Can Climate Literacy be taught in Special Education in Greece? Possibilities offered by science textbooks in upper high schools

Zisis Lampoudis and Athanasios Mogias
Democritus University of Thrace, Department of Primary Education, Greece

As we are already reaching the end of the first quarter of the 21st century, one would expect more progress toward addressing climate change issues, especially after almost four decades of discussions. Despite the admittedly many efforts carried out all these years, these have proven rather unsuccessful. A basic tool modern society has at its hands but does not seem to have made good use of, is the cognitive and emotional preparation of students within formal education to face this reality. Although several years have passed since climate issues entered the international debate regarding formal education, there is still an equally important field, Special Education, where no corresponding interest has been shown. A key element of education is the design of modern curricula and the selection of appropriate, up-to-date textbooks to overcome climate change challenges. That said, this study aims to investigate the presence of climate change issues in Greek Special Education high school (grades 10-12) science textbooks based on the recently updated version of the Climate Literacy Guide. Content analysis concerning textual and pictorial materials of three book series, namely Biology, Chemistry, and Physics, was used for this purpose. Results reveal that the textbooks under study contain rather inadequate and fragmented information concerning the eight essential principles and the seventy-six fundamental concepts of the Guide. The conclusions from the present study could help curriculum designers, textbook authors, and climate scientists collaborate toward the inclusion of Climate Change Education topics into national curricula.

Keywords: Climate Literacy, Special Education, High school science textbooks

Introduction

In recent decades, humanity has faced an onslaught of extreme weather events that threaten its survival, the economies of states and households, and the lives and safety of citizens. These unprecedented phenomena occur violently, have duration and intensity, and modern societies seem incapable of preventing them despite their enormous technological development. The latest report of the Intergovernmental Panel on Climate Change (IPCC, 2023) reveals that human activities, mainly through greenhouse gas emissions, have unequivocally caused global warming. This has led to widespread adverse impacts and related losses and damages to nature and people, although adaptation and mitigation strategies have progressed across all sectors and regions. The United Nations Framework Convention on Climate Change is the first official tool of international law that recognises the problem of climate change and its interconnection with anthropogenic greenhouse gas emissions. However, almost four decades after the signing of this and other respective agreements, global greenhouse gas emissions are still rising rapidly.

In this respect, the need for global climate change education was already reflected in the early ’90s (Henderson & Holman, 1993). However, it was realised only at the end of the first decade of the new century with references to socio-constructivist approaches, conceptual change, and experiential learning (Pruneau et al., 2003), and later with the Agenda 2030 Framework, while key terms such as adaptation and mitigation also begun to associate with climate change education (e.g., Pruneau et al., 2010). According to Anderson (2010), climate change education seeks to teach an understanding of the causes and consequences of climate change, its impact,

and appropriate responses; it further fosters attitudes and motivations to make informed decisions and take responsible action.

This is the time when discussions about the necessity of creating a climate-literate citizenry led to a framework based on the experience of a similar effort (the Ocean Literacy campaign) that preceded a few years earlier. This framework, called Climate Literacy, originally consisted of 7 basic principles, supported by a set of 39 fundamental concepts (USGCRP, 2009) and was thoroughly updated based on current research in September 2024, now portraying 8 principles (Table 1) and 76 concepts (USGCRP, 2024). Climate Literacy is defined as the *understanding of how the climate system works, how human actions influence climate, and how climate influences people and other parts of the Earth system* (USGCRP, 2024). UNESCO (2009) describes this framework as an attempt to help people understand the effects of global warming while encouraging the change in attitudes and behaviour needed to take action on climate change.

Table 1. The Essential Principles of the Climate Literacy Guide.

Principle #1	**[How we know]**	Scientists understand the climate system through interdisciplinary observations and modelling
Principle #2	**[Climate change]**	Greenhouse gases shape Earth's climate
Principle #3	**[Causes]**	Burning fossil fuels and other human activities are causing the planet to warm
Principle #4	**[Impacts]**	Rapid warming and other large-scale climate changes threaten human and ecological systems
Principle #5	**[Equity]**	Climate justice is possible if climate actions are equitable
Principle #6	**[Adaptation]**	Humans can adapt social, built, and natural environments to better withstand the impacts of climate change
Principle #7	**[Mitigation]**	Reducing emissions of greenhouse gases from human activities to net zero by 2050 can help limit global warming and climate change impacts
Principle #8	**[Hope & Urgency]**	A liveable and sustainable future for all is possible with rapid, just, and transformational climate action

Although several years have already passed since climate issues entered the international debate and, therefore, became a topic of interest within the boundaries of formal general education, a corresponding interest focusing on Special Education does not seem to have been a similar concern for the experts of the field. UNESCO defines Special Education as the one designed to *facilitate learning by individuals who, for a wide variety of reasons, require additional support and adaptive pedagogical methods to participate and meet learning objectives in an education programme* (UIS, 2012). Even though significant research has been published concerning Special Education and science and/or environmental education, to our knowledge no respective research has been conducted regarding Special Education and climate issues in particular. A key element of education is the design of modern curricula and the selection of appropriate, up-to-date textbooks to overcome climate change challenges. This becomes even more imperative when addressing scientific issues within the framework of Special Education. Tracana et al. (2008) have reported that textbook analysis is an important parameter in implementing national educational objectives at the school level. Therefore, this study attempts to investigate the presence of the Climate Literacy basic principles and fundamental concepts according to the corresponding Guide in Greek Special Education high school science textbooks.

Materials and Methods

The corpus under study comprised three series of reading books, namely *Physics*, *Chemistry*, and *Biology* (Figure 1), all corresponding to compulsory courses in Greek upper high school grades 10-12 (15-18 years old), used in Special Education. Content analysis was selected based on both textual and pictorial material from the corresponding school manuals to evaluate the presence of

climate science issues according to the Climate Literacy Guide. With regard to the presence of climate sciences issues, both the manifest and latent content were examined, referring to both visible and underlying components of each passage of the text (e.g., Downe-Wamboldt, 1992). The unit of analysis and the construction of categories were also considered. Concerning the former, the "theme" was chosen as, according to Krippendorff (2004), thematic excerpts are rich in information and preferable to other kinds of distinctions; in terms of the latter, a deductive coding scheme (Stemler, 2001) was followed, as the 8 essential principles and 76 fundamental concepts of the recently updated Guide (USGCRP, 2024) constituted the categorical context for the respective analyses. In addition to the above, the validity and reliability of the procedure were also ensured.

Figure 1. The Special Education upper high school science textbooks under study.

Results

The present study revealed that although all Climate Literacy principles (CLps) are presented in Special Education upper high school science textbooks, twenty-six of the total seventy-six supporting concepts are lacking (Figure 2), while the existing ones are not entirely addressed, according to the corresponding Guide. Climate Literacy principle 2 referring to the greenhouse gases that shape Earth's climate, CLp 3 regarding the causes, CLp4 providing valuable information about the impact, and CLp7 concerning mitigation strategies are adequately covered in terms of the number of concepts for which information is displayed, and the number of references to these principles reflected in all textbooks (Figure 2). On the contrary, CLp1 referring to the fact that scientists understand the climate system through interdisciplinary observations and modeling, and CLp6 regarding adaptation strategies, seem to be the least representative both in terms of the number of concepts covered and number of references that appear in all science textbooks (Figure 2). In Figure 3 we can easily detect that almost the same Climate Literacy fundamental concepts are recorded in all three studied textbook series, although we observe a remarkable quantitative difference between the Chemistry textbooks on one hand and Physics and Biology textbooks on the other. More specifically, the textbook with the most relevant information, Chemistry, appears with 8 principles, 48 concepts, and 528 references in total,

followed by Biology (8 principles, 30 concepts, and 115 references), and finally Physics (7 principles, 33 concepts, and 55 references) (Figure 4). With regard to the grade level, grade 11 appears to be the richest in information with 8 principles, 48 concepts, and 344 references, followed by grade 10 and grade 12 (Figure 4).

Figure 2. Total number of Climate Literacy fundamental concepts in Special Education upper high school science textbooks.

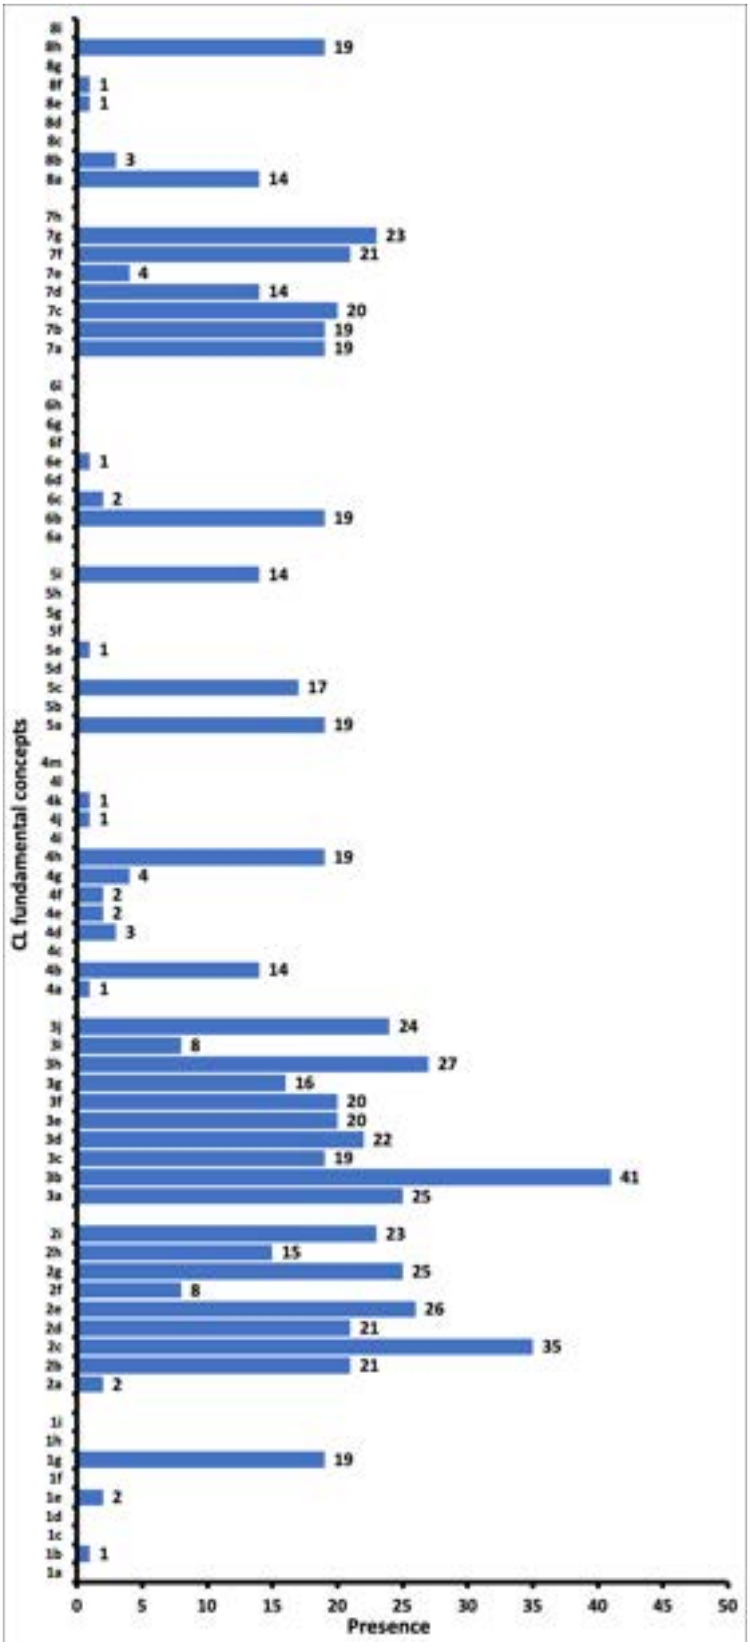

Figure 3. Total number of Climate Literacy fundamental concepts per science textbook.

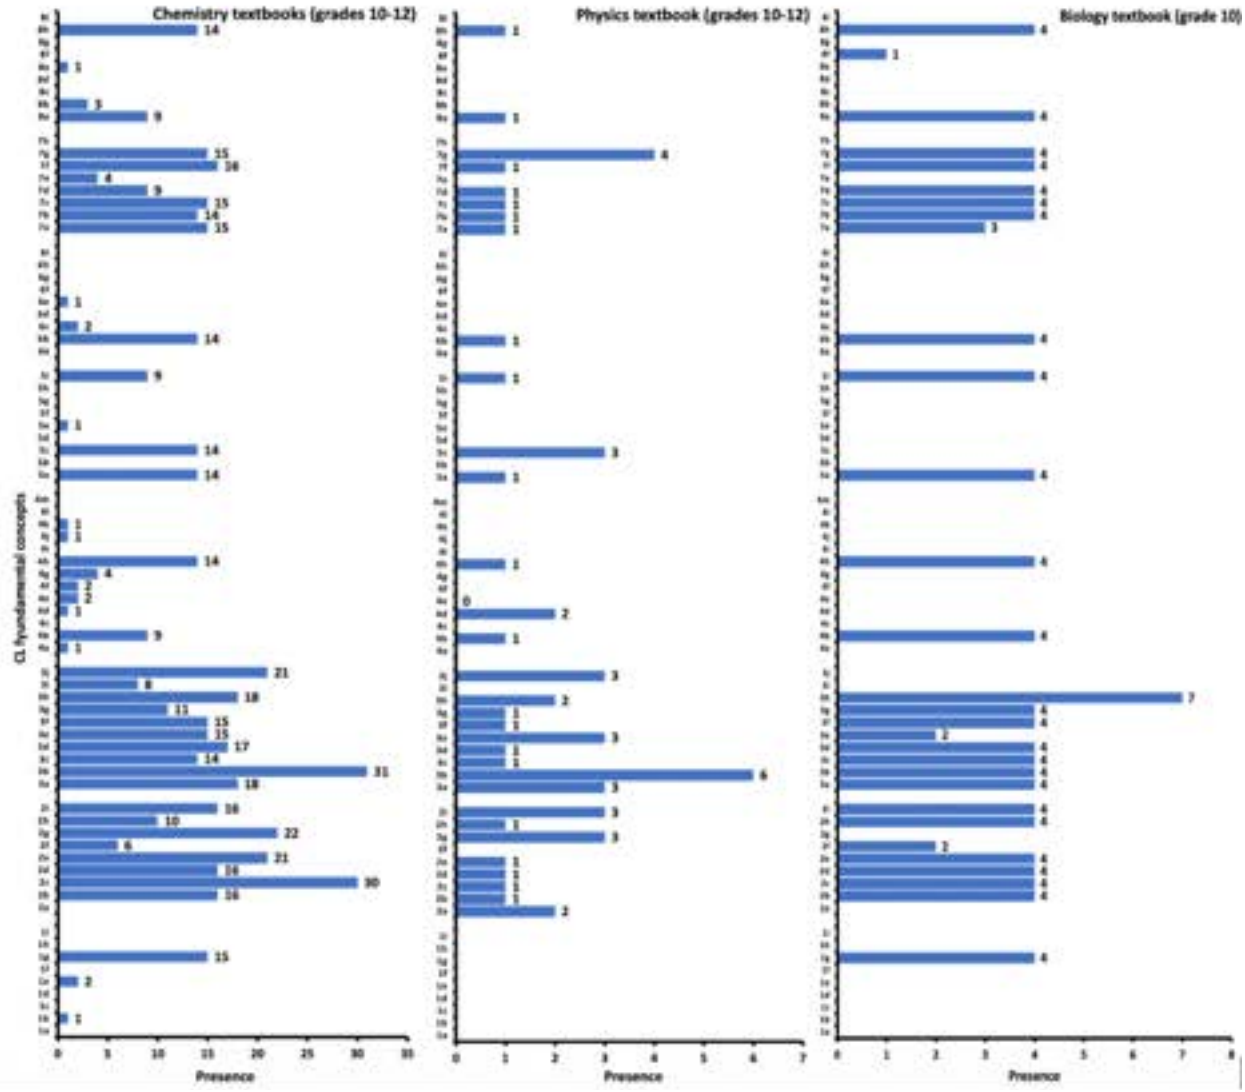

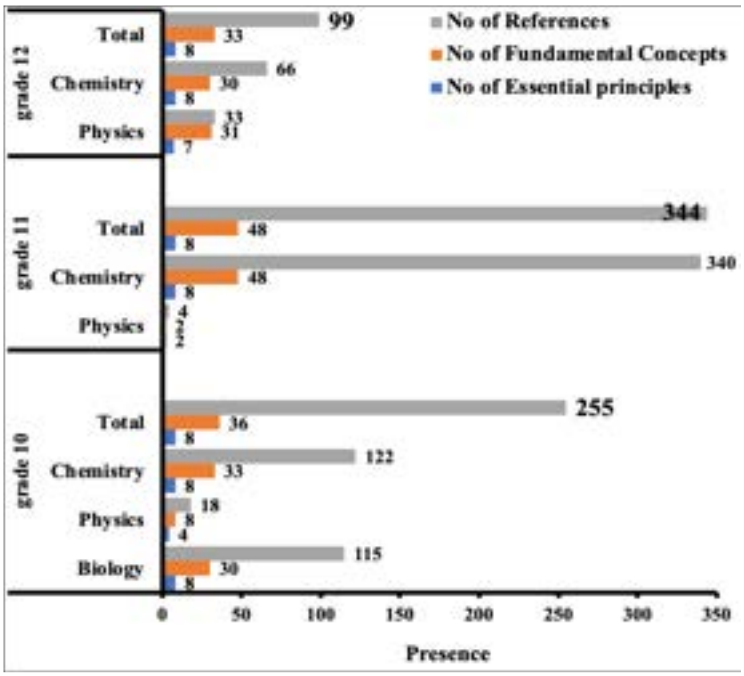

Figure 4. Number of Climate Literacy basic principles, fundamental concepts, and references per grade and science textbook.

Discussion

Content analysis of Greek science textbooks' textual and pictorial material revealed that although all eight essential principles and some aspects of many fundamental concepts of the recently updated Climate Literacy Guide (USGCRP, 2024) are mentioned in the Special Education upper high school (grades 10-12), nevertheless these are only partially covered, making the relevant information rather superficial and fragmentary. Most principles and concepts are found in Chemistry, while grade 11 appears well-stocked in pertinent information. Important issues such as, among others, the distinction between climate and weather, climate variability, exposure of marginalized and low-income populations to climate hazards and associated health problems, climate impact on businesses, governments, and economies, necessary shifts in institutions, behaviours, and values, the demand of huge financial investments in new technologies, infrastructure, and education are missing, making climate change education rather unpromising for upper high school students enrolled in Special Education settings. Furthermore, the existing information seems to be rather inappropriately presented, as the degree of difficulty exceeds the cognitive capabilities of students with special needs.

Although research on climate change education has thrived over the last 15 years, to our knowledge, relevant issues are not currently included in national curricula or school textbooks. As a result, we cannot reliably assess the impact of the Climate Literacy framework on formal education systems worldwide. Moreover, it appears that no scientific interest at all exists in making climate change education more inclusive by incorporating it into Special Education. It seems that either this innovative framework has not been properly communicated, particularly to policymakers, or we have not fully grasped the critical need to introduce this knowledge to modern society. As the USGCRP (2009) elegantly states, only "*a climate literate person understands the essential principles of Earth's climate system, knows how to assess scientifically credible information about climate, communicates about climate and climate change in a meaningful way, and is able to make informed and responsible decisions regarding actions that may affect climate*."

