics has improved over the course of his schooling and he enjoys problem solving aspects of the subject, he is unable to identify clear reasons for this development. His interest in STEM subjects is primarily topic-specific, for example related to atoms in chemistry or to gravity and electricity in physics, rather than generalized to the disciplines. Consequently, this interest does not translate into a stable STEM-related identity.

When choosing elective subjects, David explicitly decided against STEM-oriented options and in favor of AES (everyday culture, nutrition, social issues) aligning his subject choices with his occupational aspirations. He does not perceive STEM subjects as relevant for his everyday life but acknowledges their instrumental relevance for his future professions, for example mathematics for cooking (measuring ingredients) or biology for understanding the human body in caregiving contexts.

David reports no regular engagement in co-curricular or informal STEM activities. Occasional conversations about mathematics at home occur only when he finds specific topics particularly interesting. Overall, STEM does not constitute a central component of his self-concept or future imagination.

Cross-Case Comparison

Comparing Julia and David illustrates how similar levels of teacher-perceived STEM affinity can lead to fundamentally different educational aspirations. Below the authors conduct a cross-case comparison of the two students from a (STEM) identity perspective.

Competence, Performance, Recognition And Interest:

Julia expresses high competence beliefs, especially in mathematics and physics. She compares herself favourably to peers, helps others, and recognizes herself as a mathematics/STEM person. She attributes her success to internal factors such as logical thinking, quick understanding and inherent interest. Even social tension - friends "get[ting] pissed off" by her in comparison to them, high skills - does not undermine her confidence but it confirms her positioning towards STEM as competent. She chose her subjects by considering her abilities, her interest and the perceived value for her future. Her interest in STEM goes beyond school subjects as she also enjoys the STEM subjects because of their underlying logic and problem-solving nature, not just specific topics. This allows her interest to transfer across school subjects and into future aspirations. Also, she does STEM activities in her leisure time with her family and on her own but not on a regular basis.

David´s competence beliefs are more ambivalent. Although his grades improved (especially in mathematics) and he enjoys solving problems, he cannot identify the success factors for this development. He explicitly names specific topics as interesting but doesn't generalize that to the whole subject. This episodic and topic-specific (atoms, gravity, electricity) interest does not translate into sustained disciplinary identification, as once the topic changes, the interest may fade, too. He isn't involved in STEM activities but sometimes if the topic is interesting, he talks about his mathematics class. His decision against choosing a STEM subject was not due to distancing himself from STEM in general but because it does not align with how he sees himself in the future.

Comparing Julia und David illustrates how similar levels of teacher-perceived high STEM affinity can result in diverging educational aspirations. Julia's STEM identity is inter alia characterized by strong and stable competence beliefs, and consistent recognition from peers and family. This supports Hazari et al's (2010) argument that interest, competence and recognition, both self-recognition and recognition by others, are key stabilizing factors in identity development. Whereas David's STEM identity is characterized by only topic-specific interest and besides his self-recognition as a math-person he does not mention being recognized by others.

Representation Of STEM

Julia's descriptions of STEM professionals reveal some stereotypes, particularly in biology and chemistry (lab coats, working in a laboratory) and mathematics (glasses, Jeans, plaid shirt, leather briefcase) but also, she describes them as understanding things quickly, finding different ways to solve a problem and interested in their own work. A description that fits the image she draws of herself and lets her imagine to be capable of working in a STEM field.

David has also a stereotypical concept of STEM professionals (quiet computer scientist, mathematician with glasses). Even though he describes himself as quiet, he sees himself more as a cook or a caregiver. Professions which he knows from his family surroundings.

Both students' descriptions of STEM professionals reveal persistent stereotypical representations, particularly regarding appearance, work environments, and personality traits. However, these stereotypes function differently in their identity negotiation. Julia's self-description overlaps with her image of STEM professionals, enabling identification despite stereotypical imagery while David, despite partially matching some characteristics (e.g. being quiet), does not perceive STEM professions as something for him. The career he aspires is known by him due to his family members and for that it is probably more imaginable.

Educational Pathway Decisions And Future Selves

Julia imagines her future self in STEM, particularly in mathematics or computer science, even though she is uncertain about specific career paths. She is sure about her aspirations but struggles to map the field.

David imagines his future self clearly non-STEM but recognizes the need for certain topics/skills even for a non-STEM job like cook (mathematics for measuring the ingredients) or caregiver (biology to understand the human body).

Educational pathway decisions in this study appear to be strongly guided by students' future imaginaries and perceived alignment between current school subjects and envisioned adult roles. Julia's uncertainty does not concern whether she belongs in STEM, but rather how to translate her interest into concrete occupational pathways. David, on the other hand, makes a clear decision against STEM subjects not because of rejection or failure, but because STEM does not fit into his imagined future as a cook or caregiver.

Limited Salience Of Co-Curricular STEM Activities

Co-curricular STEM activities played a minor role in students' narratives at this stage. Both Julia and David struggled to recall such activities, and when they did, these experiences were not strongly linked to identity development or decision-making. This finding may reflect limited availability, insufficient integration into classroom learning, or a lack of explicit reflection opportunities. It also aligns with studies questioning the long-term impact of isolated informal STEM interventions when they are not embedded in broader educational trajectories (Tillmann & Wenger, 2021).

Discussion And Conclusion

The findings from the first interviews underline that students' decisions for or against STEM cannot be understood as binary choices, nor as a result of isolated factors. Instead, they emerge from dynamic and situated negotiation processes in which subject-specific experiences, social recognition, future imaginaries, and structural conditions interact.

A significant finding of the preliminary analysis presented in this paper is that students do not perceive STEM as a coherent or unified domain and most students were unfamiliar with the term STEM itself and even after clarification, their attitudes and identifications varied strongly across individual subjects.

David's narratives demonstrate that identification is constructed at the level of specific classroom experiences, topics, and perceived demands rather than at the level of an abstract STEM category. This differentiated positioning towards STEM subjects aligns with Hazari et al.'s (2010) emphasis on subject-specific identity components such as interest, competence beliefs or recognition. On the contrary Julia's narratives demonstrate that she sees her current and future self as a STEM person linking this self-description to a more abstract level of STEM categories like quick understanding and logical thinking.

The study contributes to STEM identity research by empirically illustrating how similarly perceived high STEM affinity can lead to divergent trajectories and by highlighting the importance of reflexive sense-making in identity stabilization. Methodologically, the longitudinal approach holds promise for capturing how critical moments, experiences, and interpretations accumulate over time.

However, the findings are based on a limited, selective number of interviews and should therefore be interpreted cautiously. Future analyses will benefit from the full longitudinal dataset, allowing for a more nuanced understanding of negotiation processes and probably the delayed impact of co-curricular and informal STEM experiences.

Acknowledgement

The research was funded by the Wittenstein-Stiftung. Many thanks to the participating students who contributed to the study.

Queer In STEM Queering STEM: The Story And Insights Of A Trans, Ace, White Woman In Chemical Engineering

Nelly K.M. Marosi[1,2], Lucy Avraamidou[1], Monica López López[1] and Apostolia Galani[2]

[1]University of Groningen, Netherlands

[2]National and Kapodistrian University of Athens, Greece

*This case study explores the intersections of trans*ness and STEM through a combined framework of queer theory, intersectionality, the construct of figured worlds and science identity. The study uses a life-history approach to characterize the trajectory of Cassandra, a trans, ace, white woman in Chemical Engineering. We collected data through in-depth, semi-structured interviews which we analysed in three rounds using narrative analysis, artefacts, such as the River of Life, and a focus group consisted of queer and trans individuals, including Cassandra, to identify aspects of STEM education that constrained or supported the participants' trajectory and to offer strategies for queering STEM educational spaces. The findings of this study include data of the participant's reflections on her STEM trajectory as for example, the course of her life as she moved towards or away from STEM. Moreover, the findings illustrate the exclusionary cultural models of the figured world of STEM, that were shaped by cisheteronormativity, sexism, white supremacy, ableism, defined by neoliberal values and depoliticized. Finally, the findings highlight the importance of transforming a) the culture of STEM, b) the image of STEM, c) the curriculum and pedagogies, and d) the teacher-student relationships, to foster more inclusive and affirming environments. The study aims to challenge cisheteronormative frameworks, promoting a reimagined and supportive learning environment for all students.*

Keywords: Gender equity, Inclusive Education, Science Identities

Introduction

Broadening STEM participation is a central focus within the STEM education community. Research indicates that enduring inequalities in STEM perpetuate the dominance of white males, while women, people of colour, and individuals with disabilities face underrepresentation (NSF, 2021). Queer individuals have also been recognized as an underserved group. Despite limited data, studies reveal that queer individuals face exclusion, discrimination, and harassment in STEM, which affects their careers, prompting the need to examine both the mechanisms that marginalize them and the factors that sustain their persistence, and leading to a push to reimagine academic environments and transform STEM education spaces (Marosi, 2024). Addressing inequalities in STEM is essential for reducing disparities and fostering inclusive, sustainable development (UNESCO, 2024).

Therefore, this study aims to contribute to the queering of STEM by a) exploring the intersections of trans*ness with the science identity throughout schooling and university, and by b) using a bottom-up approach, prioritizing the voices of marginalized individuals in the process of transforming STEM education. This study is part of a larger project for which we conducted interviews and a focus group with queer individuals, but we currently present the findings relevant to Cassandra, a trans woman in Chemical Engineering. The research questions were the following:

- How did the participant (re)negotiate her science identity throughout her educational trajectory?
- How do the intersections of her social identities shape and interact with the cultural norms of the figured world of science to afford or constrain her participation?

- How does she envision queering science education based on her lived experience?

Theoretical Framework

This study combines queer theory and intersectionality to analyse how power, privilege, and oppression shape the lives of the participant in STEM, using the constructs of figured worlds and science identity to explore her positioning in and out of STEM spaces. Queer theory challenges normative binaries of gender (Gunkel 2009), while intersectionality examines the interconnected forms of oppression that shape identity and lived experiences (Crenshaw, 1989). Science identity, a construct tied to how individuals see themselves and are recognized as science participants, highlights the role of recognition and co-construction in fostering engagement and persistence in science (Carlone & Johnson, 2007). Figured worlds frame these identities by establishing cultural models and norms that determine who is valued and recognized within the STEM community, with these models influenced by broader societal structures and localized contexts (Gonsalves, 2014). Together, these frameworks provide a lens to explore how cultural norms in STEM afford or constrain Cassandra's participation and identity development.

Method

We employed a qualitative case study approach. We utilized artefacts (River of Life, a visual exercise that helped participants to map out their science trajectory) and semi-structured interviews which we analysed in three rounds using narrative analysis, to explore participants' STEM trajectories, focusing on the intersections of queerness and STEM. After the interviews, we developed conceptual themes addressing problematic aspects of STEM education and participants' suggestions for queering these areas. An online focus group was then conducted to collaboratively generate ideas for queer-affirmative STEM education from a bottom-up perspective. The participants were purposefully selected from social media. The current study presents the findings relevant to Cassandra, a 27-year-old, trans, lesbian, ace, white woman who grew up and studied in the US and is currently a lecturer in Chemical Engineering in the US.

For the purpose of data analysis, we transcribed the interviews and focus group discussions verbatim and analysed them using Atlas software. Through in vivo and line-by-line coding, we prioritized the participant's direct statements while minimizing researcher interpretation. An inductive and deductive approach was used to identify: a) elements or experiences limiting identification and participation in STEM, and b) ways to queer STEM education. Trustworthiness was ensured through triangulation, verbatim transcripts with in vivo coding to reflect participants' voices, and member checking to validate interpretations with the participants.

Findings

Cassandra's Story

Cassandra, who grew up in a privileged, conservative, all-white town in the US and was perceived as a cis-heterosexual male before transitioning during grad school, was deliberately pushed into STEM from an early age, benefiting from systemic privilege and familial support, which shaped her STEM trajectory despite her awareness of the sexism, elitism, and competitiveness in engineering spaces. Cassandra's experience in engineering was marked by an elitist and competitive culture that promoted the idea of exceptional individual labor while marginalizing certain identities, such as neurodivergent, queer, and trans individuals. Faculty and institutional norms supported exclusionary practices, with high dropout rates and strict expectations for "good students" that had a bigger impact on marginalized groups. Bioessentialism and the lack of queer representation further alienated individuals, as gender and queer issues were largely absent from

STEM spaces, leaving students like Cassandra without visible role models or safe opportunities for expression.

Cassandra's pre-transition years were marked by dissociation and intense academic focus, using her demanding engineering studies as a way to avoid confronting her gender identity. After transitioning, with the crucial support of friends, the queer community, and supportive women in her faculty, she began to feel more aligned with her true self, discovering a passion for teaching engineering that gave her life new meaning despite initial challenges. Cassandra's transition allowed her to live authentically and brought a holistic connection between her mind and body, making her a happier and more empathetic person. Now a lecturer in Chemical Engineering and an advocate for inclusive education, she integrates her lived experiences into her teaching and activism, challenging patriarchal and exclusionary norms in STEM and creating spaces where everyone can bring their full selves into STEM.

Envisioning A Queer Inclusive STEM Education

This section highlights various problematic aspects of science education which hindered participants' progress in science as highlighted by the participants in the interviews and the focus group, namely the a) culture of STEM, b) image of STEM, c) curriculum and pedagogies, and d) relationships and presents their strategies for queering these aspects. In what follows, we present the findings relevant to Cassandra. According to Cassandra, the culture of STEM often reinforces cisheteronormativity, sexism, and bioessentialism, marginalizing queer individuals and perpetuating harmful stereotypes. As Cassandra stated, besides implementing policies that protect queer individuals, "What you shouldn't do is attach our gendered expectations to like cells and molecules and atoms and animals as well [...] maybe we shouldn't assign any agency or passivity to fucking animals," emphasizing the need to challenge gendered biases and adopt inclusive, curiosity-driven perspectives for more accurate scientific inquiry.

The competitive, individualistic, and elitist culture in science often stifles collaboration, fosters harmful competition, and negatively impacts mental health and inclusivity, with Cassandra critiquing this mindset, saying, "I don't want to win so that someone else loses [...] I want us all to win. I want to collaborate." She actively works to counter these norms by abolishing exams in her classroom, implementing labour-based grading, promoting collaboration, and advocating for sharing both successes and failures in scientific research to improve transparency and inclusivity.

Cassandra critiqued the traditional image of scientists as white, middle-class, cisgender, straight men, highlighting the lack of representation of queer and trans identities and the depoliticized portrayal of STEM disconnected from social issues. Cassandra proposed queering this image by integrating social justice into STEM education, emphasizing diverse contributions, promoting authentic self-expression, and redefining success to prioritize mental health, community, and diverse career paths over financial gain or traditional metrics of achievement: "You don't have to be the guy and I do mean guy in this case, who makes 100k," and questioning "What is the point of diversity in STEM? Are we going to try to make more Black Raytheon employees, more female oil drillers, more non-binary forest destroyers?"

She also criticized the absence of queer issues in STEM curricula, highlighting the need to challenge Western science's claim to pure objectivity, advocating for the inclusion of diverse epistemologies, including feminist, Indigenous, and queer perspectives, to reshape both the curriculum and pedagogy. She emphasized the importance of integrating social justice and mental health into teaching, suggesting that STEM education should be more inclusive and adaptable, while also advocating for a rebalancing of tenure criteria to prioritize teaching alongside research: "How do we rebalance that and make it so that teaching is weighted more in the tenure process?"

Finally, Cassandra emphasized the importance of personal relationships in STEM, noting that a supportive faculty member helped her maintain mental stability when she was struggling with her trans identity: "It was because of her, that I didn't completely lose my mind." She also stressed the need to challenge hierarchies in the classroom, advocating for a more empathetic, care-driven approach to teaching that includes affirming students' identities, offering mental health resources, and creating inclusive environments. An example of her behaviour is when she opened one of her classes with a big slide saying: I give a shit about you", underlining her commitment to her students' well-being.

Discussion

In response to the first research question, the cultural models of STEM in the story of Cassandra often reinforced exclusionary norms, portraying fields like engineering as competitive, masculine, and elitist, while marginalizing queer and trans identities and individuals with mental health challenges. This created environments that prioritized individual achievement over collective support and depoliticized social issues. Addressing the second research question, Cassandra's identity trajectory in STEM was shaped by her initial alignment with privileged cultural models as a cisgender, able-bodied, white, middle-class person. However, after transitioning during her PhD, she faced the challenges of navigating a still-exclusionary field. With the support of others, she embraced her transness, which ultimately reshaped her path towards a more inclusive and socially conscious role in academia.

Finally, in response to the third research question, Cassandra emphasized the need to address heteronormativity and sexism in STEM by implementing policies that protect marginalized groups and challenge gendered language and biases. She pointed out that neoliberal and competitive structures in STEM promote individualism and elitism, which hinder collaboration and innovation, and called for education reforms such as labor-based grading contracts and a greater focus on interdisciplinary work. Additionally, she argued that true diversity in STEM requires more than superficial representation; it necessitates a shift toward inclusive perspectives, alternative career paths, and the dismantling of traditional norms and capitalist-driven roles. Recognizing the depoliticized nature of STEM education, she advocated for queering the field to reintroduce discussions on power, social justice, and exploitation, while challenging capitalist and gender norms. Furthermore, she emphasized the importance of dismantling hierarchical structures in classrooms by fostering personal, empathetic teacher-student relationships that promote inclusivity, respect, and safety, particularly for marginalized groups.

Implications

This study emphasizes the marginalization of trans individuals in STEM and calls for the redesign of learning spaces, the exploration of intersectional identities, and the implementation of inclusive policies, support networks, and queer-inclusive pedagogies to foster diversity and inclusion. It also suggests further research on integrating critical theories, inclusive curricula, and alternative assessments to address systemic barriers.

Acknowledgement

I would like to thank Dr. Allison Gonsalves for her thoughtful feedback, intellectual generosity, and support during the development of this work.

ESERA 2025 Copenhagen

A Multiple Case Study Of Translanguaging And Systemic Functional Linguistics In K-12 Science Education

Kaycie Barron[1], Shamya Karumbaiah[1], Cynthia T. Baeza[2], Mariana Castro[1] and Diego Román[1]
[1]University of Wisconsin-Madison, USA
[2]University of Arkansas, USA

This multiple case study explores how science teachers interact with and respond to translanguaging as it naturally occurs among English Learners (ELs) who bring varied levels of English proficiency into distinct classroom contexts. The study focuses on two participants working in linguistically diverse public schools: one 6th grade biology teacher who is monolingual English-speaking and identifies as White/Caucasian, and one 10th grade chemistry teacher who identifies as Hispanic/Latine and is bilingual in English and Spanish. Using a Systemic Functional Linguistic (SFL) framework as a lens, we examine how translanguaging manifests within the three metafunctions of language: ideational, interpersonal, and textual. Classroom data included audio and video recordings of both teachers and students (n = 88) during routine science instruction to analyse when and where translanguaging occurred, to whom it was directed towards, and how instructional tasks created space for its use. Semi-structured interviews offered further insight into how teachers understood and navigated linguistic diversity in their classrooms. Findings suggest that translanguaging emerges through fluid, collaborative classroom discourse and is shaped by teachers' language-related decisions, including how they (1) use language to scaffold scientific reasoning, (2) attend to the functional purposes of language in content learning, and (3) affirm bi/multilingual expression as a resource for students' meaning-making in science classrooms.

Keywords: Classroom Practices, Languages and literacies in science education, Multicultural Education

Introduction

In the United States (U.S.), schools test multilingual students upon entry to determine whether they need language support to succeed. If they do, they are classified as English Learners (ELs). ELs in U.S. science classrooms face the dual task of understanding scientific content while simultaneously developing English proficiency (Garza & Arreguín-Anderson, 2018; Meskill & Oliviera, 2019). This cognitive and linguistic demand can hinder their ability to fully engage in ambitious science learning practices, which require reasoning, argumentation, and evidence-based explanations (Windschitl et al., 2020). Translanguaging, a pedagogical approach that encourages students to use their entire linguistic background to inform meaning-making processes, has emerged as a promising strategy to address this gap in learning environments (García & Lin, 2016; Wei, 2018). However, little is known about how varying instructional practices either encourage or impede translanguaging in science classrooms.

To address this gap, systemic functional linguistics (SFL) provides a valuable critical lens for understanding how teachers use or encourage translanguaging to guide ELs through scientific reasoning and discourse. SFL views language as a semiotic tool for meaning-making and emphasizes the importance of helping students navigate the linguistic features (e.g., terminology) of academic disciplines, such as science (Schleppegrell & Oteíza, 2024; García & Kleyn, 2016). Central to SFL are the three semantic metafunctions: (1) the ideational, which focuses on how language represents and organizes experiences and knowledge; (2) the interpersonal, which examines how language facilitates social interactions and expresses attitudes and relationships;

and (3) the textual, which explores how language creates cohesive and meaningful communication (Banks, 2002). We position SFL as a theoretical framework to analyse how teachers and students use language in the classroom. Through this framework, we examine how teachers and students leverage their linguistic backgrounds to connect prior knowledge to new scientific concepts (ideational), engage in argumentation through collaborative learning (interpersonal), and organize thoughts cohesively to communicate scientific ideas (textual). By investigating teachers' pedagogical strategies, we aim to understand teachers' (1) purposes for language use in science classrooms and (2) how they legitimize translanguaging as a linguistic tool for meaning-making. Therefore, we are motivated by the following research question: *How do science teachers create opportunities for translanguaging in their varied learning environments to support English Learners in science classrooms?*

Methods

Participant Selection

Participants included two science teachers from different U.S. school districts in the Midwest: 1) Aaron, a 6th-grade biology teacher in a small rural city with a monolingual English background, and 2) Maria, a 10th-grade chemistry teacher in a suburban Midwestern city, who grew up as a dual-language student, speaking both English and Spanish. They were selected due to their experience teaching science and simultaneously teaching ELs and monolingual English speakers in the same classroom. Both teachers worked with ELs from different linguistic backgrounds, including Spanish and Arabic, at varying levels of English proficiency. Student participants included 64 students from Aaron's biology classes and 22 from Maria's chemistry class (N = 88).

Data Collection

We employed semi-structured interview and observation protocols (Authors, 2013), including audio and video recordings of teachers' science classes. In the first stage (individual interviews), we met virtually with Aaron and Maria to discuss their teaching background, views on language use in their schools, and their students' linguistic and learning environments. Sample interview questions included: "How do your students translanguage (fluidly switch between English and Spanish or other languages) during learning?" "When and where does this likely occur?" and "Why do you feel that your students do this?" Additionally, we asked, "How do you encourage and/or scaffold translanguaging practices during instruction?" In the second stage (classroom observations), we observed 10 classroom periods over the span of four days. To highlight pedagogical strategies and language use, we used 8 hours of video and audio from both classroom observations and individual interviews.

Data Analysis

We employed a multiple case study design (Román, 2013) to examine science teachers' perspectives on working with ELs and the factors influencing their translanguaging practices. This method let us capture individual differences and shared approaches in how teachers used translanguaging strategies to support ELs during science instruction. Applying an SFL lens, we used a priori codes derived from the ideational, interpersonal, and textual metafunctions of language to code the notes from observations and interview transcriptions. This allowed us to investigate how teachers' translanguaging practices support meaning-making, social interaction, and coherence in science classrooms.

Results

Ideational: Connecting The Language Of Science To Real-World Contexts

Aaron led a project where students designed reusable cups using recyclable materials and tested how well they maintained drink temperatures as a way to examine thermal energy transfer. He tapped into the ideational metafunction of language by connecting the concept of thermal energy transfer to his students' real-world experiences. For instance, Aaron problematized the design challenge by explaining how iced drinks from coffee shops often warm up too quickly on sunny days, prompting students to think critically about an innovative design solution. ELs in Aaron's class used translanguaging to connect this knowledge to the scientific concept of energy transfer. For example, three students, Nora, Ryan, and Maya, discussed using aluminum foil to contain more heat inside the bottom of their cup (see Figure 1).

Figure 1. Transcript on English Learners' Interactions Representing the Ideational Metafunction.

Nora: *Oh Ryan, you gave me an idea. When I make this thing, right? [points to the fabric intended for the bottom of the cup] we put the aluminum in the bottom.*
Ryan: *Mucho? A lot?*
Nora: *Maybe, yeah maybe.*
Ryan: *Alright, but we are not gonna use this [points to fabric] in the bottom.*
Nora: *No, like. Porque mira, dame eso [Ryan hands Nora the fabric]... okay so it's gonna be like this right? [shows the fabric material] And we put alumino aqui right? [points to the inside of the fabric]. I don't know.*
Ryan: *Mmm I don't think so.*
Maya: *I don't know.*
[All students think for a moment]
Ryan: *I don't think that will work ... probably actually .. yeah it probably would, yeah*
Nora: *Pick, pick right now. Yes or no? Are you sure?*
Ryan: *Yes.*
Nora: *Positive? Seguro? Si?*
Ryan: *Yes, yes, yes*

In the figure above, Ryan invites translanguaging into meaning-making when he uses "Mucho?" followed by the English version of the question, "A lot?" This shows students all language varieties are welcomed. Nora then uses Spanish later on, "Porque mira, dame eso," to ask Ryan to hand her the fabric while continuing to make sense of the phenomenon without worrying about *what language* counts as the language of science.

Similarly to Aaron, Maria's teaching focused on reducing cognitive load and making scientific concepts accessible to her ELs. In her 10th-grade chemistry unit on the electronegativity of atoms, she used Spanish to support her ELs, explaining, *"My expectation for them is to try and write in English, but that doesn't necessarily happen because they can't really express themselves very well in English. We teach all the vocabulary in English, so I expect them to use those words… but I allow them to produce in their home language using a Chromebook to translate."* By providing key vocabulary in English while allowing students to produce work in their home languages, Maria helped students construct scientific meaning while navigating English as an additional language.

Interpersonal: Building Collaborative Translanguaging Spaces

Despite being a monolingual English speaker, Aaron created opportunities for interpersonal interactions by intentionally pairing students with varying levels of English proficiency in small groups during classroom instruction (e.g., students with higher English proficiency worked with students with lower English skills). We noticed that ELs with varying levels of English proficiency spoke predominantly in Spanish when forming the majority in their small groups, particularly after being prompted by the research team to use whatever language they feel comfortable with. On day two of our observations, Aaron reflected on this, stating, *"I had never heard them [group of ELs] speaking Spanish before this. It's great."* Although Aaron did not explicitly encourage his students to use their home language, his receptiveness to ELs' translanguaging practices highlights his adaptability to foster a classroom environment that embraces linguistic diversity.

In contrast to Aaron's pedagogical strategies, Maria fostered an inclusive environment by leveraging her bilingualism to support her ELs. Early in the school year, she paired students who spoke the same language (e.g., Spanish-speaking students and Arabic-speaking students) to encourage dialogue, while gradually transitioning them to work with monolingual peers to promote English use. Reflecting on the dynamics in her classroom, she said, *"It's frustrating for me because I try to only speak in English to them, but since they know I speak Spanish, their comfort level in Spanish is way higher in my classroom."* While she aimed to speak only in English, Maria recognized that her bilingualism increased students' comfort, especially for those with lower English proficiency who might otherwise avoid engaging.

Textual: Supporting Meaningful Language Use Through Structured Scaffolding

Aaron's use of scaffolding strategies helped his ELs navigate the task of learning science content in their non-native language. For instance, he adjusted expectations for language use depending on the task, stating, *"I have students just write in Spanish if the task is a 'heavier lift' in my class. Final assessments can be completed in Spanish so that students engage more deeply with the content rather than focusing on the language …"* By focusing on how students' linguistic and cultural resources could be leveraged in meaning-making, Aaron enabled students to draw from both their home languages and English to structure their scientific ideas cohesively.

Unlike Aaron, who supported translanguaging between ELs, Maria led a discussion with two ELs about how atoms with higher electronegativity "steal" electrons from other atoms when forming bonds. Following the textual metafunction, Maria used translanguaging as a pedagogical strategy to help Carmela, one of the native Spanish-speaking ELs, articulate her understanding (See Figure 2).

Figure 2. Transcript on Teacher-Student Interaction Representing the Textual Metafunction.

Maria: *Okay so let's talk. So the other one ... [points to atom] everything around it was the same, right?*
Carmela: *Mhmm.*
Maria: *It was chlorine, chlorine, chlorine, chlorine [points]. What do you notice about this one? What do you guys think? [points at two Spanish-speaking students]*
Carmela: *This is named, es hidrógeno, es el primero, no?.... Electrones ...*
Maria: *Right, and we have a different atom here than chlorine, and you see how it's partially positive. On the other one, everything was partially negative ... What's the electronegativity of carbon?*
Carmela: *¿Qué?*
Maria: *¿Qué es la electronegatividad de carbón?*
Carmela: *Ahhh, yo sé son los electrones*
Maria: *2.5, right? And what's the electronegativity of chlorine? So who's gonna steal the electrons?*
Carmela: *Como ellos son los fuertes, ¿le roban a este?*
Maria: *Ahaa, so it's gonna pull a little bit, right?*
Carmela: *Mhm. Ohhhh.*
Maria: *And here we're stealing the electrons. So electrons move this way.*
Carmela: *Ohhhh. Entonces este le quita a este y estos le quitan a este?... "*

In the above interaction, Maria's prompting guided Carmela to connect her prior knowledge to understand electronegativity. When Carmela initially didn't understand the question in English, Maria clarified it in Spanish: "¿Qué es la electronegatividad de carbón?" This allowed Carmela to recall relevant information and respond, "Ahhh, yo sé son los electrones." As the conversation progressed, Carmela used her linguistic background to reason in Spanish. Through a textual lens, Maria demonstrated how translanguaging helped Carmela organize and communicate complex scientific ideas while drawing on her native language and the language of instruction. Unlike a traditional approach, where students in science classrooms construct their reasoning in a single language (e.g., English), Maria allowed Carmela to use her full linguistic background to structure her questions and responses across languages.