The latest IPCC report (IPCC, 2023) is undeniably clear about the causes of climate change and the anticipated consequences if adaptation and mitigation measures are not implemented immediately. Drawing inspiration from a recent book by Gates (2021), we must achieve something monumental; we need numerous groundbreaking discoveries in science and engineering, we need to reach consensus where it currently does not exist, and we need to design government policies that will accelerate a transition that would not happen otherwise. None of these will be accomplished if we do not make climate change education an integral part of our national education systems, and the Climate Literacy Guide can serve as a solid foundation for student awareness in formal education.

In conclusion, the above mapping could help curriculum designers, textbook writers, classroom teachers, and climate scientists successfully integrate Climate Literacy issues into current educational systems.

The Science Curriculum as a Vehicle for Climate Change Education: A Cross-Country Project

Russell Tytler[1], YingShao Hsu[2], Maija Aksela[3], Peta J. White[1], Joseph Paul Ferguson[1], Amrita Kamath[1], Shefali Sharma-Wallis[1], Fernanda Rezende[1], Pilvi Sihvonen[3] and Veera Uusi-Äijö[3]

[2]National Taiwan Normal University, Taiwan
[3]University of Helsinki, Finland

Climate Change Education (CCE) is an increasing focus of global curriculum advocacy, as countries come to terms with the future threats posed by the Anthropocene polycrisis and the need for an informed citizenry that can make critically informed and responsible decisions. Given the crucial role of science in monitoring and responding to Anthropogenic Climate Change, the Sciences are of crucial importance to CCE, yet to date education systems have been slow in taking this up. The recent OECD PISA 2025 Science Framework places fresh emphasis on students' critical evaluation of evidence to make informed decisions in relation to socio-ecological challenges, advocating a focus on student decision making, action, and agency. This symposium represents selected explorations in a cross-country project focused on enacting CCE within Science curricula consistent with these ideas. The three explorations map out the potential to productively include CCE in these subjects, through 1) a cross-country survey of teachers' knowledge, practice, and confidence of CCE, 2) a cross-country analysis of the structure and amount of ACC content in middle years textbooks in the science disciplines, and 3) co-design research with a primary school science specialist exploring how best to infuse CCE into a traditional science curriculum across multiple topics. The set of three explorations identify systemic constraints on the infusion of CCE, but provide confidence that the conditions exist with teachers, students, and education system commitments and resources for expansion of science curricula to contribute to CCE.

Keywords: Climate Change Education, Teacher learning, Curriculum

Introduction

We are living in an epoch of human induced Climate Change (CC) (Lee et al., 2023), the 4th industrial revolution (Schwab, 2016), and the 6th mass extinction (Dirzo et al, 2014) - the Anthropocene (Lewis & Maslin, 2015). There are urgent calls for education to focus on developing students' knowledge and agency with respect to the global socio-ecological challenges of CC These issues have been well represented in the fields of *Environmental Education* (EE) and *Education for Sustainable Development* (ESD) for decades, and as the cross-curriculum priorities in a number of countries. Currently, increasing urgency in the scale and global nature of impacts have encouraged the formulation of CCE that better represents the climate science, societal impetus, and social impacts and that integrates more directly with school disciplinary subjects. CCE is different from either EE or ESD (Monroe et al., 2019; White et al., 2024) in referring to key content and concepts associated with the complex interactions of climate science and the social systems that have generated unprecedented and significant impact on all Earth systems (OECD, 2019).

Calls for the development of a systematic CC Education (Academy of Social Sciences in Australia [ASSA], 2023) have slowly been taken up by most systems (Dawson et al., 2022; Roussel et al., 2020), reprising challenges in incorporating Education for Sustainability (EfS) as a core commitment (ASSA, 2023). CCE, while related to EfS, brings new elements of science into focus, as well as enhancing temporal and global spatial dimensions concerned with

interconnected Earth systems. In contemporary scientific research and development, CC related initiatives are increasingly important, identifying interruptions to Earth systems; investigating the interconnections between global systems to build increasingly complex climate models; monitoring temperature and the effects of global temperature rise; designing climate mitigation approaches; developing technologies for the transition to low carbon energy systems; and understanding climate related events (Lee et al., 2023).

The OECD PISA 2025 Science Framework (OECD, 2023) is a transformative document in expanding the remit of science education to prepare students not only to explain and engage in the traditional knowledge building practices of science, but to develop the competency to *research, evaluate and use scientific information for decision making and action*. The strong environmental science agenda has been introduced into the Science Framework, informed by the companion document 'Agency in the Anthropocene' (White et al., 2023; 2024), to further interpret and expand the competencies such that 15-year-olds should be able to:

1. Explain the impact of human interactions with Earth's systems.

2. Make informed decisions to act based on evaluation of diverse sources of evidence and application of creative and systems thinking to regenerate and sustain the environment.

3. Demonstrate hope and respect for diverse perspectives in seeking solutions to socio-ecological crises.

Thus, what has been mainstream in EE and EfS has now been recognised within the science framework as an important aspect of a mainstream science education, going beyond explanation, interpretation and engagement in core science practices to consider science knowledge and practice related to the socio-ecological challenges of the Anthropocene (White et al, 2024).

This paper describes the developing research agenda of a cross-country research project 'Enacting Climate Change Education (ECCE) through representing Scientists' Practice' (ECCE, 2025) that responds to the agenda enabled by the OECD PISA Science Framework 2025. ECCE involved science education researchers from Australia, Finland and Taiwan co-designing teaching and learning sequences that infuse CCE with teachers and with scientists' input into the science curriculum. An emphasis on student knowledge, dispositions and decision making and action leading to student agency as envisaged in 'Agency in the Anthropocene' was the priority. The explorations described are structured to explore the possibilities and potential pathways for the much needed substantial infusion of ACC into the science curriculum (Dawson et al., 2022). The set of three explorations represent preliminary scoping work for the project, which investigate: 1) teacher engagement with ACC; 2) textbook representation of ACC across the three countries, and 3) an Australian example of a Design Based Research approach with teachers to explore the possibility of infusion of CCE into a full year's science curriculum.

Exploration 1: Teacher Knowledge, Practice, And Confidence In CCE: A Cross-Country Comparative Analysis

In any major curriculum reform agenda, teachers are key. This is particularly the case with contexts such as climate science where the complexity of interacting Earth systems are impacted by social priorities and practices resulting in socio-ecological challenges. Not only is the science contemporary and situated, but essential to addressing socio-ecological related crises are the complicated relationships between human behaviour, technologies and environmental degradation. Teachers of science thus need to extend their science knowledge by drawing on contemporary research, but also complex socio-ecological dynamics underpinning. Thus,

teachers, and teacher professional learning is critical to enacting a CCE curriculum in science (Tytler & Freebody, 2023).

Methodology

A Qualtrics online survey was administered to secondary school teachers of Science and Humanities, invited through online invitations through teacher organisation in each country. The questions were translated into the three languages and cross checked by the team. Participant numbers were 67 in Australia, 68 in Finland, and 86 in Taiwan. Survey participants were mostly secondary teachers, mostly teaching science.

The survey consisted of 23 questions of mixed type, focusing on the following aspects of teachers' experience with CCE: knowledge of CC phenomena; perceptions and confidence in relation to CCE; the nature of their CCE practice in terms of the degree of embeddedness, nature of focus; resources and engagement with climate scientists; degree of support; reasons for teaching/not teaching CCE; the nature of outcomes that should drive CCE; the urgency of including CCE in the curriculum.

Analysis

The reliability of the questions was tested using Cronbach's alpha. The results revealed that most of the questions showed high reliabilities (alpha > .90), excluding two questions. Questions with a single sub-item or "yes or no" questions were excluded from calculating Cronbach's alpha. Analysis of the data mainly used descriptive statistics, but cross-country comparisons involved an ANOVA analysis to identify significant differences in response patterns. Extended responses were thematically analysed and verified by team discussion.

Results

Attention to CCE: The responses to the question 'Is CCE embedded in your teaching' yielded a distinct hierarchy in 'yes' responses: Taiwan 86%; Finland 98% and Australia 67%. This reflected curriculum histories in the three countries, with Taiwan including CCE since 2018 and Australia only since 2022 in a limited way. This hierarchy was reflected in many of the question responses.

Knowledge of CCE: Despite the difference in practice, teachers across the three countries expressed strong knowledge of 'the scientific explanations for CC', 'the role of human impacts of CC, and 'the impacts of CC on the environment and on humans', with mean scores in each case above 4.2 on a 5-point scale. Knowledge of 'approaches to CC mitigation at the personal and societal level' were equally strong for Finnish and Taiwanese teachers but significantly lower for Australia ($p=0.004$). Knowledge of 'the way individuals and societies must adapt everyday practices' was strong for Taiwan, but significantly lower for Finland and Australia ($p=0.0001$). The picture of teacher knowledge is thus strong overall, but with significant gaps in responses to CC reflecting curriculum histories.

Confidence in aspects of teaching CC: Teachers across all countries expressed confidence (mostly 4 on the 5-point scale) about a variety of aspects of teaching CC, generally without significant differences, including: 'I welcome learners' questions about C'; 'Although this is a complex topic, I feel prepared to teach it'; 'I know how to effectively address learners' misconceptions related to CC' (slightly lower score); 'I am able to use local and global examples to teach about CC.'

Knowledge of key terms and phenomena: In an exploration of teachers' understanding of terms related to CC (e.g., tipping points, net zero), teachers from the three countries generally expressed

confidence in their knowledge of these terms. There were some differences with Australian teachers, for instance, showing significantly lower confidence in understanding 'Circular economy' than Finnish and Taiwanese teachers.

Outcomes of teaching CC: We asked what the main outcomes were when including CCE in science or humanities. Teachers' responses were diverse, but the key focus was empowering students to make appropriate agentic choices and to act accordingly. Teachers emphasised the urgency of teaching about the climate crises but discussed the importance of hope and positive attitudes. The significance of developing scientific literacy in students was highlighted. One teacher focussed her students proactively: "Agency, voice, the feeling that they can do something about it and making students active contributors in community science."

Resources: Teachers' responses indicated the use of a range of formal and informal resources that include textbooks, online materials, news articles, videos (specifically YouTube), social media and documentaries. Some teachers gave specific examples of websites and resources, others stated broad categories. The Australian teachers were significantly less confident in finding reliable resources for teaching about CC" ($F = 5.9635$, $p = 0.0030$).

Discussion

The survey uncovered patterns in both strength of response across countries, and difference between countries on particular aspects of CCE. Overall, the results are very encouraging in terms of supporting the agenda of widening the scope of the science curriculum in line with the PISA 2025 Science Framework (OECD, 2023) and its companion Agency in the Anthropocene document (White et al., 2023). Teachers generally expressed confidence, not only in their own knowledge in teaching the various dimensions of CC Science, but in engaging with students' perceptions and misconceptions about CC. In terms of outcomes of CCE, they focused on empowering students and on the development of student agency in making responsible decisions concerning climate related challenges.

The findings provide confidence that teachers are generally knowledgeable about and committed to a CCE agenda that focusses on student understandings, attitudes and actions. Teachers' preparedness to probe and negotiate with student perspectives and open discussions that attend to student voice is encouraging for establishing a curriculum agenda in science in line with advocacy of activities and content found in the CCE literature (Monroe et al., 2019; White et al., 2023; Academy of Social Sciences in Australia, 2023).

We interpret the difference between patterns of responses between the three countries through a lens of curriculum politics and national political landscapes. In general, the confidence of teachers, and particularly their access to resources, was strongest in Taiwan and weakest for Australian teachers. In Taiwan, Anthropogenic CC has been included in the core Science and Geography curricula since 2018, and textbooks are officially endorsed only if they reflect this (Taiwan Ministry of Education, 2018). In contrast, Australia only included CC in its curriculum in 2022, with inaction before that determined by a decade of CC Denial politics influenced by fossil fuel interests (Crowley, 2021). Nevertheless, Australian teachers are only recently entering this curriculum space, and their confidence and commitments are encouraging. Finland's in-between position is related to considerable support by the Finnish government promoting ecologically sustainable practices and strengthening learners' climate knowledge and skills (Hilldén et al., 2022).

Exploration 2: Representations Of Anthropogenic CC In Science Textbooks: A Cross-Country Comparative Analysis

In recognition of the importance that resources play in supporting Science teachers to embrace new topics, particularly those representing contemporary science and socio-ecological challenges associated with ACC, we analysed Science and Geography textbooks across the three countries; Australia, Finland and Taiwan. The analysis was framed to ascertain the proportion of the total curriculum in these subjects devoted to CCE, interpreted through the space devoted to ACC topics in each subject as a percentage of total textbook page area.

The research questions for this exploration are: 1) What is the percentage of textbook space devoted to anthropogenic CC in the core Science and Geography subjects across the secondary schooling years, and across subjects, in the three countries? 2) What different themes are represented concerning ACC, and what are their patterns of representation in the different subjects? 3) What can we learn, from this cross-country comparison, about the different ways ACC can be addressed through different subjects and topics? An account of the methodology and findings can be found in Tytler et al. (2025).

Methods

We used the Comparative Case Study (CCS) approach by Bartlett and Vavrus (2016), designed to examine varying contexts and scales. In comparing CCE content in lower secondary school textbooks from three countries, it allowed us to explore how each country addresses CC in their textbooks, considering both similarities and distinct features. We situated the analysis within the particular curricular contexts of each country, and also the wider policy landscape, to generate multidimensional insights into national distinctiveness and shared patterns in CCE across the three countries.

We developed a Framework consisting of a set of code categories and codes that was refined over a series of meetings and a substantive coding exercise by the Taiwanese team. A coding scheme was developed and refined through further comparative discussion. The flowchart of coding steps is shown in Tytler et al. (2025). The relevant inter-rater reliability exceeded 0.75 in each case.

The unit of analysis was a sentence or coherent section of the text, including figures and tables, related to ACC. For each such unit, the percentage of page area relating to particular codes was measured to the nearest 10%, and a running total collected to calculate the percentage of total text area devoted to ACC, and of that, the % area dedicated to each code.

The major coding categories, each of which consisted of multiple codes, were:

- Science and technology ideas (SI)
- Nature of science (NOS)
- Human-environment interactions relevant to CC (H/E)
- CC impacts on humans (CCI)
- Response to CC and environmental threats (SR)
- Principles around sustainable human environments and CC (SHE)
- Suggested activities (Act)

Within each of these categories were a set of distinct codes. The analysis identified the percentage of curriculum space for each of the Sciences, and Geography, dedicated to ACC, and within that the breakdown of coding categories and codes. The results represent a proxy measure of the extent of CCE embedded in each country's Science curriculum.

Information about the curriculum context for each country, including the relationship of textbook design to the formal curriculum, the degree of autonomy allowed for writers and teachers, and the broader CCE policy context, allowed interpretation of findings in terms of curriculum policy.

Findings

The percentage area of text related to anthropogenic CC across the Science and Geography curricula varied between the countries: 2.7% in Taiwan, 1.5% in Finland, and 0.7% in Australia. We identified the following contextual factors affecting these numbers: The explicit inclusion of ACC topics in the Taiwanese curriculum since 2018; the close association of textbooks with the formal curriculum in Taiwan supported by ratification processes; the autonomy of textbook writers, schools and teachers in Finland and Australia with respect to interpreting the curriculum; the existence of significant policy initiatives in Finland supported by resources for CCE inclusion in the curriculum compared to lack of tangible support for a 'Sustainability' cross-curriculum priority in Australia; the existence in Australia over the crucial 10 years prior to 2019 of significant CC denial politics spilling into curriculum 'culture wars'.

In terms of details of CCE representation, analysis showed significant differences in patterns by year level, indicating no agreed progression model for CCE.

Representation in different subjects: There are similarities but also significant differences in representation of CCE across the Science disciplines. The bulk of ACC content is covered by Earth Science and Geography. In Finland, Earth Science is part of the Geography curriculum. There is substantial representation of CCE in each Biology, Chemistry and Physics in at least one country, but considerable variation across the countries. Percentage distribution of anthropogenic CC content by subject discipline can be found as Figure 5 in Tytler et al. (2025). Thus, a case can be made that ACC content can be productively included in each of the disciplines, but this has not been uniformly taken up.

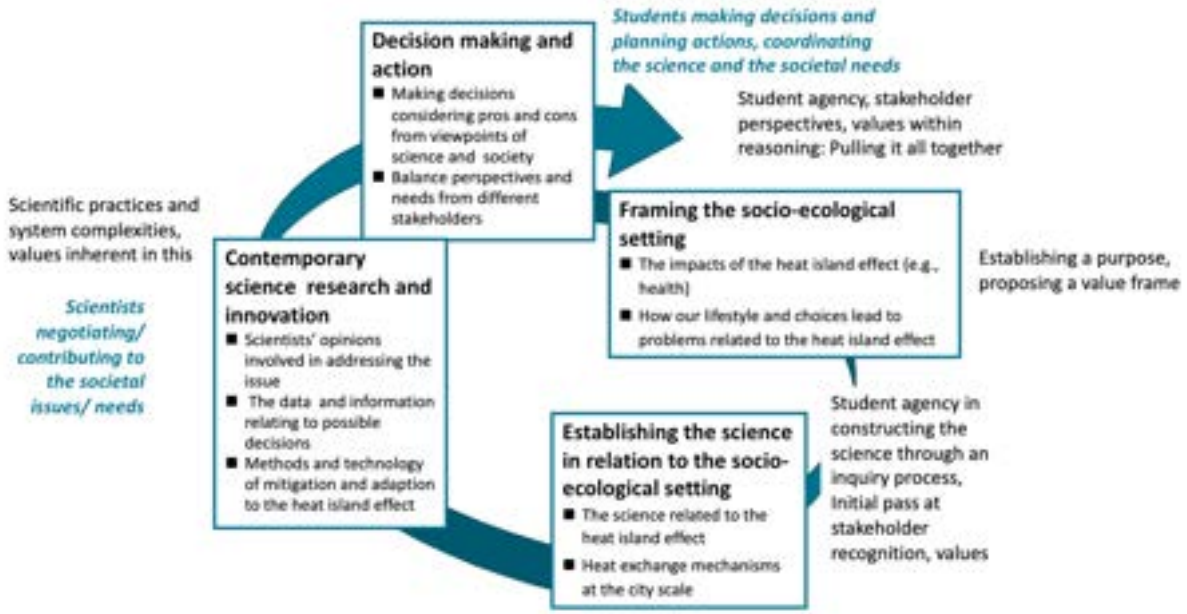
Patterns of code categories across the three countries: The bulk of textbook CCE presence in each country is the SI (Science and Technology Ideas) category representing 32-47% of ACC space. The Nature of Science (NOS) and Principles around Sustainable Human Development (SHE) codes are disappointingly small, particularly given the emphasis on NOS in contemporary science literacy advocacy. Variations from which we can learn include country differences in representation of CCI, SR and HE. Percentage representation of each of the major code categories is depicted as Figure 6 in Tytler et al. (2025).

The analysis reveals patterns in the representation of CCE in Science curricula which are significant for understanding curriculum enactments in this fast-changing field.

The positioning of ACC in the curriculum: The extent of CCE representation is related to the extent of explicit inclusion of ACC topics in the formal Science curriculum, with cross-curricular, interdisciplinary approaches leading to lower levels of representation. However, strong policy initiatives and resourcing are impacting positively in Finland, indicating a degree of political will that is missing in Australia that has compromised curriculum action.

The role of Science disciplinary subjects: Most CCE work is undertaken by Earth Science and Geography, between these accounting for over 60% of ACC content in each country. There was, however, smaller but significant ACC content in each of the Science disciplines that can point a way to greater representation of ACC in Science as advocated by the PISA 2025 Framework.