Discussion

By situating translanguaging within an SFL framework, this study highlights the interconnected roles of ideational, interpersonal, and textual metafunctions in shaping how language supports science learning. As translanguaging continues to gain recognition as a legitimate pedagogical tool, science educators are encouraged to embrace linguistically responsive teaching practices that empower ELs to participate fully in rigorous scientific inquiry.

Case studies revealed that translanguaging practices are implemented according to science teachers' pedagogical strategies and the teachers' and students' linguistic backgrounds. While Aaron encouraged translanguaging by enabling collaborative group work between students with similar multilingual backgrounds, Maria engaged her ELs in both English and Spanish to support their scientific reasoning. Both teachers demonstrated that, when purposefully integrated, translanguaging can promote conceptual understanding, reduce cognitive load, and create more inclusive science learning environments.

Future research can examine how institutional factors, such as school language policies and curriculum design, further influence teachers' ability to adopt translanguaging practices. Additionally, future studies can analyse content teachers' translanguaging practices across academic subjects (e.g., social studies, mathematics, and language arts).

Ultimately, embracing translanguaging as a pedagogical tool, whether teachers are bilingual or monolingual, can help educational researchers, teachers, and school networks reframe multilingualism as an asset. It fosters more equitable and engaging learning environments for ELs in science classrooms and beyond.

Exploring STEM Identity Development In Early Science Education In Germany: Gender Differences And The Impact Of Science Capital

Frederik Bub[1], Thorid Rabe[1], Lisa-Marie Christ[2] and Olaf Krey[2]
[1]Martin Luther University Halle-Wittenberg, Germany
[2]University of Augsburg, Germany

Despite the acknowledged societal relevance of physics, many students distance themselves from the subject, perceiving it as both challenging and male dominated. Such perceptions contribute to smaller, less diverse scientific communities. To better understand science-related educational decisions, this study applies the STEM identity framework in a longitudinal design, integrating qualitative and quantitative methods. The focus is on the early stages of physics and chemistry education at the age of 12-15 years. The longitudinal questionnaire survey presented here, was conducted at 15 German grammar schools with 688 students over two years, using validated scales to assess identity related constructs like self-efficacy and interest. Results show gender disparities in interest and self-efficacy at the beginning of physics and chemistry lessons, with males reporting higher levels. Regarding Science Capital we found that students with higher Science Capital display higher levels of interest and self-efficacy. The gap between the groups became smaller during the observation period, but at the same time self-efficacy and interest in the subjects generally declined, with the exception of biology. However, the downward trend is more pronounced among male students and students with higher Science Capital. These findings highlight the role of gender and Science Capital in shaping early STEM experiences, with problematic trends particularly evident in physics-related constructs.

Keywords: Early Science Education, Longitudinal Studies, Science Identities

Theoretical Framework And Research Interest

Although the social relevance of the natural sciences in general and physics in particular is recognised by a large number of people, many pupils personally distance themselves from physics (Archer et al., 2010). Physics is often regarded as a difficult, nerdy, male and unpopular school subject (Kessels et al., 2006). Accordingly, educational decisions are often made against physics which, among other things, leads to fewer and less diverse young scientists (DeWitt & Archer, 2015).

The construct of identity affords a comprehensive framework for examining educational choices, conceptualizing them as emergent from intrapersonal negotiations (identity work) embedded within an individual's social environment. It allows a wide range of influences and underlying conditions to be taken into account (Lee, 2012; Morf & Koole, 2014). This theoretical premise suggests to integrate qualitative approaches (via narratives, e.g. from interviews) and quantitative approaches (e.g. via psychological constructs from questionnaires). Psychological constructs such as self-efficacy, interest and self-concept in science can be taken as indicators of a comprehensive STEM identity (Hazari et al., 2010; Rabe & Krey, 2018).

With regard to science education, the initial subject classes can be considered a critical phase in students' educational decision-making. In German grammar schools these begin in the 6th or 7th grade and coincide with the onset of adolescence, when identities are strongly (re)negotiated (Schreiner & Sjøberg, 2007). Analysing this phase from the perspective of STEM identity is still a desideratum in Germany (Rabe & Krey, 2018).

Research Questions And Methods

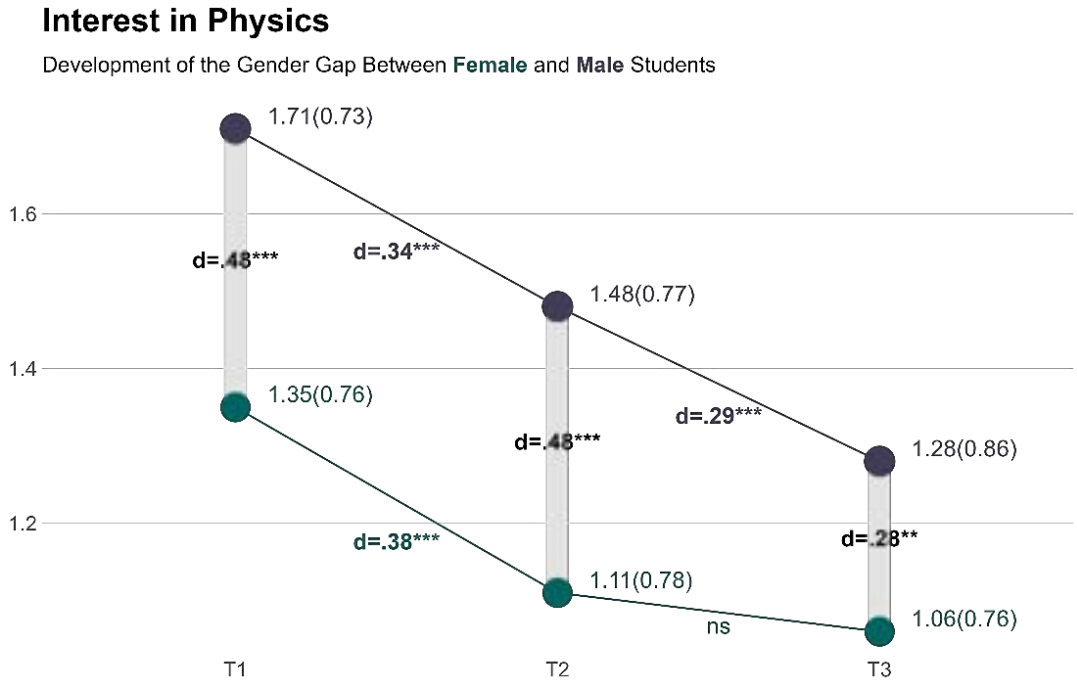
Our research project aims to use the identity perspective to better understand young people's educational decisions and, in particular, to shed light on the identity negotiations in initial physics and chemistry classes. To this end, we focus on the research questions: (1) How do indicators of a STEM identity develop in introductory physics and chemistry classes? (2) How do students relate other identities (e.g. gender) to their developing STEM identity?

To answer the research questions, the project IdentMINT uses a mixed methods approach with qualitative interviews and a quantitative longitudinal questionnaire survey. In the following, we report on the quantitative part of the inquiry.

Surveys were carried out in two federal states of Germany at a total of 15 grammar schools (9 in Bavaria and 6 in Saxony-Anhalt) at three points in time (T1-T3). The surveys cover a period of nearly two years of initial physics (T1-T3) and one year of chemistry (T2-T3) classes. Complete data sets covering all survey points are available for n=688 pupils, 56% of whom identify as female, 43% male, 0.7% diverse or unspecified.

We used established scales to gather data on identity related constructs, including self-efficacy related to physics, chemistry, and biology (Jerusalem & Satow, 1999), interest in physics and chemistry (Frey et al., 2009), perceptions of physics and chemistry lessons, engagement in extracurricular science activities, aspects of gender identity, Science Capital and the perceived attitudes of significant others, such as peers and parents (ASPIRES, 2016). In the following, we report on the constructs of interest and self-efficacy. These scales have undergone validation through confirmatory factor analysis (Hu & Bentler, 1999) and have been tested for measurement invariance (Chen, 2007), which is essential for our cross-sectional and longitudinal analyses. With the validated scales, we conducted cross-sectional mean comparisons (Wilcox tests due to robustness against violation of normal distribution) with comparisons by gender and by the parents' occupational background in natural sciences as an indicator of Science Capital. We distinguished between students having none, one or two parent(s) with an occupational background in science. Effect sizes are reported using Cohen’s d. For the longitudinal analysis, we performed an ANOVA for repeated measurement and then conducted paired Wilcoxon tests between T1-T3 and calculated effect sizes of the longitudinal development.

Results: Development Of Self-Efficacy And Interest



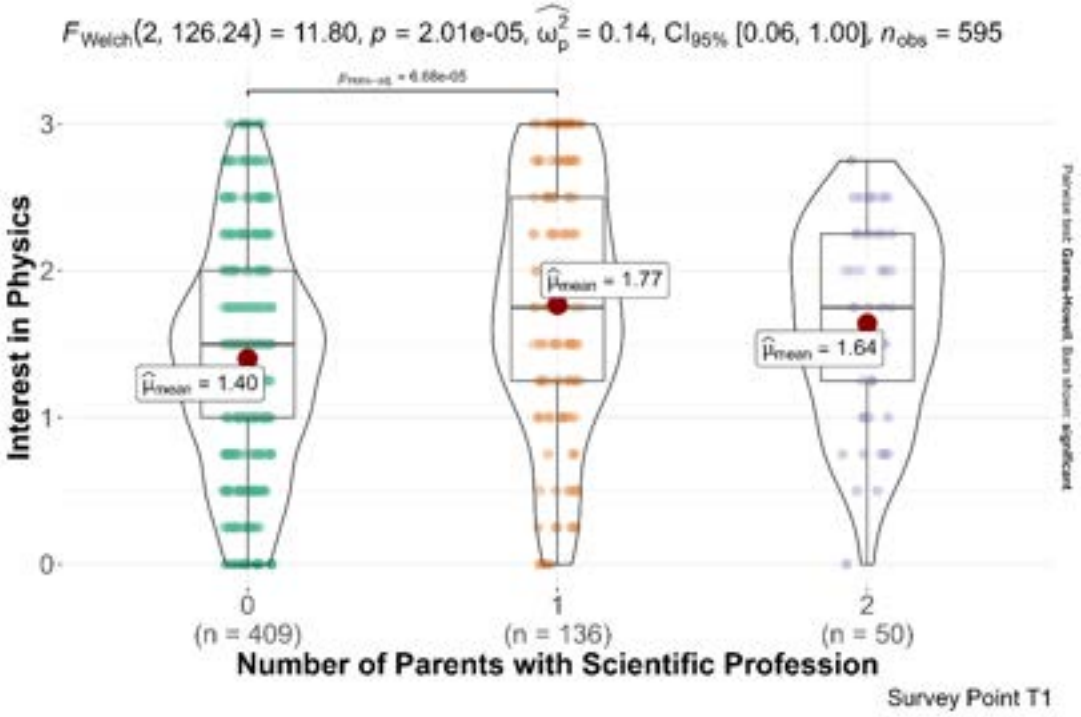
All scales show a satisfactory quality according to Hu & Bentler (1999). Cross sectional measurement invariance with the criterion according to Chen (2007) is given for almost all group comparisons with $\Delta CFI<.01$ (if not, no differences are reported or explicit reference is made to the violation of measurement invariance). Longitudinal measurement invariance across the survey time is given (with $\Delta CFI<.01$) in all groups except for the group with two parents with a background in natural sciences. In the following, we present the developments of self-efficacy in physics, chemistry and biology, as well as interest in physics and chemistry.

Gender Specific Results

Due to the small number of participants who identify as diverse, the gender specific results are only given for male and female students. The results for biology differ significantly from the other two natural sciences: There are no significant gender differences for self-efficacy in biology at T1 and T2 (with no measurement invariance at T3). In physics and chemistry, we find a significant and substantial gap in interest and self-efficacy, with male pupils reporting higher scores at the beginning of the initial lessons. The largest gender gap is found for self-efficacy in physics (d=.62*** at T1) and for interest in physics (d=.48*** at T1 and T2). All observed gender

gaps are smaller at the end of the two-year survey period and are only significant for physics-related constructs. For self-efficacy in physics, the gender effect decreases from medium (d=.62***) to small (d=.38**), and similarly for interest in physics from d=.48*** to d=.28** (see Figure 1). The gender differences in chemistry decrease from d=.33*** to d=.10 for self-efficacy and from d=.28*** to d=.06 for interest and are no longer significant at the end of the survey period. This observation is mainly due to the fact that most of the values decrease in both groups (there is only one slightly significant but very small increase in self-efficacy in biology from T2 to T3: d=.17** all other values decrease or remain unchanged). However, the longitudinal decline is much larger for male students than for female students (e.g. from T1 to T3 for interest in physics for female students with d=.38*** and for male students with d=.54***). The development of the effect sizes of the group differences between female and male pupils is summarised in Figure 4 on the left.

Figure 1. Development of the gender gap in interest in physics (scale 0 to 3) over the three survey points (T1 to T3); for cross sectional and longitudinal effects Cohens' d is shown.



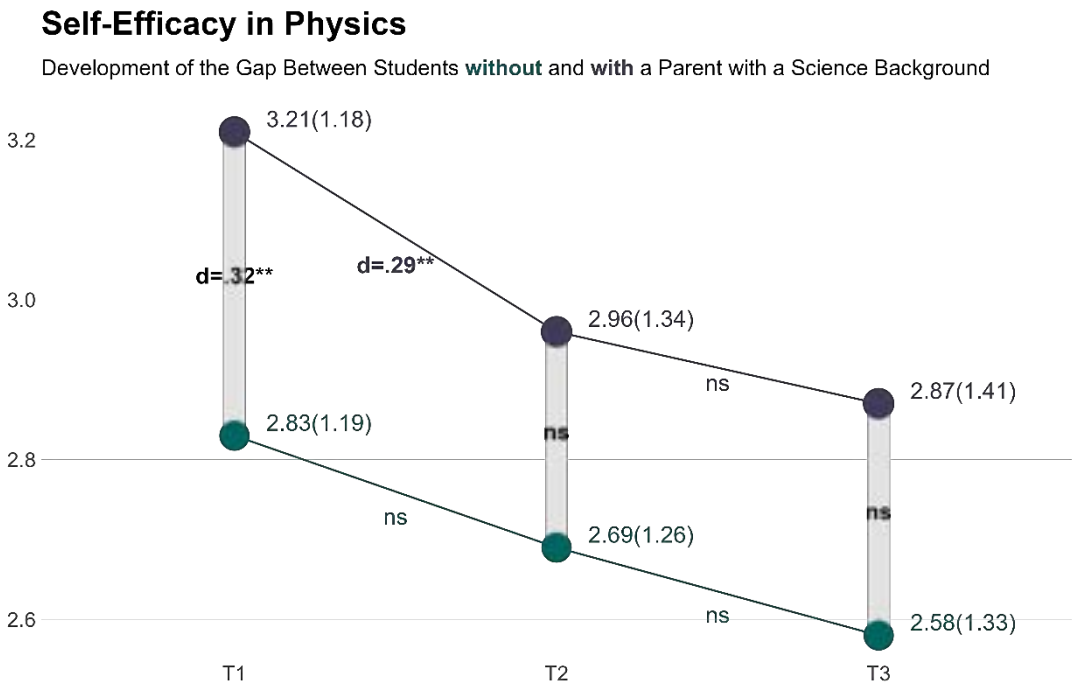
Results On Science Capital

As a means of accessing Science Capital, we examined the professional background of the parents. Participants were asked whether their parents have a job related to science. It is important to note that the survey measured pupils' perceptions of whether their parents' occupations were related to science – rather than an 'objective' classification of specific jobs. From this, we formed groups of pupils without a science-related parent (n=458), pupils with one parent with a science-related background (n=156) and pupils who stated that both parents have a science-related occupation (n=53). In 21 cases, there were no responses or invalid responses. We then analysed whether there are significant differences in self-efficacy and interest and how the constructs develop in the three subgroups over the study period.

In the first survey (T1 for the physics and biology related variables, T2 for chemistry related variables), there are significant differences with medium effect sizes (d>.25*) in all reported variables between the group with one and the group without parents with a scientific occupation.

Students with a science background report higher levels of interest and self-efficacy at all data collection points. The largest differences due to Science Capital can be observed in interest in physics (d=.46*** at T1) and interest in chemistry (d=.39*** at T2). Surprisingly, there are no significantly higher values in the group with two parents working in science-related professions; in fact, for some measures, such as interest in physics the mean values are even lower in this group (see Figure 2).

Figure 2. Interest in physics at survey point T1 showing higher values for students with one parent working in a science-related profession, but no higher values, if both parents have a background in natural sciences.

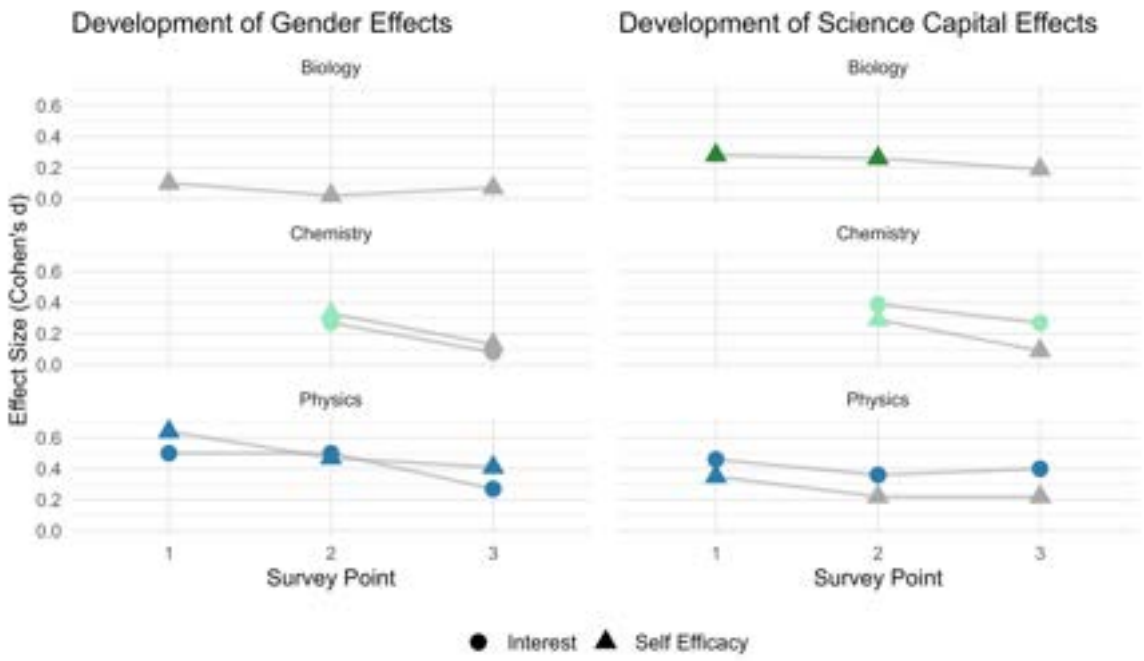


Due to a lack of longitudinal measurement invariance for the group with two parents with scientific professions, the development of interest and self-efficacy is only reported for the other two groups (without and with one parent with a scientific profession).

In contrast to the gender gap, we found a gap in self-efficacy expectations in biology depending on Science Capital (d=.25* at T1 and d=.27* at T2). Almost no significant longitudinal developments can be observed for the self-efficacy in biology. In the group without a parent with a scientific background, self-efficacy in biology increases slightly from T2 to T3 (d=.12*), so that the Science Capital gap at T3 is no longer significant (d=.18).

For interest and self-efficacy in physics and chemistry, we see – similar to the gender gap – that high values (in the groups with high Science Capital) decline the most over the survey period. For example, the decrease in self-efficacy in chemistry is much lower for the group without scientific parents (d=.15**) than in the group with one parent with a science background (d=.35**) from T2 to T3. Due to these longitudinal trends, the differences between the Science Capital groups become smaller and, at the last survey point, are only measurable in terms of interest in physics (d=.40***) and chemistry (d=.27*). All group differences regarding self-efficacy are no longer significant at T3 (see Figure 3 for self-efficacy in physics and Figure 4 for all reported scales).

Figure 3. Development of the Science Capital gap in self-efficacy in physics (scale 0 to 5); Cohen's d is provided for cross sectional and longitudinal effects.



Discussion And Outlook

Our analyses show that gender and Science Capital perspectives are highly relevant in early science education. The findings indicate that the role of gender and Science Capital varies across different natural science subjects and develops differently during initial teaching (see Figure 4). Our results, covering the first two years of physics lessons and the first year of chemistry lessons, indicate that the differences diminish over time, although this is only achieved through a sharp decline in self-assessments that may have been overestimated. Physics-related constructs appear to be developing in a particularly problematic manner. Only in this subject does the gender gap remain significant at the end of our survey. It was also found that students whose parents both work in scientific professions do not exhibit higher self-efficacy or greater interest, meaning that the effects must be considered differently depending on the strength of the parents' scientific background.

In addition to further analytical perspectives (e.g. peer influence, image of science), the next step is to move away from individual constructs and examine a more comprehensive construct of STEM identity (see e.g. Hazari et al., 2020) and its development in early science education. In addition, triangulation with the qualitative data from the project is planned in order to explain the developments identified.

Figure 4. Development of gender gap and Science Capital gap in interest and self-efficacy in biology, chemistry and physics. Grey colour indicates insignificant effects.

ESERA 2025 Copenhagen

Deconstructing Stereotypes: A Critical Approach To Indigenous Knowledge In Chemistry Education

Daniele Raupp and Vânia Vanuchi
Federal University of Rio Grande do Sul, Brazil

Indigenous peoples, estimated at over 300 million across all continents constitute the vast majority of the world's cultural diversity and act as primary guardians of socio-biodiversity, yet their epistemologies remain marginalized by colonial legacies. In the Brazilian educational context, marked by the historical invisibility of indigenous peoples, this research addresses the need to deconstruct stereotypes in Chemistry teaching. Grounded in Law No. 11,645/2008 and decolonial perspectives, the study emerges from the gap in indigenous thematic integration within the scientific curriculum. The theoretical framework is anchored in Critical Meaningful Learning and intercultural theories that question epistemological hierarchies. This paper presents a theoretically validated pedagogical model, focusing on its didactic architecture rather than classroom implementation. The central research question interrogates: In what way can a Potentially Meaningful Teaching Unit (PMTU), structured under decolonial perspectives, provide a methodological framework for integrating Indigenous themes into Chemistry and overcoming curricular fragmentation? By structuring the PMTU through decolonial lenses, this study provides educators with a robust and replicable framework to operationalize the inclusion of Indigenous knowledge, offering a concrete methodology to mitigate the historical invisibility of these epistemologies. The proposal promotes an integrative reconciliation between scientific and traditional knowledge, fostering a contemporary understanding that recognizes epistemological diversity. Designed for adaptation to various global contexts, this framework favours the valorisation of Indigenous peoples and promotes a restorative, truly intercultural science education.

Keywords: Epistemological Pluralism; Interculturality, Epistemic Justice.

Introduction

Brazil, a territory originally inhabited by hundreds of indigenous peoples with millennial linguistic, cultural, and traditional knowledge diversity, still bears deep marks of the colonial process in its educational system. These marks manifest themselves in the marginalization of indigenous history, cultures, and knowledge in school curricula, perpetuating stereotypes and reductionist views, disqualifying traditional methods of knowledge transmission, and privileging Western scientific knowledge; resulting in epistemological violence and historical erasure. Such invisibility compromises the very understanding of Brazilian history by disregarding these peoples' millennial contributions to society's development (Baniwa, 2025; Kayapó, 2021; Munduruku, 2020) and ignores the contemporary, dynamic, and diverse presence of more than 279 indigenous peoples in present-day Brazil (Brazilian Institute of Geography and Statistics [IBGE], 2022).

This dynamic constitutes a profound form of epistemic injustice. As Yarbrough and Smith-Colin (2025) highlight, justice in this context involves correcting the "credibility deficit" imposed on marginalized groups. In science education, this means moving beyond the historical invisibility of traditional knowledge and recognizing Indigenous peoples not just as sources of cultural data, but as legitimate holders of expertise. Addressing this deficit is a restorative act, essential for a curriculum that seeks to repair the historical silencing and the "epistemic violence" often directed at original peoples (Potiguara, 2019; Yarbrough & Smith-Colin, 2025).

In the Brazilian context, this restorative effort finds a concrete expression in the recognition of Indigenous epistemologies. The cultural richness of the Indigenous peoples in Brazil is not

limited to the preservation of ancestral traditions but is manifested in complex systems of knowledge production that engage directly with science. As Law 11.645/08 indicates, the inclusion of this knowledge in the school curriculum is a fundamental step toward an anti-racist and decolonial education. This epistemological plurality challenges the hegemony of Eurocentric thought by highlighting the sustainable management of biodiversity and the social technologies developed by different ethnic groups (Munduruku, 2020; Krenak & Doyle, 2025). In the field of science education, this valorisation allows for what Vanuchi and Raupp (2025) characterizes as a necessary integration between scientific knowledge and Indigenous cosmovisions, promoting a scientific literacy that respects the alterity and cultural heritage of the Brazilian territory. In practice, this integration aligns this research with the concept of epistemological pluralism, which, as Morgan (2011) discusses, involves a shift away from a single, reductionist worldview toward an integrated perspective that values diverse ways of knowing. In Chemistry education, this pluralism acts as a 'corrective' to the limitations of Western science, allowing for a more holistic understanding of reality where indigenous perspectives on the environment and matter are not merely 'included' but are foundational to a broader scientific literacy.

This theoretical framework provides the necessary tools to address a historical context of struggle, where Indigenous and Black social movements have fought for recognition and appreciation of their contributions to Brazilian society's formation, an achievement breaks centuries of silencing and invisibility in the school environment: the enactment of Law No. 11,645 of March 2008, which mandates the teaching of Afro-Brazilian and indigenous history and culture in Basic Education school curriculum (Brasil, 2008). Although enacted nearly 16 years ago, little has been done to change the established scenario. Its effective implementation creates tension for a new positioning that involves questioning an educational model that not only promotes but also perpetuates these peoples' invisibility (Kayapó & Brito, 2014; Marques, 2014).

Furthermore, the challenge of integration is deeply tied to the universalist and Eurocentric view of modern science. However, contemporary studies reveal that Western science has always been spatially situated and dependent on its encounters with non-Western knowledge systems. The case of the Sámi people in Scandinavia demonstrates that "indigenizing" Western science is not about replacing it, but about recognizing it as an evolving intellectual culture that is modified by human and physical challenges posed by Indigenous residents (Wråkberg & Granqvist, 2014).

Under the premise that the inclusion of Indigenous themes is a vital strategy for this deconstruction within the Brazilian context, this study investigates how to operationalize such a dialogue through the following research question: In what way can a Potentially Meaningful Teaching Unit (PMTU), structured under decolonial perspectives, provide a methodological framework for integrating Indigenous themes into Chemistry and overcoming curricular fragmentation? This proposal was conceived as part of a doctoral research project in Science Education, developed at a public university in Southern Brazil.

Bridging The Gap: Challenges Of Law 11,645/08 In Chemistry

Despite legal requirements, a systematic review study (Vanuchi & Raupp, 2022) revealed a significant research gap in science education, where indigenous themes remain concentrated in arts, literature, and history disciplines, failing to achieve the transversality intended by Law 11,645/08. This gap is not merely a technical failure in curriculum design, but a reflection of deeper epistemological barriers. This concentration in non-scientific fields reinforces the stereotype of Indigenous peoples as historical or folkloric figures, lacking technical and scientific

agency. By failing to achieve transversality in Chemistry, the education system implicitly perpetuates the myth that Indigenous knowledge is incompatible with rigorous scientific thought.

Brazilian indigenous intellectuals point out critical challenges in implementing the Law in science education. Gersem Baniwa (2025) shows the persistence of structural obstacles to plural education due to the colonial nature of academic knowledge, while Daniel Munduruku (2019) emphasizes that effective implementation requires a curricular reconfiguration to include historically marginalized indigenous scientific practices. Ailton Krenak adds that the current system reproduces epistemic hierarchies that disqualify ancestral knowledge (Krenak & Doyle, 2025).

According to Eliane Potiguara (2019), genuine change will only occur through truly intercultural education that recognizes Brazilian epistemological plurality. Understanding the roots of this resistance requires considering the perspectives of Indigenous intellectuals who identify the colonial foundations of these educational obstacles. These Indigenous critiques are deeply aligned with the broader academic framework of critical interculturality, which provides the theoretical tools to dismantle the power structures that sustain such colonial resistance.

Interculturality represents a significant evolution in global academic thinking, based on fundamental contributions established in decolonial perspective foundations (Quijano, 2020). The field was enriched by critical analyses of subalternity and power structures that silence marginalized voices (Spivak, 1988), explaining how epistemological colonialism resulted in the exclusion of non-Western knowledge (Dussel, 2019). Furthermore, explorations of cultural hybridity and identity (Bhabha, 1994; Hall, 1996) contribute to deconstructing Eurocentric narratives and promoting knowledge decolonization, significantly influencing education and science (Mignolo, 2011). Such perspectives are essential for rethinking school curricula to recognize and value different epistemologies (Walsh, 2013).

However, there is still a long way to go to effectively incorporate indigenous contributions into pedagogical practices without limiting them to commemorative dates. Insufficient teacher training and undergraduate courses that rarely include indigenous themes remain major hurdles (Bergamaschi, 2012: Oliveira & Almeida, 2023). Teaching materials often reproduce stereotypes (Grupioni, 1995) and invisibilize contemporary indigenous scientific contributions by limiting these peoples to a colonial past (Kayapó, 2021; Munduruku, 2019). This institutional resistance to accepting non-Western epistemologies confirms that the coloniality of knowledge remains a formidable obstacle (Quijano, 2020; Walsh, 2013).

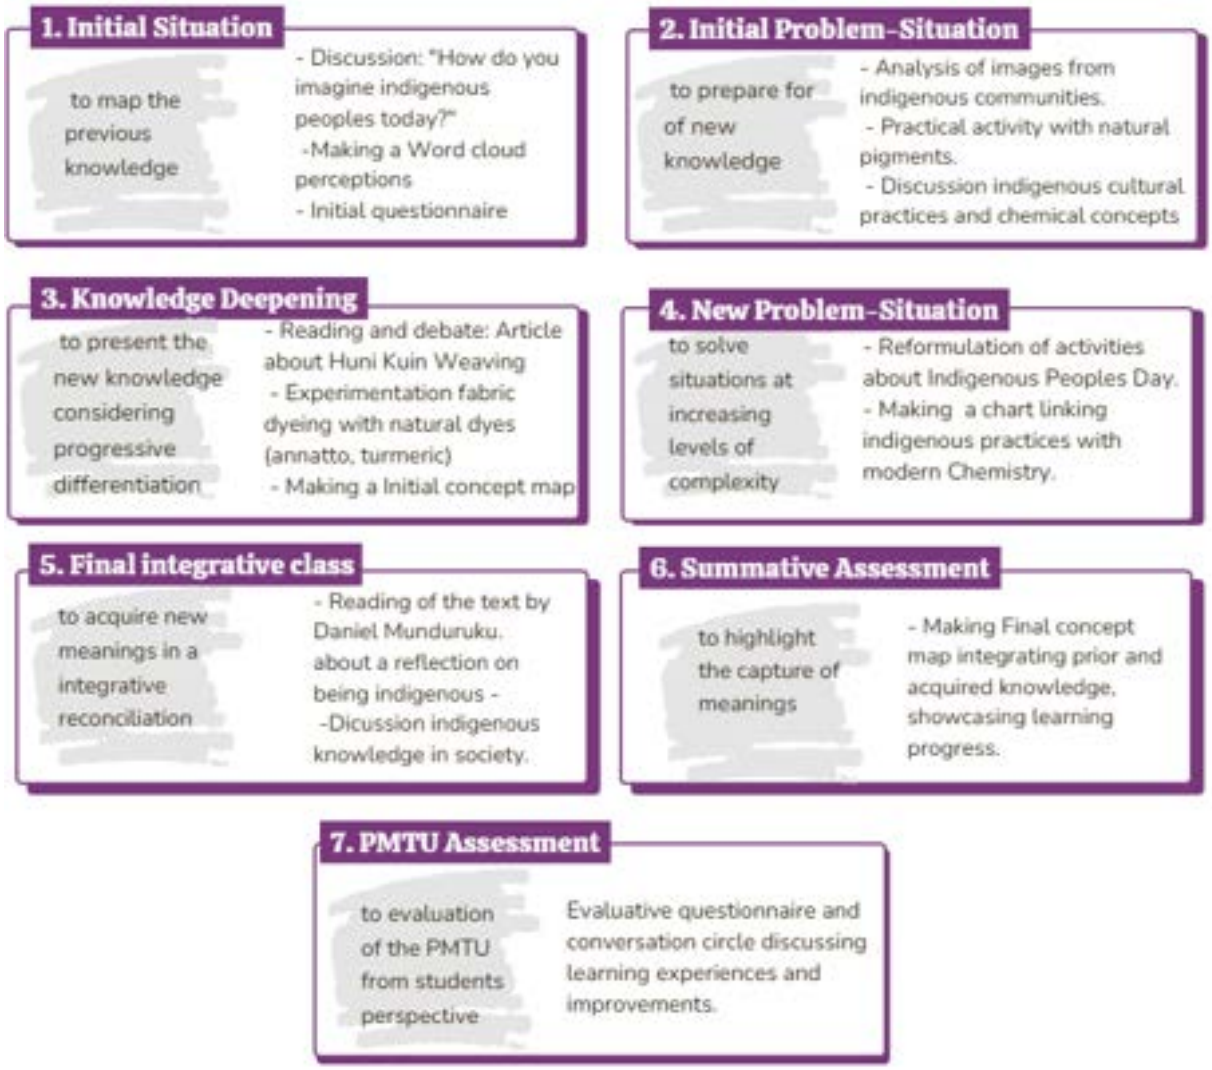
The analysis of these structural and epistemological barriers demonstrates that implementing Law 11,645/08 in Chemistry requires pedagogical tools that operationalize intercultural dialogue. Moving beyond normative guidelines, it is essential to develop strategies that challenge Eurocentric curricula and deconstruct deeply rooted stereotypes.

Proposal: A Didactic Strategy Based On Significantly Critical Learning

Acknowledging that interculturality requires a critical approach beyond simple content inclusion (Walsh, 2013), this didactic proposal is founded on Critical Meaningful Learning (Moreira, 2000; 2011), expanding upon Ausubel's theory (2012) by emphasizing learners' critical engagement with content through questioning its validity and contextual relevance to their sociocultural environment. In the context of this research, Critical Meaningful Learning (CML) is not merely a cognitive process but a political and ethical stance against the coloniality of knowledge. According to Moreira (2000; 2011), CML allows the learner to participate in their culture while simultaneously distancing themselves from it critically. For indigenous themes in Chemistry education, this means that students can recognize the historical stereotypes embedded in their

social fabric while using critical thinking to 'unlearn' folkloric representations—the 'generic indigenous' person—and anchor new meanings based on contemporary indigenous scientific contributions. This process of 'unlearning' serves as an epistemological break, essential for decolonizing the curriculum and acknowledging indigenous peoples as dynamic producers of knowledge rather than figures fixed in the past.

Within the scope of Chemistry education, addressing Indigenous themes acts as a catalyst for intercultural education by challenging the universalist and Eurocentric view of modern science. By integrating traditional knowledge, the curriculum shifts from being a transmitter of abstract concepts to a space for dialogue between different forms of knowledge. This pedagogical practice, grounded in decoloniality, allows students to recognize Chemistry as a plural human construction, where Indigenous social technology is validated as legitimate scientific knowledge. In this way, chemical education contributes to the recognition of alterity, promoting respect for diverse ways of interacting with matter and the environment, which are fundamental pillars for a truly intercultural society.



In order to transform this theoretical critique into a structured learning experience, the proposal is materialized through Moreira's (2011) Potentially Meaningful Teaching Units (PMTU) framework. This methodology utilizes logically structured, meaningful materials specifically designed for the target audience to promote meaningful rather than mechanical learning. Consequently, PMTUs facilitate a higher quality of knowledge. Briefly, the PMTU is composed of the initial situation: which aims to map the previous knowledge of students. Initial problem-situation: a problem-situation of an introductory level, seeking to give meaning to the concept. Deepening of knowledge: approach from progressive differentiation. New problem situation: questions with a higher level of depth, evidencing the correspondences and contradictions between the concepts. Individual summative evaluation: test evidencing the capture of meanings. Final integrative class: seeks integrative reconciliation between concepts. Learning assessment: evidence should be sought for understanding meanings and the ability to use knowledge for different situations throughout the implementation of the PMTU, focusing on collaborative activities, and ending it with an individual summative assessment. Evaluation of the PMTU itself: In order to improve teaching strategies, to assess the perspective of students (Schittler; Moreira, 2014).

The PMTU methodology comprises seven progressive stages supported by formative assessment (Figure 1), utilizing problem-based situations to evaluate the acquisition of meanings. Although this proposal is grounded in the Brazilian legal framework (Law No. 11,645/2008), its methodological structure is designed to be flexible, adaptable, and replicable in diverse international contexts. The core objective — the integrative reconciliation between Western scientific language and ancestral epistemologies — addresses a global challenge in science education: the need for pluralistic and intercultural curricula that respect local identities while promoting scientific literacy.

The sequence of activities comprised in the PMTU is detailed below, highlighting the pedagogical intent of each stage and its alignment with the goals of decolonial science education

1. Initial Situation: designed to identify students' prior conceptions, which are often permeated by colonial stereotypes. This diagnostic phase is crucial for the subsequent pedagogical insurgence, allowing the instructor to confront biased views with the complexity of Indigenous social technologies. We suggest three instruments: (1) a collective debate focused on students' perceptions of Indigenous peoples in contemporary times; (2) the collaborative construction of a word cloud using digital tools; and (3) an individual questionnaire exploring the understanding of Indigenous peoples in the present day and the recognition of Indigenous cultural heritage.

Figure 1. PMTU Organization with definition of the seven progressive stages, selected activities and didactic resources.

2. Initial Problem-Situation: the goal is to provoke a critical confrontation between colonial imaginaries and the diversity of Indigenous identities using image analysis (Figure 2). A stereotypical depiction showing reductionist folkloric views (nudity, straight hair, uniform skin tone, headdresses, and life restricted to nature) and Ailton Krenak, who challenges limiting perspectives by occupying prominent spaces, such as the Brazilian Academy of Letters.The proposal operationalizes what Walsh (2013) terms 'pedagogical insurgence.' Methodologically, this stage initiates the process of progressive differentiation, challenging the 'epistemic violence' (Spivak, 1988) that historically relegated Indigenous existence to a static past, thereby opening space for the recognition of Indigenous peoples as contemporary producers of knowledge and science.

The stage suggests an experimental activity (Vanuchi & Braibante, 2021) preparing natural dyes using genipap and annatto - pigments traditionally used by indigenous peoples for ritual and identity markings (Figure 3). This stage operationalizes integrative reconciliation (Moreira, 2011) by connecting traditional Indigenous knowledge with scientific concepts of Organic Chemistry. The preparation of natural dyes from genipap and annatto substances historically used for ritual and identity markings—serves as a critical subsumer.

The role of this stage is to validate ancestral knowledge as complex technoscientific systems, allowing students to understand chemical phenomena (such as polarity and functional groups) from a culturally relevant basis, effectively deconstructing the view of Indigenous knowledge as merely folkloric.

Figure 2: Stereotyped Indigenous Person vs. Contemporary Indigenous Person.

Figure 3: The use of natural pigments in body ornamentations.

3. Knowledge Deepening: discussion of the article about Huni Kuin (Silva et al, 2016) weaving and the complex textile production techniques of this ethnicity, in a progressive differentiation when general concepts progressively broken down into more specific concepts (Moreira, 2011), showing how this knowledge is closely linked to various chemical concepts, such as acids and bases, pH, intermolecular forces, and mixture separation techniques, like decantation and filtration, maceration processes, decoction. Each ethnicity develops its own techniques and symbologies for the extraction and use of pigments (Figure 4) that not only decorate but carry deep cultural meanings.

Figure 4. Fabrics dyed with annatto.

The role of this phase is to demonstrate that each ethnicity develops specific methodologies for pigment extraction. This approach reinforces the deconstruction of stereotypes by moving from

a general appreciation of Indigenous culture to a rigorous technical understanding of their scientific contributions

4. New Problem-Situation: in greater level of depth, students will be encouraged to critically reformulate commonly used stereotypical school activities, especially those related to "Indigenous Peoples Day" (Figure 5). After, they will also organize a flowchart that relates indigenous knowledge, natural pigments, and Chemistry principles, promoting an integrative reconciliation between traditional and scientific knowledge.

Figure 5. School activity on April 19th in homage to the First Inter-American Indianist Congress, held in 1940, with stereotypical representations that reinforce misconceptions about these peoples.

April 19th
Indian Day

Indians were the first inhabitants of Brazil
In the beginning, there were many Indians living free in our forests.
Today, they are very few in number.
Indians live in groups called tribes.
Each tribe has a warrior chief, called cacique or morubixaba,
and a religious leader, called a shaman, who is also the tribe's healer.
The Indians' houses are called hollows. These are huts built with
sticks and clay, covered with straw or tree leaves.
The gathering of hollows forms a small village,
called taba.
The weapons of the Indians are the bow, the arrow, the
spear, club and blowgun.
Indians usually sleep in hammocks or
mats.
They feed on hunting, fishing and vegetables.
They plant cassava, corn, sweet potatoes, etc.
They like to sing and dance. Your
musical instruments are the drum, the rattle, the
flute and maraca.
The Indians are naked or almost naked. Some
wear loincloths and headdresses made of colourful feathers
birds.
They usually paint their bodies with dyes extracted
of plants.
They adorn themselves with necklaces and bracelets made from
animal teeth.
They worship the sun, which they call Guaraci, the moon,
which they call Jaci, and other gods.

Dia 19 de Abril
Dia do Índio

Os índios foram os primeiros habitantes do Brasil.
No começo, havia muitos índios vivendo livres nas nossas florestas.
Hoje, eles são em número bem reduzido.
Os índios vivem em grupos chamados tribos.
Cada tribo tem um chefe guerreiro, chamado cacique ou morubixaba,
e um chefe religioso, chamado pajé, que também é curandeiro da tribo.
As casas dos índios chamam-se ocas. São cabanas construídas com
paus e barro, cobertas de palha ou folhas de árvores.
A reunião de ocas forma uma pequena aldeia
chamada taba.
As armas dos índios são o arco, a flecha, a
lança, o tacape e a zarabatana.
Os índios costumam dormir em redes ou
esteiras.
Alimentam-se da caça, da pesca e de vegetais.
Plantam mandioca, milho, batata-doce, etc.
Gostam de cantar e de dançar. Seus
instrumentos musicais são o tambor, o chocalho, a
flauta e o maracá.
Os índios andam nus ou quase nus. Alguns
usam tangas e cocares feitos de penas coloridas de
aves.
Costumam pintar o corpo com tintas extraídas
das plantas.
Enfeitam-se com colares e pulseiras feitos com
dentes de animais.
Adoram o sol, que chamam de Guaraci, a lua,
que chamam de Jaci, e outros deuses.

This stage aims to combat curricular fragmentation and the 'folklorization' of Indigenous themes, which are often restricted to isolated commemorative dates such as 'Indigenous Peoples Day.' By encouraging students to critically reformulate stereotypical school activities, the proposal operationalizes the challenge of moving beyond mere symbolic inclusion. The role of this phase is to promote a final integrative reconciliation, where traditional knowledge and chemical principles are organized into a flowchart of interdependence.

5. Final Integrative Class: discussion of the text "I can be who you are without ceasing to be who I am: a reflection on being indigenous" by Daniel Munduruku in a circle, to reflect on the presence and valorization of indigenous knowledge in/by contemporary society and science.It demands an integrative reconciliation - the construction and reconstruction of conceptual relationships, as new concepts were incorporated into the cognitive structure and need to be reorganized (Moreira, 2011).

6. Summative Assessment: Construction of a final conceptual map with the focal question: What knowledge do you have about Indigenous peoples and their role in contemporary society? By comparing both maps, it will be possible to observe progressive differentiation and integrative reconciliation, as well as identifying changes in students' representations of Indigenous peoples.

7. PMTU Assessment: An evaluative questionnaire for feedback and a discussion circle to reflect on how students' perceptions of Indigenous peoples have changed and how this new perspective has impacted their understanding of Chemistry.

The integration of these seven stages within the PMTU framework transcends a mere instructional sequence; it constitutes a deliberate pedagogical intervention aimed at fostering anti-racist and intercultural chemistry education. By centering Indigenous social technologies, such as the chemistry of natural pigments, this strategy operationalizes what Walsh (2013) defines as 'pedagogical insurgence,' challenging the Eurocentric hegemony that historically silenced non-Western forms of knowing. The iterative cycle of problem-situations and integrative reconciliation provides the necessary scaffolding for students to recognize 'epistemic pluralism' (Baniwa, 2025), acknowledging Indigenous peoples as contemporary producers of scientific knowledge rather than figures of a folkloric past. Consequently, this didactic approach acts as a restorative practice, aligning chemical concepts with social justice to deconstruct racialized hierarchies and promote a more equitable and pluralistic understanding of science (Munduruku, 2019; Quijano, 2020).

Within the scope of Chemistry education, addressing Indigenous themes acts as a catalyst for intercultural education by challenging the universalist and Eurocentric view of modern science. This challenge is supported by the understanding of technoscience, which reveals that Western science has historically been dependent on and shaped by its encounters with non-Western knowledge systems (Wråkberg & Granqvist, 2014). By integrating traditional knowledge—such as natural pigment extraction and textile production techniques (Silva et al., 2016)—the curriculum shifts from a transmitter of abstract concepts to a space for 'indigenizing' Western science. This process transforms colonial science into a tool for emancipation (Baniwa, 2025; Walsh, 2013), where Indigenous social technology is validated as a legitimate scientific contribution that modifies and enriches global scientific practices.

Final Considerations

This research addressed the persistent challenge of integrating Indigenous themes into the Chemistry curriculum, a field historically dominated by Eurocentric and universalist perspectives. By developing a didactic strategy grounded in Potentially Meaningful Teaching Units (PMTU) and Critical Meaningful Learning, we demonstrated that it is possible to move beyond the mere fulfilment of Law 11,645/2008 toward a practice of epistemic justice.

The proposal, by centring Indigenous social technologies, served as a catalyst for decolonizing the science curriculum. This process allowed for the deconstruction of folkloric stereotypes, positioning Indigenous peoples not as relics of the past, but as dynamic producers of contemporary scientific knowledge. A key contribution of this study is the structural flexibility of the PMTU framework, which is designed to be adaptable and replicable in diverse international contexts. This allows the methodology to be tailored to the specific scientific realities and ancestral epistemologies of different Indigenous peoples across various global regions. Although the results of the evaluation of the UEPS have not yet been systematized, this proposal outlines the theoretical and methodological foundations that will guide this stage. The different phases of the UEPS — which range from the assessment of prior knowledge to problematization and integrative reconciliation — were organized to facilitate the identification of possible changes in students' understanding of Indigenous peoples and the chemical concepts addressed throughout the proposal.

In conclusion, this proposal aims to contribute to the global dialogue on Diversity, Identity, and Inclusion in Science Education by offering a validated and structurally flexible methodology. A key contribution of this framework is its potential for adaptation; it is designed to be replicable in diverse international contexts, allowing the pedagogical stages to be tailored to the specific scientific realities and ancestral epistemologies of different Indigenous peoples across various

global regions. Thus, decolonizing Chemistry teaching is presented not only as a local necessity but as a global opportunity to honor epistemological plurality and promote the inclusion of historically marginalized voices in the scientific field.

ESERA 2025 Copenhagen

How Families' Everyday Engagements Hold Potential For Cultivating Students' Science Capital And Align With School Science

Sanne Schnell Nielsen[1], Lars Sejersgård Jakobsen[1]
Camilla Bech Blomgren[2] and Nadia Møller Christiansen[2]
[1]University College Copenhagen,
[2]VIA University College

This study investigates how students' everyday activities outside school, across family contexts, hold potential for shaping distinct forms of Science Capital and how these forms can align with school science. The findings are based on 54 interviews with Danish families of students aged 6 to 15 from five schools.

While family life encompasses a wide range of science-related experiences, these activities are often not recognized or framed as relevant to formal education. Instead, parents primarily value these experiences for fostering lifelong skills, personal development, family bonding, and well-being. In addition, family engagement in science-related activities often involves sensory, creative, and aesthetic interactions with natural objects and phenomena, which contrast with the academic approaches emphasized in science education.

Finally, our results reveal that parents' valued childhood leisure experiences, interests, values, knowledge, and skills, together with opportunities afforded by place and local surroundings, influence how science is approached, discussed, and enacted within families.

Consequently, the ways students engage in science-related activities vary across family contexts, leading to different degrees of alignment between students' science experiences outside school and school science. These findings show that students' family experiences play a critical role in shaping the forms of Science Capital they bring into the classroom and how these forms are recognized within school science. The results highlight the importance of aligning science education with students' everyday lives to foster more relevant and inclusive school science. A "Science Capital Teaching Approach" is discussed as a framework for bridging students' experiences with school science.

Keywords: Family Science Habitus, Science Capital, School Science

Introduction

Science education has been criticized for reinforcing systemic inequalities by failing to recognize and address the diversity in students' family contexts. It has been suggested that the misalignment between students' family engagement and school science maintains disparities in participation, engagement, and achievement (Nomikou, Archer, & King, 2017). Recent TIMSS findings highlight these issues, revealing significant inequalities in science achievement linked to family background. Notably, some countries, including Denmark, have experienced an increase in these disparities in recent years (von Davier, Kennedy, Reynolds, Fishbein, Khorramdel, Aldrich, Bookbinder, Ummugal, & Yin, 2024). To understand these inequalities, this study draws on the concepts of Science Capital and family science habitus, as well as the interplay between the two.

Science Capital

Science Capital can be defined as an individual's science-related knowledge, attitudes, and experiences. It is argued that students' Science Capital plays a crucial role in shaping their opportunities to develop a strong science identity, engage with school science, and pursue future

aspirations (Archer et al., 2015). However, not all forms of Science Capital hold the same exchange value in school science. Certain forms - such as knowing scientific concepts - are more likely to be recognized and valued as Science Capital in school. In contrast, more applied forms - such as engaging in gardening, repairing machines, or cooking - often remain invisible within school science (Nomikou, Archer, & King, 2017).

Family Science Habitus

Families play a critical role in shaping students' engagement with science through their values, attitudes, and everyday practices, which can be understood as family habitus (Archer et al., 2012). Family habitus influences how students perceive and relate to science; however, not all forms of family habitus align equally well with the norms and practices of conventional science education (Archer et al., 2012; Suortti, Havu-Nuutinen, & Kärkkäinen, 2023).

In this way, the concept of family habitus is not only useful for understanding how and why science is embedded in everyday family life but also for examining how its alignment - or misalignment - with school habitus (i.e., the norms and curricular expectations of school science) can reinforce or mitigate inequalities in students' ability to relate to, participate in, and benefit from science education.

The Interplay Between Family Habitus And Science Capital

Family habitus and Science Capital are closely interrelated concepts, and their interplay is important for understanding how family everyday life shapes students' opportunities to participate in, benefit from, and relate to school science. Indeed, it is argued that family habitus cultivates different forms of Science Capital, each carrying varying degrees of potential to be recognized and valued within school science (Archer et al., 2012).

This means that family habitus directly influences students' engagement in school science through its alignment - or misalignment - with school habitus. Additionally, it indirectly shapes the types of Science Capital students develop, which in turn affects their participation and success in science education. Ultimately, these outcomes depend on both the degree of alignment between home and school habitus and the extent to which students' different forms of Science Capital are recognized within the field of school science.

Taken together, students enter science classrooms with varying possibilities to relate to, engage with, and participate in science education, depending on how their family science habitus and the form of Science Capital cultivated in their everyday science engagement align with school science expectations. This leads to unequal opportunities for students to fully access science learning and perceive it as meaningful and relevant to both their present and future lives. Ultimately, the interplay between family habitus, the development of Science Capital, and its alignment with school science has significant implications for students' participation, success, and long-term aspirations in science.

By exploring how family science habitus cultivates different forms of Science Capital, this study addresses a rarely explored perspective in science education research, as called for by the science research community (Wenner, 2024). This article argues that understanding how and why families engage with science-related activities is essential for fostering more inclusive and equitable science education, particularly for a more diverse group of students.

Against this background, we set out to answer the following research question:

How and why do families engage with science-related activities – and in what way does this engagement hold potential for cultivating different forms of students' Science Capital, and how do these forms of Science Capital align with school science?

Research Methods

Data were collected through interviews with families of students from five Danish schools, selected to ensure diversity in geography, urbanity, and students' socioeconomic and ethnic backgrounds. Using a maximum variation sampling approach, 15 students were selected from each school across grades 0, 5, and 8. Of the planned 75 interviews, 54 were successfully conducted. Interviews took place in families' homes, with primary caregivers (predominantly parents) serving as the main informants, while in most cases, the student and occasionally their siblings also participated. In a few cases, interviews were conducted online or at an alternative location chosen by the family for reasons of comfort or practicality.

The interviews were guided by a semi-structured interview protocol and a "family wheel poster", which illustrated physical and temporal aspects of families' everyday lives. The questions were informed by a conceptual framework combining Science Capital and family science habitus (e.g., Jones, Ennes, Weedfall, Chesnutt, & Cayton, 2021). Additionally, families were presented with photos depicting various science-related places and activities to prompt reflections and discussions about their experiences, perceptions, and attitudes toward science.

Throughout the interviews, family members and the interviewer jointly contributed to the family wheel with drawings, comments, and examples. All interviews were recorded, transcribed, and analysed using a combined deductive and inductive thematic analysis approach (Braun & Clarke, 2006). For illustration, an example of a deductive code related to Science Capital was "Access to physical science-related resources" (e.g., 3D printers, greenhouses, pets/livestock). In contrast, an inductive theme that emerged was "Togetherness and Shared Experiences," capturing parents' rationale for engaging in science-related activities with their children.

Results

First, we describe the dominant pattern across families, showing how science-related engagement is embedded in everyday life without being articulated as ‘science’. We then examine how this engagement is shaped by parents’ interests and place, and how it is characterized by embodied, sensory, and lived experiences. Finally, we highlight important variations across families, where some everyday practices come to resemble ways of engaging that align more closely with school science, pointing to differences in how students’ Science Capital is likely to be recognized within school science.

Science As Part Of Everyday Family Life

The findings indicate that, although family everyday life involves a wide range of science-related individual activities (e.g., jewelry crafting, taking mobile snapshots, strength training) and collective activities (e.g., forest outings, cooking, hunting/fishing, gardening, tractor drags, collecting natural artifacts, home repairs), these activities are often not recognized, connected to, or framed as relevant to school science by the families.

Parents’ Interests Shaping Shared Family Activities

Furthermore, while parents support their children’s individual interests, both parent-child activities (e.g., horseback riding, hiking) and organized leisure activities (e.g., team sports, scouting) often reflect parents' own valued childhood pursuits. The following example illustrates how a shared leisure interest becomes a practice passed on across generations within the family:

(Family A; Girl, 7 years)

> Father: “My father collected a lot of model airplanes … and that definitely helped build my interest in airplanes, one hundred percent. If he hadn’t done that, I wouldn’t have had that interest.”
>
> Mother: “…dad is very interested in model airplanes it’s really his big thing. This used to be an old guild hall that we turned into a hobby room, and that’s where he spends time tinkering. He’s very interested in technology. You’re a bit into that too, aren’t you? You also think it’s fun, this whole model airplane camp and things like that, right?”
>
> Girl: “Yes.”
>
> Mother: “[…] she is probably the one who is most interested in the airplane stuff and all of that - I honestly don’t understand a thing about it, but she really wants to.”

Additionally, parents' personal interests (e.g., gardening, building airplanes, birdwatching, and home repairs), values (e.g., viewing nature as a space for well-being and seeing practical skills as important), skills (e.g., recognizing species, using tools), and attitudes (e.g., sharing enthusiasm and inviting children to participate without obligation) strongly influence the shared experiences children are invited to take part in as part of everyday family life. In several families, this became clear through everyday workshop activities, where children participated alongside their parents in making, repairing, and constructing things together:

> (Family B; Boy, 7 years)
> Boy: “Sometimes, when I hear a hammer, I come.”
> Father: “Then we go down to the basement together, and you bring out your toolbox, where you can saw and screw.”
> Boy: “I even have an old-fashioned drill.”

This example shows how parents’ everyday engagement in making and repairing, together with the availability of tools and workspace in the home, naturally draws children into these activities as part of family life.

In another family, this everyday engagement appeared in time spent together outdoors:

> “It is more about observing. I have done that since I was a boy. I was involved in nature associations for young people and the Danish Ornithological Society to watch birds. I am not part of an organization anymore, but I still look for birds. These things still fill a lot for me - plants, animals, mushrooms, birds. We sometimes go on trips to the forest to collect mushrooms or go out to look at birds and plants. If we find a mushroom, I like to show it to the children. There is always a kind of excitement in finding things. I get enthusiastic about it, so I would like to share it with them. They should have the opportunity. If they are not interested, they can just say so.” (Father, Family C; Girl, 12 years)

Together, these accounts show how parents’ own interests, values, skills, and attitudes shape how families spend time together. What began as a parent’s own long-standing interest becomes visible in shared activities, in what the family stops to look at, and in how time is spent together. Whether through shared making in a workshop or shared attention to birds, plants, and mushrooms, children participate in activities that emerge from what is natural to the parents themselves in everyday family life. In this way, children are drawn into these practices through parents’ enthusiasm and repeated shared experiences rather than through planned learning situations.

Nature As Lived, Sensory And Creative Experience

Our data suggest that when children engage in science-related activities within the family, parents do not primarily focus on enhancing their children's school science performance or fostering aspirations in science. Instead, parents value these activities for their perceived contributions to lifelong skills for everyday life and personal development, fostering bonds within the family and friendships through shared experiences, and promoting physical and mental well-being.