Widening the science curriculum to include socio-ecological challenges: Current research and curriculum advocacy in CCE focuses not only on knowledge and attitudes but on decision making and responsible action (OECD, 2023; Monroe et al., 2019). We argue that if the Science



disciplines are to be an important part of CCE, they need to include not only knowledge of systems and effects, but also human-environment interactions around socio-ecological challenges. Patterns of codes show each of these are included in at least some of the texts, giving confidence that Science writers accept this challenge. These cross-country differences present an opportunity to further explore what effective representation of CCE themes might include, as a contribution to advancing our understanding of the dimensions of a quality CCE-rich disciplinary curriculum (Tytler et al., 2025).

Project 3: Developing A Co-Design Model For Infusing CCE Into The Science Curriculum

The central intent of the ECCE project is to work with teachers to develop approaches to infusing CCE into the science curriculum to foster student agency.

Drawing on the experience of the researchers from the three partner countries (Australia, Finland and Taiwan), we developed a learning sequence design model (Figure 1) that leads from a socio-ecological challenge through establishing the required science knowledge, representation of current research, and finally to student consideration of decision making and action in relation to the challenge.

Figure 1: Learning sequence design model with illustrative examples referring to a simulation module on the heat island socio-ecological challenge in Taipei.

While the nature of co-design processes across the countries varies, each of the learning sequences is evaluated against student outcomes in terms of: knowledge (science of CC and human causes, processes for dealing with ACC and impacts); values (eco-justice, hope and resilience); decision-making and action (design approaches, commitment to acting, self-efficacy, engage with civic processes). In drafting sequences, strategies designed to support student agency are prioritised, which involves privileging student idea generation, decision making and action.

This exploration focuses on a particular co-design partnership with a specialist Year 5-6 science teacher in Australia, involving the entire year's science curriculum to infuse ACC related content while attending to the core science curriculum requirements. The research questions we addressed were: 1) What are the affordances and challenges of infusing CCE into the science curriculum? 2) What is the experience of a primary teacher of science, of co-designing CCE- focused curriculum sequences? 3) What student outcomes can be discerned from a year-long CCE infused science curriculum?

Methodology

In the project we utilise Design Based Research (Plomp & Nieveen, 2013) with a strong co-design approach, to generate draft classroom sequences that are negotiated with the teacher, and then iteratively refined both during the sequence and across sequences. Design research reflects a pragmatist epistemology by which theory development is grounded in interrogation of practice (Cobb et al., 2003).

To develop the draft Year 5-6 sequences, the research team drew on scientific expertise regarding, for instance, energy transition research, bushfire disaster expertise, and research into bees and environmental threats. For each topic the team consulted with the teacher concerning ACC links.

Evaluation of the sequences during the design cycle drew on: interviews with the teacher and students following each sequence; pre-and post-sequence written assessments; field notes and video capture of classroom interactions; capture of student work samples; and notes taken during planning and review sessions within the team and with the teacher.

Results

We discuss the results in the order of the research questions: the experience of infusing CCE into science curricular topics; the experience of the teacher in emphasising ACC; and student outcomes from interview and survey data.

Infusing CCE into the science curriculum: For the different science topics represented in the Victorian (Australia) curriculum the school follows, the possibility of infusing CCE varied considerably. However, it proved possible to use ACC as a significant context for teaching science content within each of the eight sequences we worked with across the two-year levels. Table 1 provides examples of some of the inclusions of CCE into these science topics, together with activities designed to support student decision making and agency.

Table 1: Examples of CCE infusion into traditional science topics

Science topic	CCE content based in science research	Activities focused on student agency
Energy transformation	The nature of transformations in renewable energy sources and electrification in the energy transition. Hydrogen energy research, electrolysis and social licence.	Development of scenario around fuel cell conversion of a local bus line. Future energy scenario building.
Astronomy	Earth as a Cinderella planet and the greenhouse effect. Investigation of satellite climate monitoring data.	Students investigating patterns in online satellite data.
Biodiversity	Sequence on bees, informed by bee research expertise, and focusing on hive collapse threats and biodiversity loss.	Role play focused on socially acute question of managing varroa mite spread.
Light and vision	Electromagnetic spectrum and infrared. Use of infrared cameras to identify heat loss points in school buildings.	Development of design proposals to the school to improve energy efficiency.

The experience of the teacher in co-designing sequences: The teacher, Maja, is a science specialist leading three classes each of Years 5 and 6 for science, for a one-hour lesson each week.

The repeat classes allowed us to informally discuss a lesson prior to the repeat. Our negotiations with Maja often concerned clarifying the science or providing background to the relevant socio-ecological issues, while she provided advice on how to frame activities, and on structure and timing. Maja has a strong sense of how to engage students in discussion and was increasingly confident with and dedicated to both emphasising students having a voice on the science and socio-ecological issue, and in interacting with each other in developing explanations and arguing for positions. Her advice was particularly strong on matters of students discussing decisions and actions that could influence school policy.

Student outcomes: Student focus group interviews were held at the end of each sequence and a review interview at the end of the year. Students generally were very positive about the science they were doing, engaged with science ideas, and expressed a commitment to the need to act on CC and sustainability more generally. Assessment results at the end of each sequence generally showed strong growth in knowledge of science concepts. In an end of year survey, over 80% expressed confidence to explain key features of ACC, and a clear distinction between climate and weather.

One question on the survey distinguished between interest and importance of three types of activity: design activities denoting action; doing practical activities; learning about science phenomena; and learning about implications of CC for the future. Each was given a score from 0 (not at all interesting/important) to 3 (very interesting/important).

The results show a uniform level of 'interesting' for these activities, but the 'importance' level is strikingly higher for learning about implications of CC for the future (2.7) and design activities denoting action (2.5) compared to learning content or doing practical activities (1.5-2.2). If this finding is repeated more generally, it has significant implications for the expansion of the science curriculum to include student decision making and action, and consideration of socio-ecological challenges as advocated in the OECD PISA Science Framework 2025 (OECD, 2023).

Discussion And Conclusion

These three explorations were part of the initial phase of the ECCE cross country project. Research is ongoing concerning the development of learning sequences and approaches to CCE that foreground critical understandings, systems thinking and student agency related to climate impacted futures and regenerative learning. The incorporation of contemporary science research in a co-design process is central to the project.

The explorations described in this paper demonstrate the viability of introducing education system responses to CC challenges. The first exploration demonstrates teacher confidence in climate science and in developing pedagogies related to not only science knowledge but also focused on affective and perceptual outcomes and student agency. The second exploration identifies substantive differences in the amount of CCE content in the three countries which are related to curriculum policy and contextual system influences but demonstrates that this rich array of CCE ideas are represented across the Science disciplines and Geography in at least some countries, providing confidence that CCE can be productively and richly represented in the science curriculum. The research identified particular roles for the different disciplines in representing CCE, and the analysis promises to yield useful data to inform the design of a systematic approach to CCE in the sciences.

The third exploration identifies a variety of ways CCE can be included in diverse science topics to provide substantive engagement with learning and agency. Teacher commitments and positive student outcomes demonstrate that the science curriculum can be enriched through infusion of CCE in ways that benefit both teachers and students. The exploration also demonstrates the power

of a co-design approach to CCE that involves contemporary scientists and their research, teachers, and in some cases students. We continue to refine our understandings and approaches, drawing on insights based in our cross-national collaboration to sharpen understandings of the contextual factors that frame possibilities of innovation in this CCE.

Introduction

Evaluation and assessment are integral in contemporary Science Education. Together, they provide evidence that informs educational decision-making at multiple levels, from monitoring student learning to improving classroom practice and educational programmes. Within this broader landscape, assessment increasingly serves as a means of supporting learning, informing teaching, and facilitating the development of complex scientific competencies. As Science Education expands its focus towards modelling, systems thinking, sustainability, and other higher-order capabilities, assessment practices must also evolve to capture these multidimensional forms of learning. Increasing attention has been given to assessment approaches that make students' thinking visible, support learning throughout the educational process, and provide evidence of students' conceptual understanding and broader scientific competencies. The two contributions included in this strand illustrate this shift particularly well. Although they address different educational contexts and scientific domains, both investigate assessment as an integral component of learning. They demonstrate how carefully designed assessment tasks can reveal learners' reasoning, inform instructional decisions, and support the development of sophisticated scientific competencies.

Two themes connect the two contributions. The first theme is that assessing a complex competence begins with decomposition. Gómiz-Aragón and colleagues make secondary students' analogical reasoning assessable by resolving it into five operations, each rated on a four-level scale. Botzaki and Stavrou analyse how pre-service primary teachers design formative assessment by coding both the competency objectives the teachers target and the formative-assessment elements they deploy. In each study, the category system is the instrument through which competence is made visible.

The second theme has to do with the difficulty of reflection. In both studies the generative, evidence-gathering steps are handled competently, while the reflective moves are handled less surely. The students readily characterise the target and map similarities, but falter when asked to weigh the analogy's limitations and utility. The pre-service teachers elicit and even interpret evidence in varied ways, yet plan feedback, and opportunities for students to act on it, far less often, leaving the formative cycle unclosed.

Read together, the two studies span both sides of assessment—the student being assessed and the teacher learning to assess. We hope the ideas presented here prompt continued attention to how assessment can guide learning in a time when science education is increasingly concerned with sustainability and complex competencies.

ESERA 2025 Copenhagen

Assessment of Analogical Activities for Learning an Immune System Model

Marta Gómiz-Aragón, María del Mar Aragón-Méndez, José María Oliva
University of Cádiz, Spain

This study investigates the use of analogies in secondary-school immunology teaching, comparing the immune system to a security system within a modelling framework. A total of 181 students participated in activities focused on five analogical operations: target characterisation, mapping of similarities, use of analogical language, identification of limitations, and recognition of utility. Regarding the first research question (RQ1), high levels of performance were observed in target characterisation and the mapping of similarities, whereas students encountered difficulties in using analogical language and identifying limitations. The perceived utility of the analogies varied considerably. For the second research question (RQ2), correlation and principal component analyses indicated that all five indicators contributed to a common construct of analogical performance. Nevertheless, the identification of limitations and the perceived utility showed weaker relationships with this construct. These findings suggest that constructing and reflecting upon analogies fosters both understanding of the immunity model and the development of skills in constructing and evaluating scientific models.

Keywords: Analogies in Science; Secondary Education; Teaching Processes

Introduction

Teaching immunology is essential for educating citizens capable of understanding information related to this field and making informed decisions that enhance their quality of life (Mixter et al., 2023). However, learning how the immune system functions presents significant challenges due to the large number of concepts involved and the multiple scales that must be considered, ranging from the molecular to the systemic and even the social level (Haidaris & Frelinger, 2019). Consequently, it is necessary to implement teaching strategies that facilitate the comprehension of these complex topics.

A particularly effective approach to addressing this challenge is through the use of analogies. Analogies act as mediators between the observable world and scientific models (Marzabal et al., 2024), allowing familiar phenomena to be related to complex scientific concepts. In this way, they support the construction of mental models (Clement, 2000) and assist in the creation, revision, and validation of scientific models (Gilbert & Justi, 2016). Within this context, analogies constitute a valuable resource for modelling-based approaches, as they enhance the understanding of school-level scientific models and promote engagement with the modelling process itself (Oliva & Aragón-Méndez, 2009).

This work forms part of a broader study analysing how students construct models of immunity using an analogy based on a security system. Specifically, the aim of the present study is to assess students' performance in analogical activities, thereby contributing to a better understanding of the role of analogies in modelling and how they can facilitate the comprehension of complex concepts in immunology.

Theoretical Framework

In science education, the use of models as learning objects and modelling as a scientific practice is well established. School-based models arise from the didactic transposition of scientific models, being simplified, restructured, and adapted to suit students' characteristics and the educational context (Coll et al., 2005; Treagust et al., 2002). Modelling, understood as the construction of models in the classroom, provides opportunities for students to engage in school-based scientific practices and plays an important role in their scientific development.

Analogies constitute a particular type of model, as each involves an underlying abstract representation that gives rise to the *analogy model*. This second-order model synthesises the relational structure between the *target* (what is to be explained) and the *analogue* (the known). Analogies are fundamental tools for teaching complex concepts, as they facilitate the understanding of unfamiliar ideas by relating them to familiar concepts that share similar structure or function (Gilbert & Justi, 2016; Tise et al., 2023). Traditionally, analogies have been used in science teaching as illustrative resources to explain isolated concepts. However, their more effective use requires articulating multiple ideas and relationships, thereby fostering the construction of structured and interconnected knowledge and avoiding fragmented or superficial learning.

Analogical reasoning represents a system of relational thinking based on identifying structural similarities and is considered one of the cognitive foundations of higher-order thinking (Eriksson et al., 2024; Richland & Simms, 2015). Its development promotes knowledge transfer and the construction of conceptual models (Coll et al., 2005; Gray & Holyoak, 2021). Through this process, students generate abstract conceptions from similarities between phenomena, supporting the understanding, application, and reconstruction of scientific models (Gilbert & Justi, 2016). Furthermore, analogies facilitate the practice and acquisition of scientific language, assisting students in articulating and explaining abstract concepts (Eriksson et al., 2024).

The approach based on identifying structural patterns across different domains is enhanced through modelling practices, which enable the generation of explanations, predictions, and inferences about the phenomena under study (Mozzer & Justi, 2018). In this process, students must assess the correspondences between the analogy and the scientific model, evaluating its validity and utility, and recognising when an analogy is appropriate and how to use it effectively (Petchey et al., 2023). Analogical thinking thus stimulates the construction, use, and evaluation of scientific models, while also fostering the acquisition of skills and epistemological perspectives essential to science and modelling (Oliva & Aragón-Méndez, 2017). The relationship between analogical thinking and modelling is bidirectional: constructing analogies involves, to some extent, building models in a domain familiar to students, while engaging in modelling processes enriches the use and meaning of analogies, promoting verbalisation, argumentation, and metacognitive reflection (Aragón-Méndez et al., 2014; Mozzer et al., 2011).

Thus, analogical reasoning, enhanced by modelling practices, not only contributes to the understanding of complex scientific concepts but also fosters advanced cognitive skills and competencies associated with knowledge construction, critical thinking, and scientific creativity (Zorlu & Zorlu, 2022).

For analogies to be effective in the classroom, careful planning is required, taking into account students' prior knowledge and potential risks of misunderstanding (Petchey et al., 2023). Teaching models such as *Teaching With Analogies* (TWA) by Glynn (1991) provide a structured framework to guide learning through analogies. The TWA model comprises six stages: (1) presentation of the target concept; (2) introduction of the analogue and activation of students'

creativity. (3) identification of relevant features in the analogue that show similarity with the target. (4) mapping of similarities and analysis of the compared systems. (5) drawing conclusions, generalising, and formulating hypotheses. (6) establishing the limits of the analogy and critically evaluating its relevance. This approach ensures effective knowledge transfer and promotes active student engagement, as students construct and refine their own analogies rather than receiving information passively (Saleem & Akbar, 2024).

Research in science education has explored, for decades, the cognitive processes involved in analogical reasoning, strategies for teaching with analogies, and factors affecting their effectiveness (Marrero & González, 2023). Analysing analogies created by students can reveal their conceptual understanding and reasoning processes (Tise et al., 2023). Given the multidimensionality of this process, student performance must be assessed using multiple indicators.

Nevertheless, questions remain regarding how to assess students' performance in analogy construction. Therefore, the present study addresses the following research questions:

RQ1: How does students' performance in constructing the immune system analogy vary across different performance indicators?

RQ2: To what extent do these indicators converge and form part of a single construct?

Research Design

Didactic Context

The study involved 181 students aged 14–15 (3rd year of secondary education) from two public schools in Spain. It was embedded in a teaching–learning sequence based on modelling. In this sequence, a security system analogy was employed to facilitate the learning of the immunity and vaccination model at the microscopic level, with a focus on the cellular processes of the immune system.

In immunology teaching, the defence or warfare system analogy is commonly used to represent the immune system (cf. Niebert et al., 2012). The security system is an appropriate analogue due to functional similarities: both detect threats, respond to them, and store information to prevent future attacks. To reinforce the analogy, a silent animation adapted from Bryce (2018) was used. In this animation, pathogens were represented as criminals and immune cells as security agents. Databases and emergency services were also included to strengthen functional correspondences. The absence of audio allowed students to interpret the animation with teacher guidance, promoting interaction, dialogue, and active model construction.

Two activities related to the analogy were analysed: its construction and metacognitive reflection on the analogical model.

In the first activity, students constructed the analogy in two steps. First, they mapped the similarities between the target (immune system) and the analogue (security system). Second, they drew conclusions regarding the characteristics of the target. The analysis focused on the language used, distinguishing analogies from metaphors. Analogies establish a systematic correspondence between the two domains, whereas metaphors transfer meaning from the source to the target (Gilbert & Justi, 2016).

The analogy was interpreted based on Gentner's (1982) structural mapping theory. According to this theory, students establish systematic correspondences between objects in the analogue domain (criminals, agents, databases) and the target domain (pathogens, leukocytes, immunological memory). These correspondences are based on the functional relationships

connecting the two domains. This approach preserves coherent systems of relations and prioritises higher-order structural connections, facilitating the construction of mental models of the immune system and enabling understanding of complex processes beyond the superficial attributes of the elements. Students worked individually with an incomplete analogy. They were required to identify correspondences and relationships between the security system and the immune system.

The second activity focused on fostering students' metacognition regarding the analogical model. Students reflected on the model's usefulness for understanding immune system mechanisms and its limitations. This promoted critical evaluation of the analogical model itself. Guiding questions included: *To what extent does the analogical model allow understanding of how the immune system functions? What are the limitations of the model? To what extent can immune cells be compared to human agents in a security system?*

The aim was for students to understand that scientific models are approximate representations of reality. Models have limitations, and a single phenomenon can be explained using different models. Furthermore, participating in the reconstruction and evaluation of the analogical model allows students to gain a deeper understanding of their own learning process. It also supports the development of competencies related to modelling, analogical thinking, and metacognitive reflection (Gray & Holyoak, 2021).

Overall, students were expected to engage in five analogical operations. Three of these correspond to the TWA model: identifying relevant features of the target, mapping similarities, and indicating the limitations of the analogy. Two additional operations were included: the use of analogical language and metacognitive processes related to the analogy's usefulness in learning the immunity and vaccination model.