One father explained, in response to how nature is approached and valued within the family:

> "Nature is basically the foundation of where we come from. If you become aware that everything around us originates there in its original form, it gives a better understanding of environmental conditions and of how to act responsibly in relation to what we eat and how we cultivate the land. It is also something spiritual and related to well-being. Being in nature gives an inner calm that you do not find in hectic surroundings. But it is difficult to have those kinds of conversations with children because it becomes too abstract. I think it comes by itself without having to say it. You develop an awareness of animals, plants, and the landscape simply by being in it. When we go out to pick blackberries or mushrooms, you get a closer relationship to nature that way."
>
> (Father, Family C girl grade 5)

This account illustrates how nature is understood as a meaningful and lived part of everyday family life. These understandings develop through shared activities rather than explicit explanation, as children participate in practices such as being outdoors and foraging together with their parents.

The Role Of Place And Access To Local Environments

Likewise, family science engagement is strongly shaped by place of residence, as geographical location, urbanity, and community resources influence opportunities. Indeed, access to organized leisure activities, playgrounds, home gardens, and natural areas affects both the frequency, diversity, and content of families' science-related experiences. The following example illustrates how access to local natural environments shaped and continues to shape families' everyday opportunities for science-related experiences:

> "We live in the last row of houses, and then you just walk out onto the heathland and further out onto the spit. It's incredible. I have never seen so many birds as after we moved there […] We have even been out looking for amber in the evenings when it's dark, and it's fascinating how the whole beach changes when night falls […] If the weather was good, we would suddenly go to the beach or go fishing […] We would often just go to the beach together. It takes two minutes and then we are there."
>
> (Mother, Family D; Boy, 7 years)

Or another family, referring to a nearby managed recreational nature park:

> "We have a dog, and I love going for long walks. We walk a lot out there - it's basically our backyard. I love it, so I am outside a lot." (Girl, Family E; 11 years)

Together, these accounts show how proximity to local natural environments makes spontaneous visits part of everyday life and a regular way of being. Rather than organized outings, the local landscape becomes a natural extension of the family's living space, offering ongoing opportunities to notice, explore, experience, and come to value the richness of this environment.

Nature As An Embodied, Sensory, And Lived Experience

In addition, our findings show that most families engage with natural objects and phenomena through multisensory, physically embodied, aesthetic, and sometimes creative approaches:

> "During the storm we were completely covered up with goggles… and the sand was hitting us. It was wild, but also fascinating to be right in it […] We experience so many things… and you don't have time to take pictures. You simply have to be in it […] I enjoy going to the beach and finding things we can use for something - creating something out of what we find."
>
> (Mother, Family D; Boy, 7 years)

Taken together, these accounts illustrate how family engagement with nature can be simultaneously sensory, physically embodied, place-based, and creative. They also show how such experiences are valued as lived moments that do not need to be documented, but rather fully experienced as they unfold.

Everyday Practices Resembling School Science

Finally, although the findings indicate that parents do not explicitly frame or value family activities in relation to school science, they still highlight differences linked to alignment with school science. For example, parents with backgrounds in science, technology, or pedagogy are more likely to engage in science-related activities in ways that resemble a school-oriented perspective. This includes practices such as naming natural objects, fostering curiosity, searching for information, and encouraging children to identify what they encounter in nature:

> "We really enjoy going out to explore and discover new places. It is very much about nature and experiencing different local areas. When the children were younger, they loved going to the pond to look for small animals. In the spring, we would run out and turn over the same tree stump, waiting for insects to appear. They are still very good at noticing butterflies and insects. For example, my son once found a beautiful caterpillar and really wanted to look it up to find out what kind it was. I can even remember the name of it. That is typically what we would do at home - try to identify what we find." (Mother, Family F; Boy, 12 years)

Similar patterns appeared in other families: *"It is mostly when we are out walking that you ask, 'Can you remember what this flower is called*?'" (Boy, Family G, 13 years). "*Yes, because I find it a bit embarrassing if they cannot remember*." (Mother, Family G, Boy, 13 years) or

> "We sometimes go on trips to collect mushrooms or look at birds and plants, and I always bring a mushroom guidebook to figure out what we find. The children sometimes find it exciting to search for things, sometimes they do not." (Father, Family C; Girl, 12 years).

In some families, this school-oriented perspective was also supported through the use of books and shared reading about nature at home as part of everyday activities:

> "When she was very little, we used to read those bird books… she found that really fun […] We would sit with books and read about all the sea animals… and at one point you even said yourself that you wanted to be a marine biologist" (smiling). (Family A; Girl, 7 years)

Together, these examples show how everyday walks and explorations in nearby nature involve paying attention to, noticing, identifying, and sometimes seeking further knowledge about what is encountered - including through books and shared reading at home. They indicate that being able to notice, recognize, name, and know elements in nature holds value within these families. In this way, everyday activities come to resemble the noticing, inquiry-oriented, and knowledge-seeking practices typically associated with school science, even though the activities themselves are not framed as such by the parents.

While some families in this way engage in practices that resemble a more school-oriented approach to science, the overall and more dominant pattern across families is that science-related engagement is embedded in everyday life without being articulated or valued as ‘science’.

At the same time, the findings show that science is enacted differently across families. How children encounter science in everyday life depends on parents’ interests, values, skills, long-standing engagements - often rooted in their own childhood and youth - as well as on the opportunities afforded by place and local surroundings.

As a result, children encounter science in different ways in everyday family life, with varying potential for alignment with school science.

Discussion And Conclusion

Our findings show that families possess substantial amounts of Science Capital, but that this capital appears in highly diverse forms. Rather than being expressed through formal scientific knowledge, Science Capital is embedded in everyday practices shaped by parents’ interests, values, skills, and long-standing engagements, often rooted in their own childhood experiences, as well as by the opportunities afforded by place and local surroundings. In this way, family science habitus plays a central role in shaping how science is enacted, talked about, and experienced in everyday life. As a result, children develop different forms of Science Capital depending on the form of family habitus within which they grow up, and thus enter school with varying forms of Science Capital, each with different degrees of alignment with school science (Archer et al., 2012; Suortti, Havu-Nuutinen, & Kärkkäinen, 2023).

These findings contribute to a more nuanced understanding of how family science habitus cultivates diverse forms of Science Capital. Indeed, this study indicates that family habitus functions as a key mechanism through which certain forms of Science Capital are developed, while others remain less likely to emerge.

At the same time, the findings point to a need for a broader understanding of what Science Capital can look like in everyday family life. In most families, Science Capital is not expressed through explicit science talk, visits to science institutions, or articulated interest in science. Instead, it appears as sensory, place-based, embodied, and practice-oriented engagements with natural phenomena and materials, often without being recognized or described as ‘science’ by the families themselves. These forms of engagement challenge common indicators of Science Capital found in previous research and suggest that Science Capital may be present in ways that remain largely invisible when viewed through traditional lenses.

In line with the Science Capital Teaching Approach (Nomikou, Archer, & King, 2017), our findings point to an untapped potential in linking students’ family experiences, local surroundings, and everyday practices to school science. By personalizing, localizing, and grounding school science in students’ sensory and lived experiences, science education can move towards a more inclusive understanding of what counts as science and who can participate in it.

Such an approach can help bridge the gap between students’ family science habitus and school science habitus by bringing a broader and more diverse range of students’ Science Capital into classroom practice, enabling more students to experience science as relevant to their lives and to recognize their own valuable contributions.

Acknowledgment

We sincerely thank the families who participated in this study for welcoming us into their homes and sharing their experiences through interviews. This study is part of the Danish national SCOPE project. SCOPE is funded by the Novo Nordisk Foundation [Grant Number: NNF19SA0059041] and the Villum Foundation [Grant Number: 27446].

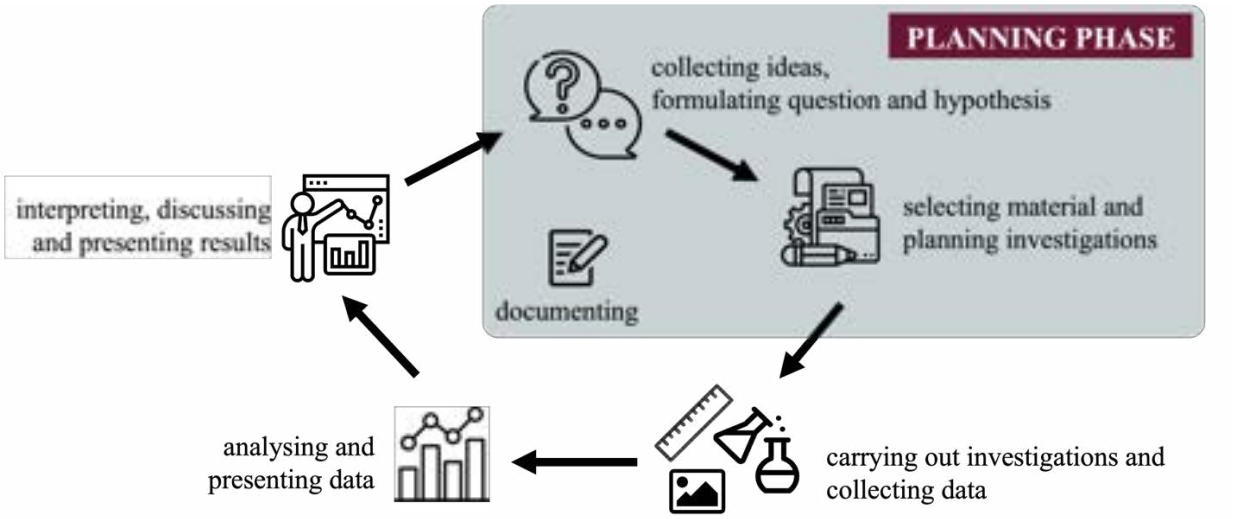
ESERA 2025 Copenhagen

Barriers In The Planning Phase Of Open Inquiry-Based Learning: Analysis From The Perspective Of Inclusive Science Education

Simone Abels[1], Oliver Schneide[1], Levi De Waardt[1] and Elisabeth Hofer[2]
[1]Leuphana University Lüneburg, Germany
[2]University of Vienna, Austria



Open Inquiry-Based Learning (oIBL) offers a flexible, inclusive approach to science education by allowing students to construct knowledge through self-directed inquiry while engaging in scientific practices. A critical determinant of successful oIBL is the planning phase, which involves the core activities [A1] generating research questions, [A2] formulating a theory-driven assumption or hypothesis, and [A3] planning appropriate investigations. Challenges in this phase can negatively affect subsequent inquiry stages and student learning, and are often attributed to perceived deficits in student competencies. However, such a student-centred perspective overlooks barriers inherent to the activities themselves. This study addresses this gap by systematically identifying the requirements and challenges associated with the planning phase of oIBL and reframing them as object-related barriers – barriers rooted in the structure and characteristics of the subject matter. Using a scoping review, qualitative content analysis, and AI-assisted rephrasing, requirements and challenges for the three core activities [A1], [A2] and [A3] were extracted, analysed, and categorised. Key findings reveal that many barriers arise from subject-specific demands, methodological constraints, and the empirical nature of inquiry, rather than from students' skills alone. Reformulating challenges in this object-oriented manner supports the development of targeted, inclusive scaffolding materials. Future steps include expert validation, implementation, and evaluation of these materials, which will be made freely available as Open Educational Resources (OER) under a CC-BY license on the platform "twillo". The results highlight the importance of shifting from a deficit-oriented to a systemic perspective in analysing barriers of oIBL, enabling educators to address structural barriers and better support diverse learners in scientific inquiry.

Keywords: Open Inquiry-based Learning, Barriers, Inclusive Science Education, Diversity

Introduction

With the function as an inclusive instructional approach, open inquiry-based Learning (oIBL) can be used to incorporate subject-related aspects of diversity such as different procedural skills, subject specific knowledge, students' interests or prior experience. At the same time, oIBL offers students the opportunity to construct scientific knowledge and engage in scientific practices through an individually planned, self-determined and independently conducted approach in all phases of the inquiry process (e.g., Abrams et al., 2008). OIBL opens up for both individual and collaborative ways of inquiry learning (Liljeström et al., 2013) and promotes the development of problem-solving skills, while also fostering and requiring student motivation and creativity (Chin & Osborne, 2010; Jiang & McComas, 2015). A critical factor determining the success of the oIBL approach lies in the planning phase – the first phase of inquiry (Baur, 2018, 2021; Chen & Klahr, 1999; van Uum et al., 2017). As highlighted in Fig. 1, challenges particularly arise during this initial phase of oIBL, in which several key activities take place that are essential for its success (Hakkarainen & Sintonen, 2002): [A1] generating the research question, [A2] formulating a theory-driven assumption or hypothesis, and [A3] planning an appropriate investigation.

Figure 1. The planning phase of open IBL (adapted from Hofer & Abels, 2025).

Potential problems associated with these activities may not only negatively affect the quality of subsequent inquiry phases but may also hinder or delay students' acquisition of subject-matter knowledge (Hakkarainen & Sintonen, 2002). From the perspective of teaching, another challenge to the successful implementation of oIBL is the high demand placed on teachers in terms of subject-matter expertise and instructional experience. In addition, limited experience with the oIBL approach – on the part of both teachers and students – represents a further difficulty (Brand & Moore, 2011; Forbes et al., 2020; Hofer et al., 2018). Nevertheless, experience and knowledge of the fundamental principles of oIBL are crucial, as they enable the approach to function as intended and in its most effective form, namely as a flexible and adaptive learning environment (Hofer & Abels, 2025; Wischgoll et al., 2015). Such expertise is crucial for teacher-led support of students through appropriate scaffolding measures that are aligned with students' specific demands and needs (Arnold et al., 2014; Baur & Emden, 2021). For the realisation of a holistic oIBL approach combined with effective scaffolding, the teacher's role becomes particularly central – both in terms of designing and adapting the learning environment and in supporting students' individual inquiry processes through adaptive scaffolding (Hofer & Abels, 2025; Mumba et al., 2015; van der Valk & Jong, 2009).

The challenges that arise in oIBL are often attributed to individual students, with a primary focus on the perceived lack of competencies required to accomplish the task at hand (see Tab. 1). This perspective, however, neglects the fact that challenges do not emerge solely from students, but that barriers are inherent in the activities themselves. Abels and Witten (2023) argue that it would be more appropriate to move away from a student-centred perspective toward a systematic one (Köpfer, 2021), in which barriers are not primarily attributed to individual skill deficits but are instead located within the structure and characteristics of the subject matter. This object-oriented perspective suggests that subject matter should be analysed for potential barriers and hindrances that may impede learners' inquiry, while the instructional setting and learning environment are adjusted, adapted, and organised in a way that suits learners' diversity, needs, and strengths – rather than expecting only learners to adapt to requirements (Abels & Witten, 2023).

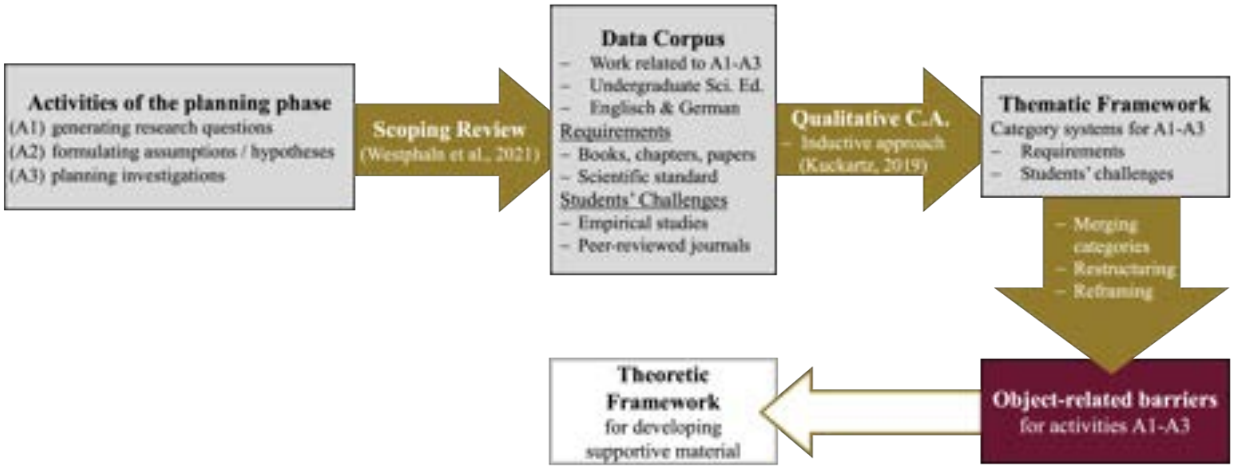
Table 1. Selected challenges for the activities of the planning phase of open IBL (selected from Kranz et al., 2023)

Phase	Challenge	Description
A1) generating the research question	Stating non-causal research questions	Learners only ask factual type questions that cannot be investigated by means of an experiment. Example of a factual-type question: How is a heart constructed? What is in this lotion?
A2) formulating an assumption or hypothesis	Working without a hypothesis	Learners do not generate hypotheses during the experiment.
A3) planning an investigation	Working without control conditions	Learners are just working with a single test condition and without a control (= results cannot be compared).

With this in mind, the project *PlanFoL – Auf die Planung kommt es an* (*Planning is Key*), which is funded by the Joachim Herz Foundation (2023-2026), aims to develop, test and evaluate practical cross-thematic support materials in order to reduce and address the barriers occurring in the planning phase of oIBL. Furthermore, the project explicitly focuses on a shift in the perspective regarding the attribution of challenges and barriers, respectively.

To do this, it is necessary to first identify the requirements and challenges of the planning phase and derive object-related barriers from them, which can then be addressed by the support materials. This raises the following research questions for the activities [A1] generating the research question, [A2] formulating a theory-driven assumption or hypothesis, and [A3] planning an appropriate investigation:

RQ1: Which requirements and challenges exist for the activities [A1-A3] in the planning phase of open inquiry-based learning?



RQ2: What are the object-related barriers of the activities [A1-A3] in the planning phase of open inquiry-based learning?

Method

To identify the requirements and challenges associated with activities [A1]-[A3] in the planning phase of oIBL (RQ1), we first reviewed the existing literature (see Fig. 2). As a comprehensive and relevant systematic review on students' challenges in performing inquiry activities already existed (Kranz et al., 2023), we extracted the results relevant to the activities [A1]-[A3] and used them to address the aspect of "challenges" in the following research process.

To gain comprehensive theoretical insights into the "requirements" of activities [A1]-[A3], we conducted a scoping review following the approach proposed by Westphaln et al. (2021). Initial exploration of the literature indicated that requirements for activities [A1]-[A3] are not addressed explicitly; instead, the literature mainly focuses on practical guidance (e.g., what constitutes a good research question). Consequently, we searched for literature – including textbooks, book chapters, and journal articles – that provides guidance on how to successfully perform activities [A1]-[A3]. This search was conducted via Google Scholar using search strings such as "good research question" and "good research hypothesis". To identify the most suitable and relevant sources, we screened the search results from the first ten pages for each activity [A1]-[A3] and applied the following eligibility criteria: citation count (N>100), academic publisher or provider, demonstrated expertise of the authors, language (English or German), and relevance of content, taking into account different research disciplines.

Figure 2. Overview of the research design.

After selecting the relevant sources, we conducted a qualitative content analysis following an inductive approach (Kuckartz, 2019; see Fig. 2). In the first step, we identified relevant text passages related to the requirements and analysed them using the chat function of the AI Assist in MAXQDA (version 24.11.0), the posed questions for this analysis are listed in Tab. 2. The AI Assist is designed to support users in identifying patterns within documents (e.g., desirable and undesirable characteristics associated with activities [A1]-[A3]) and is therefore suitable for facilitating the initial phase of text analysis (Kuckartz, 2019). The results emerging from this initial analysis were then summarised across all documents and further analysed using an AI chatbot (u:ai chatbot GPT-4o – University of Vienna) with the following prompt: "Please summarise the results from these three lists in the form of qualitative content analysis and inductive category development" (see Tab. 2). The resulting summaries were subsequently compared, leading to the development of a preliminary category system, which was then applied to the data and iteratively refined and expanded (see Fig. 2).

The challenges identified by Kranz et al. (2023) were formulated from a student-centred and predominantly deficit-oriented perspective, i.e., what students are not able to do. To adopt a more systemic perspective, these challenges were reformulated in an object-oriented manner (Abels, 2026). For this purpose, AI was used as a supportive tool for rephrasing (see Tab. 2), enabling multiple reformulations to be generated simultaneously.

Table 2. Overview of AI application for data analysis.

Aspect	Purpose of application	AI tool	Prompt
Requirements	Initial text analysis	MaxQDA 24.11.0 with AI Assist	"Please answer the following questions by presenting the answers in numbered lists: What are the requirements for a good [A1-A3]? What should one obey when [A1-A3]? What are features of a bad [A1-A3]? What should one avoid when [A1-A3]?"
	Creating inductive categories	u:ai ChatbotGPT 4o (University of Vienna)	"Please summarise the results from these three lists in the form of qualitative content analysis and inductive category development."
Challenges	Object-oriented rephrasing	Model: Meta Llama 3.1 8B Instruct, temperature: 0, top_p: 0.05	"Rewrite the following sentence making clear that the requirement comes from the subject itself and not from the students. Please note that the tone is academic, is scientific in nature, and that the sentence is rephrased in such a way that it is easy to understand and informative. Give me a list which is numbered like the original sentence. The original sentence is. …"

The results of the analyses of requirements and challenges were finally related to each other and reinterpreted as object-related barriers (see Fig. 2).

Results & Discussion

Due to the large scope and high complexity of the results, we will present, explain, and discuss one key result for each of the activities [A1-A3]. Tab. 3 provides an overview.

Table 3. Overview of selected results.

Activity	**Category & Subcategory**	**Source material** (paraphrased and summarised)	**Object-related barrier**
[A1] generating the research question	**Category**: Feasibility & Practicality **Subcategory**: Empirical testability	**Requirement** Research questions should be answerable through systematic observation, measurement, or data collection.	Research questions that aim to identify causal relationships between variables often require a specific type of inquiry, one that is empirically testable and grounded in the subject matter. In some cases, questions may be more descriptive or factual, rather than causal, which can limit the scope of investigation and the potential for meaningful conclusions.
		Challenge Students do not state causal research questions, but factual type questions which are not empirically testable.	
[A2] formulating a theory-driven assumption or hypothesis	**Category**: Consistency & Integrity **Subcategory**: A-priori Statement & Immutability	**Requirement** The hypothesis should be formulated before the research begins and must not be adjusted or changed throughout it.	The iterative nature of the scientific process often requires revisiting and refining hypotheses as new information becomes available. However, the modification of hypotheses without thoroughly testing can compromise the validity of the conclusions drawn.
		Challenge Students change their hypotheses during the process without having tested them first.	
[A3] planning an appropriate investigation	**Category**: Experimental Design & Control **Subcategory**: Test and Control Approaches	**Requirement** Experimental designs should include test and control approaches (qualitative design) or a series of measurements (quantitative design).	The investigation of complex phenomena requires consideration of multiple factors, including control of variables and the conduct of test and control trials. However, many experiments in school or everyday life lack these fundamental aspects, which can compromise the accuracy of the results.
		Challenge Many students experiment without a test or control trial and neglect the control of variables strategy (CVS).	

[A1] Generating The Research Question

The results indicate that one fundamental requirement for oIBL is the formulation of research questions that are empirically answerable and allow for systematic observation, measurement, or data collection. One typical form of such questions addresses relationships between variables, what provides a clear basis for selecting appropriate methods of investigation. In practice, however, a key challenge arises because students often tend to formulate descriptive or factual questions rather than causal research questions. These questions may focus on identifying or describing phenomena but do not readily support empirical testing or systematic inquiry. But instead of attributing students, we take a systemic perspective, which leads to an object-related barrier located in the research question itself: When research questions are oriented toward causal relationships, they constrain the type of inquiry that can be conducted (especially regarding methodological requirements) as there is a necessity of empirical testability, being anchored in subject-matter knowledge. However, research questions that students find interesting (or in different science disciplines) may also be more exploratory or descriptive in nature. This can limit the scope of investigation and reduce the potential for producing explanatory insights and meaningful conclusions. When teachers and teacher educators know about these object-related barriers, they can think of ways to enable participation in oIBL.

[A2] Formulating A Theory-Driven Assumption Or Hypothesis

One crucial requirement of activity A2 is the formulation of a hypothesis prior to the start of the investigation, with the expectation that this hypothesis remains unchanged throughout the research process. In this way, the hypothesis serves as a stable epistemic reference that guides the design of the study, the selection of methods, and the interpretation of the collected data. However, several studies found that students frequently revise or replace their hypotheses during the inquiry process without having systematically tested the original ones. Such modifications are often driven by emerging observations, unexpected results, or uncertainties during data collection and analysis. If we take a more systemic view, we can derive a barrier regarding the coherence between hypothesis, methodological approach, and empirical evidence. When hypotheses are altered without prior empirical testing, their role as structuring and validating objects of inquiry is weakened and results are limited in reliability, transparency, and explanatory power of arguments. Teachers and teacher educators who know that phrasing hypotheses is really difficult, can prepare scaffolds in advance to support students' science learning.

[A3] Planning An Appropriate Investigation

The findings show that one fundamental requirement for planning investigations [A3] is the implementation of well-structured designs that allow systematic approaches. In qualitative experiments, this entails the inclusion of test and control approaches, while in quantitative studies, it involves conducting a series of measurements that enable reliable observation of changes in variables. These strategies are essential for ensuring that differences in outcomes can be attributed to specific factors rather than uncontrolled influences. However, empirical results show that students often fail to adhere to this systematic approach. Several challenges arise because many students carry out experiments without including test or control trials and frequently neglect the control of variables strategy (CVS). As a result, multiple factors may vary simultaneously, making it difficult to determine which factor is responsible for the observed effects. Relating requirements and challenges to each other, the following barrier can be derived: When experiments are not carefully structured to control variables and provide appropriate comparisons, the investigation of complex phenomena becomes limited. Such designs compromise the accuracy, reliability, and interpretability of results, reducing the potential for drawing valid, meaningful, and generalizable conclusions from the inquiry process. Teachers and teacher educators can inform their students about these barriers and work on them instead of seeing students as the ones who fail the challenges.

Discussion

A key insight from the scoping review is that the requirements for individual activities [A1]-[A3] are often highly specific to particular disciplines, even within the natural sciences (e.g., biology vs. chemistry). Explanations frequently reflect a form of tacit, community-specific knowledge that is either imprecisely stated (e.g., the research question should be 'investigable') or not explicitly articulated at all. For instance, guidance often refers to 'relevant questions' or questions that 'contribute to the field' of research without providing concrete criteria. Additionally, the literature provides little clarity on when activities [A1]-[A3] should be considered 'successful'. This creates a significant challenge in educational contexts, particularly in science education at the school level, where uncertainty and high difficulty are prevalent. Part of this difficulty arises from scientific requirements being transferred into school contexts (e.g., the application of the Control-of-Variables Strategy (CVS) in elementary schools; Chen & Klahr, 1999). Addressing these aspects requires well-prepared and knowledgeable teachers, effective scaffolding within oIBL, and an appropriate attitude toward the inquiry process and inclusion.

Moreover, the literature highlights the importance of a perspective shift for successful inquiry, although most reported challenges are person-related and deficit-oriented, as shown in Tab. 1 (Baur, 2023; Kranz et al., 2023). Focusing on the identification and categorisation of barriers in the inquiry process (adapted from Krönig, 2015) reveals that relatively few challenges need to be located in the "Self" domain (barriers that are caused in the persons themselves), whereas the majority emerges from the subject matter itself. This indicates that many barriers are not caused by students' lack of skill or experience but are inherent to the structure of activities [A1]-[A3]. Consequently, a more systematic and accurate approach to barrier localisation requires reformulating student-centred barriers into object-related barriers, as illustrated in Tab. 3. This shift in perspectives could also help teachers to stop being constantly overwhelmed by oIBL because they focus on their students' lack of knowledge and skills and instead become capable of addressing these barriers – as strived for in the project *PlanFoL*.

Summary And Outlook

Across the analysed literature focusing on the requirements and students' challenges in the planning phase of oIBL, studies that explicitly address the numerous and diverse subject-related demands are rare. To enable a more accurate and systematic approach that both helps to identify barriers and supports students during their inquiry process – in the sense of an inclusive approach – it is necessary to reformulate and re-categorise students' challenges into object-related barriers. The process of reinterpreting barriers in this way is demanding, requiring extensive epistemic knowledge and expertise. One effective method for reframing students' challenges into object-related requirements is the use of AI.

The next steps involve finalising and validating the object-related barriers with experts and using the rephrased barriers to develop inclusive materials for the planning phase of oIBL. These materials will then be implemented, evaluated, and refined according to the observed barriers. Ultimately, the developed materials, along with guidance on their use, will be made freely available as Open Educational Resources (OER) under a CC-BY license on the platform *twillo*.

ESERA 2025 Copenhagen

The Challenges Of Inclusive Science Education From Teachers' Perspectives

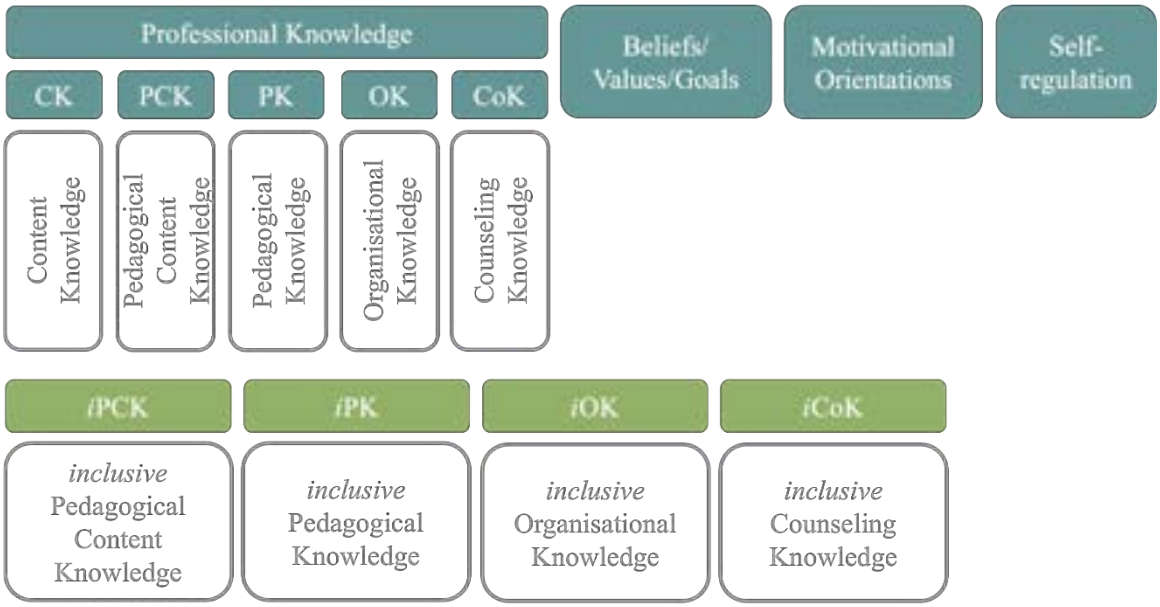
Laura Pannullo[1], Melanie Basten[1], Laura Ferreira González[2], Felix Aberle[3] Bianka Wartig[1] and Lisa Stinken-Rösner[1]
[1]Bielefeld University, Germany
[2]University of Cologne, Germany
[3]University of Tübingen, Germany

International assessments, such as PISA, consistently show that many students in Germany and other countries lack key competencies, with a significant portion underperforming. Germany has also not fully implemented an inclusive school system in line with the UN Convention on the Rights of Persons with Disabilities, partly due to teachers' competencies in inclusion. Given these challenges, it is crucial to find ways to ensure all students can develop their competencies by enhancing teacher professional skills. This study investigates in-service teachers' perspectives on challenges in inclusive science teaching. By identifying competency requirements for teacher training that align with educational policies and inclusive practices, this research aims to enhance teacher preparedness for inclusive science education. Differentiating between subject-specific and general pedagogical challenges helps define targeted improvements in science teacher education. Using a qualitative-explorative methodology, guided interviews were conducted with 19 teachers to capture their experiences and perspectives. The findings reveal, for instance, challenges with learner prerequisites, individual competence development, selecting content and methods, enabling participation, using methods and media, as well as challenges related to experimentation and scientific language. This study highlights the urgent need for targeted teacher training programs that integrate both general pedagogical skills and subject-specific didactics, ensuring that science educators are better equipped to foster inclusive learning environments.

Keywords: inclusion, teachers, challenges

Introduction

International assessments like PISA show that many students lack scientific literacy, with a significant number underperforming (OECD, 2023). Additionally, the implementation of inclusive education remains insufficient (Klemm et al., 2023), partly due to teachers' competencies in inclusive pedagogy (Pit-ten Cate et al., 2018). Teachers play a crucial role in the success of inclusive education (Boer, 2012), and their professional skills significantly impact students' learning outcomes (Blömeke et al., 2022). However, teachers continue to face difficulties in fulfilling the additional requirements for inclusive science teaching (Pit-ten Cate et al., 2018). This study aims to explore these challenges and propose competency requirements for teacher training.



Theoretical Framework

Professional Competency Models

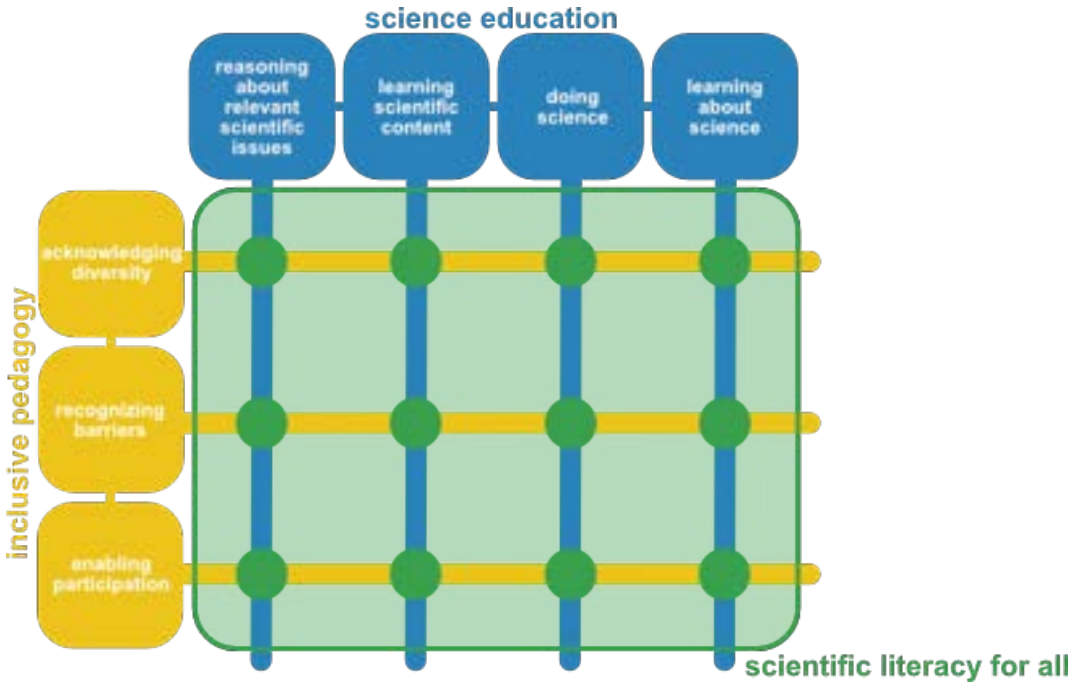
Despite policy efforts toward inclusion, teachers struggle to implement inclusive science teaching effectively (Moser & Lütje-Klose, 2016). Teaching expertise is shaped by knowledge, professional values, beliefs, motivation, and self-regulation skills (Baumert & Kunter, 2013). The competency model (see Figure 1) developed by Baumert and Kunter (2013) includes four aspects of professional competence: 1) Beliefs/Values/Goals, 2) Motivational Orientations, 3) Self-Regulation, and 4) Professional Knowledge. These aspects are further divided. Professional Knowledge is categorized into Content Knowledge (CK), Pedagogical Content Knowledge

(PCK), and Pedagogical Knowledge (PK), and expanded to include Organizational Knowledge and Counseling Knowledge (Baumert & Kunter, 2013).

Figure 1. Extended Competency Model for Inclusive Teaching Based on Baumert and Kunter (2013).

König et al. (2019) and Bertram et al. (2020) have expanded this model to include competencies specific to inclusive education. König et al. (2019) introduced inclusive general pedagogical knowledge (iPK) and inclusive organizational knowledge (iOK). Their review identified four key areas:

1. Diagnosis (assessment of support needs, initial and progress diagnosis),
2. Intervention (methods for individualization and addressing student diversity),
3. Management and Organization (collaboration with colleagues and external partners), and
4. Counseling and Communication.



These areas were integrated into the competency domains: inclusive pedagogical content knowledge (iPCK), inclusive general pedagogical knowledge (iPK), inclusive organizational knowledge (iOK), and inclusive counselling knowledge (iCoK). Bertram et al. (2020) further refined the model, adding areas in iPCK (e.g. knowledge about learners' conceptions), iPK (e.g. methodological repertoire), iOK (e.g. school development processes), and additional areas in beliefs/values/goals, motivational orientations, and self-regulation.

The competency model for inclusive teaching (see Figure 1) (König et al., 2019, based on Baumert & Kunter, 2013) has been validated and was transformed into a category system (Bertram et al., 2020). For this study, the model and category system had to be adapted for (inclusive) science education.

NinU Framework

The NinU Framework (Stinken-Rösner et al., 2020) offers an initial theoretical orientation for adapting the competency model for inclusive teaching (see section before) to (inclusive) science education. This framework (see Figure 2) integrates inclusive pedagogical considerations with a scientific perspective in a unified model.

Figure 2. NinU Framework, Adapted from Stinken-Rösner et al. (2020).

The vertical axis of the NinU Framework emphasizes firstly the acknowledgment of student diversity. Teachers recognize the potential and resources of each student and incorporate these into their lesson planning (Booth & Ainscow, 2016). In a second step, the framework recognizes potential barriers, that can exist in teaching materials, classroom conditions, or even in the behaviour of the teachers themselves (Stinken-Rösner et al., 2020). Lastly, the framework's goal is adapting teaching methods accordingly to enable the participation of all students.

The horizontal dimension of the NinU Framework addresses the goals of science education, following Hodson (2014), including reasoning about scientific issues, learning science content in the sense of a conceptual understanding (Taber, 2013), doing science (engaging with scientific methods and procedures), learning about science (understanding the processes of science itself; Millar, 2006), and the use of digital media for accessibility (Abels & Stinken-Rösner, 2022).

State of Research and Research Questions

Although the competency model for inclusive teaching (based on Baumert & Kunter (2013) and expanded by König et al. (2019) and Bertram et al. (2020)) offers a strong starting point, it does not sufficiently capture the subject-specific demands of inclusive science instruction. Furthermore, the second dimension of the NinU Framework, "Recognizing Barriers", is currently addressed primarily through individual studies.

Overall, the field still lacks a shared definition of inclusive science teaching, and subject-specific criteria for required affordances remain underspecified. Some authors have outlined characteristics of individual scientific disciplines that might provide insights into their specific affordances (Hoffmann & Menthe, 2015). However, a coherent normative catalogue of subject-specific affordances is still missing. Therefore, the aim of this study is to explore the specific challenges teachers face in inclusive science lessons to define key competencies for teacher education. The research questions include:

- What general pedagogical challenges impact inclusive science teaching?
- What subject-specific challenges do teachers face in inclusive science lessons?

Research Method And Design

A qualitative-explorative research approach was adopted to capture teachers' perspectives on the challenges of inclusive science teaching. We conducted semi-structured interviews (Helfferich, 2014) to balance openness to participants' experiences with the possibility of targeted follow-up questions (Kuckartz & Rädiker, 2022).

The interview questions were developed based on the NinU framework, emphasizing barriers to inclusive education (Ferreira González et al., 2021; Stinken-Rösner et al., 2020). The term 'barrier' was replaced with 'challenge' to reduce associations. The interview guide began with the question: "When you think about the planning, implementation and reflection of your [science/physics/biology/chemistry] lessons, what were and are challenges for you?" (see Figure 3), allowing respondents to highlight specific concerns regarding inclusive science education. The respondents' understanding of inclusion is implicitly explored in the further course of the interview.

Figure 3. Excerpt from the Interview Guide with the First Question.

The study focused on in-service teachers in northern Germany, with a total of 19 structured interviews analysed. The teachers were recruited through a network-based approach. Interviews were transcribed and analysed using qualitative content analysis (Mayring, 2022) resulting in the summarization of the interview's core statements into paraphrases. A coding guide was developed based on the competency model for inclusive teaching and the deductively identified categories. The paraphrased data was coded independently by two researchers, achieving an interrater reliability of Cohen's Kappa = .67. Discrepancies were resolved through consensus discussions, ensuring consistency in the categorization of responses.

Findings

The qualitative content analysis (Mayring, 2022) of the interviews yielded 275 codes. Overall, teachers' accounts clustered strongly around challenges that are intervention-oriented—i.e., challenges that arise when planning, enacting, and adapting instruction in inclusive science classrooms, with the largest clusters located in "Intervention iPK" (inclusive Pedagogical Knowledge on Intervention) with 122 codes and "Intervention iPCK" (inclusive Pedagogical Content Knowledge on Intervention) with 60 codes. 50 codes were assigned to the category "framework conditions", whereas 43 codes are dispersed across all remaining categories of the Extended Competency Model for Inclusive Teaching.

In the following, the challenges related to iPK and iPCK are discussed in more detail, with particular attention to "Intervention iPCK", as it is especially informative from a science education research perspective. For a comprehensive analysis and further insights into all categories, see Basten et al. (submitted).

General Pedagogical Challenges Impacting Inclusive Science Teaching

"Intervention iPK" includes general pedagogical knowledge. Inductively, challenges were grouped into the following subcategories:

Learner Prerequisites

Teachers frequently described the difficulty of addressing a wide spectrum of students' individual characteristics, prior knowledge and beliefs/conceptions about a topic.

> "The presence of diverse resources across multiple domains—such as pre-instructional experiences, values, prior knowledge, and reading and writing skills—can constitute a challenge both for the teacher and for the learner themselves." (HI-002; F15)

Individual Competence Development

A major challenge concerned supporting students' individual learning progress in a way that is feasible in everyday teaching. Teachers emphasized that "adequately support[ing] each student in the learning process according to their individual level of learning progress" requires continuous adaptation and individualized support structures.

> "It constitutes a challenge for the teacher to create a safe environment in which even introverted students feel confident to participate and verbalize their solutions." (2022-LG-011_F8)

Topics And Contents

Teachers often described challenges in preparing lessons that motivate students. In addition, didactic reduction was mentioned as demanding—particularly when adapting science content for students with special educational needs.

Participation

Many statements addressed the challenge of ensuring that all students—especially those with special educational needs—can participate in learning activities. Teachers reported "additional support efforts for students with special educational needs".

Methods And Media

Teachers highlighted the challenge of identifying working methods and materials that meet diverse needs while remaining inclusive (and not excluding students with special educational needs).

> "Taking into account individual support needs and the accompanying necessity for instructional adaptations (for visual impairment: larger illustrations, magnifying glasses for reading texts, etc.; for learning difficulties: texts in simplified language, temporal adjustments) constitutes a challenge for teachers." (LFG; HI-002; F17)

Communication

In the last subcategory, some teachers reported challenges in adapting to heterogeneous language needs in science lessons. One example concerned dealing with language accuracy during learning processes, such as the perceived difficulty of "correcting language errors immediately".

Subject-Specific Challenges In Inclusive Science Lessons

"Intervention iPCK" focuses on pedagogical content knowledge specific to science teaching. Here, teachers' statements concentrated on three inductively formed subcategories:

Experiments

Experiments emerged as a key challenge in inclusive science teaching. Teachers referred to difficulties across preparation, implementation, and follow-up, mainly regarding time and materials. They reported that extensive preparation and set-up time competes with time needed for in-class support, and that clean-up/follow-up often cannot be completed immediately due to everyday time pressure. The prevailing 45-minute lesson rhythm was described as incompatible with longer inquiry cycles, including experimentation and consolidation phases.

Beyond time constraints, teachers highlighted material and organizational demands, such as compiling experimental materials for an entire class and selecting experiments that fit both the topic and the learners' age and needs. Teachers also emphasized the inherent unpredictability of experimental outcomes and the dependence on external conditions, which complicates planning and inclusive scaffolding.

From an inclusion perspective, experimentation was described as requiring continuous adaptation to heterogeneous learner prerequisites, including different competence levels and, in some cases, limited experimentation skills on the learners' side. Teachers additionally reported challenges in classroom management during experiments (e.g., increased noise and unrest, especially in younger classes) and in finding a productive balance between allowing exploration and providing sufficient guidance.

Finally, several paraphrases pointed to safety and specific support needs: teachers described the difficulty of keeping all students in view during potentially dangerous experiments, enabling participation of students with disabilities (including autism spectrum conditions), and supporting anxious students during hands-on activities.

> "Including students with autism spectrum disorder in experimental lessons constitutes a challenge." (2022-LG-016_F10)
>
> "Keeping all students in view during dangerous experiments constitutes a challenge." (2022-LG-016_F4)
>
> "Designing experiments in a way that allows students with disabilities to participate." (2022-LG-10b)
>
> "A restless learning group constitutes a challenge during experiments." (2022-LG-012_F2)
>
> "Finding a group composition favorable for all learners during experiments constitutes a challenge." (2022-LG-012_F2)

Scientific Language And Scientific Methods

Teachers described scientific language as a major challenge, especially for students with German as a second language, where "technical language may make it difficult […] to understand the content". At the same time, teachers framed this as a tension: they need to respond to learners' linguistic prerequisites while also promoting the development and active use of scientific terminology. Paraphrases also indicated that the distinction between everyday language and scientific language remains challenging even in higher grades, requiring repeated and systematic language work. In addition, teachers associated subject-specific accessibility with reading and

text difficulty: due to low reading levels textbooks in primary science are perceived as too complex.

> "The teacher faces the challenge of enabling students to master and use subject-specific language." (2022-LG-011_F7)

> "In summary: the low reading level of students constitutes a challenge, as the texts in elementary science textbooks are often too difficult." (2022-LG-008_F2)

Beyond language, teachers also reported challenges related to scientific methods, for instance scaffolding inquiry processes and helping students approach a research question, raising the issue of how to prepare students for inquiry-oriented phases.

> "The prerequisites of students for guiding them toward the research question vary in heterogeneous classrooms." (2022-LG-009-F001)

Presenting Information

Another subject-specific challenge concerned the appropriate presentation of information, including responding to students' misconceptions and missing foundational prerequisites. Teachers noted situations in which students lack key conceptual foundations (e.g., "when children have no concept of quantities"), which makes it difficult to introduce or build scientific explanations without extensive preparatory conceptual work. Closely connected, teachers described didactic reduction and student-friendly representations as demanding, especially the need to simplify without introducing inaccuracies, which was perceived as particularly challenging in physics and chemistry.

> "Didactic reduction—simplifying without making errors—constitutes a challenge for the teacher; this is more pronounced in physics and chemistry than in biology." (2022-LG-008_F1)

> "Student-appropriate presentation constitutes a challenge for the teacher; this challenge is greater in physics and chemistry than in biology." (2022-LG-008_F1)

> "Demonstrating the relevance of the subject to students through everyday and societal topics (such as climate change, the environment, ecosystems)." (2022-LG-13-F004)

Additional iPCK-Related Challenges (Emerging Themes)

Beyond the three main clusters, some paraphrases pointed to further subject-specific inclusive demands: handling sensitive topics such as evolution and sexuality education in relation to students' religious/worldview backgrounds; conveying the societal relevance of science topics; teaching interdisciplinary science formats; and implementing short excursions or out-of-school learning activities.

> "Topics such as evolution and sex education pose a challenge for teachers and students, as they are not necessarily compatible with religious beliefs or worldviews." (LFG; HI-002; F13)

> "Planning and alignment of out-of-school learning sites relevant to the science domain (e.g., weather) constitutes a challenge." (2022-LG-005-F003)

Overall, the iPCK paraphrases depict inclusive science teaching as highly dependent on teachers' capacity to design and manage resource-intensive science practices (especially experimentation and inquiry) while simultaneously ensuring linguistic accessibility, conceptual scaffolding, and safe participation for all learners.

Discussion And Implications

Overall, the findings indicate that many teachers feel insufficiently prepared with regard to both general pedagogical and subject-specific didactic skills necessary for effectively implementing inclusive education in science classrooms. The prominence of intervention-related challenges suggests that teachers particularly struggle with translating inclusive aims into concrete classroom practices (e.g., differentiation, participation, scaffolding experiments and inquiry, and language-sensitive science teaching). Accordingly, the results point to a need for targeted professional development that strengthens these specific, practice-oriented competencies.

More than fifteen years after the UN-CRPD, its implementation in schools remains inadequate. Recent monitoring reports suggest that political and societal commitment to inclusive education is currently weakening (Lepper & Steinmann, 2024). At the same time, teachers report substantial workload and pressure, which are associated with frustration and an increased risk of burnout. Against this backdrop, it appears particularly urgent to systematically identify the concrete challenges teachers face and to address them through coherent support structures. Our findings suggest that one major gap concerns knowledge and skills related to concrete lesson design in inclusive science classrooms. Consequently, initial teacher education (including university-based coursework) should place greater emphasis on evidence-informed, feasible instructional approaches and resources that enable teachers to plan and enact inclusive science lessons under real-world constraints.

Acknowledgement

We would like to thank all participating in-service teachers for sharing their experiences and perspectives, which provided the foundation for this study. We also thank the members of the research team who conducted the interviews.

Youth's Environmental Attitudes And Use Of Digital Media And Social Networks: A Comparative Exploration From Seven Spanish-Speaking Countries

Maria-Antonia Manassero-Mas and Ángel Vázquez-Alonso
University of the Balearic Islands, Spain

This study presents an international comparison among seven Spanish-speaking countries on the two main themes of the ESERA-2025 conference: the environmental attitudes (EAs) and the use of digital media and social networks (DM). Both categories are quantitatively and qualitatively assessed from the voices of a large sample of 15-year-old students from seven Spanish-speaking countries. The students answered the questionnaire of an international project (The relevance of science education second, ROSES) that explores some attitudes and experiences of science education. Further, gender and cross-country differences are also checked through the probability of signification and the effect size of the differences. The main overall findings point to students' proactive EAs and moderate DM use in science classes that are also quite parallel across countries, though Argentina and Mexico tend to display more polarized scores on EAs and DM use. Another finding shows generalized gender differences about EAs and DM use across countries. Girls tend to hold more positive EAs than boys across all countries, though their effect size ranges from moderate to small differences. Regarding DM use, boys reported higher overall DM use than girls, though the gender effect sizes are insignificant. The consequences of these results for science education and for research on these issues, the limitations of this study, and the future prospective are discussed.

Keywords: environmental attitudes, digital media, gender differences

Introduction

This study explores an international comparison on the two themes of the ESERA-2025 conference through assessing the environmental attitudes (EAs) and the use of digital media and social networks (DM), as reported by young people from seven Spanish-speaking countries. Further, international comparisons constitute an additional instrument of educational research that contributes contexts to absolute evaluation measurements, thus lending a value-added meaning, thanks to the comparisons between the different contexts (e.g., OECD, 2025). These features frame the relevance and the methodological foundations of this study to science education research and practice.

For decades, the study of attitudes has been a fruitful area of social psychology because attitudes, in addition to their evaluative component (acceptance/rejection), further act as guides to behaviour (e.g., sustainable actions or digital use). Thus, the dispositions (acceptance/rejection) toward the environment, or EAs, guide environmentally sustainable conduct, which also has a long history within science education. Pro-environmental conducts have been gaining research and educational relevance on the global agenda due to the growing impact and social emergency of the increasing environmental deterioration, such as climate change. The UN declared the Decade of Education for Sustainable Development (2005-2014) and then the 2030 Agenda (UN, 2015), which sets out 17 priority Sustainable Development Goals for guiding governments and citizens' actions until 2030, which represent a global challenge for education. Understanding EAs

is crucial for developing strategies for sustainable development through targeted and effective messaging.

The literature on conceptualizing and defining EAs is large and complex to show consensus. Above all, EAs are attitudes and share with general attitudes the same theoretical base, which involves cognitions (beliefs), affects (acceptance/rejection), and behaviours (actions). A current significant consensus acknowledges that EAs involve a single overall attitude to the environment but hold a multi-dimensional structure that organizes a range of environmental topics. However, the field is fragmented by disagreements that include the number of EA dimensions and the nature of the EA specific topics. Thus, some unified definition and conceptualization of EA, the measurement methodology, and even the evaluation survey are highly pursued (Somerwill & Wehn, 2022).

The Environmental Attitudes Inventory (EAI) provides a theoretical reference framework and a comprehensive method of the material currently available in the field, because EAI has been used across a range of contexts and has been found to be highly consistent and reliable (Milfont & Duckitt, 2010). The EAI short form is made of 72 items across twelve first-order factors (dimensions), grouped into two second-order factors, Preservation (seven first-order factors) and Utilization (five first-order factors).

On the other hand, the educational importance of digital media and social networks (DM) arises from the effectiveness and impact of their implementation in the various contexts of education, due to their advantages for the pedagogy, the DM literacy and the skills, and, in general, the relevance of digital learning for science education. Further, the endless risks and drawbacks of digital misuse need to be recognized, addressed, and overcome in science education (Tibaná-Herrera et al., 2018). In particular, a good attitude towards DM, trust in DM, and firm beliefs in their usefulness and their autonomous use had a positive relationship to students' academic performance in mathematics and science (Courtney et al., 2022). Further, similar results have been obtained for the overall digital development of a country and the use of DM at home by students (Skryabin et al., 2015).

Since the first studies, men have shown better attitudes to science than women, though the magnitude of the gender differences ranges from mild to moderate (Osborne et al., 2003; Potvin & Hasni, 2014). Regarding EA, the revision of Gyurián Nagy (2025) found that women exhibited higher EAs, greater awareness of environmental problems, and a higher willingness to change their behaviour to reduce their environmental impact. In contrast, men’s attitudes are more varied, reflecting a broader diversity of opinions.

Gender has not been a frequent variable in DM studies. For instance, the review by Momani et al. (2023) does not mention it. With respect to the opportunities offered by DM, social studies place women in an unfavourable position that displays three digital gaps: unequal access to infrastructures and digital tools, low level of digital skills, and Internet use (Sáinz et al., 2020). Thus, gender is important for DM too.

The international study “The Relevance of Science Education Second” (ROSES) listens to students’ voices and opinions on their EAs and on their use of digital media and social networks at home, school, and in the science classroom, as well as their perceptions of the DM quality for learning (Jidesjö et al., 2020).

The research questions about the exploration of young students’ EAs and DM use in seven Spanish-speaking countries are the following: How much do students hold proactive EAs and use general and specific DM in science classes? What are the main differences across countries about EAs and the DM use? What are the differences between boys and girls across countries?

Methodology

ROSES uses a mixed-method methodology, which involves qualitative and quantitative procedures to analyse the students' answers and to develop comparisons between groups.

Materials

The ROSES-Q is a large survey that was developed by an international team of science education experts to gather diverse affective data that impact science education (Jidesjö et al., 2020). The item wording is direct, simple, and short, and the students are asked to tick the appropriate box number that best fits their attitudes through a four-point Likert format (1-2-3-4). The meaning of the Likert numbers varies across scales (Disagree-Agree, Never-Often, etc.).

The categories about EA challenges and the use of DM at home and school science are analysed here. The category "Me and the environmental challenges" displays 13 items on the personal dispositions towards the environment, asking How much do you agree with the item? All responses are expressed on a four-point Likert scale (1-4), whose extreme points spread from disagree (1) to agree (4).

Six EA items are marked with (-) because they display anti-EAs (e.g., Threats to the environment are not my business), as they are contrary to pro-EA (e.g., People should care more about how to protect the environment). The average scores of the dysfunctional negative items should be interpreted in an opposite way to pro-environmental items. The EAs items correspond with the following dimensions of the short EAI: (2) Support for interventionist conservation policies, (3) Environmental movement activism, (4) Conservation motivated by anthropocentric concern, (5) Confidence in science and technology, (6) Environmental fragility, (8) Personal conservation behaviour, and (11) Ecocentric concern (Milfont & Duckitt, 2010).