Analysis Method

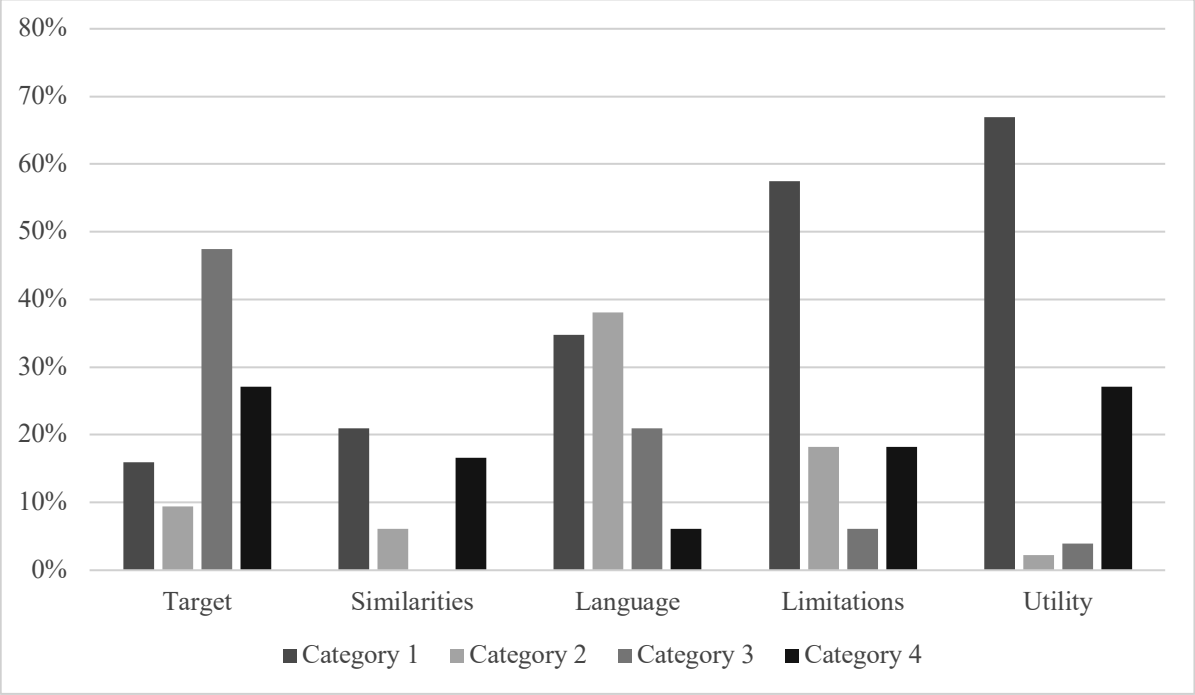
With respect to the five analogical operations identified in the activities—characterisation of the attributes of the target domain, mapping of similarities between the analogue and the target, use of analogical language, identification of the analogy's limitations, and recognition of the model's usefulness for learning—four performance categories were established. These categories allowed the assessment of students' levels of understanding and application (Table 1). The categorisation system was agreed upon through inter-rater consensus to ensure consistency in the classification of responses. Inter-rater reliability was verified using Cohen's kappa coefficient, appropriate for ordinal categorical variables, thereby ensuring consistent classification of students' responses.

Table 1. Category system for performance in analogical activities.

Indicator	Category 1	Category 2	Category 3	Category 4
Target (T). Characterization of the target domain attributes	No correspondence with model elements.	Names immune elements or mechanisms but without description.	Describes immune elements or mechanisms but without naming them.	Fully characterizes immune elements or mechanisms.
Similarities (S). Mapping similarities	No similarities established.	Inadequately established.	Correct but incomplete mapping.	Fully accurate mapping.
Language (A). Use of analogical language	No comparative structures used.	Simple comparative structures.	Metaphorical language without full analogical comparison.	Fully adequate comparative structures.
Limitations (L). Identification of analogy limitations	No limitations identified.	Superficial or unspecific limitations.	Structural limitations identified.	Functional limitations identified.
Utility (U). Recognition of the utility of the analogy for learning the model	No assessment of utility.	Negative assessment.	Both positive and negative assessment.	Positive assessment.

To address RQ1, a descriptive analysis was conducted. The frequency distribution for each category was calculated for each operation, with the aim of identifying patterns and trends in students' responses.

Subsequently, to address RQ2, the relationships between the different indicators were analysed. Kendall's tau-b coefficient, suitable for ordinal variables, was employed. Additionally, a categorical principal component analysis was carried out, allowing exploration of whether the different indicators converge into a single construct of analogical performance.



All analyses were performed using IBM SPSS Statistics v.29. This procedure ensured the validity and reliability of the results and provided a robust framework for interpreting students' performance in the analogical activities.

Results

Assessment Of Performance In The Construction Of The Analogy

In response to RQ1, which examined students' performance in constructing the immune system analogy, Figure 1 presents the frequency distribution of performance levels across the five analogical activities.

Figure 1. Patterns in performance on analogical activities

The highest levels of performance were observed in the mapping of similarities and in the use of analogical language, whereas identification of limitations emerged as the weakest area, with many students failing to reflect on the boundaries of the analogical model.

By contrast, recognition of the model's usefulness exhibited marked polarisation: 27.1 % of students positively valued the effectiveness of the analogy for understanding the model, while the majority, with few exceptions, did not perceive its applicability. This pattern indicates a limited degree of reflection on the model's usefulness.

Table 2 presents representative examples of students' responses across the different categories for the five indicators of the analogical operations. Reference responses correspond to the expected answers for each indicator, while the subsequent columns display actual student responses, selected to illustrate performance patterns and the difficulties observed.

Table 2. Representative Examples of Student Responses

Indicator	Categorised examples from student portfolios
Target	Reference: Immunological memory allows a faster and more effective secondary response upon a new infection by the same pathogen. Category T1: Antibodies detect the microorganism and reject it Category T2: Having fought that pathogen, they are prepared for another attack Category T3: Lymphocytes remember the pathogen for when it returns and know how to eliminate it quickly. Category T4: Immunological memory allows lymphocytes to produce specific antibodies, so that if a second encounter occurs, they neutralise it faster.
Similarities	Reference: In both systems, there are elements (phagocytes and riot police) capable of stopping threats (pathogens and criminals). Category S1: The systems act like a threat. Category S2: Both have transport. Category S3: They try to eliminate the threat. Category S4: In both cases, responses are general and rapid.
Language	Reference: Just as different security agents protect populations from various criminals, white blood cells are responsible for protecting the organism from infections. Category A1: For identifying. Category A2: Both defend the place. Category A3: Both systems have elements that watch and inspect for threats. Category A4: Both systems have mechanisms that help detect and eliminate threats.
Limitations	Category L1: It explains very well how the immune system works. Category L2: The immune system can be compared with other systems; although similar, each has its own characteristics. Category L3: The police model and the immune system are similar but differ in important aspects: a single microorganism can cause an infection, whereas a single criminal does not represent a great threat; microorganisms act independently, without a leader. Category L4: The model is very useful but cannot literally represent reality: we will not see phagocytes fighting with weapons. The comparison has limits between the biological and the social or ethical domains.
Utility	Category U1: Knowing the terms and having learned a bit more about the topic, I can understand the model and why many things work as they do. Without prior knowledge, I would not have understood anything, as the terms are not fully explained. Category U2: The model does not explain the order in which different types of immune cells act. Category U3: Models are essential to understand reality, but they must be updated with new discoveries, as they do not reproduce it completely. Category U4: The analogy facilitates understanding by relating the immune system to something familiar, although its abstract and non-visible nature may hinder comprehension.

Note. The students' original responses were in Spanish. The examples presented in this table have been translated into English for clarity and consistency.

Convergence Of Indicators

In response to RQ2, Table 3 presents the correlation matrix calculated using Kendall's tau-b coefficient. The Target and Similarities indicators exhibit the strongest relationship among all pairs of variables. The Language indicator shows significant correlations with all other variables, although these are of smaller magnitude compared with Target and Similarities. The Limitations and Utility indicators display weaker correlations, yet they remain statistically significant. This suggests that these dimensions are less directly related to performance in constructing the analogy.

Table 3. Kendall's tau-b correlation matrix.

	Target	Similarities	Language	Limitations	Utility
Target	1,000				
Similarities	0,616***	1,000			
Language	0,434***	0,569***	1,000		
Limitations	0,336***	0,339***	0,139*	1,000	
Utility	0,359***	0,303***	0,183**	0,229***	1,000

* p < .05; ** p < .01; *** p < .001

Finally, a categorical principal component analysis for ordinal variables was performed (Table 4). This analysis revealed a single-factor solution explaining 54.1 % of the variance. This indicates that all five indicators contribute to a common construct, despite differing levels of difficulty and assessment methods. The extracted factor is particularly associated with the characterisation of the target domain and the mapping of similarities. In contrast, the identification of limitations and the evaluation of utility are more weakly connected to the other indicators.

Table 4. Factor loadings from nonlinear principal component analysis.

	Factor 1
Target	0,867
Similarities	0,886
Language	0,736
Limitations	0,583
Utility	0,538

Discussion, Conclusions, and Implications

Although the literature provides extensive exploration of the use of analogies as a teaching resource in science education, few studies have assessed students' performance in analogy-based activities. This study seeks to contribute to this area. The results indicate that the analogical operations involved in an activity comparing the immune system to a security system, designed according to the TWA model, allow for a comprehensive evaluation of students' performance in completing these tasks.

Students achieved medium to high performance in characterising the attributes of the immune system and in mapping similarities with a security system. However, their performance in using analogical language was lower, possibly due to a general tendency towards laxity in written expression (Archila, 2015).

Difficulties were also observed in analysing the limitations of the analogy, suggesting that this task is more complex than identifying similarities. This complexity relates to the potential of analogies to promote critical thinking, as learning occurs not only by establishing correspondences but also by questioning them and recognising their boundaries (Heywood, 2002; Haglund, 2013). Therefore, providing scaffolding to support the identification of analogy limitations could further enhance students' critical capacity. In this process, analogical reasoning facilitates higher-order thinking, such as the evaluation of ideas and the generation of inferences (Richland & Simms, 2015; Zorlu & Zorlu, 2022).

Although students often noted the analogy's usefulness for learning about immunity, this perception was not clearly reflected in the assessment instruments. When asked about the analogy's usefulness for understanding the immune system model, many students merely used the analogy to demonstrate conceptual understanding, without explicitly indicating whether it had been helpful. This ambiguity suggests a limitation in the formulation of the question.

For future implementations, rather than posing the open question, "To what extent does the analogical model allow you to understand how the immune system works?", it may be useful to reword the question and provide prompts to guide reasoning, such as: "Does the analogy allow you to explain what happens when a pathogen enters the body?" or "Can it be used to predict what would happen if another type of substance were introduced?"

Statistical analysis suggests an underlying factor accounting for students' performance in reconstructing the immune system–security system analogy. This factor may reflect the impact of the activities on developing analogical thinking, linking analogical use with modelling

competencies. Both share cognitive operations –such as identifying structural correspondences, drawing inferences, and evaluating representations– that support model construction and revision (Aragón-Méndez & Oliva, 2020; Justi & Gilbert, 2002). This aligns with Lin and Chao (2024), who define analogical modelling competence as the ability to use analogical reasoning to construct models, integrating cognitive, metacognitive, and behavioural aspects. Classroom use of analogies fosters this competence by offering opportunities to construct and evaluate models.

In line with this, the findings of the present study suggest that students' performance in reconstructing the immune system analogy may reflect not only progress in understanding the immunity and vaccination model but also advancement in their competence to construct and revise scientific models. This hypothesis will be explored further in future research.

Enhancing Climate Literacy Through Assessment Activities Designed by Pre-Service Primary Teachers

Eleni Botzaki and Dimitris Stavrou
University of Crete, Greece

Addressing Climate Change (CC) challenges requires fostering climate-literate students by developing CC competencies, which can be strengthened through integrated assessment in CC teaching. However, a significant lack of guidance on assessing CC competencies highlights the need for meaningful support to teachers in effectively implementing assessment strategies. The present study examines how nineteen pre-service primary teachers design and develop activities to assess CC competencies. Conducted in two phases, the study first introduced participants to key CC concepts, aspects of climate literacy, and assessment principles. Subsequently, they designed and developed CC teaching scenarios, with a particular emphasis on integrating assessment dimension to foster climate literacy among students.

The findings shed light on the pre-service primary teachers' choices regarding the CC competencies that they aim to foster through their scenarios and the structure of formative assessment elements they employ for assessing these competencies. In more detail, they place particular emphasis on assessing Systems Thinking. Additionally, although participants develop their activities to elicit evidence of students' progress, their feedback practices remain limited, indicating a gap in their formative assessment design. Thus, these findings stress the importance of enhancing assessment practices in teacher education to foster climate literacy.

Keywords: Formative Assessment, Pre-Service Teacher Education, Sustainability

Introduction

Climate Change (CC) is one of the most crucial environmental challenges, mainly caused by anthropogenic activities that harm the environment, affecting multiple aspects of human life (IPCC, 2023). Addressing CC issues requires the preparation of citizens, capable of mitigating the impacts of CC and partially adapting to them. CC education needs to foster climate literacy in students by developing CC competencies - a combination of knowledge, skills, and attitudes (Bianchi et al., 2022). Various frameworks were developed to define the necessary competencies, with a general focus on sustainability, as climate change is inherently part of the broader domain of sustainability. Widely recognized frameworks include Wiek et al. (2011) and the European GreenComp framework (Bianchi et al., 2022), identifying competencies such as systems thinking, futures thinking, and action-taking. Nevertheless, to address key aspects of climate literacy more effectively, recent efforts focus on defining CC competencies using broader sustainability frameworks, such as that of Taurinen et al. (2024).

In this context, achieving the complex goal of developing CC competencies requires contemporary teaching approaches emphasizing active learning (UNESCO, 2017). Such approaches view teaching and assessment as interconnected processes that together enhance student learning (Harris et al., 2019). Accordingly, focusing solely on the final outcome and knowledge acquisition, as is common in traditional assessment methods (e.g., summative assessment), is insufficient to capture the complexity of CC competencies (Annelin & Boström, 2022; Redman et al., 2021). Thus, the assessment of CC competencies requires methods that focus on the whole learning process and provide feedback (Grangeat et al., 2021), such as formative assessment (Annelin & Boström, 2022). The implementation of formative assessment in classroom contexts is based on five key elements: a. setting and sharing with students clear learning objectives and assessment criteria; b. eliciting information from students; c. interpreting

the elicited information; d. providing constructive feedback; and e. creating opportunities for students to apply feedback. These five elements form a cyclical process that supports ongoing learning (e.g., Dini et al., 2020; Grob et al., 2019; Black & Wiliam, 2018; Haug & Ødegaard, 2015).

Nevertheless, teachers face challenges when integrating assessment into their teaching, especially when dealing with multidimensional learning goals, such as the development of competencies (Grangeat et al., 2021). These challenges vary across the steps of the formative assessment cycle, as each step involves different teacher decisions and practices. First of all, teachers tend to focus mainly on assessing knowledge-related objectives rather than students' skills or attitudes (Ropohl & Rönnebeck, 2019; Cisterna & Gotwals, 2018;). In addition, although the literature highlights the importance of co-designing learning goals with students, teachers often avoid setting learning goals collaboratively or explicitly sharing them with students (Cisterna & Gotwals, 2018). Another challenge concerns the elicitation of evidence, in order to assess students' performance and progress in relation to the learning objectives. In particular, when the learning objectives refer to competency development, assessing the conceptual knowledge is not sufficient. Instead, teachers need evidence of students' thinking and reasoning, as well as their skills and attitudes (Grangeat et al., 2021). Thus, a wide variety of evidence is required in order to build a more holistic picture of students' progress (Grob et al., 2021; Cisterna & Gotwals, 2018). Besides the elicitation of evidence, teachers - especially pre-service teachers - often face difficulties during the interpretation of the collected evidence. Particularly, they tend to interpret the elicited information more superficially (Ropohl & Rönnebeck, 2019), either because they do not consistently connect it to learning objectives or because they do not examine in depth how students understand, reason, and argue. This, in turn, limits their ability to identify students' actual learning needs (Ropohl & Rönnebeck, 2019; Ateh, 2015). Consequently, limited interpretation of evidence can prevent teachers' instructional decision-making, particularly about designing the appropriate next steps and providing feedback that moves learning forward (Ropohl & Rönnebeck, 2019). Regarding teachers' actions after the interpretation of evidences, research shows that their decisions often do not meaningfully support the teaching and learning process. Many teachers face challenges in providing effective feedback. When feedback is given, it is often general, limited in depth, and non-individualized (Ropohl & Rönnebeck, 2019). Teachers also tend to focus mainly on whether students' answers are correct, rather than responding to students' thinking in ways that support deeper learning (Ateh, 2015). As a result, formative assessment cycles often remain incomplete and, consequently, may not effectively promote students' learning (Cisterna & Gotwals, 2018).

Overall, both pre- and in-service teachers need further support in order to use formative assessment for the development of competencies. At the same time, research on assessing CC competencies remains limited, particularly with respect to formative assessment in primary education (e.g., Cebrian et al., 2025). There is also a lack of guidance for teachers on how to use assessment tools effectively, which highlights the need for meaningful support (Redman et al., 2021).

Based on the above, the study aims to explore how pre-service teachers design and develop activities for assessing CC competencies. More specifically, emphasis is given to the phase of the planning of the formative assessment, which is considered as a critical component of its effectiveness (e.g., Grangeat et al., 2021). Accordingly, the main research question of the study is, "*How do pre-service teachers design assessment sequences to support the development of the CC competencies?*", which is analyzed through two sub-questions:

- What CC competency objectives do pre-service teachers set to assess in their activities?

- How do pre-service teachers structure the elements of formative assessment?

Methods

Empirical Study Description

This study involves nineteen pre-service primary teachers, who participated in a 13-week seminar course of the Department of Primary Education at the University of Crete, developing teaching scenarios about the development of CC competencies with the integration of assessment dimension. The empirical study is divided into two phases, as presented in Table 1.

Table 1. Description of CC competencies categories.

Empirical Study Phases	Meetings	Content
Phase A *Participants' Preparation*	***1st***	*CC scientific concepts*
	2nd - 3rd	*CC competencies*
	4th	• *Assessment of CC competencies* • *Formative assessment strategies*
	5th - 6th	• *Framework for the design of assessment tools and activities* • *Examples of assessment activities and tools*
Phase B *Design & Development of Teaching Scenarios*	***7th***	*Setting Learning Objectives for Whole Teaching and Individual Activities*
	Reflection & Personalized feedback (per group)	
	8th – 9th	• *Refinement of the Learning Objectives* • *Activities & Tools Design: Determining the indicators to monitor learner progress*
	Reflection & Personalized feedback (per group)	
	10th	*Activities & Tools Design: Determining the activity characteristics (e.g., task format)*
	Reflection & Personalized feedback (per group)	
	11th	*Development of activities and assessment tools (plus Worksheets)*
	Reflection & Personalized feedback (per group)	
	12th	*Teaching scenario refinement*

During **Phase A (**six meetings), participants were introduced to a. core concepts of CC (e.g., drivers, causes) and climate literacy, b. principles for assessing CC competencies, c. formative assessment strategies, and d. specific examples of designing and utilizing assessment tools and activities to foster CC competencies. Then, in **Phase B**, pre-service teachers developed teaching scenarios, emphasizing the integration of the assessment tools and activities to foster CC competencies. Six plenary meetings were thus dedicated to supporting participants during the development process. Additionally, four individual meetings were held with each group between

the main meetings to address challenges, provide personalized feedback, and support reflection on their teaching scenario.

Data Collection

Data were collected through participants' developed teaching scenarios (n=7), including the assessment activities and tools that they designed. Due to the nature of the research, qualitative methods of content analysis were used (Bryman, 2016). Specifically, the category systems were developed based on the relevant literature and were refined or adjusted in response to the empirical data.

Data Analysis

Data analysis examines participants' teaching scenarios along two main axes: a. CC competencies objectives, and b. elements of formative assessment. Regarding the first sub-research question, a categorization scheme for the CC competency objectives was developed based on literature (e.g., Taurinen et al., 2024; Bianchi et al., 2020; Wiek et al., 2011) and empirical data, as presented in Table 2.

Table 2. Description of objectives for CC competencies.

Categories	Criteria
Systems Thinking	• Complex systems' features (e.g. feedback loops) • Various domains (e.g. society, economy) • Effects of actions/choices
Futures Thinking	• Time scale o Real data (past-present) o Trends (future) • Future scenarios development
Strategic Competency	• Fostering action-taking • Design of solutions/action plans
Normative Competency	• Evaluation of the sustainability of current or future states • Sustainability values • Decision-making (e.g., addressing dilemmas
Interpersonal Competency	• Evaluation of diverse perspectives • Communication, negotiation, and collaboration skills

Additionally, each activity's objectives were examined to identify the specific dimensions of CC competencies—knowledge, skills, and attitudes. Specifically, ***knowledge*** **objectives** focus on understanding and elaborating principles, theories, and facts about scientific core concepts and phenomena of CC. ***Skills objectives*** emphasize applying knowledge and expertise to accomplish tasks, fostering cognitive and practical skill development. ***Attitude objectives*** involve forming personal values, attitudes, and intentions that influence individuals' behavior.

Regarding the second research sub-question, the assessment activities and tools included in the participants' teaching scenarios were analyzed to identify how formative assessment elements were structured and combined across the scenarios. For this purpose, a categorization scheme (see Table 3) was applied, which was based on formative assessment elements described in the

literature (e.g., Dini et al., 2020; Grob et al., 2019; Black & Wiliam, 2018) and refined through the empirical data.

Table 3. Description of Formative Assessment Elements.

Categories	Description
Using Assessment Criteria	Specific criteria are used to assess the students' performance
Eliciting Information	Activities designed to capture aspects of competencies – knowledge, skills, attitudes.
Interpreting Information	Interpreting the collected evidence to identify students' progress and needs in developing CC competencies.
Providing Feedback	Providing information/comments to support CC competencies development and enhance learning outcomes.
Applying Feedback	The instructional design supports the direct use of feedback in following tasks.

Findings

CC competencies objectives

To address the first research sub-question about the CC competency objectives that pre-service teachers set to assess in their activities, Tables 4-5 summarize the findings.

According to the analysis of the participants' teaching scenarios, Table 4 presents the absolute frequency of the CC competencies objectives that addressed in the assessment activities developed by the pre-service teachers. Most learning objectives focus on Systems Thinking (n=30), while the other competencies were covered less frequently, especially Interpersonal Competency. This indicates a priority given to assessment of Systems Thinking over the other competencies.

Table 4. Learning objectives for CC competencies.

Categories	Absolute Frequency
Systems Thinking	30
Futures Thinking	14
Strategic Competency	17
Normative Competency	17
Interpersonal Competency	10

Additionally, Table 5 presents the absolute frequency of the different dimensions of CC competencies, demonstrating the tendency of participants to primarily assess the cognitive dimension, while indicating an effort to include skills assessment (n=22). Assessing values seems challenging for participants, resulting in a considerably lower frequency of values-related objectives (n=12) compared to the other two dimensions.

To answer the second research sub-question on how pre-service primary teachers structure formative assessment elements, Tables 6-7 and Figure 1 were created to summarize the findings.

Table 5. Dimensions of CC Competency Objectives.

Categories	Frequency
Knowledge	27
Skills	22
Attitudes	12

Formative Assessment Elements

Specifically, Table 6 presents how many times participants designed each of formative assessment elements. Participants used only assessment criteria that they designed themselves without considering engaging students in this process. These criteria were typically presented as checklists or detailed rubrics. Regarding "eliciting information", participants recognized its importance and designed different types of elicitation tasks beyond whole-class discussion or simple questioning, including tasks requiring the creation of artifacts (e.g., concept maps, leaflets, posters) and demonstration of skills (e.g., diagram construction, action-plan design). In addition, participants most of the times did not plan just to collect data, but also to make sense of it, identifying points in their scenarios where interpretation would occur, based either on predetermined criteria or on more intuitive judgement. They also specified if evidence would be interpreted by the teacher or by students through self-assessment and peer-assessment. However, although the element "interpreting information" was frequently mentioned, feedback based on these interpretations was planned to be given much less often, indicating a difficulty for pre-service primary teachers. They organised the provision of feedback through multimedia (e.g., video, images), rubrics and individual or plenary discussions. Finally, "applying feedback" was the least frequently designed element by participants, indicating that feedback rarely leads to follow-up actions. In the few cases that participants integrated this element in their teaching scenarios, they focused on creating opportunities for students to revise their answer, artifact or their performance on the task.

Table 6. Elements of Formative Assessment.

Categories	Frequency
Using Assessment Criteria	16
Eliciting Information	51
Interpreting Information	47
Providing Feedback	27
Applying Feedback	6

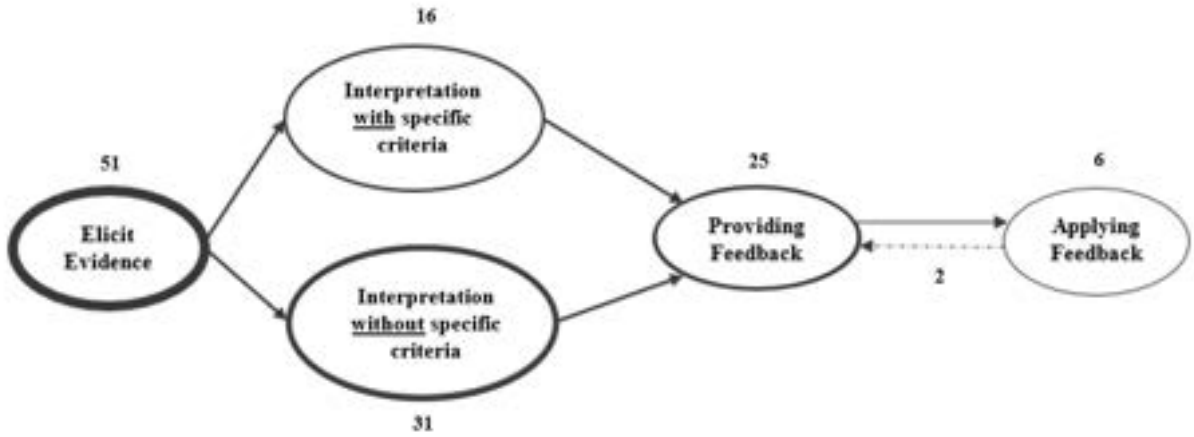

Table 7 provides a more detailed view by breaking down participants' choices of formative assessment elements by CC competency. While the previous table summarized the elements used in general, Table 7 shows the pattern of element selection within each competency. Reading across the rows, the table indicates that complete formative assessment cycles were only attempted for Systems Thinking and Futures Thinking. The findings also reveal that pre-service teachers may consider Systems Thinking a demanding competency for both themselves and their students and they tried to better support its development. Accordingly, most formative assessment elements appear more frequently in Systems Thinking, particularly "Providing Feedback".

Table 7. Formative Assessment Elements across CC Competencies.

FA Elements / CC Competencies	Using Assessment Criteria	Eliciting Information	Interpreting Information	Providing Feedback	Applying Feedback
Systems Thinking	8	18	17	14	4
Futures Thinking	2	7	7	3	2
Strategic Competency	3	10	9	3	0
Normative Competency	1	10	8	5	0
Interpersonal Competency	2	6	6	2	0

Furthermore, the analysis of teaching scenarios revealed that participants structured the formative assessment elements that were examined earlier (see Table 6 & 7), forming integrated assessment pathways within activities. These pathways were illustrated for each CC competency, with Figure 1 presenting a comprehensive pathway summarizing all CC competencies, where line thickness reflects the frequency of each strategy and the dashed line indicates a return to a previous phase. However, providing feedback is challenging for pre-service teachers, who do not often incorporate it into their activities. When included, it is typically given at the end and does not provide students with the opportunity to apply it constructively.

Figure 1. Comprehensive assessment pathway of all CC competencies.

Discussion & Conclusions

The findings show how pre-service teachers planned formative assessment elements within teaching scenarios developed to support the development of CC competencies. Overall, they primarily targeted knowledge-related objectives, with a particular emphasis on Systems Thinking. The findings also reveal challenges in relation to feedback practices.

More specifically, pre-service teachers designed activities aimed at fostering climate literacy, with a particular emphasis on assessing the cognitive dimension of CC competencies (Redman et

al., 2021), while also making efforts to address the skills dimension. This pattern may reflect greater confidence in assessing knowledge-related objectives. The participants' choices are consistent with the literature, which shows that competencies related to values, attitudes, and action appear to be addressed to a more limited extent (Monroe et al., 2019). Additionally, pre-service teachers placed particular emphasis on Systems Thinking in their assessment activities, recognizing it as a key CC competency and essential for CC teaching, in line with what is highlighted in the literature (Lorenzo-Rial et al., 2025; Levrini et al., 2019).

Moreover, the findings provide insights into how formative assessment elements were structured by pre-service teachers and how they were integrated into teaching scenarios. Participants placed emphasis on observing the overall learning process and planned to use, apart from common activities such as discussions and reports, a range of activities to elicit different types of information (e.g., written, oral, observational) about students' progress in CC competencies. This emphasis on "Eliciting Information" is in line with the literature, which highlights its importance for effective formative assessment (e.g., Dini et al., 2020; Ateh, 2015). In addition, feedback is either underutilized or avoided by pre-service teachers, highlighting a weakness in the integration of this element to their teaching (Ropohl & Rönnebeck, 2019). The lack of planning for providing and using feedback may have led to fewer planned formative assessment cycles and less support for learning goals, such as competency development (Cisterna et al., 2018). Therefore, pre-service teachers may benefit from support in feedback practices, as a core element of assessment to promote the development of competencies (Grangeat et al., 2021), and more specifically to foster climate literacy.

To conclude, this study highlights how pre-service teachers approach formative assessment for CC competencies at the planning level. The findings indicate that pre-service teachers place emphasis on addressing knowledge-oriented objectives and eliciting evidence of students' learning more systematically, while they struggle to plan systematic feedback and opportunities to act on it. Teacher education could equip pre-service teachers with the knowledge and skills needed to use contemporary assessment approaches, such as formative assessment.

Introduction

Pre-service science teacher education plays a central role in preparing future teachers for the demands of science teaching. Beyond disciplinary knowledge, teacher education programmes are expected to promote the development of Pedagogical Content Knowledge (PCK in advance), reflective and inquiry-oriented teaching practices, professional identity and the capacity to respond to emerging educational and societal challenges. Research in this field has therefore focused on how future teachers connect theoretical knowledge with teaching practice while developing the competences required for their profession.

The contributions in this chapter reflect several current directions in pre-service science teacher education across different educational contexts and science disciplines. A central aspect addressed is the development of professional knowledge and competence, including PCK, pedagogical reasoning, topic-specific understandings of science teaching and learning, and the integration of disciplinary, pedagogical and technological knowledge. Across the chapter, these issues are considered and examined in relation to different areas of Science Education, emphazising the importance of understanding how future teachers construct the knowledge needed to design, implement and reflect on science teaching-learning.

A common feature across many contributions is the exploration of innovative approaches to teacher education. Several contributions examine how pre-service teachers learn through mentoring, guided reflection, collaborative work, practicum experiences and other forms of approximation to practice. The chapter reflects a broad view of teacher education in which learning to teach is not reduced to the acquisition of conceptual knowledge, but is also understood as participation in professional communities, identity development, and engagement with the practical, ethical and relational dimensions of teaching. The chapter also includes works that extends this perspective to science teacher educators themselves, thereby drawing attention to teacher education as a professional field in its own right.

Another trend across the different studies included in the chapter is the prominent of innovation in teacher education design. This can be noticed in some contributions that examine digital and technology-supported learning environments, including online learning, AI supported reflection, and digital tools for supporting professional learning and reflective practice. Other studies focus on innovative teaching approaches and organizational formats to support professional learning through a deeper understanding of the nature of scientific models after implementing approaches such as Model-Based Inquiry (MBI).

The chapter also reflects growing attention to broader societal challenges that increasingly shape science teacher education. Sustainability, climate change education, environmental awareness and socially relevant perspectives on science illustrate the role of pre-service teacher education in preparing future teachers to engage learners with contemporary scientific and societal issues.

Methodologically, the contributions illustrate the diversity of research approaches currently used in science teacher education, including qualitative interview studies, implementation and design-based research, questionnaire-based studies, case studies, phenomenographic approaches and

mixed-methods designs. This wide range of methodological approaches reflects the breadth and diversity in the field, including issues of teacher knowledge, identity, reflection, mentoring, innovation, and curricular challenges. Furthermore, all the contributions position initial science teacher training as a dynamic area of educational research, constantly evolving and focused on how to promote the learning of future teachers for the effective and ambitious teaching of science in current contexts marked by the complexity of the content, the often negative perception of science, digital transformation, and pressing social challenges.

Content Knowledge And Its Impact On Pedagogical Content Knowledge: A Case Study Of A Pre-Service Chemistry Teacher In A Residency Program

Luciane Goes[1], Paulo Loureiro[2] and Carmen Fernandez[1]
[1]University of São Paulo, Brazil
[2]University of Georgia, USA

This study explores how variations in content knowledge (CK) are reflected in the integration of pedagogical content knowledge (PCK) in the student teaching of a pre-service chemistry teacher, Marie, participating in a Pedagogical Residency Program (PRP) in Brazil. The PRP is an 18-month teacher education initiative designed to immerse pre-service teachers in school contexts during the final stages of their undergraduate programs, fostering reflection on teaching practice under the guidance of experienced teachers and university supervisors. Data were collected through lesson plans, reports, audiovisual recordings of classroom practice, and interviews using the stimulated recall technique. The analysis was guided by the PCK framework proposed by Park and Oliver, with particular attention to the integration of PCK components. The findings indicate that patterns of PCK component integration varied across teaching topics and were sensitive to the nature of the content. In topics more closely aligned with Marie's disciplinary background, such as the history of chemistry, PCK components were more extensively articulated. In contrast, lessons involving DNA structure and chemistry-art connections revealed more fragmented integration, suggesting that limitations or uncertainties in CK may constrain the coordination of PCK components in situated teaching contexts. These findings highlight the role of CK in shaping PCK and contribute to current discussions on the enacted and topic-specific nature of teachers' professional knowledge in initial teacher education.

Keywords: Pre-service teacher education, Professional development, Educational Policy

Introduction

In Brazil, recent public policies have been seeking to address longstanding challenges in teacher education, such as low professional valorization and the need to better integrate theory and practice during pre-service training. Within this scenario, the Pedagogical Residency Program (PRP) was created as a national policy designed to immerse pre-service teachers in school contexts during the final stages of their undergraduate programs, fostering reflection on teaching practice under the guidance of both school-based mentors and university supervisors.

To understand how such practice-based programs contribute to teacher professional learning, it is necessary to consider the specific types of knowledge involved in teaching. A key construct for understanding teacher professional knowledge in such contexts is the Pedagogical Content Knowledge (PCK). PCK, a concept introduced by Shulman (1986), refers to the unique knowledge teachers possess about how to teach a particular subject, distinguishing teaching expertise from disciplinary expertise. Since its introduction, PCK has been widely recognized as a central element of teaching, as it enables teachers to transform subject matter knowledge into forms that are pedagogically meaningful to learners.

Although the literature has consistently highlighted the importance of content knowledge (CK) for teaching (Magnusson et al., 1999; Neumann, Kind, & Harms, 2019), the relationship between CK and PCK remains theoretically and empirically complex. In this study, CK is not conceptualized as a component of PCK, but rather as a condition of possibility that shapes how PCK components are mobilized and integrated during teaching practice. Previous studies suggest

that insufficient CK may constrain teachers' instructional decisions, limit their responsiveness to students' ideas, and reduce the coherence of their pedagogical approaches (Gess-Newsome & Lederman, 2019). However, much of this research has focused on identifying correlations between CK and PCK or documenting their parallel development, rather than examining how variations in CK shape the integration of PCK components in situated teaching contexts.

In response to this gap, this study examines variations in CK in chemistry and their relationship with the integration of PCK components in the teaching practice of a pre-service chemistry teacher participating in the PRP. By focusing on different science topics, the study explores patterns of integrations of PCK components during instructional planning and classroom enactment. Guided by this perspective, the study addresses the following research question: How do changes in a pre-service chemistry teacher's content knowledge influence the integration of PCK components across different teaching topics within the PRP?

Framing

Pedagogical Content Knowledge

Teachers develop a unique body of professional knowledge throughout their education and teaching experiences, which distinguishes teaching from other professions. This knowledge encompasses not only subject matter knowledge, but also an understanding of how specific content can be taught and learned in particular contexts. Grossman (1990) conceptualizes this body of knowledge as the knowledge base for teaching, highlighting that effective teaching relies on the integration of multiple forms of knowledge developed through formal education and classroom practice.

Within this knowledge base, Pedagogical Content Knowledge (PCK) occupies a central position. Introduced by Shulman (1986), PCK refers to the distinctive knowledge teachers use to transform subject matter into pedagogically meaningful representations for learners. It is this form of knowledge that differentiates teachers from disciplinary specialists, as it encompasses not only what is taught, but how and why specific instructional approaches are used to promote student understanding.

Since its original formulation, the concept of PCK has been refined and expanded in the literature, while remaining a key construct for understanding teaching practice. Among the various models proposed, the pentagonal model developed by Park and Oliver (2008) has been particularly influential in science education research. This model conceptualizes PCK as comprising five interrelated components: Orientations to Teaching Science (OTS), Knowledge of Assessment of Science Learning (KAS), Knowledge of Instructional Strategies for Teaching Science (KIS), Knowledge of Science Curriculum (KSC), and Knowledge of Students' Understanding in Science (KSU). According to Park and Oliver (2008), effective teaching requires not the isolated use of these components, but their dynamic and coherent integration during instructional practice.

An important assumption of the pentagonal model is that improvements in one PCK component should be accompanied by corresponding growth in the others. From this perspective, PCK is not a static body of knowledge, but a dynamic construct that is enacted and reshaped through teaching, reflection, and interaction with students. Teaching, therefore, is understood as an adaptive process in which teachers continuously interpret classroom situations, make instructional decisions, and revise their approaches in response to students' understanding.

While PCK has been widely studied as a form of professional knowledge, its relationship with content knowledge (CK) remains theoretically and empirically complex. Studies have emphasized that a certain level of CK is necessary for effective teaching and for the development

of PCK (Magnusson et al., 1999; Neumann, Kind, & Harms, 2019). Weak content knowledge may constrain teachers' instructional decisions, limit their ability to anticipate student difficulties, and reduce the coherence of their pedagogical strategies (Gess-Newsome & Lederman, 1995). However, much of the existing research has examined CK and PCK either as parallel domains or through correlational approaches, offering limited insight into how CK shapes the organization of PCK during teaching practice.

In this study, CK is not conceptualized as a component of PCK. Rather, CK is understood as a condition of possibility that enables the integration of PCK components in specific instructional contexts. From this perspective, variations in content mastery may influence how teachers mobilize instructional strategies, interpret students' ideas, align their teaching with curricular goals, and design assessment practices. When CK is robust, teachers may be better positioned to integrate multiple PCK components coherently; when it is limited or challenged, such integration may become fragmented or uneven.

Building on classical conceptualizations of PCK (Shulman, 1986; Grossman, 1990; Park & Oliver, 2008), this study addresses an analytical question by focusing on the integration of PCK components rather than on their isolated presence or development. By examining how variations in CK across different teaching topics shape the integrations of PCK components in a pre-service chemistry teacher, the study contributes to ongoing discussions about the role of CK in teacher education and the conditions under which PCK can be effectively enacted during initial teacher preparation.

Methodology

Context And Participants

Data were collected within the Brazilian Pedagogical Residency Program (PRP). The PRP is an 18-month program in which undergraduate students engage in sustained school-based experiences under the supervision of experienced school teachers and a university educator. Participants receive government-funded scholarships and take part in regular planning meetings, classroom observations, and teaching activities.

The study involved six undergraduate chemistry students enrolled in the PRP. From this group, one participant, here referred to as Marie, was selected for in-depth analysis. This purposeful case selection was guided by the analytical goals of the study rather than by representativeness. Marie participated in all phases of the program and planned and implemented three distinct teaching lessons addressing different content domains: Solo Role Play Game (RPG) (history of chemistry), The chemical structure of DNA, and Chemistry and Art: A Playful Exploration of Organic Functions. These science topics differed in terms of disciplinary focus and content complexity, making the case particularly suitable for examining how variations in content knowledge shape the integration of pedagogical content knowledge components.