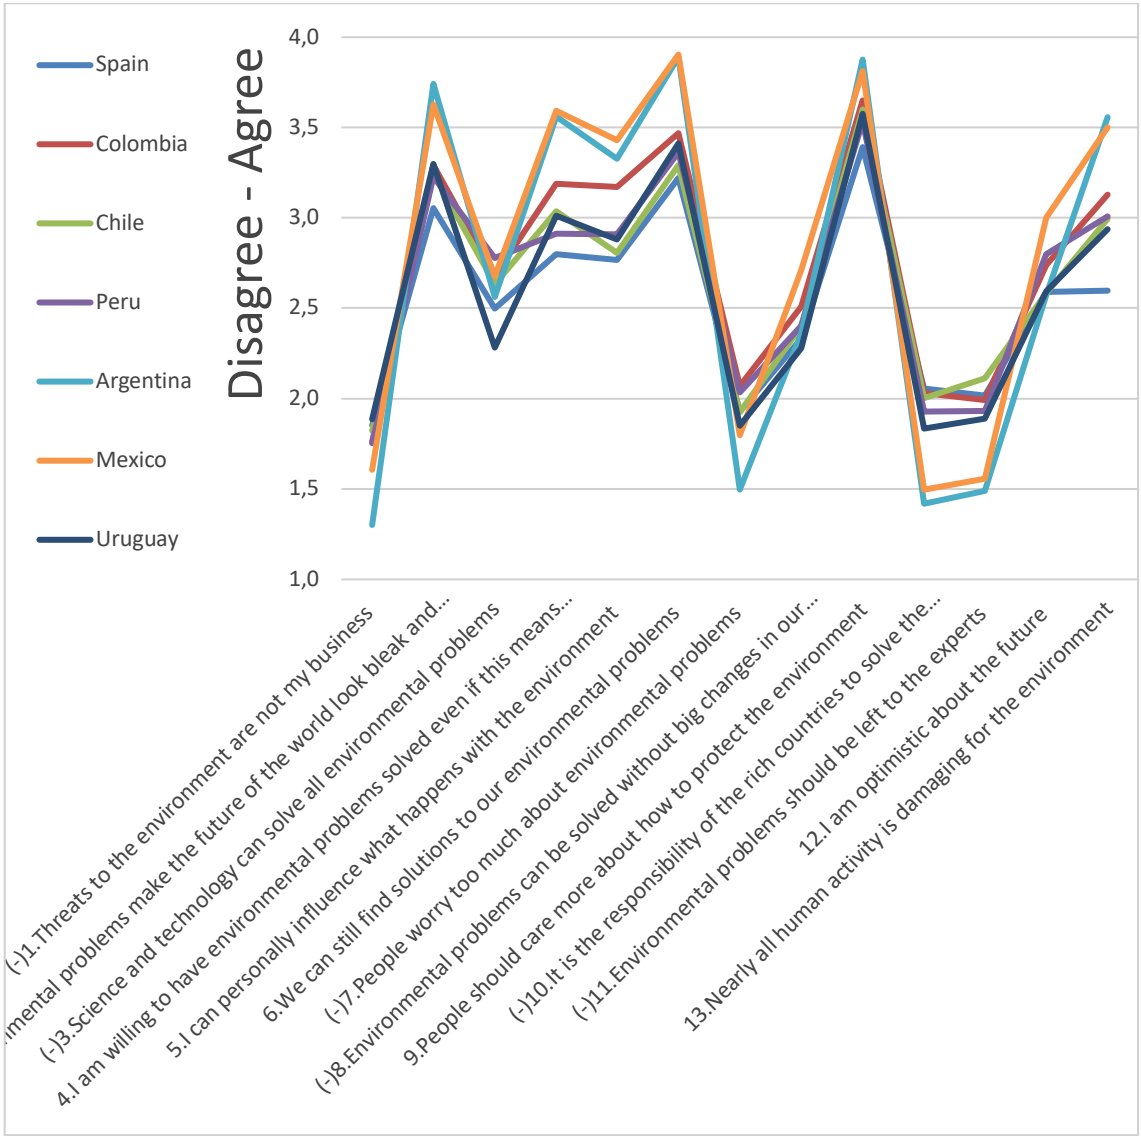
The category "Use of digital media and social networks" is made up of 16 statements, which investigate digital experiences from three different perspectives: the time of DM use at school and at home (first 2 items), the use of several digital resources in school science education (10 items), and the appreciation of the quality of DM for learning science (last 4 items). Students were asked in the first two perspectives, "How much do I use the DM?" and in the third perspective, "To what extent do you agree with the following statements?" The responses are expressed on a four-point Likert scale (1-4), whose extreme points are as follows: first perspective, less than 2 hours a day (1) to more than 6 hours a day (4); second, never (1) to often (4); third, disagree (1) to agree (4) (Figure 1).

Participants

The target population of ROSES is 15-year-old students, because they are about to end compulsory education can look back to their school science education and reflect on what they have learned. The participants in this study validly answered the ROSES-Q in Spain (6014), Colombia (1279), Uruguay (729), Chile (729), Peru (470), Argentina (232), and México (191). The country samples are approximately split in halves between girls and boys.

The approval of the ROSES project by the Spanish State Research Agency implied the commitment to comply with the ethical principles and the relevant national, European, and international legislation on human rights. Students were informed that answering meant consent to participate, they could leave items unanswered, and the survey was anonymous.

Procedures



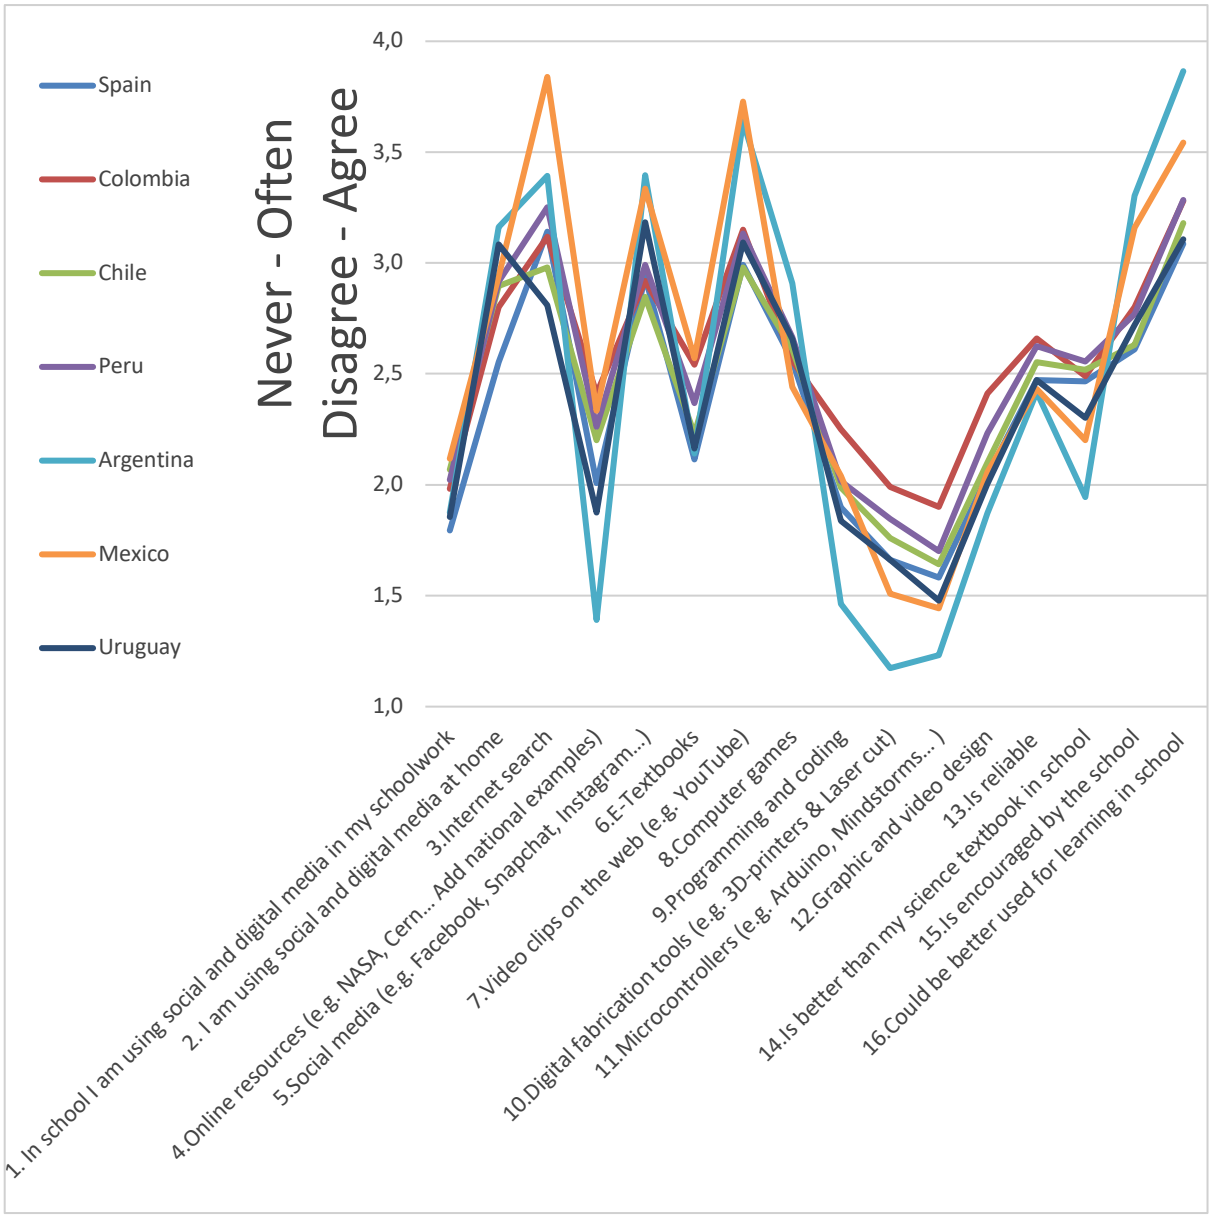
The data gathering took place from 2021 to 2024, and students anonymously and digitally answered the ROSES-Q as a class assignment led and collected by their teachers at each participating school.

The analysis summarizes the four percentages of each item within one single parameter, the item weighted average. The effect size (ES) of the differences (measurement of differences in normalized scores) allows analysis of the magnitude of the differences (low, medium, or large) that go beyond the statistical significance probability test ($p < .05$). Parametric (Cohen *d*) and non-parametric (Cohen *r*) ES tests were computed and interpreted this way: very small (< .10), small (< .30), moderate (< .50), large (> .50), and very large (> .80). ES scores of gender differences are computed as girls minus boys, so that positive differences represent higher scores of women.

Results

The main global qualitative feature exhibited by the EAs item averages of the seven countries shows that the countries' profiles are quite parallel among them. All country lines display their maximum and minimum scores on the same items with some minor exceptions (Figure 1).

Figure 1. Weighted average of environmental items for the seven countries.



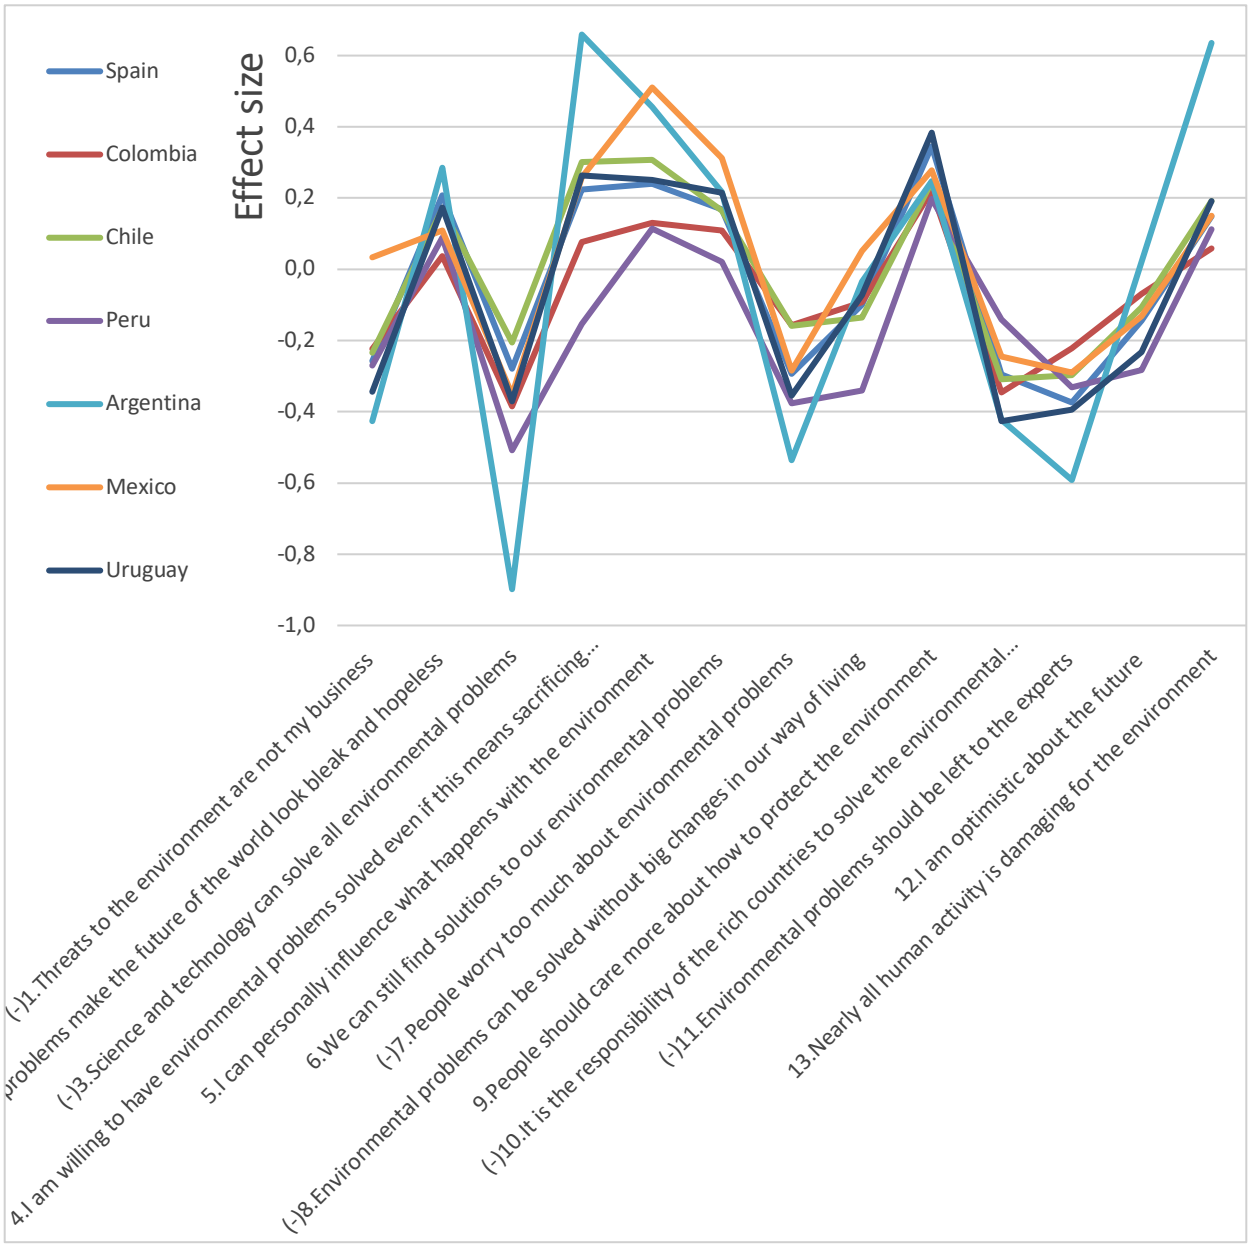
The items with the highest scores (large agreement) are three positive items: item 2 ("Environmental problems make a hopeless future"), item 6 ("We can still find solutions to

environmental problems"), and item 9 ("People should worry more about environmental problems"). Similarly, the points with the lowest scores (large disagreement) correspond to item 1 ("Threats to the environment are not my business"), item 7 ("People worry too much about environmental problems"), item 10 ("The responsibility lies with rich countries"), and item 11 ("Environmental problems should be left to the experts") (all three negative items).

On the other hand, the comparison among countries shows that most EAs items display large differences, which approximately score over one unit of the Likert scale between the country with the highest and lowest score (this difference corresponds to one standard deviation ES). The lowest differences between countries (under one unit of the Likert scale) correspond to item 3 ("science and technology can solve all environmental problems"), item 8 ("problems can be solved without major changes in our way of life"), and item 12 ("optimistic about the future").

The profiles of the seven countries along the 16 DM item averages are quite parallel. All country lines display their maximum and minimum scores on the same items with some minor exceptions, which is their main global feature (Figure 2).

Figure 2. Weighted average of digital media items for the seven countries.



The items that reach the highest scores (largest use) are 2 ("use of social and digital media at home") and item 7 ("Video clips on the web"), and there is large agreement on item 16 ("DM

could be better used for learning in school"). Similarly, the items with the lowest scores (scarcest use) correspond to items 1 ("use of social and digital media at school"), 4 ("Online resources"), 9 ("Programming and coding"), 10 ("Digital fabrication tools"), and 11 ("Microcontrollers").

Further, Figure 2 also shows that almost all DM items display large differences between the highest- and lowest-score countries that are approximately higher than one unit of the Likert scale (over one standard deviation). The lowest differences between countries (under one unit of the Likert scale) correspond just to item 1 ("use of social and digital media at school").

Globally, Argentina's and Mexico's EAs stand out for being more positive than the rest of the countries. Their averages are well above the other countries in the positive items, and they are well below the other countries in the negative items. This result is also observed in the use of DM in science education: Mexico and Argentina tend to score lower than the other countries in the lowest-score items and tend to score higher in the highest-score items.

Figure 3. Effect size of gender differences on environmental items for the seven countries.

Gender differences

Gender differences in EAs and DM use have been assessed using parametric and non-parametric methods for computing statistical significance and effect size. Most items show significant gender

differences ($p < .05$) through parametric and non-parametric tests, even for low effect sizes (< .10). For this reason, the following analysis focuses on effect size statistics that are much more demanding and relevant for practice than the simple hypothesis testing statistics (probability of significance test). Parametric (Cohen *d*) and non-parametric (Cohen *r*) effect size statistics have been compared for EAs and DM use. Both effect size statistics produce highly coincident results, so that Cohen *d* has been selected (Figures 3 and 4).

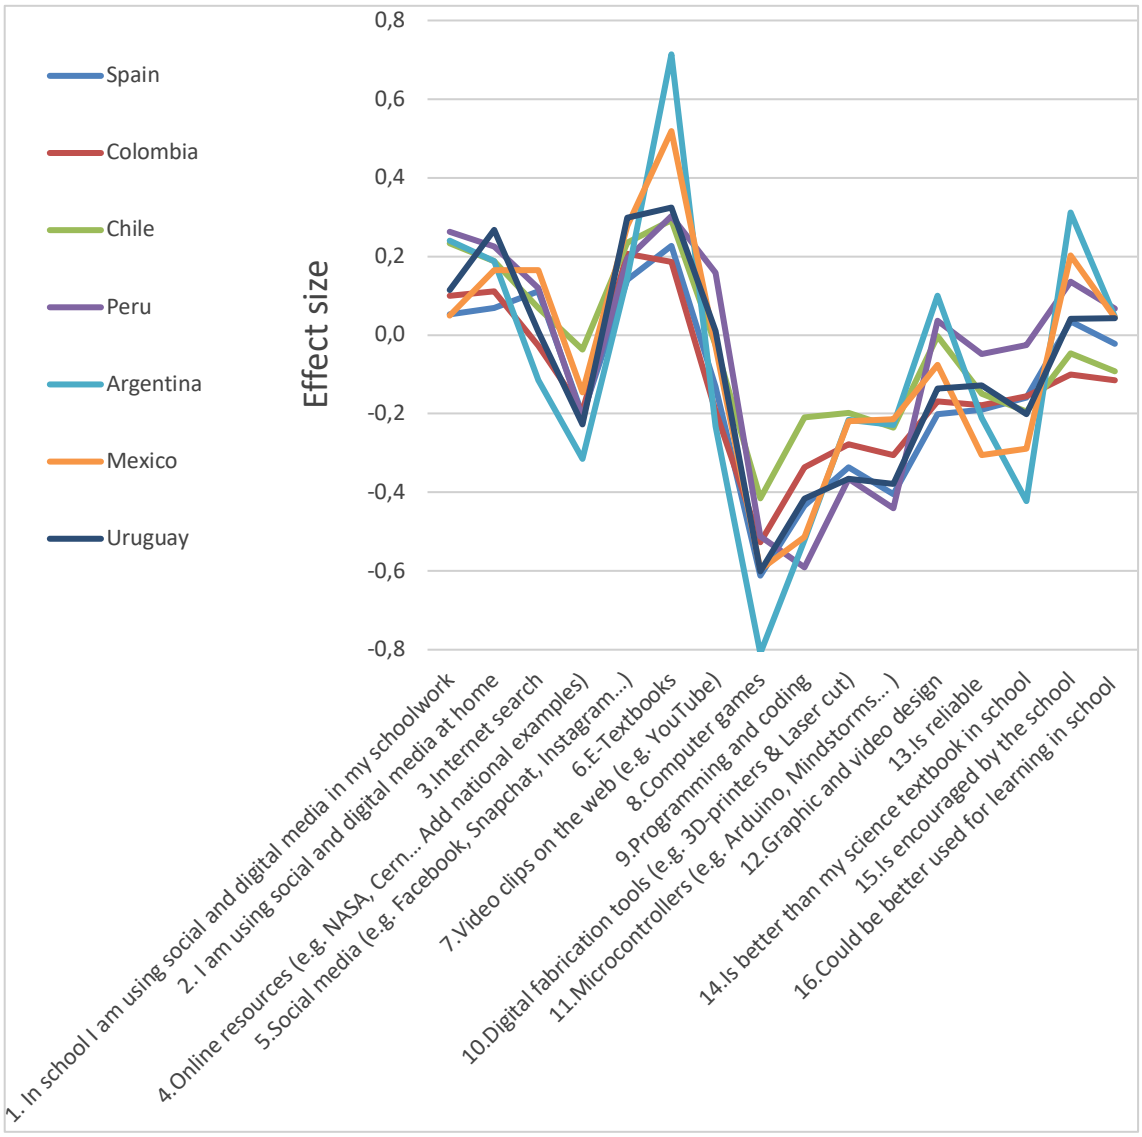
The EAs (Figure 3) show that many items in many countries do not exceed the threshold of the effect size magnitude corresponding to small differences (-.20 - +.20). However, some items stand out of this interval with moderate to large differences. The items with positive differences (favourable to women) correspond to items 4 ("I am willing to have environmental problems solved even if this means sacrificing many goods"), 5 ("I can personally influence what happens with the environment"), and 9 ("People should care more about how to protect the environment"). These results mean that women agree more than men with the EAs represented in these items. As all these items display a positive formulation (pro-environmental), women hold better EAs than men, and the effect size of the gender differences is moderate to large.

The items with negative and moderate to large gender differences (favourable to men) are item 1 ("Threats to the environment are not my business"), 3 ("Science and technology can solve all environmental problems"), 7 ("People worry too much about environmental problems"), and 8 ("Environmental problems can be solved without big changes in our way of living"). Thus, men agree more than women with the negative (anti-environmental) attitudes represented in these items. The negative (anti-environmental) content of the former items requires a reversed interpretation of their scores, which means that women hold better attitudes than men on these items.

After reversing the scores of the anti-environmental items, the global differences on EAs show that girls have more positive attitudes than boys across all countries, and the effect size of the differences is noteworthy in the EA items mentioned above.

The overall effect size of gender differences on EA items approaches a positive moderate effect size, approximately .20. Exceptionally, Argentina exhibits a higher overall effect size of gender differences (over .40) that nearly reaches significant differences in effect size. This means that Argentine girls stand out for having the highest magnitude of the gender differences in comparison to the rest of the countries. Argentinian girls have much better attitudes than Argentinian boys, and just double the gender differences of other countries on EAs.

Argentinians' averages in the negative items are well below the other countries, yet they are well above the other countries in some positive items. Thus, Argentinian girls display much better EAs than Argentinian boys and double their gender differences in comparison to the other countries. According to this trend, some outlier effect size scores are noteworthy. Argentina scores much higher than the other countries in the positive items 4 ("I am willing to have environmental problems solved even if this means sacrificing many goods") and 13 ("Nearly all human activity is damaging for the environment"). Further, Mexico scores well over the other countries and against the former trend in the negative item 1 ("Threats to the environment are not my business").



The gender differences in DM use (Figure 4) show that many items in many countries fall well below the threshold of the effect size magnitude, which corresponds to small differences (-.20 to +.20). However, some items stand out of this interval, showing moderate or large differences. The items with moderate or large positive differences favourable to women (positive) correspond to items 5 ("Social media") and 6 ("E-Textbooks"), which means that women report greater use

than men with these DM. Thus, women hold better DM use than men along these two items with moderate to large positive effect sizes of gender differences.

The items on the DM use that reach an overall moderate to large negative gender difference (favourable to men) correspond to items 8 ("Computer games"), 9 ("Programming and coding"), and 10 ("Digital fabrication tools"). Men use more than women the resources depicted in these DM items. Overall, these results allow us to conclude that women and men widely differ between them in the use of the DM mentioned above, giving different patterns tied to gender.

Regarding overall gender differences on DM use, Argentina again stands out for having more extreme scores than the rest of the countries. The effect size average items are well below the other countries in the DM with negative effect size (Argentinian men do use these DM much more than men of the other countries do) and they are well above the other countries in some positive effect size items (Argentinian women do use these DM much more than women of the other countries do).

Figure 4. Effect size of gender differences on digital media use for the seven countries.

Regarding DM use, the global effect size scores of the gender differences are negative for all countries, indicating that boys report a higher DM use than girls. However, these negative scores correspond to very small gender effect sizes. It is worth noting that Argentina displays the highest range of the distribution of effect size across DM items compared to other countries, indicating

that Argentina shows the highest and lowest effect sizes of gender differences across some DM items.

Discussion And Conclusions

The findings of this study answer the research questions about the current EAs and DM use in school science education through surveying students in seven Spanish-speaking countries.

The first finding points to students' overall proactive EAs, as the weighted averages of all EA items are over the midpoint of the Likert scale (after reversing the scores of negative items). Further, the EA items that display the highest and lowest attitudinal strength have been identified (Somerwill & Wehn, 2022). Regarding DM use, the item weighted averages are quite varied, giving rise to the more and less used DM resources (Skryabin et al., 2015).

Second, the students' EAs and DM use in school profiles across the set of items exhibit overall similar qualitative patterns for countries. However, the quantitative comparison between countries within each item shows large differences among countries for most EAs and DM items. Then, the items that display the largest and smallest differences among countries have also been identified and displayed as findings of this study.

Third, the weighted averages of Argentina and (partially) Mexico play the role of outliers in relation to the weighted averages of the other countries; that is, Argentina and (partially) Mexico often score in the top or the bottom of each EA and DM use item. Taking into account the overall scores on EAs and DM use, the seven countries seem to fit the following tentative table league (from top to bottom weighted averages): Argentina, Uruguay, Spain, Chile, Mexico, Peru, and Colombia.

Fourth, the study found generalized gender differences about EAs and DM use and a notable variance among countries. The overall differences on EAs show girls displaying more positive attitudes than boys across all countries, and the effect size of the gender differences is noteworthy in some EA items that have also been identified. The exploration of countries shows that Argentina exhibits the highest effect size of EAs' gender differences, which means that Argentinian girls have much better attitudes than Argentinian boys. Further, the magnitude of the gender differences on EAs just duplicates the gender differences of other countries (Gyurián Nagy, 2025; Sáinz et al., 2020).

Regarding DM use, the global effect size scores of the gender differences are mostly negative for all countries, which means that boys overall report higher DM use than girls. However, these negative effect size scores correspond to insignificant gender differences. Further, these gender differences induce different patterns of DM use that are tied to gender: girls report much more frequent use of e-textbooks than boys, and the reverse pattern applies to computer games, where boys report much more frequent use than girls. Again, Argentina tends to display the highest and lowest effect size of gender differences across many DM items. Overall, these results lead us to conclude that women and men widely differ in DM use.

The findings about students' EAs and DM use project obvious consequences for practice. First, school science education should remedy the weaknesses of EAs and DM use, such as increasing the educational use of computer games or trying to change anti-environment attitudes of the minority of students. Further, research should deepen the analysis within each country and the contrasts between countries (Courtney et al., 2022; OECD, 2024).

The limitations of this study mainly stem from its dependency on the ROSES-Q instrument, as its specific design conditions the results. For instance, the EA items do not develop all the environmental dimensions of the EAI (Milfont & Duckitt, 2010), and the DM does not include

the impact of artificial intelligence. Further, the samples in some countries (Mexico and Argentina) are small and harm their representativeness.

The future of this study envisages practical applications and developments of all the findings presented above for school science education and for research in science education. Particularly, the weaknesses and strengths of EAs and DM use and their gender differences may need future confirmation through new studies with renewed samples and contexts in the different countries.

Introduction

We are living in a transformative era shaped by profound technological advances. While these developments offer fascinating opportunities, they also present major societal and environmental challenges. Science Education should be responsive to these societal and environmental challenges and refine its practices and purposes (White & Tytler, 2025).

Under the theme *Transitions in Science Education: Sustainability and Digital Advances*, this chapter explores how science education can best prepare future citizens to face such challenges. Within this context, the science curriculum plays a crucial role, given that educational systems remain heavily curriculum driven. By examining how science curricula and educational policies worldwide are being reshaped, we contribute to a broader scholarly dialogue on what it means to educate scientifically literate and globally competent citizens. The Science Curriculum and Educational Policy Strand within ESERA focuses on the design, development, interpretation, implementation and evaluation of science education policies across local, regional, national, and international levels, as well as critical reflections on their border implications for science education.

Aligned with the main topics presented at the ESERA 2025 Conference within this strand, this chapter offers eight selected works, three of which are presented together as part of an ESERA symposium paper. The contributions span a wide variety of geographical contexts, displaying a cross-national, critical perspective with an emphasis on the interplay between science curricula and sustainability issues. Specifically, the selected works examine different curricular aspects, including the contribution of influential educational frameworks and comparative analyses of textbooks and guidelines across various countries. Furthermore, they explore teacher preparedness and the role of co-designed lessons involving researchers, scientists, and teachers to translate educational aspirations into school practice.

Among the frameworks discussed in this chapter are DeSeCo 2003 (OECD, 2003), the Learning Compass 2030 (OECD, 2019), GreenComp (Bianchi et al., 2022), the new Guide for Climate Literacy (USGCRP, 2024) and PISA 2025 (OECD, 2023) — including the concept of Agency in the Anthropocene (White et al., 2023, 2024). Among the studies examining curricular guidelines and textbooks, Watson and Li present a content analysis of curricular documents in Canada and Taiwan, based on the PISA 2025 framework. Following a similar approach, Dawud et al. focus on the presence of dynamic equilibrium as a key concept in Israeli and Manitoba textbooks. Climate Change Education (CCE) is the focus of the textbook content analysis conducted by Lampoudis and Mogias in Greece, as well as that by Tytler et al. in Finland, Australia and Taiwan.