At the time of data collection, Marie had completed most of her K-12 education in private institutions and was pursuing a teaching degree alongside her chemistry studies. She was also enrolled in a master's degree program in science education, with a particular interest in the history of science. This background provided a rich context for examining how content knowledge developed unevenly across topics and how such variations were reflected in her pedagogical reasoning and instructional decisions.

Data Collection

Multiple data sources were used to capture both planned and enacted aspects of Marie's teaching. These included written reports, lesson plans, audiovisual recordings of weekly PRP meetings,

and recordings of the three lessons taught at the school she was doing her student teaching. These materials provided access to Marie's instructional decisions, reflections, and interactions with students and peers throughout the teaching process.

In addition, a semi-structured interview using the stimulated recall technique was conducted to support reflective analysis of her teaching practices. During the interview, selected excerpts from lesson recordings and planning materials were used to prompt Marie to reflect on her instructional choices, content-related decisions, and perceptions of student understanding (Nilsson, 2014). This approach allowed for deeper insight into the relationship between content knowledge and pedagogical reasoning as articulated by the participant herself.

Data Analysis

Data analysis followed a qualitative interpretative approach consistent with the study's analytical focus on the integration of PCK components. Initially, a thematic analysis was conducted following the procedures outlined by Clarke and Braun (2017). Inductive coding was used to identify salient themes emerging from the data, capturing patterns related to instructional strategies, student understanding, assessment practices, and content-related reasoning.

Subsequently, a deductive analytical phase was conducted in which the codes were organized according to the five components of PCK proposed by Park and Oliver (2008): Orientations to Teaching Science (OTS), Knowledge of Assessment of Science Learning (KAS), Knowledge of Instructional Strategies (KIS), Knowledge of Science Curriculum (KSC), and Knowledge of Students' Understanding in Science (KSU). This process enabled the identification of how each component was mobilized across different teaching topics.

To examine the integration of PCK components, PCK maps were constructed following the methodology proposed by Park and Chen (2012). These maps represent the frequency and intensity of connections between PCK components within each teaching sequence, allowing for comparative analysis across topics. Following this approach, all identified connections between components were initially treated as having equal strength, and interactions involving more than two components were represented through pairwise connections (Park & Chen, 2012). Episode-level maps were then aggregated to produce a single map for each teaching sequence, reflecting overall patterns of PCK integration (Park & Suh, 2019). Variations in the frequency of connections were interpreted as differences in the strength of relationships between components and were visually represented by the thickness of the connecting lines in the maps.

Findings and Results

Marie's Content Knowledge

Instead of providing an exhaustive assessment of Marie's CK, we focused on how her understanding is enacted during her teaching across the three lessons developed within the PRP. This section examines how Marie mobilizes chemical concepts in interaction with students, how she connects ideas across topics, and how moments of confidence and uncertainty emerge in situated instructional contexts.

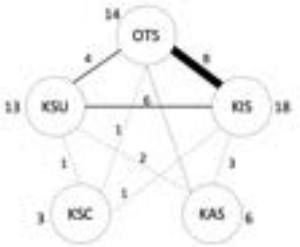
Across the three teaching sequences, Marie generally draws on chemistry concepts to support explanations and to connect chemistry with historical, biological, and everyday contexts. In the Solo Role Play Game (RPG) lesson, her enactment of CK is marked by the sustained use of historical narratives and conceptual reasoning to frame the development of key chemical ideas. While discussing the theory of phlogiston and Lavoisier's experiments, Marie consistently situates chemical concepts within their historical context, emphasizing the tentative and human character of scientific knowledge. For instance, when explaining the increase in mass observed

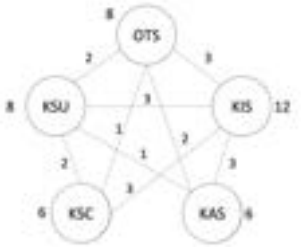
during the combustion of iron, she highlights the role of oxygen incorporation, explicitly connecting the experimental observation to the law of conservation of mass*:* "When we burn steel wool, the oxygen from the air is incorporated, and that is why the mass increases" (Marie, RPG lesson). Throughout this lesson, Marie mobilizes CK to respond to students' questions, clarify misconceptions, and sustain the narrative logic of the activity.

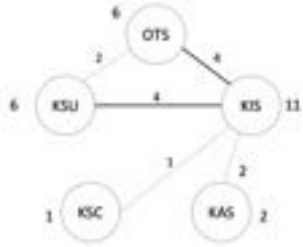
In the lesson on the chemical structure of DNA, Marie's enactment of CK reveals both coherent explanations and localized conceptual difficulties. She draws extensively on prior chemistry content, particularly organic chemistry and intermolecular interactions, to support students' understanding of DNA structure. When discussing base pairing, she accurately explains the difference in the number of hydrogen bonds between base pairs: "Guanine with cytosine makes three intermolecular interactions, whereas adenine with thymine makes two" (Marie, DNA Structure lesson). She also makes deliberate connections between the numbering of carbon atoms in organic molecules and the 5′–3′ orientation of the DNA strand, explicitly linking prior chemistry concepts to a biological structure.

At the same time, a conceptual inaccuracy emerges when Marie characterizes RNA as simply "one half" of the DNA molecule, suggesting that the distinction lies primarily in the number of strands rather than in structural differences in the sugar component. This moment illustrates how CK is not uniformly enacted across all aspects of the topic, even within an otherwise coherent explanation. Importantly, this struggle does not interrupt the overall flow of the lesson, but it indicates a point where limitations in CK may shape the way specific ideas are represented to students.

In the Chemistry and Art lesson, Marie mobilizes CK to support interdisciplinary connections between chemistry, artistic practices, and everyday materials. She explains the chemical composition of paints, solvents, binders, and pigments, frequently translating abstract representations into more accessible forms. While discussing the limonene molecule, she explicitly addresses structural representations, noting that "each vertex represents a carbon atom" (Marie, Chemistry and Art lesson). She also draws on organic chemistry concepts to differentiate between functional groups, such as alcohols, aldehydes, carboxylic acids, and ketones, often using the board to support visual explanation.







Across these lessons, Marie's CK is enacted in ways that are closely intertwined with instructional goals, student participation, and the unfolding of classroom interactions. Rather than appearing as a fixed background resource, CK emerges as a situated and dynamic element of teaching, occasionally revealing tensions or gaps that become analytically relevant when examined in relation to the integration of PCK components.

Marie's Integration of PCK Components Across Topics

Marie's PCK maps illustrate how different components of PCK were articulated across the three teaching topics developed within the PRP. Table 1 shows the PCK maps for three topics, highlighting the frequency and intensity of component connections. Rather than indicating levels of proficiency, the maps make visible patterns of integration among PCK components, allowing for a comparative analysis of how these configurations vary according to content and instructional context.

Across all three topics, KIS occupied a central position in Marie's PCK maps, functioning as a hub through which other components were connected. This prominence suggests that instructional decision-making played a key role in structuring her teaching practice, regardless of topic. However, the overall degree and configuration of integration differed across the three lessons.

Table 1. PCK Map for the Resident Marie.

Solo RPG (Role Play Game)	The chemical structure of DNA	Chemistry and Art: A Playful Exploration of Organic Functions
		
1-3: ----------	4-7: ———	>8: ■■■

OTS: Orientations of Teaching Science; KIS: Knowledge of Instructional Strategies; KAS: Knowledge of Assessment of Science Learning; KSC: Knowledge of Science Curriculum; KSU: Knowledge of Students´ Understanding in Science.

The Solo RPG lesson exhibited the highest number of connections among PCK components, indicating a more articulated integration pattern. In this topic, Marie frequently connected KIS with KSU, OTS, and, to a lesser extent, KSC. Her choice of an RPG-based strategy to address the History of Chemistry illustrates how instructional decisions were informed by epistemological and pedagogical concerns. As she explained in the interview, "I wanted a different way to approach the History of Chemistry, which is rarely addressed by teachers, partly because it is challenging and often reduced to names and dates that reinforce a heroic view of science" (Marie, interview). This strategy created opportunities for student participation and critical engagement, supporting the articulation between KIS and KSU observed in the maps.

The integration between KIS and KSU emerged as a recurrent pattern across all topics. Marie frequently used questions and dialogic interactions to elicit students' prior ideas and adjust her explanations accordingly. For example, in the DNA lesson, she asked: "What do you think of when you hear DNA?" (Marie, DNA class), signaling an attempt to anchor instruction in students' existing conceptions. These interactions contributed to the repeated coupling of instructional strategies with KSU, suggesting a student-oriented approach to teaching.

In contrast, KSC appeared less frequently integrated with other components, particularly in the Chemistry and Art lesson. Although Marie knew about the school's curriculum, such as prior content coverage, references to curriculum mainly informed localized instructional decisions rather than broader planning or assessment considerations. This pattern is consistent with previous studies that report weaker integration of KSC in PCK maps (Park & Chen, 2012). For instance, when planning the Chemistry and Art lesson, Marie noted that students had already studied organic functions and therefore intended to revisit alcohols and ketones based on students' observations of molecular structures: "To ask the students what they see as different and notable in this structure. If they mention the heteroatoms as expected, revisit the two organic functions present alcohol and ketone" (Marie, lesson plan). While this indicates curricular awareness, it was not systematically connected to assessment or to explicit curricular goals within the lesson.

The Chemistry and Art lesson displayed a more limited integration among PCK components overall. Although OTS, KIS, and KSU remained central, fewer connections involved KSC and KAS. Much of the interaction focused on identifying and revisiting previously taught concepts, as illustrated by questions such as "Do you remember the lesson on alcoholism? What

characterized alcohol?" (Marie, Chemistry and Art lesson). These patterns suggest that, in interdisciplinary contexts, Marie's PCK integration was primarily oriented toward activating and diagnosing prior knowledge rather than coordinating multiple components around shared curricular or assessment goals.

In the DNA structure lesson, Marie mobilized several PCK components, but the resulting integration was less articulated than in the RPG lesson. While KIS and KSU were frequently connected, links involving assessment and curriculum were sparse. The use of visual representations, such as images of the DNA double helix and X-ray diffraction photographs, supported the contextualization of abstract concepts, but these strategies were not consistently connected to assessment practices or curricular choices.

Discussion

The variability observed across Marie's PCK maps highlights the topic-specific and situated nature of PCK integration. Rather than reflecting stable characteristics of the teacher, these configurations appear to be shaped by the nature of the content, the degree of interdisciplinarity involved, and the extent to which CK could be mobilized to support instructional coherence. In topics more closely aligned with Marie's disciplinary background, such as the history of chemistry addressed in the RPG lesson, PCK components were more extensively articulated. In contrast, in topics requiring the integration of chemistry with biology or art, component integration was more fragmented, suggesting that limitations or uncertainties in content knowledge may have constrained the coordination of instructional, curricular, and assessment-related decisions.

The findings of this study contribute to ongoing discussions in PCK research by shifting the analytical focus from the identification of individual components to the examination of their integration in situated teaching contexts. Recent studies have increasingly emphasized PCK as an enacted, dynamic, and topic-specific form of professional knowledge that emerges through instructional decision-making rather than as a stable body of knowledge possessed by teachers (Carlson et al., 2019; Kind & Chan, 2019). In line with this perspective, the variation observed across Marie's PCK maps reinforces the view that PCK integration is sensitive to content characteristics and instructional demands.

While prior research has consistently documented relationships between CK and PCK, often emphasizing their co-development or mutual dependence, the present study advances this discussion by examining how variations in content knowledge are reflected in the integration of PCK components within the teaching practice. Rather than treating PCK as a collection of discrete components or as a stable attribute of the teacher, this analysis explores the configuration and connections between components as they are enacted across different topics.

The comparative analysis of PCK maps across three teaching lessons demonstrates that integration patterns are not uniform, even within the practice of a single pre-service teacher. These variations cannot be fully explained by general teaching competence, but appear to be shaped by topic-specific demands, degrees of interdisciplinarity, and the extent to which CK can be mobilized to support instructional coherence. In this sense, the study moves beyond confirming that CK matters for PCK development, offering instead a fine-grained account of how CK influences the internal organization of PCK during instructional enactment.

Although based on a single case, the study does not seek to generalize about levels of PCK or teaching effectiveness. Instead, its contribution lies in illustrating the analytical potential of PCK maps for examining the situated and topic-dependent integration of pedagogical knowledge in initial teacher education. In doing so, the study opens possibilities for future research that explores

how different configurations of CK and instructional context shape the enactment of PCK across subjects, topics, and stages of teacher development.

Conclusion

This study examined how variations in CK are reflected in the integration of PCK components in the teaching practice of a pre-service chemistry teacher participating in a Pedagogical Residency Program. Rather than aiming to assess levels of CK or pedagogical expertise, the analysis focused on how content understanding was enacted and mobilized across different teaching topics.

The findings indicate that patterns of PCK integration varied across instructional contexts, suggesting that CK may condition how coherently PCK components are articulated during teaching. In topics more closely aligned with the teacher's disciplinary background, such as the history of chemistry addressed in the RPG lesson, PCK components were more extensively integrated. In contrast, in topics involving interdisciplinary demands, such as DNA structure and chemistry and art, the integration of components was more fragmented, highlighting how uncertainties or limitations in CK may constrain the coordination of instructional, curricular, and assessment-related decisions.

Although based on a single case, the findings underscore the importance of examining the enacted integration of knowledge components in practice-based programs such as the Pedagogical Residency Program. Future research could build on this approach by exploring how different configurations of content knowledge, instructional context, and support structures shape the development and enactment of PCK across subjects and stages of teacher education.

What Do Pre-Service Early Childhood Teachers Learn About The Nature Of Models When Engaging In Model-Based Inquiry?

Marta Gómiz-Aragón and Lourdes Aragón
University of Cádiz, Spain

This study investigates whether pre-service Early Childhood Education teachers at the University of Cádiz (Spain) develop a deeper understanding of the nature of scientific models after implementing a Model-Based Inquiry (MBI) Teaching-Learning Sequence (TLS). The TLS focused on the water cycle, using the ecological garden as a real-world learning context. Students' knowledge of model nature was measured before and after the TLS using the Spanish CoNaMo questionnaire. Statistical analyses revealed significant gains, particularly in the dimensions "beyond exact replicas" and "changing nature of models." These findings highlight the importance of designing TLS that foster authentic epistemic practices and explicitly address students' understanding of model nature to support the development of Pedagogical Content Knowledge (PCK) related to modelling and inquiry.

Keywords: Inquiry-Based Learning, Nature of Science, Pre-service Teacher Education

Introduction

Teaching science involves the challenge of engaging students in scientific practices such as modelling and inquiry. These practices not only support the understanding of complex concepts but also promote a deeper comprehension of the Nature of Science (NOS). However, implementing them effectively in classrooms requires teachers to have a strong Pedagogical Content Knowledge (PCK). Understanding the nature, purpose, and limitations of scientific models is essential in teacher education, as it shapes how future teachers approach science instruction and influences students' learning (Akerson et al., 2010). Science as a cultural product, through its explanatory models, theories, and concepts, has a substantial impact on citizens' lives (Tamayo et al., 2005). Consequently, instructional design should foster a more critical engagement with scientific knowledge.

Addressing NOS in science classes enables students to develop broader perspectives on science, which can in turn influence their own views of the world. According to Lenderman et al. (2023), explicit and reflective instruction, together with teaching approaches such as inquiry, appears to significantly enhance learners' understanding of NOS as a key component for authentic scientific literacy (Vázquez et al., 2001). Within NOS, the nature of models is particularly relevant (Brandão et al., 2011), including, for example, what students understand a model to be and how they consider the evolving nature of scientific models (Treagust et al., 2002).

Integrating these ideas in pre-service teacher education is essential, as it helps future teachers develop the metamodeling skills that form a core component of modelling competence (Nicolaou & Constantinou, 2014). It also provides them with the tools and resources needed to use scientific models appropriately and to recognise their role in scientific knowledge and in future science teaching (Oh & Oh, 2010). According to Bell and Clair (2015), young children can develop scientific skills and understanding aspects of science when guided by teachers with strong scientific preparation. This highlights the need to design instructional interventions that offer explicit and targeted support for learning about the nature of models.

Early Childhood Education is considered a critical stage for fostering the scientific thinking skills that underpin a more sophisticated understanding of the NOS (Bell & Clair, 2015). In this context, the main aim of this study is to analyse the progression in pre-service early childhood teachers' understanding of the nature of models through a training proposal that integrates inquiry and modelling to address the water cycle in a real context, namely the university ecological garden.

Theoretical Framework

PCK emerges from the interaction between disciplinary knowledge and the pedagogical strategies required to teach it. PCK enables pre-service teachers not only to understand the scientific concepts they teach but also to guide students in developing metacognitive and epistemological skills that support deeper engagement with scientific processes (Zohar & Barzilai, 2013). Beyond conceptual mastery, PCK incorporates the ontological status and epistemic value of scientific ideas, together with instructional strategies that promote reflection, scientific thinking, and cognitive self-regulation (Papadouris & Constantinou, 2017).

Epistemic practices are the core processes through which scientific knowledge is generated, validated, and communicated. They can be grouped into three interrelated spheres: empirical investigation, the development of explanations, and critical evaluation—corresponding to inquiry, modelling, and argumentation (Jiménez-Aleixandre & Crujeiras, 2017). Passmore and Svoboda (2012) emphasise that science instruction should engage students in constructing, using, evaluating, and revising models to explain, interpret, and predict phenomena, positioning modelling as a central feature of scientific knowledge (Nersessian, 2002). This work is closely tied to inquiry, which involves asking questions, collecting data, and identifying patterns to support models, and to argumentation, which enables students to justify explanations, assess evidence, and refine conclusions in critical and reflective ways.

Instruction grounded in authentic scientific practices—such as Model-Based Inquiry (MBI)—integrates these three epistemic practices and supports students' understanding of scientific processes and the development of metacognitive skills (Seraphin et al., 2012; National Research Council, 2012). However, engaging in isolated practices is not sufficient for developing the full set of abilities required to work with models critically and reflectively. For this reason, model-based learning is conceptualised in terms of modelling competence, which includes modelling practices—constructing, applying, and revising models—and the metaknowledge needed to reflect on models, their nature, and the processes involved in modelling (Oliva, 2019; Nicolaou & Constantinou, 2014).

Within this framework, metamodeling enables students to understand the nature, purpose, and limitations of scientific models, promoting critical reflection on their use in science and in teaching (Schwarz et al., 2009; Gobert et al., 2011). Knowledge of the nature of models can be organised around four key ideas:

- Models are not exact replicas of phenomena but partial representations of reality (Jansen et al., 2019; Krell & Krüger, 2017; Upmeier zu Belzen & Krüger, 2010).
- Models serve explanatory, interpretive, and predictive functions, helping to make sense of scientific phenomena (Jansen et al., 2019; Krell & Krüger, 2017).
- Multiple models can exist for the same phenomenon, reflecting the diversity of perspectives and approaches in science (Justi & Gilbert, 2002; Upmeier zu Belzen et al., 2019).
- Models are provisional and evolving, subject to revision or modification based on new evidence, alternative theories, or different purposes (Crawford & Cullin, 2004).

PCK, by integrating disciplinary knowledge with pedagogical strategies oriented to epistemic practices such as modelling and inquiry, not only guides the teaching of scientific concepts but also shapes how pre-service teachers foster students' understanding of the nature of models. This perspective underpins the implementation of specific educational interventions, such as MBI Teaching-Learning Sequences (TLSs), which allow researchers to assess how future teachers develop PCK applied to modelling and epistemic reflection.