The work by Tytler et al. presents two further studies aimed at identifying opportunities and systemic constraints for CCE. The first of these additional explorations was a cross-national survey of teachers' knowledge, practice, and confidence in teaching CCE. The second exploration involved a process of co-designing research-based sequences through iterative cycles of evaluation and improvement. This evaluation was based on observations, interviews and students' pre- and post-tests. The cross-national insights presented contribute to sharpening our

understanding of how science education can support CCE as well as the contextual factors that frame the possibilities for innovation.

The work by Scarongella analysed several international competence frameworks providing an important reference point to curriculum shaping, with a view to the introduction of sustainability education. The analysis reveals an evolution from literacy-based, economics-driven skills to fostering transformative agency for sustainability. The emphasis on sustainability, especially in GreenComp, PISA 2025 (Bianchi et al., 2022) and "Learning Compass 2030" (OECD, 2019) marks a shift from training knowledge-based competence to cultivating change agents who can think systemically, collaborate, and foster hope to collaborate on climate challenges actively. It is worthy to mention the introduction of the concept agency, defined as “the belief that students have the will and the ability to positively influence their own lives and the world around them, as well as the capacity to set a goal, reflect and act responsibly to effect change" (OECD, 2019). Three key developments stand out from the analysis conducted by Scarongella: the evolution of sustainability from a marginal concern to a central guiding principle, transforming it from "a theme among many" into a paradigm through which education itself must be rethought; the incorporation of agency-related concepts and the redefinition of teachers as catalysts for transformation, highlighting the pending need to translate aspirations to concrete curriculum strategies.

Watson and Li highlight the importance of promoting scientific literacy as a central goal of science education to thrive in an era of uncertainty. Specifically, they present the results of a comparison between the Taiwan and Manitoba science curricula (grades 7-9), which share a similar structure, using the PISA 2025 Science Framework that emphasises scientific literacy through the development of scientific competencies. According to the content analysis, while both curricula align with PISA 2025 in content coverage, they fall short in fostering epistemic and procedural knowledge or general scientific competencies, and a sense of science identity, suggesting key areas for improvement. The authors argue that PISA should not be treated as the sole measure of education quality, but it can serve as a useful tool to identify gaps and inform directions for curriculum development.

In a different context, Dawud et al. focus on the importance of Dynamic Equilibrium (DE), a structuring concept in learning natural sciences that fosters students’ systems thinking. The study presents a qualitative mixed-methods content analysis of the content and representations related to DE in the main high school textbooks and national standards of Israel and the US across biology, chemistry, and physics. According to the findings, DE-related phenomena are present in roughly 14% of science curricula, though not always explicitly. While students struggle to connect microscopic processes with macroscopic phenomena, computational models appear valuable for improving systemic understanding. The study recommends developing unified, cross-disciplinary representations of DE and suggests that future research should explore its integration across more scientific fields.

Lastly, the work by Lampoudis and Mogias highlights the value of the recently updated Climate Literacy Guide (USGCRP, 2024) and advocates for it as a solid foundation for raising students’ climate literacy in formal education. Taking this guide as a referent framework, these authors investigate the presence of climate change issues in Greek Special Education science textbooks. The content analysis shows rather limited and fragmented information concerning the eight essential principles and the seventy-six fundamental concepts of the Guide, identifying key areas for improvement.

We hope that this chapter contributes to sharpening our understanding of the contextual factors that support or hinder responsive and innovative education, while stimulating debate about how

best to prepare students to address current societal and environmental challenges through science education.

ESERA 2025 Copenhagen

he Evolution Of Competence And Agency In Science Education: A Conceptual Analysis

Mariateresa Scarongella[1,2]
[1]University of Bologna, Italy
[2]Liceo Virgilio, Milano, Italy

The development of competence in science education reflects a significant shift from literacy-focused, economically driven models to comprehensive frameworks that incorporate transformative agency and sustainability. This study traces the conceptual journey from Aristotle's fundamental distinction among episteme, techne, and phronesis—which already highlighted the ethical aspect—through modern frameworks such as OECD DeSeCo 2003, Learning Compass 2030, GreenComp 2022, and PISA 2025. The analysis shows how competence has progressed from simply acquiring knowledge to the ability to act within complex socio-ecological systems, illustrating the enduring presence of Aristotelian ethical components over centuries. Three key developments stand out: the evolution of sustainability from a marginal concern to a central guiding principle; the incorporation of agency-related concepts (systems thinking); and the redefinition of teachers as catalysts for transformation. In particular, values and ethical responsibility in current frameworks have experienced a revival—from DeSeCo's economic focus to PISA 2025's —that reflects a return to the holistic roots of competence. Yet, a persistent tension remains between these comprehensive visions and their practical realisation. This analysis underscores both the persistent influence of ethical dimensions from Aristotle to today and the ongoing challenge of translating transformative aspirations into practical curriculum strategies for the Anthropocene.

Keywords: sustainability agency, science education, competence

Introduction

Over the past three decades, competencies have become a key topic in European and international debates. In Europe, this policy began with the European Council's December 2006 recommendation on key lifelong learning competences, which influenced Italy and other EU countries. Student competencies are divided into four areas: languages, mathematics, science-technology, and social history, later adding citizenship skills. Anyway, despite growing interest, schools struggle to define essential competencies and what it means to develop them (European Council, 2006).

Nevertheless, competencies must be defined to provide students not only with knowledge content but also with holistic, complex skills and attitudes that enable them to navigate an increasingly challenging and uncertain society. In this context, knowledge alone is insufficient; systemic thinking, critical analysis, and ethical judgment are also essential. This is particularly evident in a society and era where the climate and sustainability emergency has gained significant importance, especially in recent years, leading to personal and general uncertainty.

At the international level, attention to the competence topic began in 2003 with the emergence of the first frameworks that began discussing competencies, such as the OECD DeSeCo. However, the historical origin of competence dates back considerably further. Indeed, as Pellerey analysed in his book “Competenze”, the philosophical foundations of competence can be traced back to Aristotle (4th century BC), who already provided a complex and holistic definition of competence. He distinguished between episteme (theoretical knowledge), phronesis (ethical wisdom), and techne (technical ability). Aristotle, therefore, was the first to highlight the importance of conceiving knowledge not only in terms of practical action but also as

encompassing a much more holistic and complex dimension, emphasising the ethical and moral dimension (Pellerey, 2010).

The legacy of this can be noticed, considering that recently the evolution of the concept of competence has shifted from an economic drift—oriented satisfying society's financial needs and requirements, as exemplified by DeSeCo, to more complex aspects of the individual who tends to value ethical and moral agency aspects in the challenges and choices of society.

The explicit introduction of sustainability competence into the European Key Competences Framework occurred with the 2018 Recommendation (European Council, 2018), in response to the global challenges articulated in the United Nations' 2030 Agenda (United Nations, 2015). This integration rendered environmental sustainability a transversal component spanning multiple key competences, with particular emphasis on scientific, citizenship, and entrepreneurial competences (European Council, 2018). It's clear that a significant transition has occurred from the literacy model of the 2000s—articulated around linguistic, mathematical, and scientific competencies—to a comprehensive sustainability-oriented paradigm. Also, the OECD has been forward-thinking in this regard, placing sustainability as a **central priority**, even if its central role has only recently been recognised in PISA-25, with some aspects already addressed in the OECD Learning Compass 2030. Besides, the OECD has been forward-thinking in its approach with respect to the evolution of the literacy paradigm, shifting from a focus on practical skills to fostering transformative capacity. In 2019, following the European Green Deal (European Commission, 2019), which established sustainability as a central EU priority, the integration of sustainability into education was significantly accelerated, transforming it from "a theme among many" into a paradigm through which education itself must be rethought. GreenComp comes up within this revolutionary context. The year 2020 marked a pivotal shift, during which the Joint Research Centre conceived GreenComp as a framework explicitly dedicated to sustainability competencies (Bianchi et al., 2022). This last framework encompasses systemic complexity, ethical dimensions, critical thinking, and uncertainty management, thereby promoting active and transformative citizenship.

In this work, we want to provide a comparative analysis of the conceptual, structural, and purposive evolution of international institutional frameworks, particularly about the emergence of transformative and sustainable dimensions, to review competence in science education. In relation to this, the research question is the following:

How has the concept of competence evolved in science education to address sustainability challenges and transformative agency?

Methodology

To address our research questions, we implement a comprehensive scoping review methodology to map and analyse the historical trajectory and conceptual development of competence and agency in science education. This methodological approach proves particularly valuable for investigating complex, cross-disciplinary subjects that necessitate comprehensive concept mapping, gap analysis, and theoretical integration across multiple perspectives (Arksey & O'Malley, 2005). Our research process follows five systematic stages:

Stage 1 - Research Question Development: Our investigation examines how competence, specifically sustainability competence, has evolved in science education, using international and European conceptual frameworks.

Stage 2 - Literature Identification: We conducted an extensive review of seminal works ranging from OECD-DeSeCo (2003), to more recent educational frameworks, including the OECD Learning Compass 2030 (2019), GreenComp (2022), and PISA Science Framework 2025.

These frameworks were selected because they represent both policy-driven and academic contributions that have significantly shaped the development of the concept of competence. They provide insight into the evolution of competence by offering a reading that is grounded in the relationship between education and society. Furthermore, these frameworks enable us to trace the emergence and institutionalisation of sustainability competences as a concept—from its first academic articulation to its current status as a central dimension of international and European educational policy.

Stage 3 - Selection Process: We established specific inclusion parameters centred on theoretical frameworks of competence and agency in education, while deliberately excluding research focused solely on specific scientific content knowledge.

Stage 4 - Data Analysis: The analysis focuses on key aspects, including tracking the development of competence as a concept, observing the emergence of transformative competences, and examining the gradual integration of values and ethics. We systematically coded whether sustainability was explicitly included or omitted in each framework, enabling the identification of patterns in sustainability incorporation. Finally, we analysed the persistence and evolution of the classical Aristotelian structure and potential implications for curriculum applicability.

Stage 5 - Synthesis and Documentation: Our findings are presented comprehensively, highlighting both the continuity and evolution of competence and agency concepts, with a specific focus on their implications for science education.

The following section presents our analysis, which reveals a gradual evolution from economically oriented competence definitions toward frameworks that emphasise transformative agency, values, and sustainability. Here, we present the key frameworks chronologically, highlighting the conceptual shifts and emergent themes."

Results And Discussions

The Evolution Of The Concept Of Competence In Major Frameworks In Science Education

The following section highlights three phases in the development of competence: the economic-focused phase (1997-2003), the transformative and agency-oriented phase (2018-2019), and the sustainability-centred phase (2020-2025). Throughout this progression, the traditional tripartite model—reflecting Aristotle's distinction among episteme (knowledge), techne (skills), and phronesis (ethical wisdom)—remains but evolves, with values and ethical considerations gaining increasing importance.

At the educational level, two key frameworks at the European and international levels that provide essential guidance for shaping educational paths are the OECD framework for different periods and GreenComp. Comparing these frameworks will specifically highlight how and why the concept of competence shifts from a simple understanding, such as knowledge, to a more complex and articulated notion. This will also be analysed in relation to societal change, as well as the historical origin and initial purpose of the framework. The emergence of environmental competencies over time will also be examined. The first frameworks to be analysed are the OECD frameworks across different periods, starting with their origin. The OECD (Organisation for Economic Co-operation and Development) is an international organisation founded in 1961 to promote policies that improve the economic and social well-being of people worldwide by

reducing disparities, poverty, and social inequalities. His birth occurred after the Marshall Plan, established by the United States after World War II to address Europe's economic crisis. Its predecessor was the **Organisation for European Economic Co-operation (OEEC)**, which coordinated the distribution of financial aid and helped European countries rebuild their economies by promoting economic cooperation, and was active from 1948 to 1961. It primarily focused on managing the Marshall Plan and post-war economic reconstruction, with a limited scope confined to Europe. The OEEC had not yet developed a competency framework. During this period, due to social needs, the emphasis shifted to technical and professional education, with a focus on practical knowledge and skills. This approach was adopted to better address the socio-economic problems faced at that historical time. Then, in 1961, the OECD was born to serve as a source of information, providing economic data, policy analyses, and recommendations to its 38 member countries, both European and non-European (OECD, n.d.).

Over time, the OECD has expanded its sphere of action from a purely economic area to one that first concerns education and then also the environmental aspects. For the first time, the concept of competence was introduced in 1997 when the **DeSeCo-Defining and Selecting Key Competencies** project was launched by the OECD and concluded with the final report in 2003 with **"Key Competencies for a Successful Life and a Well-Functioning Society"**, to provide a conceptual framework for identifying key competencies necessary for modern life (OECD, 2003). The definition of competence is the following, given on page 4 in OECD DeSeCo Project: *"A competency is more than just knowledge and skills. It involves the* **ability to meet complex demands** *by drawing on and mobilising psychosocial resources (including skills and attitudes) in a particular context"*(OECD, 2003, p. 4). It is clear that in this definition, the economic dimension remains fundamental, and while the social benefits are present, they are not essential. The document that follows DeSeCo and most comprehensively encompasses the ongoing changes in competencies is the new **OECD Learning Compass 2030** framework, published in **2019.** The **OECD Learning Compass 2019** is a guidance tool designed for all actors in the educational system, from policymakers to students and their families. It arises from the need to redefine the competencies necessary for 2030 and guide educational systems in addressing future challenges. It is a framework, not designed like DeSeCo, that represents an expansion of the previous one towards a concept of competencies with a connotation related to **agency, co-agency, and transformative competencies.** This framework first introduced the word agency: "*Student agency is defined as the belief that students have the will and the ability to positively influence their own lives and the world around them as well as the capacity to set a goal, reflect and act responsibly to effect change*" (OECD, 2019, p. 17). White et al. (2023) later further developed this idea for sustainability by defining individual and collective agency using measurable constructs such as hope, self-efficacy, and outcome expectancy. The framework expands by, for the first time, including not only knowledge and skills for professional use but also attitudes and values. This explicit inclusion of values marks a return to the holistic conception of competence, recalling Aristotle's phronesis (ethical wisdom). Competencies are seen as tools for navigating the uncertainties and complexities of the modern world, defining the skills students must acquire to face future challenges. The peculiarity of this framework is to identify three transformative competencies (creating new values, reconciling tensions and dilemmas, taking responsibility) and a series of values and attitudes that students must develop to be responsible citizens (respect for self, others, country, diversity, empathy, integrity and resilience). This is the definition of competence given in the document: "*A competency is a holistic concept that includes knowledge, skills, attitudes and values. The OECD Future of Education and Skills 2030 project defines a competency as more than just 'skills". Skills are a prerequisite for exercising a competency. To be ready and competent for 2030, students need to be able to use their knowledge, skills, attitudes*

and values to act in coherent and responsible ways that change the future for the better" (OECD, 2019, p. 25).

Also, the OECD logo effectively conveys the framework's structure and founding message (see OECD, 2019, p. 24). It can be described as follows: a compass can be observed with student agency at its centre, enabling them to become active protagonists of their own learning and capable of making conscious decisions. The competencies provided by the Learning Compass (knowledge, skills, attitudes, and values) are fundamental for navigating a complex, continually changing world. They must work together to build a shared sense of wellness. At the base of the compass are the "Core foundations" (basic foundations), which are the competencies that constitute a premise for the development of any other competency. These foundations encompass cognitive competencies (including literacy, numerical competency, digital literacy, and data literacy), health (including physical and mental well-being and individual well-being), and social-emotional skills (moral and ethical). These foundations are also functional to the development of three transformative competencies: creating new values, reconciling tensions and dilemmas, and taking responsibility. In particular, creating new values means "*Creating new value refers to a person's ability to innovate and act entrepreneurially, in a general sense, by taking informed and responsible actions*"(OECD, 2019, p. 62). The concept of co-agency is also evident in the figure, which illustrates collaboration among students, teachers, families, and the broader community. While student agency is defined as the belief that students have the will and ability to positively influence their own lives and the world around them, as well as the capacity to set goals, reflect, and act responsibly to produce change. Because it is only through the joint work of multiple actors that one can achieve everyday wellness. Moreover, knowledge is intended to encompass theoretical concepts and ideas that extend beyond practical understanding, grounded in experience performing specific tasks. Besides, it recognises four different types of knowledge: disciplinary, interdisciplinary, epistemic, and procedural. And finally, skills are understood as the ability to perform processes and use one's knowledge responsibly to achieve a goal, which distinguishes between four types of skills: cognitive and metacognitive, social and emotional, practical, and physical. Lastly, attitudes and values refer to the principles and beliefs that influence a person's choices, judgments, behaviours, and actions on the path towards individual, social, and environmental well-being. Moreover, in the 2018 position paper (The future of education and skills 2030), the urgency of creating an educational system that addresses not only economic and social challenges but also environmental ones (including the depletion of natural and climate resources) is highlighted. In both documents, the ecological theme is consistently presented as one of the challenges to be addressed, but not the only one (OECD, 2018).

The Rise Of Sustainability Competences

What follows reveals a critical turning point around 2020: in this year, sustainability shifted from being one challenge among many to becoming a central dimension of educational competence. The following section examines this transformation through GreenComp and PISA 2025, which shows how sustainability competences have been systematically integrated into contemporary educational frameworks.

Analysis shows a shift in the role of sustainability in frameworks. Before 2020, sustainability competence was minimal or embryonic, but from 2020 onwards, it gained importance. According to GreenComp (2022), it became central to educational competencies, reflecting the urgency of the climate crisis and a shift from training competitive workers to shaping change agents within planetary boundaries (Bianchi et al., 2022).

GreenComp belongs to the five frameworks developed by the European Union (LifeComp, EntreComp, DigComp, GreenComp, and Competences for a Democratic Culture), which specify

additional, more detailed competences that allow for a more precise definition of the objectives within the eight key competences (Bianchi et al., 2022).

It differs from the first in that it was specifically created to address environmental and climate-related issues, and it is European rather than international. The GreenComp (European Sustainability Competence Framework) is aimed at educators, trainers, policymakers, and students of all ages. It was created by the European Commission in 2022 through the Joint Research Centre (JRC) and aims to provide a reference framework for teaching and learning sustainability-related competencies. This framework guides the integration of sustainability-related competencies into educational and training systems. The main objective, therefore, is to help people develop the knowledge, skills, and attitudes necessary to live, work, and act sustainably.

In it, sustainability is defined as: "sustainability means prioritising the needs of all forms of life and the planet, ensuring that human activity does not exceed the planet's limits". GreenComp, therefore, tends to foster an image of sustainability that balances nature and humans and develops in humans an awareness of their own limits.

In this framework, competencies are consistently linked to sustainability: "A sustainability competence enables learners to embody sustainability values and accept complex systems, to act or request actions that restore and maintain ecosystem health and increase justice, by envisioning sustainable futures". The teaching/learning of sustainability, therefore, aims to develop a sustainable mindset throughout the entire lifespan, from childhood to adulthood, promoting awareness that human beings are an integral part of nature and depend on it. Through greenComp, students gain knowledge, skills, and attitudes that empower them to be agents of change. They contribute both individually and collectively to create a future that respects the Earth's ecological boundaries. In the framework, the following definition of competence is given: *"a dynamic combination of knowledge, skills, and attitudes"*. Specifically, the GreenComp articulates competence into 12 competencies organised into four main areas: sustainability values, systemic thinking, sustainable future, and sustainability action.

These peculiarities ensure that GreenComp focuses not only on knowledge acquisition but also on the ability to act for change, promoting sustainable development at both personal and collective levels. As can be seen, all four areas refer to different approaches: some are more practical and action-oriented, while others are more theoretical, focusing on the development of mental strategies. It is important to note that GreenComp also emphasises the value dimension. Still, unlike the Learning Compass ‘30, it highlights three specific values related to sustainability: valuing sustainability, supporting fairness, and promoting nature.

Furthermore, the authors of the framework use a pollination metaphor to represent how the different areas of the framework are interconnected (see Bianchi et al., 2022, p. 12). In this scheme, the bees symbolise the 'acting for sustainability' area, as each bee plays a fundamental role in the colony's well-being and collaborates to achieve common goals. The flowers represent 'imagining sustainable futures' because they produce new fruits and seeds, fostering continuous renewal. The hive represents 'embodying the values of sustainability' as it protects and supports the bees. Finally, the pollen and nectar, which attract the bees to the flowers, symbolise the 'accepting the complexity of sustainability' area. This image thus highlights an ecosystemic vision where everything is interconnected.

GreenComp's ecosystemic vision exemplifies a growing trend where sustainability is no longer just one aspect but a key, organising element in education. This change is clearly demonstrated

by PISA 2025, marking a significant shift in how the idea of competence in science education has developed.

PISA 2025 exemplifies a crucial new phase in the conceptualisation of competence within science education. The omission of the term "literacy" from this framework indicates a significant transition: it is no longer only concerned with students' capacity in science, but also emphasises their connection to the subject.

A key innovation in PISA 2025 is the concept of "Agency in the Anthropocene," which aligns with the OECD Learning Compass 2030's transformative vision but explicitly emphasises sustainability. The core competencies assessed include understanding how human actions affect Earth systems, making decisions informed by evaluating various evidence sources, applying creative and systemic thinking to sustain and regenerate the environment, and respecting diverse perspectives while maintaining hope in addressing socio-ecological challenges (White et al., 2023).

PISA 2025 attributes particular relevance to sustainability and environmental education, not as a separate theme but as a transversally integrated dimension. A person with scientific preparation must be capable of engaging in reasoned discourse on science, sustainability, and technology to inform action.

The supporting document 'Agency in the Anthropocene' (White et al., 2023) offers theoretical insights into these competencies, explaining the concepts of hope, self-efficacy, and outcome expectancy. It also distinguishes between individual aspects (such as critical evaluation and personal resilience) and collective aspects (such as consensual decision-making and action across various scales) of agency.

The analysed frameworks reveal varying curriculum specificity. Some provide operational guidance through detailed competency descriptors that break down knowledge, skills, and attitudes (GreenComp, Appendix 2), practical scenarios that demonstrate real-world application (GreenComp, Appendix 1), and specific pedagogical approaches, including active learning, place-based education, and systems thinking. Others explicitly clarify their non-curricular nature (OECD Learning Compass 2030), offering generic principles without operational indicators. Regarding the teacher's role, all frameworks reject transmissive models, positioning teachers as "transformative facilitators" who co-construct learning with students, model sustainability values, and facilitate democratic processes. The concept of co-agency is strongly evident, yet frameworks offer minimal guidance on preparing teachers for these demanding roles or on transitioning from current practices.

Conclusions

The evolution of competence frameworks from DeSeCo (2003) to PISA 2025 reveals a shift from literacy-based, economics-driven skills to fostering transformative agency for sustainability. Tracing the evolution from Aristotle's complex structure (episteme, techne, phronesis) to modern models, it shows both continuity and change in the integration of knowledge, skills, and ethics. The emphasis on sustainability, especially in GreenComp, PISA 2025, and "Learning Compass 2030," marks a shift from training knowledge-based competence to cultivating change agents who can think systemically, collaborate, and foster hope to collaborate on climate challenges actively. However, a tension exists between holistic visions and practical application: while frameworks promote interconnected approaches, they also need some metrics that may fragment curricula. All agree on shifting from transmissive to transformative and co-constructive teaching roles, which lack clear guidance and have no standard methods for transversal skills. Sustainability education faces the challenge of turning transformative visions into a practical

curriculum. Future efforts should create concrete pathways for holistic integration and provide teachers with support and tools to empower students amid the complexities of the Anthropocene.

Ready for PISA 2025? A Comparative Analysis of Taiwan and Manitoba Science Curricula

Ellen Watson[1] and Wei-Ting Li[2]
[1]Brandon University, Canada
[2]National Sun Yat-sen University, Taiwan

The PISA 2025 framework shifts focus from scientific literacy to scientific competencies, emphasizing the ability to apply knowledge effectively as a key aspect of scientific competence. Given this radical shift, we, as teacher educators, wonder whether our current curricula are preparing students to succeed in the updated PISA framework. Although using a specific test as an evaluation mechanism for the overall curriculum is problematic, the PISA 2025 can provide a systematic method to understand whether students possess the critical competencies needed to face the rapidly changing modern society. This study employs a document analysis method, using the PISA 2025 Science Framework to analyse the science curriculum guidelines for grades 7 to 9 in Taiwan (TWN) and Manitoba (MB), Canada. Results reveal the curricula in both TWN and MB are lacking in procedural knowledge and epistemic knowledge, which is a major critique of modern curriculum guidelines. In terms of context, both TWN and MB have a significant gap compared to the PISA 2025 goals. This might make it more challenging for students to deal with scientific problems in various situations. Finally, regarding science identity, the analysis results reflect the environmental differences between TWN and MB. To summarize, both the TWN and MB science curriculum documents have rich content knowledge, but they fall short of the PISA 2025 goals in other aspects. This study provides a potential direction for curriculum developers and further expands the possibilities for teaching scientific literacy and the nature of science. Although the PISA 2025 framework is not perfect, it serves as a meaningful goal for continuous improvement.

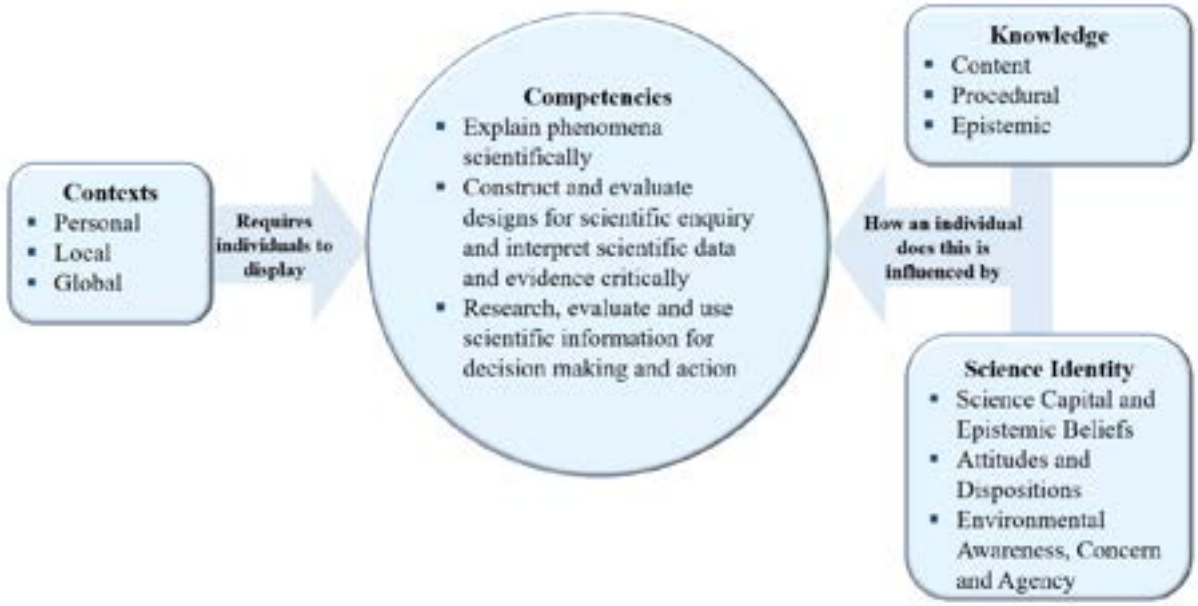
Keywords: PISA 2025, Science Curriculum, Comparative Analysis

Introduction

Since 2000, Programme for International Student Assessment (PISA), one of the most influential, international, student learning assessments (McGaw, 2008), has used a globally recognized framework to assess the performance of national education systems. In 2023, a new assessment framework in PISA 2025 Science Framework (PISA 2025) was unveiled and it prioritized scientific competencies, marking a departure from the previous structure, which focused on scientific literacy.

Scientific literacy is a goal of education, yet scholars cannot agree on its definition (DeBoer, 2000; Osborne & Allchin, 2024). DeBoer (2011) called for science education to determine the knowledge and competencies needed for global citizenship. Scientific literacy points to a diverse set of aims for society and citizens (Osborne, 2023), whereas scientific competencies focus on those skills required for a person to engage in reasoned discourse about science (OECD, 2023). Shifting from literacy to competencies implies the goals of science education, under PISA 2025, are defined in terms of what an individual can do with their knowledge instead of by what they know. Competencies opened space to consider more types of knowledge, such as epistemic knowledge (Zetterqvist & Bach, 2023), than previously included in PISA efforts.

This new framework brings the preparedness of science education curricula to meet PISA expectations into question. Are students in our contexts ready for PISA 2025? To answer this, we compare the contexts of Taiwan and Canada. Despite their geographical distance, these two nations share striking historical and cultural parallels; both are multicultural societies with deep



Indigenous traditions, and both have evolved into their current state following histories of European colonization. However, their geographical distinctions, Canada as a vast continental landmass and Taiwan as an island nation, expose them to different Socio-Scientific Issues. These environmental differences inevitably influence the design philosophies of their respective science curricula.

Regarding the selection of specific regions, education in Canada falls under provincial jurisdiction rather than a federal mandate. Consequently, this study selects the province of Manitoba (MB) as a comparative basis, a choice further motivated by the researchers' geographical location and familiarity with the local context. While Taiwan adopted a revised national curriculum in 2019, at the time of this research Manitoba's framework was unchanged since the early 2000s. Since both contexts use curriculum documents developed before PISA 2025, we questioned whether our curriculum contexts prepared students for PISA. That is, are PISA 2025's knowledge, context, and science identity components appropriately represented in Taiwan's curriculum guidelines (2019) and Manitoba's curriculum framework (2000)?