This study is part of a broader research project evaluating a TLS designed for pre-service teacher education and focused on developing PCK related to modelling and inquiry. Specifically, it examines whether students in the Early Childhood Education degree progress in their understanding of the nature of models after implementing a TLS on the water cycle using the MBI approach. The study is guided by the following research questions:

RQ1. Do students show changes in their understanding of the nature of models after implementing an MBI sequence?

RQ2. Which aspects of the nature of models show these changes?

Methodology

Participants and Educational Context

The study involved 52 students (1 male, 51 female) enrolled in the course Didactics of the Natural Environment, third year of the Early Childhood Education degree at the University of Cádiz, Spain, during the 2024–2025 academic year. A TLS based on the MBI approach was designed and implemented (Gómiz-Aragón & Aragón, 2025), focused on the water cycle, consisting of six 90-minute sessions. The university ecological garden served as a real learning context.

The TLS was structured in five phases to promote the progression of students' initial models of the water cycle toward more complex representations. Table 1 summarises the phases, the main activities, and the aspects of students' understanding of the nature of models (CoNaMo[1] dimensions) addressed in each phase. The four dimensions are: D1 (models beyond exact replicas), D2 (model utility), D3 (multiple model representations), and D4 (evolving nature of models).

Instrument

Data were collected using the CoNaMo questionnaire (Oliva & Blanco-López, 2021), designed and validated to assess knowledge of the nature of scientific models. The questionnaire, originally in Spanish, includes 20 Likert-type items on a 5-point scale (1 = strongly disagree; 5 = strongly agree), distributed across four dimensions (D1–D4), each with 5 items. Scores for each dimension range from 0 to 20 points, and the total score ranges from 0 to 80, providing a quantitative measure of students' understanding of scientific models.

Before administration, the instructor explained the study purpose, and students provided informed consent. The questionnaire was administered in paper format as a pretest at the beginning of the TLS and as a posttest at the end.

[1] From the Spanish *Conocimiento de la Naturaleza de los Modelos*, or 'Knowledge of the Nature of Models'

Table 1. Phases and Activities of the MBI TLS.

Phase	Activities	Nature of models dimensions
1. Defining the TLS objective	A1: Exploration of initial water cycle models through drawings and CoNaMo pretest questionnaire	Identification of prior ideas about model nature, utility, diversity, and evolution (D1, D2, D3, D4)
	A2: Reflection on water, the natural environment, and water footprint	Model utility for understanding and acting on socio-environmental water issues (D2)
2. Initial conceptions	A3: Explicit expression of initial water cycle models	Contrast different representations of the same phenomenon (D3)
	A4: Expression of conceptions about the nature of models	Awareness of what a model is, its purposes, diversity, and evolution (D1, D2, D3, D4)
3. Modelling-based learning	A5: Use of thought experiments and drawings for water cycle modelling	Understanding the need for a model to explain the phenomenon, alternative representations, and reflection on model evolution (D2, D3, D4)
4. Model application through inquiry	A6: Introduction of the garden as a learning context	Model utility for interpreting a real phenomenon in the environment (D2)
	A7: Formulation of the main inquiry question	Definition of the model's purpose to guide the investigation (D2)
	A8: Identification of difficulties and formulation of sub-questions	Need for different models or representations to explain various aspects of the phenomenon (D3)
	A9: Formulation of hypotheses, experiment design and execution, data collection, analysis, and conclusions	Use the model to predict and explain; represent results through drawings or diagrams (D2, D3)
	A10: Answering the main inquiry question	Reflection on model simplification and its utility for addressing the inquiry (D1, D2)
5. Model reconstruction	A11: Final review of the water cycle model through drawings and CoNaMo posttest	Review of final understanding of model nature, utility, diversity, and evolution (D1, D2, D3, D4)
	A12: Group reflective report on the teaching-learning process	Integration of reflection on model function and the learning process (D1, D2, D3, D4)

Data Analysis

To evaluate changes in pre-service teachers' understanding of the nature of models before and after the TLS, a within-group quantitative analysis was conducted. First, the reliability of the data was assessed using ordinal Cronbach's alpha for each dimension and for the overall scale (Table 2).

Table 2. Ordinal Cronbach's alpha for CoNaMo dimensions

CoNaMo dimensions	Pretest	Posttest
D1: Beyond exact replicas	0.700	0.782
D2: Utility	0.543	0.720
D3: Multiplicity	0.765	0.817
D4: Evolving nature	0.877	0.841
Global scale	0.883	0.891

Ordinal Cronbach's alpha values indicate improved internal reliability after the intervention. Pretest reliability ranged from acceptable (0.543) to high (0.877). Post-test reliability increased across dimensions, particularly D2 and D3, with the global scale rising from 0.883 to 0.891, reflecting strengthened reliability and potential improvement in questionnaire comprehension after the TLS.

Next, Wilcoxon signed-rank tests were performed to analyse differences between pre- and post-test scores, and effect sizes were calculated to determine the magnitude of these changes. All analyses were conducted using Jamovi software (version 2.4).

Result

Descriptive analysis of CoNaMo scores (Table 3) showed differences between pre- and posttest. In the pretest, D1 (Beyond exact replicas) had the lowest mean score (M = 2.3), while D4 (Evolving nature) had the highest (M = 3.1). The overall mean score was 2.8. After the intervention, all dimensions improved, with the largest gains in D1 (M = 2.9) and D4 reaching the highest post-test score (M = 3.5). The overall mean increased to 3.2, suggesting enhanced understanding of the nature of models.

Table 3. Descriptive statistics and Wilcoxon signed-rank test results

CoNaMo Dimensions	Pretest M	Pretest DS	Postest M	Postest DS	W	p-value	Effect size (r)
D1: Beyond exact replicas	2.3	0.6	2.9	0.7	230.0	<0.001	0.639
D2: Utility	2.9	0.4	3.2	0.5	220.0	0.002	0.513
D3: Multiplicity	2.9	0.4	3.3	0.6	146.5	<0.001	0.676
D4: Evolving nature	3.1	0.5	3.5	0.5	135.0	<0.001	0.750
Global	2.8	0.3	3.2	0.4	64.0	<0.001	0.891

Inferential analysis using the Wilcoxon signed-rank test confirmed statistically significant improvements across all dimensions. The largest effects were observed in D4 ($r = 0.750$) and the overall score ($r = 0.891$). Other dimensions also showed moderate gains: D1 ($r = 0.639$), D2 ($r = 0.513$), and D3 ($r = 0.676$). These results indicate that the intervention contributed to enhancing pre-service teachers' understanding of the nature of scientific models.

Discussion and Conclusions

The instructional intervention, implemented using a MBI approach, had a positive impact on pre-service teachers' understanding of the nature of models, consistent with previous research indicating that improvements are not explained by mere repetition of the instrument (Oliva & Caballero, 2020). Improvements were observed across all dimensions, with the largest gain in D4 (Evolving nature of models), aligning with studies suggesting that this dimension is particularly accessible for students (Jiménez-Tenorio et al., 2016).

This outcome can be attributed to the TLS design, where several activities explicitly highlighted the need to adapt models in response to new evidence, fostering understanding of their provisional nature. According to Engelschalt et al. (2024), recognizing that scientific models are evolving is closely linked to modelling knowledge itself—that is, understanding that models are provisional and develop over time.

In Activity 4, CoNaMo results were shared with the class, using multiple examples to clarify each dimension. This activity promoted dialogic metamodeling, grounded in students' own perceptions. In turn, Activity 5, a thought experiment, introduced new concepts and ideas that helped students develop more complex mental models of the water cycle, represented through detailed drawings. This activity thus exemplified the evolving and provisional nature of models in explaining a natural phenomenon.

In contrast, dimensions such as Multiplicity (D3) and Utility (D2) showed more moderate gains. This may be because the TLS did not include activities specifically designed to compare models with different functions or justify the utility of each representation for explanatory purposes. Future interventions could strengthen these dimensions by incorporating tasks that require selecting models according to their purpose, assessing the adequacy of different representations, and constructing explanations based on multiple types of models.

Overall, the results highlight the importance of explicitly addressing metamodeling, the epistemology of models, and the NOS in teacher education. Research indicates that understanding these aspects rarely develops implicitly through modelling practices; it requires intentional instructional strategies that make their epistemic dimensions visible (Schwarz, 2002). Interventions such as the one described in this study, which include guided reflection, model comparison, analysis of limitations, and discussion of model use, promote more robust learning. This is particularly relevant in pre-service teacher education, where developing PCK involves not only the ability to model but also the capacity to foster metacognitive and epistemic discourse about scientific models in the classroom.

Limitations

This study presents several limitations that should be considered when interpreting the results.

First, the TLS was implemented in the only course in the curriculum specifically dedicated to science education (Didactics of the Natural Environment) and within a limited timeframe, which may have constrained work on certain dimensions of the nature of models. The lack of continuity across other courses in the degree limits the opportunity to consolidate and deepen these learning outcomes.

Second, the study relied exclusively on a quantitative instrument. Although previously validated, it was not triangulated with qualitative sources, which limits a deeper understanding of students' conceptions and prevents clear attribution of observed changes to specific TLS activities. Without additional qualitative evidence, it is not possible to identify precisely which activities had the greatest impact or why some dimensions showed more moderate progression. Nevertheless, the instructor implementing the TLS (second author) was able to identify some key activities that likely supported improvements in certain dimensions. Future studies will examine other student outputs to better determine which activities contribute to the development of a more sophisticated understanding of the nature of models.

Finally, although results indicate gains in overall understanding of the nature of models, it is not possible to determine whether these learnings transfer specifically to the scientific model addressed, in this case, the water cycle model. Evaluating this relationship would require qualitative techniques, such as interviews or analysis of student journals, to explore how students connect what they learned with their own modelling processes in concrete tasks.

ESERA 2025 Copenhagen

Prospective Physics Teachers' Perceptions Of An Objective Structured Teaching Examination (OSTE)

Christoph Vogelsang[1], Lea Lohrsträter[1], Philipp Wotschel[1] and Thomas Janzen[2]
[1]PLAZ- Professional School of Education, Paderborn University, Germany
[2]Center for Practical Teacher Training, Bielefeld, Germany

Assessments or examination procedures should be adequately aligned with the intended learning objectives and planned learning activities, ensuring that the assessment or examination is a valid and reliable measure of the desired learning outcomes. However, academic teacher education programmes often use assessment formats that do not align well with teachers' actual professional practice. Performance-based assessments provide an alternative approach, for example in the form of role-play-based simulations with trained actors representing typical professional activities in environments of reduced complexity. We have developed such a performance-based assessment format for physics teacher education, following the concept of Objective Structured Teaching Examinations (OSTE), as used in medical education. The developed OSTE prototype consists of seven short simulation-based assessments, reflecting four areas of teachers' professional competence (Instruction, Assessment, Pedagogy and Innovation) that form a 90-minute examination course. To investigate prospective physics teachers' perceptions of such an assessment format in terms of its suitability as a summative examination procedure, we piloted the OSTE prototype with N = 54 physics prospective teachers from five German universities using short questionnaires. The results show that participants perceived the OSTE as authentic and relevant. However, they also highlight the need for adequately designed new learning opportunities to prepare for such examinations, which should be integrated into teacher education programmes.

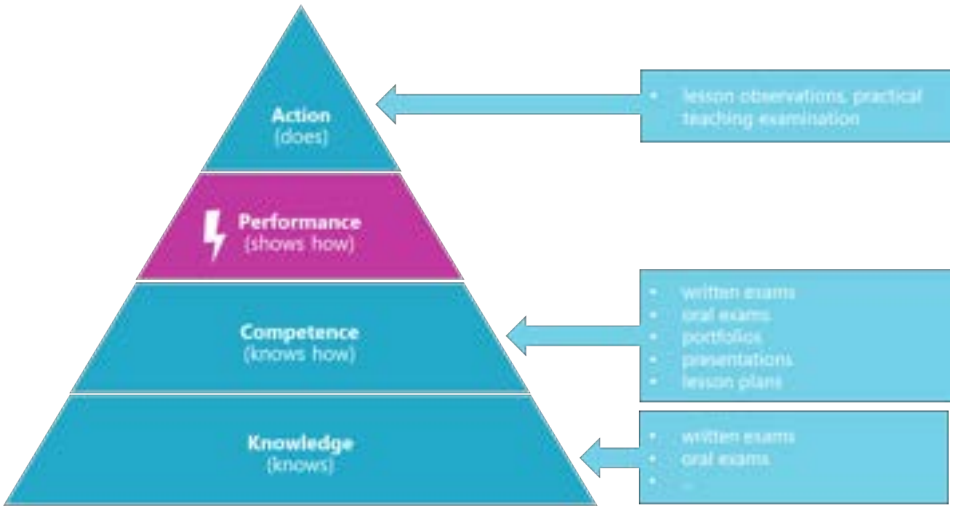
Keywords: teacher education, assessment, examination, simulation, core practice

Background

Prospective teachers often find it difficult to apply the knowledge acquired during their university studies in the classroom and often feel that their studies do not adequately prepare them for future professional practice (Tynjälä & Heikkinen, 2011). This gap between theory and practice in academic teacher education has been the subject of much research. However, the influence of the assessment or examination procedures used in teacher education on this gap is rarely considered.

The Role Of Assessments For Learning

Assessments serve various purposes. Assessment results are used for certification, which has implications for candidates' further study and careers (summative assessment). Furthermore, feedback on assessments can inform students about their performance and thus support them in achieving future learning goals (formative assessment). Hence, according to the model of Constructive Alignment, assessments – including formal examinations – learning objectives and learning activities need to be aligned in such a way that they form a coherent learning process (Biggs & Tang, 2011). Therefore, in teacher education, assessments must be designed in such a way that prospective teachers acquire the necessary skills to become good teachers.



Research in higher education indicates that students' perceptions of assessment procedures or formats have a variety of effects on how they learn and on their course choices (Struyven et al., 2005). Various aspects of assessments have been found to be particularly important. For example, the fairness of an assessment is critical, meaning the perception of fair evaluation and the

opportunity for the candidates to demonstrate their actual capabilities (Sambell, 1997). Fairness of an assessment is related to its perceived transparency, referring to clear expectations and evaluation criteria (Drew, 2001). A key factor, particularly in teacher education, is how authentic an assessment is perceived to be. The authenticity of an assessment relates to how relevant it is perceived to be for the intended learning objective, and its alignment with the professional activities of teachers. Additionally, it refers to whether the content and procedure of an assessment are considered to be authentic (Gulikers et al., 2008). Students tend to choose more in-depth learning strategies to meet the intended learning goals if they perceive an assessment to be more authentic (Villaroel et al., 2021). However, the typical assessments formats used in teacher education programmes rarely reflect later professional activities.

Assessment-Gap In Teacher Education

For a more detailed analysis of assessment formats, we use Miller's (1990) framework for clinical assessment (Figure 1). Although it was originally developed for medical education, it can also be adapted for teacher education.

Figure 1. Typical assessment formats used in teacher education.

The framework differentiates between four levels of assessment depending on which learner dispositions or abilities are focused on. Assessments at the first level (level of knowledge) focus on prospective teachers' declarative knowledge (e.g. content knowledge). Typical formats for assessing this knowledge are written or oral exams. At the second level (level of competence), assessments focus on the procedural knowledge that prospective teachers need to know in order to perform typical professional tasks (Verloop et al., 2001). Alongside written and oral exams, typical formats include portfolios, term papers and, particularly in teacher education, written lesson plans. Assessments at the third level (level of performance) focus on prospective teachers' performance. The focus of this level is on performance, in the sense that prospective teachers can demonstrate their ability to carry out specific professional tasks in a standardised, lower-complexity setting. In contrast, assessments at the fourth level (level of action) focus on prospective teachers' actions under the full complexity of the field. There is a kind of 'assessment gap' between the testing of knowledge on the one hand and professional action in the full complexity of the classroom on the other. While typical formats such as classroom observations are frequently used in teacher education programmes at the fourth level, formats at the third level are scarce. This points to an assessment gap that mirrors the broader theory–practice divide in teacher education.

Addressing The Gap: Performance-Based Assessments

Assessment formats are needed that represent typical professional activities in settings of reduced complexity (approximations of practice, Grossman, 2021). Such assessment formats have long been established in medical education. In these assessments, typical professional tasks (e.g. conducting a clinical interview) are simulated under standardised conditions, often in role-play-based simulations with trained actors. To assess medical educators' teaching and communication skills, several such simulated tasks are also combined in so-called Objective Structured Teaching Examinations (OSTE) (Fakhouri & Nunes, 2019). An OSTE typically consists of a series of 10-15-minute simulation-based assessments that are completed as a coherent examination course. Comparable performance-based assessment formats have rarely been used in teacher education, particularly in science teacher education. However, simulation-based learning approaches are sometimes used for training purposes (e.g. Dotger et al., 2010) or in research projects (e.g. Kulgemeyer & Riese, 2018). Previous findings suggest that prospective teachers positively evaluate such simulations, and especially role-playing formats, as realistic practice and perceive them as authentic and motivating (cf. de Coninck et al. 2019). However, there is seldom evidence of their suitability as an assessment format in teacher education. Therefore, we analysed prospective teachers' perceptions of performance-based examination procedures based on the exemplary case of a specific OSTE developed for Physics Teacher Education.

An OSTE Prototype For Physics Teacher Education

We developed a prototype of an OSTE with the aim of assessing performative aspects of the professional competence of prospective physics teachers (Blömeke et al., 2015). It consists of seven 10–20-minute stations designed aligned with the four areas of competence (Instruction, Assessment, Pedagogy and Innovation) defined in the German National Standards for Teacher Education (KMK, 2022). Following the core practices approach (Grossman, 2021), each station assesses a single isolated core practice. Some stations have a more pedagogical focus, and others focus more on practices specific to physics teachers and were developed based on previous work (e.g., Feser, 2019; Kulgemeyer & Riese, 2018). In terms of content, the stations focus on mechanics. The task and the corresponding response format of the stations vary: the OSTE includes simulated conversations with trained actors as well as simulated video calls on a laptop and stations that must be completed entirely in writing. An overview of all simulated scenarios is described in Table 1.

Participants complete each station in turn, though this order varied from person to person. A complete examination course takes approximately 90 minutes, including short breaks, to fit into the standard schedule of typical courses in German teacher education. All stations follow the same procedure:

1) The participant familiarises with the context of the station by using the material provided (e.g. vignette with background information, standardised auxiliary materials).
2) The participant prepares for the task in a short preparation time.
3) The participant carries out the task.
4) The participant moves on to the next station.

Performance at each station is assessed using standardised coding rubrics by trained raters. In our pilot study, different forms of data were collected depending on the response format, which provided the basis for the performance evaluation. The simulated conversations with actors were videotaped and transcribed afterwards. In the simulated video calls, participants spoke their

answers into a headset microphone. These were audio-recorded and also transcribed. The written answers were processed in the same way as traditional forms of assessment.