Study Design

The curriculum documents of Taiwan and Manitoba share a similar structure, both using lists of verb-centric outcomes. The Taiwan document has 255 specific learning outcomes, and the Manitoba document has 375. Both curriculum documents include multiple, content-focused units/topics and separate sections with outcomes intended to be woven throughout the course(s). In Manitoba, these separate sections focused on science inquiry, the design process, and scientific literacy. In Taiwan, these separate sections focus on scientific attitudes, inquiry, and cognition and on those aspects of science across content-topics.

Figure 1. PISA 2025 Framework (OECD, 2023, p.11)

Document analysis (Bowen, 2009), specifically content analysis, was used to evaluate the curriculum documents. PISA 2025 served as our a priori framework. Based on the "outcomes of science education" proposed in PISA 2025 (Figure 1), this study analysed each item in Taiwan and Manitoba grades 7-9 science curriculum documents; the PISA exam is taken in grade 9 in both countries, so we focused on grades 7-9. Each outcome item within the curriculum documents

was coded using the sub-frameworks describing the *types of knowledge*, *context*, and *science identity*; general descriptions of each of these sub-frameworks are provided in Figure 1. full descriptions available in PISA 2025. Items could represent multiple aspects under each of these sub-frameworks. For example, the outcome of "Investigate Canadian and international contributions to research and technological development in the field of genetics and reproduction (MB S1-1-16)" was coded as representing content-knowledge (life sciences), both local and global contexts, and science capital and epistemic beliefs.

To ensure inter-coder reliability, two researchers independently coded each document. Through an iterative process, results were compared and any discrepancies resolved through discussion.

Results

Codes were amalgamated and, where possible, compared to PISA 2025's expectations. Charts from each of these sections will serve as focal points for prompting discussion.

Knowledge

As shown in Figure 1, PISA 2025 labels knowledge as content, procedural, or epistemic knowledge. The knowledge content was further described by the systems of physical sciences (i.e., physics and chemistry), life sciences (i.e., biology), and earth and space sciences (i.e.., geology and astronomy). During our analysis, we noted that both documents were highly focused on content knowledge, so we chose to consider both the procedural and epistemic knowledge in terms of the physical, living, and earth and space sciences.

Table 1. Distribution of Knowledge Outcomes.

		Content	Procedural	Epistemic
Physical	PISA	15-20%	10-13%	8-11%
	MB	27.7%	4.5%	2.9%
	TWN	41.2%	0.0%	0.4%
Living	PISA	15-20%	10-13%	8-11%
	MB	16.0%	1.1%	1.3%
	TWN	27.8%	0.4%	2.0%
Earth & Space	PISA	10-15%	7-10%	7-10%
	MB	10.9%	1.1%	2.9%
	TWN	21.6%	0.0%	1.6%
Content General	MB	7.7%	1.9%	1.1%
	TWN	3.1%	1.6%	2.0%
Not Content	MB		15.5%	9.3%
	TWN		7.1%	3.9%

Further, some outcomes in both documents did not address knowledge specific to physical, living, or earth and space science but did address some type of content knowledge in science as defined by PISA 2025 (pp. 24-26); hence, we added a knowledge type, "Content General". For instance, the outcome "The process and applications of various materials in life (TWN Mc-IV-3)" illustrates procedural understanding that pertains to general science rather than any specialized subject.

On the other hands, some outcomes did not connect to content knowledge but connected to procedural or epistemic knowledge; we identify these outcomes as "Not Content". For example, the outcome "Students can properly connect acquired knowledge to observed natural phenomena and experimental data, in order to make inferences, see correlations, and justify their arguments (TWN tr-IV-1)" demonstrates how to link phenomena and data to scientific claims. This reflects a deep understanding of methodology and epistemology, independent of specific content knowledge.

Table 1 (above) presents the distribution of outcomes for knowledge in both curriculum documents, Manitoba (MB) and Taiwan (TWN). PISA 2025 defines target distributions for the assessment of knowledge (OECD, 2023, p. 43), see left-most column under each physical, living, and earth and space knowledge in Table 1.

Table 2. Distribution of Context Outcomes.

		Personal	Local/National	Epistemic
Physical	MB	1.3%	0.5%	0.5%
	TWN	1.9%	0.0%	0.3%
Living	MB	1.6%	1.9%	2.7%
	TWN	1.3%	1.9%	2.9%
Earth & Space	MB	0.0%	1.6%	1.3%
	TWN	0.3%	2.4%	1.6%
Content General	MB	0.3%	0.3%	0.5%
	TWN	0.5%	0.0%	0.0%
Not Content	MB	4.8%	2.9%	2.4%
	TWN	1.1%	0.5%	0.8%
Total	MB	8.0%	7.2%	7.5%
	TWN	5.1%	4.8%	5.6%

Science Identity

PISA 2025 does not explicitly state the expected distribution of science identity. Schiepe-Tiska et al.'s (2016) identity assessment framework suggests that the four dimensions of science identity

are equally important. Similar to context results, we present PISA 2025 aspects of science identity and the aspects of content knowledge as percentages of total outcomes (Table 3).

Table 3. Distribution of Science Identity Outcomes.

		Science Capital	Epistemic Beliefs	Attitudes & Dispositions	Environmental Awareness
Physical	MB	0.8%	0.3%	0.3%	0.3%
	TWN	1.2%	1.2%	0.0%	1.2%
Living	MB	0.5%	0.3%	0.0%	1.9%
	TWN	0.8%	3.1%	0.8%	9.0%
Earth & Space	MB	0.3%	0.0%	0.0%	1.1%
	TWN	0.4%	0.4%	0.0%	5.5%
Content General	MB	0.0%	0.0%	0.0%	0.8%
	TWN	1.2%	0.8%	1.2%	0.0%
Not Content	MB	2.9%	3.7%	5.6%	2.7%
	TWN	3.1%	3.1%	2.0%	0.4%
Total	MB	4.5%	4.3%	5.9%	6.7%
	TWN	6.7%	8.6%	3.9%	16.1%

- Standard Deviation for total: MB(1.1%), TWN(5.2%)

Discussion

Both Manitoban and Taiwan documents focus on preparing students for content knowledge rather than procedural or epistemic knowledge. The Taiwan document had a higher percentage than PISA 2025 expectations in every knowledge content area; the physical science content representation (41.2%) doubled the expectation of PISA 2025 (15-20%). Manitoba also focused on physical science knowledge. Both documents' inclusion of non-content-knowledge outcomes may have skewed percentages.

The distribution of outcomes representing each content area in both documents exceeded PISA 2025 expectations. However, the heavy weighting of the content knowledge in both the TWN and MB curriculum documents suggests a heavy focus on science as content in education. This was particularly evident in both contexts heavily emphasizing physical science, with TWN having over 40% and MB having almost 30% of their outcomes reflecting physical science content. This emphasis on content knowledge is inadequate to develop the necessary informed epistemic trust needed by students today to sift through the misinformation bombarding their lives today (Osborne & Allchin, 2024). It is with this in mind, that we recognize that while both TWN and MB students may be exposed to the knowledge content necessary to succeed with PISA 2025, we contend that neither curriculum document may be adequately preparing students for the entirety of PISA 2025.

Both documents had low representation of procedural and epistemic knowledge. Manitoba's document showed a higher representation of procedural knowledge than Taiwan's document. Procedural outcomes in both countries were often not connected to science content. Taiwan's document focused more on epistemic knowledge in relation to living sciences and general content knowledge than Manitoba, with Manitoba having higher representation in all other areas. Both documents were below PISA 2025 expectations. We conclude students from both countries should be prepared to answer content-knowledge questions but may be underprepared in procedural or epistemic knowledge.

Neither country had ratios reflecting the context expectations of PISA 2025. Both countries represented personal, local/national, and global contexts relatively evenly whereas PISA 2025 includes a much higher representation of local/national settings. Manitoba had more outcomes connected to each of the three contexts than Taiwan. Taiwan's document showed slight preference towards global contexts and Manitoba's document toward personal context, possibly due to the values toward community held in each context. Consequently, Manitoban students may be slightly more comfortable recognizing science in context than Taiwanese students.

Finally, PISA does not have expected distribution of science identity aspects, but Schiepe-Tiska et al. (2016) suggest equal distribution among each of the aspects; the standard deviation of science identity aspects for Manitoba was 1.1% and Taiwan was 5.2%. This suggests a relatively equal distribution of aspects in the Manitoban document but not in Taiwan's document. Taiwan's document focused on science capital, epistemic beliefs, and environmental awareness more than Manitoba. Taiwan's document emphasizes environmental awareness strongly in relation to both living (9.02% of outcomes) and earth and space (5.49% of outcomes) science; Taiwan is an island nation, and this may be because the impacts of climate change are felt more severely. Manitoba's document focused more on attitudes and dispositions than Taiwan, but very few outcomes connected to any aspect of science identity and content knowledge. We expect Taiwanese students to be more prepared in terms of science identity, particularly environmental awareness.

We conclude that both the Taiwan and Manitoba documents reflect the expected content-knowledge of PISA 2025—in many areas these expectations were exceeded—but are lacking in all other aspects. Of particular concern is the low representation of epistemic knowledge; this is representative of the literature on the inclusion of epistemic knowledge in science education (Zetterqvist & Bach, 2023). Science education prepares citizens for an increasingly uncertain world (Covitt & Anderson, 2022); thus, epistemic knowledge is of more importance than ever, and we hope that future documents will address its underrepresentation.

Conclusion

This study opens discussion about how science curriculum documents may or may not prepare students for PISA 2025. PISA, in many countries, is used to judge the quality of a nation's science education (Zetterqvist & Bach, 2023). We, like many scholars (Au, 2022), recognize the problematic nature of preparing our students for a specific assessment like PISA. However, we argue that while PISA should not be relied upon as the sole indicator of educational quality, it nonetheless offers a valuable directional guide for curriculum adjustment and improvement.

In this light, the PISA 2025 framework provides a way to systematically evaluate the appropriateness of science curriculum documents for grades 7-9 students. Ultimately, this evaluation highlights that science education has evolved beyond a mere focus on content knowledge. To truly equip students with a scientist's mindset, necessary for navigating a rapidly changing future, curricula must go beyond the OECD's competencies and deeply incorporate the nature of science.

Acknowledgement

This work was financially supported by the National Science and Technology Council, Taiwan, under Grant Number NSTC-114-2922-I-110-044. We are grateful to the two anonymous reviewers for their detailed and helpful suggestions. Additionally, we appreciate the insightful questions and feedback provided by the attendees during the conference, which helped refine the ideas presented in this study.

ESERA 2025 Copenhagen

Dynamic Equilibrium In Science: Comparison Between The Israeli And United States Frameworks And Representations In The Standards And Textbooks

Tamara Dawud[1], Sebahat Gok[2], Sharona T. Levy[1] and Uri Wilensky[2]
[1]University of Haifa, Israel
[2]Northwestern University, USA

The study examines how Dynamic Equilibrium (DE) is represented in science national standards and textbooks for high-school biology, chemistry, and physics in the US and Israel. DE, a crucial concept in understanding dynamic systems, is inconsistently represented across educational materials and students encounter difficulties learning about DE. Analysing 17 textbooks and national standards, the research combines quantitative and qualitative content analysis to assess the frequency and nature of presentation of DE-related phenomena. The study identifies 256 DE-related phenomena, comprising 14% of all phenomena that are studied in science. The primary systems approach used is System Dynamics, which focuses on stocks and rates of flow at one description level. The main representational format is verbal, and computational models are scarcely used. Differences across disciplines and between countries were found. These findings emphasize the need for powerful representations of DE to enhance students' understanding of dynamic systems and improve science education.

Keywords: Dynamic equilibrium; Science education; Systems thinking; Textbook analysis; Scientific representations; Cross-national comparison.

Introduction, Theoretical Perspectives, And Research Goal

This paper examines the concept of Dynamic Equilibrium (DE) in the US and Israeli high school science standards and textbooks, focusing on its role as a structuring concept across the natural sciences. DE is fundamental for understanding patterns in dynamic systems, describing systems that maintain stability through continuous balancing influences (Biology Dictionary, n.d.), such as homeostasis in biology, ecological systems, and chemical equilibrium. Despite its significance, DE remains a challenging concept for students, with difficulties arising from the contradiction between the system's stable appearance and the dynamic processes that maintain it (Sarıçayır et al., 2006). Students often struggle to understand stability as a dynamic process rather than static constancy, as seen in alternative concepts about chemical equilibrium (Nakhleh, 1992; Özmen, 2008) and homeostasis (Zion & Klein, 2015).

DE is analysed through systems frameworks like System Dynamics (SD; Forrester, 1961), Structure-Behavior-Function (SBF; Hmelo-Silver & Green Pfeffer, 2004), and Agent-Based Modeling (ABM; Wilensky & Rand, 2015). These frameworks focus on understanding system behavior and emergent patterns, helping students grasp the dynamic and parallel nature of equilibrium in complex systems. DE plays a key role in science education, particularly in the NGSS standards, which include Stability and Change as a crosscutting concept related to DE (NGSS, 2013). Proper instruction on DE fosters systems thinking and enhances students' understanding of complex processes across multiple levels of representation. The high school curricula in the US and Israel differ in structure. In the US, students are exposed to a wide range of subjects, with opportunities for specialization through programs like AP courses. In Israel, students specialize in one or two subjects, limiting exposure to other fields. Assessments also vary: in the US, GPA and standardized tests like the SAT or ACT are used, while in Israel, the Matriculation (Bagrut) exams focus on the chosen specialization subjects.

This study is part of a larger international project, which aims to develop better representations of DE to address the identified learning challenges. By comparing national standards and textbooks from both countries, we seek to understand how DE is structured, conceptualized, and conveyed within different educational contexts. The research excludes supplementary or external teaching materials. This research aims to compare how DE is represented in the science curricula and textbooks of the US and Israel and identify the DE-related phenomena and their representational formats. Additionally, it examines how different system frameworks are applied across subjects and countries. Through a cross-national analysis, this study seeks to uncover both expected and unexpected instances of DE in science education, with an emphasis on improving representations to enhance student comprehension of dynamic systems.

Methodology

The study analysed the content and representations related to DE in the main science textbooks and national standards of Israel and the US (Israel Ministry of Education, 2024; US NGSS, 2013; US National Research Council, 2012). A qualitative mixed-methods content analysis (Krippendorff, 2019; Schreier, 2012) categorized DE-related phenomena into seven representational formats: verbal, equation-based, graphical, tabular, photographic, illustrative, diagrams, and computational (e.g., simulations). “Phenomenon” is defined in the analysis as an object-involving occurrence, where an object (or system) undergoes a process, an event, or a state (Kaiser & Krickel, 2017). The analysis focused on the frequency of DE phenomena and the system frameworks used to describe them. This study does not encompass the entire student learning environment, acknowledging that lab work and external resources also play a role in student engagement with DE concepts.

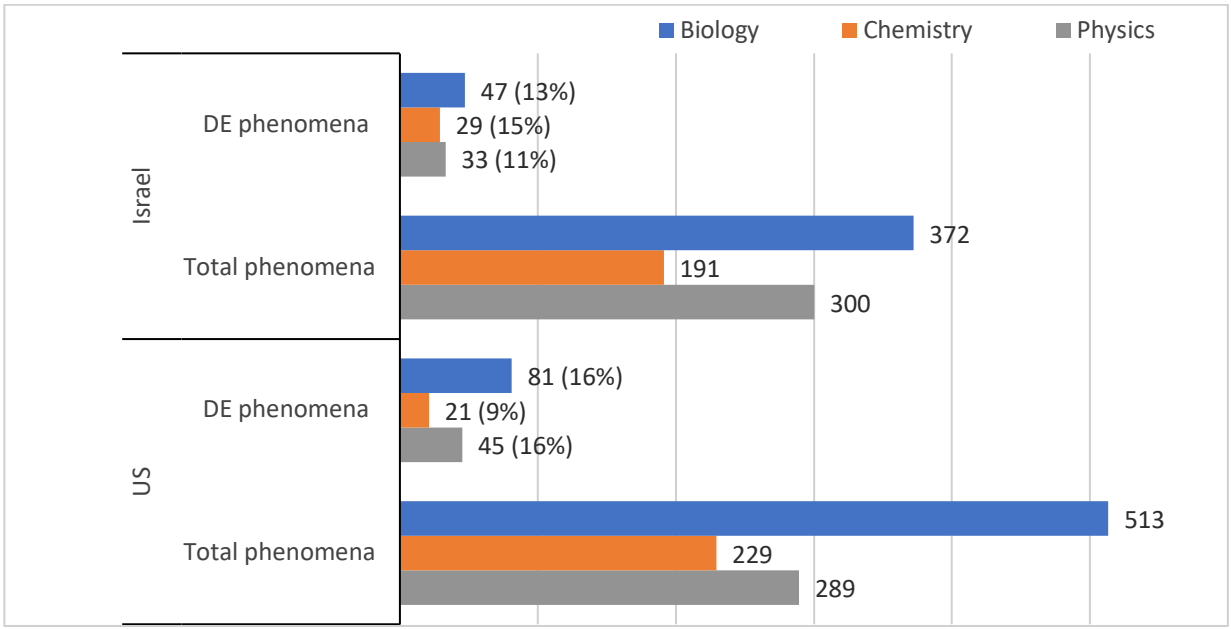
Findings

Content Of The Curricula

An overview of the high school science curricula in the US and Israel was conducted to identify overlap and facilitate comparison. The standards and textbooks’ topics were subdivided into content-based groups, aligning them as categories. The number of phenomena in each discipline in both countries was counted (see Figure 1).

In biology, the curricula in both countries cover similar topics, with some differences in emphasis. Key topics include cellular biology, human and animal biology, and ecological systems. Both countries address cell structure, organelle functions, and processes like respiration and protein synthesis. The US emphasizes substance transport, while Israel teaches fermentation and meiosis in cell division. Both countries teach human and animal biology, including body systems, physiology, and genetics. In ecology, both curricula cover ecosystems and human impact, with the US focusing more on energy flow and succession, while Israel emphasizes human impact and ecological organization. The primary difference is that the US includes evolution and biodiversity, topics absent in Israel.

In chemistry, the curricula in both countries align closely, focusing on similar principles, though differences arise in depth or emphasis. Topics include atomic structure, chemical bonds, energy changes, food chemistry, and chemical equilibrium. Both countries address oxidation-reduction, chemical reactions, and factors affecting equilibrium. The main differences are in the level of detail or emphasis in specific areas.



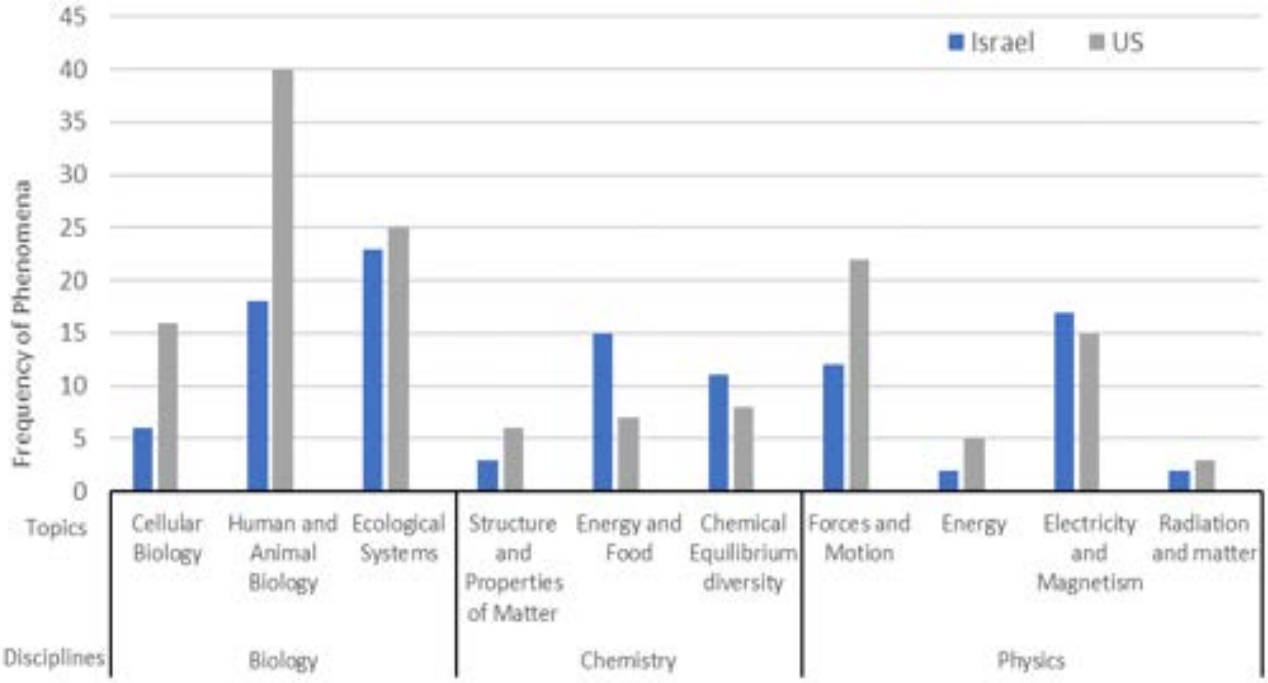
In physics, both curricula cover forces and motion, energy, electricity and magnetism, and radiation and matter, with some differences. For forces and motion, Israel emphasizes Newton's laws and momentum conservation, while the US focuses on force-mass-acceleration relationships

and real-world applications like collisions. Both curricula cover energy, with Israel focusing on mechanical energy and the US highlighting energy transfer and work-energy principles. In electricity and magnetism, both teach electric fields and Ohm's law, with Israel covering electromagnetic induction and the US emphasizing applications like circuits and power generation. In radiation and matter, both curricula address atomic and nuclear physics, with Israel focusing on atomic structure and quantum phenomena, while the US connects these topics to real-world applications like medical technologies. The differences lie in Israel's focus on foundational concepts and the US's emphasis on applications.

Identification And Counting Of DE-Related Phenomena

We identified phenomena embodying the principle of DE in the standards and textbooks, including those not explicitly defined as DE phenomena. The total number of phenomena and DE-related phenomena are shown by discipline (biology, chemistry, physics) for both countries (see Figure 1).

Figure 1. Frequency of All Phenomena and DE-Related Phenomena Across Disciplines (Biology, Chemistry, Physics) in the US and Israel Standards and Textbooks.



Overall, there are 256 DE-related phenomena across the three disciplines. In the US, 147 DE-related phenomena were identified, making up 14% of all phenomena. In Israel, 109 DE-related phenomena were found, representing 13% of the total. DE-related phenomena are most common in biology, followed by physics, then chemistry. In physics and chemistry, the total number of phenomena is similar between the two countries, but the US has a higher overall number of phenomena. The proportion of DE-related phenomena is greater in the US than in Israel for biology and physics, while in chemistry, Israel has a higher percentage of DE-related phenomena.

Distribution Of DE-Related Phenomena

We identified DE-related phenomena in the standards and textbooks, including those not explicitly defined as DE phenomena. Figure 2 shows the distribution by discipline and topic.The US and Israeli curricula align on half of the ten topics. However, the US includes more DE-related phenomena in forces and motion (physics) and cellular and animal biology (biology), while Israel emphasizes energy and food and chemical equilibrium (chemistry). Of the 256 phenomena examined, 11 describe chemical equilibrium, 27 address homeostasis, and 13 involve ecological systems, all traditionally linked to DE. Notably, 205 phenomena, representing 80% of DE-related

phenomena and 11% of all described phenomena, depict DE processes in topics not previously defined as DE-related.

Figure 2. Distribution of DE-Related Phenomena Across Disciplines (Biology, Chemistry, Physics) and Topics in the US and Israel High School Textbooks.

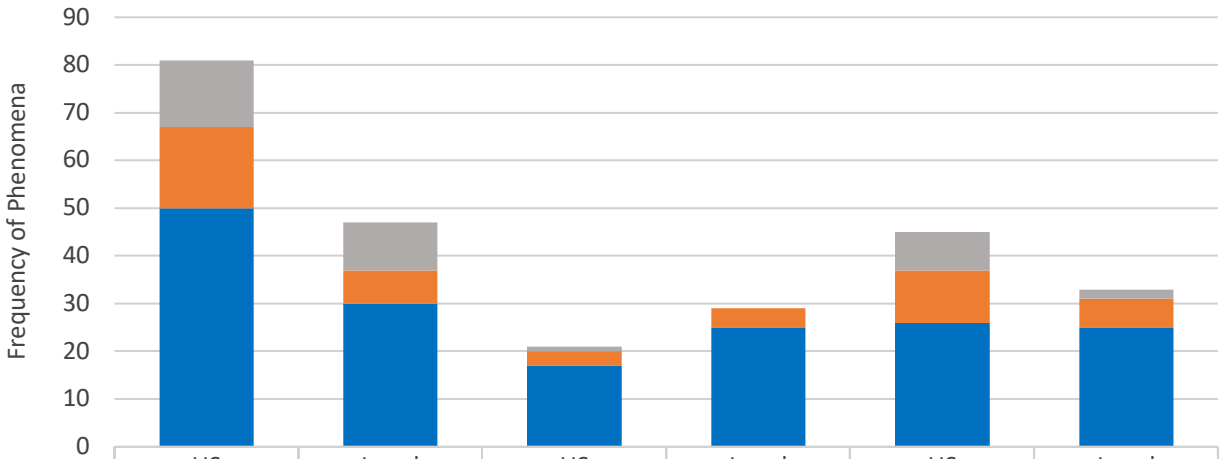
DE Representations' Format

In future research, we will develop and explore new computational representations for DE. The study examined the prevalence of various representation formats in DE-related phenomena within US and Israeli textbooks, categorized as verbal, mathematical, graphical, tabular, photographic, illustrative, diagrammatic, and computational models (see Table 1).

Table 1. Format of Representations of DE-related Phenomena According to Textbooks in the US and Israel.

			Representation Format (% of N)							
Discipline	**Country**	**Phenomena (N)**	Model	Diagram	Illustration	Photograph	Table	Graph	Equations	Verbal
Biology	UA	81	18	26	48	13	1	5	6	100
	Israel	47	0	42	38	27	22	27	9	100
Chemistry	US	21	0	25	63	17	8	25	79	100
	Israel	29	3	0	11	0	24	29	34	100
Physics	US	45	0	20	76	20	4	31	73	100
	Israel	33	0	8	82	10	8	13	62	100

The study examined the prevalence of various representational formats in DE-related phenomena within US and Israeli textbooks, categorized as verbal, mathematical, graphical, tabular, photographic, illustrative, diagrammatic, and computational models. Overall, the frequency of representation formats follows the order: verbal > illustration > mathematical > diagram > graph



> table > computational model. Israeli biology textbooks feature six representation types in at least 20% of sections, compared to three in US textbooks. In physics, US textbooks include six types at this level, versus three in Israel.

Representations' Systems Framework

We analysed textbook explanations by systems frameworks: System Dynamics (SD), Structure-Behavior-Function (SBF), and Agent-Based Modeling (ABM). Explanations were coded using seven dimensions: behaviors and properties of components (ABM, SBF), randomness (ABM), interactions between components (ABM, SBF), functions (SBF), heterogeneity of entities (SBF), and stocks and rates (SD). These dimensions helped identify the frameworks in DE explanations (Figure 3).

SD dominates across disciplines with 173 phenomena, while ABM appears in 48 and SBF in 35. In biology, SD is most common, with ABM and SBF appearing less frequently. Chemistry is dominated by SD, with minimal ABM and almost no SBF, especially in Israel. In physics, SD is again prevalent, with ABM more frequent than SBF.

Figure 3. Frequency of System Frameworks (SD, ABM, SBF) Representing DE-related Phenomena Across Disciplines (Biology, Chemistry, Physics) and Countries.

	Biology		Chemistry		Physics	
	US	Israel	US	Israel	US	Israel
SBF	14	10	1	0	8	2
ABM	17	7	3	4	11	6
SD	50	30	17	25	26	25

Discussion

The research is part of an international project focused on developing representations for DE, a central idea in science that describes how stable patterns form in dynamic systems. It examines the representation of DE in high school science curricula and textbooks in the US and Israel, comparing the content across biology, chemistry, and physics. Key objectives include exploring how DE phenomena are presented and represented through various tools such as graphs, illustrations, and computational models, while analysing differences across disciplines and countries. The study also investigates the use of system approaches like System Dynamics (SD), Agent-Based Modeling (ABM), and Structure-Behavior-Function (SBF) in explaining DE phenomena. Findings reveal that DE-related phenomena make up approximately 14% of the curricula, though many are not explicitly defined as DE-related. Significant differences in the curricula were noted, such as the emphasis on evolution in US biology education versus its exclusion in Israel, influenced by social and cultural factors (Plutzer et al., 2020). Students often struggle with understanding DE due to difficulties in connecting microscopic interactions to

macroscopic phenomena (Wilensky & Resnick, 1999; Friedler et al., 1987). Computational models, though scarce in current curricula, are identified as valuable tools for enhancing systemic understanding of DE. The study emphasizes the prevalence of SD for describing quantitative relationships in chemical and physical phenomena, while ABM is more suited for illustrating bottom-up interactions in biology and physics. SBF, primarily used in US biology and chemistry, connects the structure, behavior, and function of systems. The research concludes with recommendations to develop unified representations of DE that are adaptable across disciplines, enhancing consistency and comprehension. Future studies should explore DE's integration with other scientific concepts and its application to additional fields beyond biology, chemistry, and physics. This effort could expand the educational impact of DE by addressing its complexity through universal frameworks that bridge various scientific domains.