Table 1. OSTE-Overview

	Scenario/Task	Response
Instruction		
Station 1: Lesson planning	Participants are asked to fill in the blank in a given lesson plan for a physics lesson by devising a suitable experiment on Newton's Third Law.	written
Station 2: Analysing physics lessons	During a field placement, a fellow prospective teacher asked for feedback on his teaching. Participants therefore have to reflect on and provide feedback on short sequences of videotaped instruction.	simulated video call
Station 3: Explaining a physical phenomenon	Participants are asked to explain to a student why motorcycle accidents are more likely to happen on bends after rain.	simulated conversation (one actor)
Assessment		
Station 4: Student counseling	Participants have to conduct an individual counselling/consultative meeting with a student who is repeatedly disruptive in class	simulated conversation (one actor)
Station 5: Evaluating students' answers in a test	Participants are given two answers to a physics test on acoustics written by students and must evaluate them using provided criteria.	written
Pedagogy		
Station 6: Mediating a conflict between two students	Two students have gotten into a conflict during a break. Participants have to mediate in order to resolve or defuse the conflict.	simulated conversation (two actors)
Innovation		
Station 7: Collaborative lesson development	Participants are asked to discuss the suitability of a lesson analysis tool with a colleague for potential use in professional development.	simulated video call

Objectives

Using the OSTE prototype as an example, we investigated prospective teachers' perspectives on such a performance-based assessment format, which was adapted from medical education. The following research question was investigated.

How do prospective teachers perceive an OSTE prototype for physics teacher education in terms of its suitability as a possible examination procedure?

In particular, we focused on prospective teachers' views of authenticity, cognitive involvement and perceived academic preparation for the OSTE.

Method

We tested the OSTE with eight groups of pre-service teachers at five German universities in 2024. The sample consists of N = 54 prospective physics teachers (gender: 64.8% male, 35.2% female). At the time of the pilot study, they were, on average, in their sixth semester (M = 6.2, SD = 4.1).

44.4% of the participants already had experience teaching mechanics in schools at the time of the test (e.g. through their mandatory field experiences or working as substitute teachers).

After finishing each station, participants completed a short questionnaire with five-point Likert items about their perceptions of the station in terms of authenticity (3 items, example: *"I think the situation described is authentic."*) and cognitive involvement (3 items, example: *"I have immersed myself in the situation."*). The internal consistency of both scales was sufficient for all stations (authenticity: $0.73 < \alpha < 0.88$, cognitive involvement: $0.80 < \alpha < 0.87$). The participants were also asked how well their studies had prepared them for each station (1 item, *"I feel that my studies have prepared me well for the station."*). At the end of the whole OSTE, they completed a questionnaire covering demographic information and an overall rating of the OSTE prototype using six-point Likert items (see Table 3). We were able to conduct follow-up interviews with four participants to gain deeper insights into their perspectives and to enrich the quantitative data.

Results

Evaluation Of The Individual Stations/Scenarios

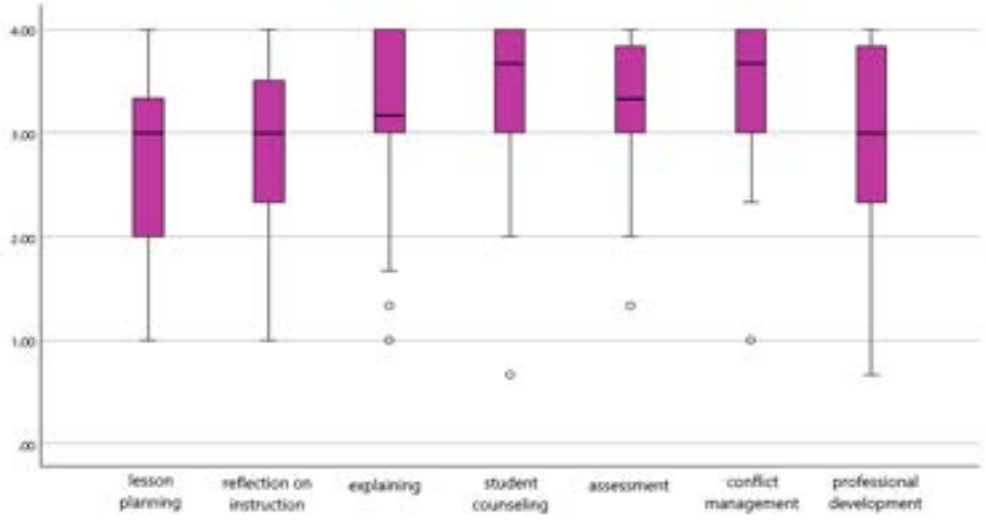
Table 2 shows the descriptive results regarding perceived authenticity, cognitive involvement and preparedness.

Table 2. Descriptive results – individual stations (range: 0 to 4, theoretical mean: 2).

Station	Authenticity		Cognitive Involvement		Preparedness	
	M	SD	M	SD	M	SD
Station 1: Lesson planning	2.73	0.91	3.13	0.74	2.45	1.01
Station 2: Analysing physics lessons	2.84	0.83	2.98	0.81	2.31	1.06
Station 3: Explaining a physical phenomenon	3.18	0.79	3.36	0.67	2.23	1.02
Station 4: Student counselling	3.35	0.61	3.42	0.59	0.90	1.04
Station 5: Evaluating students' answers in a test	3.35	0.61	3.40	0.58	1.75	1.04
Station 6: Mediating a conflict between two students	3.47	0.61	3.31	0.61	0.87	1.07
Station 7: Collaborative lesson development	2.93	0.93	3.01	0.76	1.71	1.27

Regarding the evaluation of the individual stations, Station 5 (Evaluating students' answers in a test) and the simulated conversation in Station 6 (Mediating a conflict between two students) in particular generated a high level of cognitive involvement and were perceived as highly authentic. The stations with simulated video calls and Station 1 (Lesson planning) were perceived as slightly less authentic, but cognitive involvement was still comparably high. In terms of trends, stations involving actors were perceived as more authentic. In comparison, stations closer to the lower assessment levels in Miller's (1990) framework were perceived as less authentic. On average, however, perceptions of each station were above the theoretical mean. Participants were highly cognitively involved in each station. Box plots of data for authenticity and cognitive involvement are also shown in Figures 2 and 3 to illustrate the differences among participants more concisely. Overall, students felt that their studies had done little to prepare them for the tasks set at the examination stations. They felt most prepared for tasks relating to instruction, which are found in stations 1 to 3. For more pedagogical core practices reflected in Station 4 (Student counseling) or Station 6 (Mediating a conflict between two students) most of them felt not prepared at all.

Figure 2. Perceived authenticity of the individual stations – Boxplots.



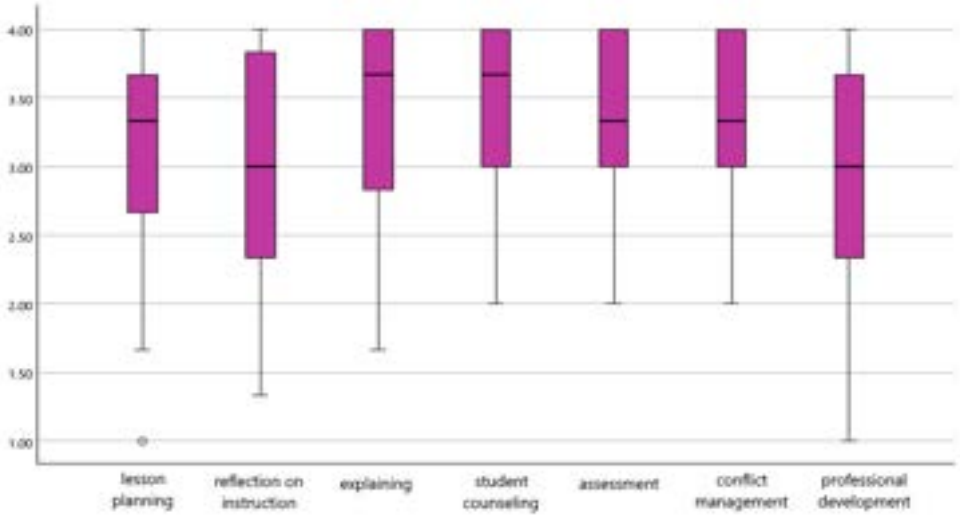


Figure 3. Perceived cognitive involvement in the individual stations – Boxplots.

Evaluation of the whole OSTE prototype

Table 3 shows the descriptive results regarding the overall assessment of the OSTE prototype.

Table 3. Descriptive results – overall evaluation (theoretical mean: 3.5).

Items	M	SD
"Such an examination course assesses what is relevant for my future career as a teacher"	5.35	0.71
"You can prepare well for such an examination course"	3.57	1.04
"In such an examination course it is easy to compare the performance of different students"	3.81	1.11
"An examination course like this reflects authentic practices of the teaching profession"	5.41	0.71
"You can plan your preparation well for such an examination course"	3.81	1.09
"An examination course like this assesses what is relevant throughout teacher education"	5.20	1.02

The results are positive in terms of their suitability as a possible examination format but also point to the challenges of the still unfamiliar format. Specifically, participants felt that the OSTE

prototype reflects authentic professional core practices of physics teachers and assesses what is relevant to their future profession. On the other hand, the participants were less positive about the possibility of preparing well for such an examination format and the comparability of students' performance in the OSTE prototype.

These quantitative results are also reflected in the interviews. For example, one participant pointed out that the OSTE prototype covers relevant professional skills.

> "Also zum einen, dass man Fachwissen halt zum Beispiel einem Schüler nahbringen kann. Das ist ja eine Kompetenz, die eigentlich sehr wichtig ist, aber die so bis jetzt in keiner Prüfung bei mir eigentlich drankam würde ich sagen. [Well, for one thing, you can teach a student content knowledge. That's a competency that's actually very important, but I would say that it hasn't really come up in any of my exams so far.]"

The time pressure aspect of the OSTE prototype was also considered to be an appropriate representation of the professional demands placed on teachers.

> "Ich habe erst gedacht, dass es so ein bisschen auch negativ [...] ist, dadurch, dass man ja so schnell 'switchen' muss zwischen diesen einzelnen Stationen, dann habe ich aber gedacht, wenn man später in dem Beruf ist wird es nicht anders sein. [At first, I thought it was a bit negative [...] because you have to switch between these different stations so quickly, but then I realised that it won't be any different when you're working in the profession later on.]"

However, the interviews also suggest that prospective teachers feel less prepared for performance-based assessments compared to traditional assessment formats.

> "So als Prüfungsformat finde ich das besser, aber ich persönlich fände die mündliche Prüfung für mich schöner, weil ich mich da halt besser drauf vorbereiten könnte, weil ich eher weiß, was da drankommt. [I think that's a better examination format, but personally I would prefer the oral exam because I could prepare for it better, as I have a better idea of what to expect.]"

Discussion

Overall, the OSTE prototype is perceived by participants as very relevant and authentic to teachers' professional practice, similar to the findings for simulation-based learning scenarios reported, for example, by de Coninck et al. (2019) and Wildgans-Lang et al. (2022). Based on the results, it can be assumed that the OSTE would be accepted as an examination procedure by prospective physics teachers, if they are adequately prepared for this innovative assessment format during the course of their studies. Adapting teaching approaches and learning environments is clearly necessary if performance-based assessments such as the OSTE are to be integrated into teacher education programmes, following the concept of Constructive Alignment (Biggs & Tang, 2011). This would not only help pre-service teachers to prepare for the assessment but also make the assessment format more transparent. The successful pilot tests at five different universities also suggest that the results are likely to be generalisable across different specific curricula.

However, it is difficult to determine the extent to which students consider the procedure to be fair. In our pilot study, we could not test the OSTE as a summative assessment, as this would necessitate modifications to the formal examination procedures at each university. The students therefore did not experience the OSTE prototype as a high-stakes assessment, but they knew that it was an initial trial designed to gather their perspectives on the format. The evaluation would probably have differed in some respects if their performance had actually been graded, which

would have had a greater impact on their future studies. Therefore, further trials under high-stakes pressure conditions are necessary. Despite its high transformative potential, the implementation of an OSTE as a summative examination procedure requires more resources than traditional examination formats (e.g. trained actors, sufficient rooms). Careful con-sideration should therefore be given to the stage of teacher education at which such an OSTE can be integrated most effectively. This also remains an open question for future research.

Dealing With Students' Misconceptions In A Virtual Reality Classroom In Pre-Service Teacher Training

Inga Kallweit, Nina Sofie Werthschulte and Insa Melle
TU Dortmund University, Germany

Pre-service teacher training at universities faces the challenge of combining theoretical knowledge and practical experience. In order to bridge this gap, enormous efforts are made to create training situations that are as close to reality as possible, for example by inviting classes to universities or conducting role plays. Modern technologies, such as virtual reality (VR) classrooms, offer innovative opportunities to simulate immersive training situations while saving on personnel and time resources. In addition, VR-based training scenarios can be reproducible and analysable. Pre-service teachers can gain experience in dealing with virtual students in a protected environment and afterwards analyse their own actions and reactions. The study presented here aims to use a VR classroom to train future chemistry teachers. The focus is on dealing with student misconceptions. While the pre-service teachers in the VR classroom can react as they would in a real classroom, a coach manipulates the virtual students and thus the teaching situation. The purpose of this study is to determine whether this VR-based training helps pre-service chemistry teachers recognize and respond to common misconceptions about combustion.

Keywords: Pre-Service Teacher Education, Virtual Reality

Introduction

Balancing theory and practice in pre-service teacher training remains a significant challenge in higher education. In response, several German states, require pre-service teachers to complete an internship semester. In the run-up to this practical experience in school, the university seminars aim to prepare pre-service teachers for teaching situations as realistically as possible.

Placing prospective teachers in an immersive environment and training them in that environment through the use of VR offers new opportunities. Although research on the application of VR in teacher education is still in its early stages, initial findings suggest that VR classrooms can have a positive impact on aspects of teacher preparation such as presence in the classroom (e.g., Wiepke, 2022). The aim of the study presented here is to utilize the potential of a VR classroom for the training of future chemistry teachers. One focus is on dealing with students' misconceptions in a virtual discussion.

Theoretical Framework

VR In Pre-Service Teacher Training

Research into the potential applications of VR environments for pre-service teacher training is not yet very advanced. At the same time, immersive VR media are increasingly being integrated into educational contexts and studies to analyse their potential benefits (Wiepke & Heinemann, 2024). Initial studies indicate positive effects on the behaviour of pre-service teachers, but also highlight the great need for further development and research. The advantages of using a VR classroom as a teaching simulation include the immersive experience and reproducibility (Wiepke, 2022). In addition, VR classrooms provide the opportunity to experience and practice teaching in a safe environment (Lugrin et al., 2016). Therefore, there is potential in exposing pre-service teachers to a virtual teaching situation, that allows them to analyse their own behaviour and repeatedly engage in the same or a similar teaching situation.

The complexity of a teaching situation can be a major challenge, especially for those just starting out in the profession. Classroom management is therefore an important aspect of pre-service teacher training (Evertson & Weinstein, 2013). For this reason, previous research on VR classrooms has focused on classroom management training. To this end, Lugrin et al. (2016) developed a VR classroom that is used in university seminars. In this setting, pre-service teachers are deliberately placed in stressful situations in order to promote and analyse classroom management skills. The results of the study indicate that the system is suitable for university education, that acceptance by pre-service teachers is high and their assessment is positive (Lugrin et al., 2016).

Students' Misconceptions

The fact that students often use every day beliefs, which are not always scientifically based preconceptions in the chemistry classrooms has been empirically investigated many times (e.g., Horton, 2007; Schmidt et al., 2007). It has also been shown that teachers and pre-service teachers know little about misconceptions or how to deal with them (e.g., Gabel, 1999; Uhren et al., 2013).

For this reason, there are established concepts for the training and further education of (future) chemistry teachers that address the diagnosis and handling of students' misconceptions in chemistry lessons (e.g., Marohn, 2008). Rohrbacher-Lochner and Marohn (2018) developed and evaluated a seminar for pre-service chemistry teachers, in which the pre-service teachers received theoretical input on student misconceptions, planned a lesson on this basis and carried it out with invited classes at the university (Rohrbacher-Lochner & Marohn, 2018). But running real classes at universities requires extensive planning and is very time consuming. At this point, the use of a VR classroom in university education can be resource-saving. In addition, it offers the advantages of reproducibility and comparability of teaching situations. The study presented here focuses on the handling of student misconceptions in a virtual classroom discussion with the topic of 'combustion'.

Method

The study takes place as part of an obligatory course for all chemistry teacher students in the master's program. In the subsequent semester, these pre-service teachers will participate in an internship semester. During the seminar sessions at university, various topics are dealt with in preparation for the practice, such as lesson planning and teaching methods. One seminar session explicitly addresses students' misconceptions, their diagnosis, and possible forms of response. At the end of the semester, the pre-service teachers participate in the VR classroom individually. They are placed in a given teaching situation on the topic of 'combustion' and their task is to lead a class discussion to analyse the experiment 'combustion of iron wool'. In this experiment, the iron wool is weighed before and after combustion. The chemical reaction of the combustion causes the iron wool to react with the oxygen in the air and is heavier after the reaction. The explanation for the increase in weight requires knowledge of chemical reactions. Concerning this, there are a number of examined misconceptions (e. g., Horton, 2007).

In this study, the VR classroom developed by the University of Potsdam is used (e.g., Wiepke, 2022; Huang et al., 2021). It is designed for two users: a pre-service teacher, who is trained and a coach supervising the training session. Using a VR head-mounted display and controllers, the pre-service teacher enters a virtual classroom with 30 virtual students (Figures 1 and 2). The virtual students are controlled by the coach via a web interface, which shows the seating arrangement of the virtual classroom so that each individual virtual student can be controlled. In order to simulate the classroom discussion, possible student responses were anticipated in advance and recorded in a path diagram. Empirically proven misconceptions on the topic of

'combustion' were included in these statements. The coach assigns the pre-service teacher's statements and reactions to one of three categories: From *"Notices and responds to students' misconceptions in a way that promotes a meaningful class discussion"* to *"Does not react to students' misconceptions and does not promote a meaningful class discussion"*. By following the paths in the diagram, the coach selects a suitable student answer.

Figure 1. Pre-Service Chemistry Teacher with VR Head-Mounted Display.

Figure 2. Virtual Students in the VR Classroom (Participant's Perspective).

Research Questions

One focus of this study is to explore the potential of the VR classroom in terms of how pre-service chemistry teachers deal with students' misconceptions:

Q1) How do pre-service teachers respond to students' misconceptions in a classroom discussion in the VR classroom?

Q2) How do pre-service teachers evaluate the teaching situation in the VR classroom?

To address the research questions, a qualitative study was conducted. Therefore, video recordings were made of the pre-service chemistry teachers during their training in the VR classroom as well as screen recordings of the virtual students including the web interface. In addition, the pre-service teachers answered a questionnaire directly after the training. This questionnaire consists of five questions, three of which are answered on a three- or four-point Likert scale and two of which are open-ended. The questions that use a Likert scale could also be answered with *"not able to assess"*. The focus of the questionnaire is on the subjective impression after training in the VR classroom. One week later, individual interviews were conducted. The interview guideline focuses on the experiences in the VR classroom, self-perception and their own assessment of how they dealt with students' misconceptions. Furthermore, excerpts from the

video recordings were used to reflect on the conversation. The interview transcripts were used to answer research questions Q1) and Q2).

First Results

Eight pre-service teachers participated in the first trial in February 2025. They only reacted visibly to the misconceptions in 23% of cases, which is very low. Interestingly, prospective teachers usually responded immediately with an explanation, rather than, for example, asking follow-up questions or involving other students in the conversation. There seems to be room for improvement, particularly since classroom discussions based on misconceptions provide great learning opportunities (Sommer et al., 2022).

The evaluation of the questionnaire, which was completed directly after the training, shows that the pre-service teachers described the experience in the VR classroom as consistently positive. In one of the open-ended questions, five pre-service teachers mentioned that they needed a short time to get used to the VR classroom, but then quickly found their way around. Half of the pre-service teachers reported that they had identified all the misconceptions, while the other half assumed that they had not recognized all the misconceptions (Likert scale: *recognized all misconceptions, recognized not all misconceptions, recognized none misconceptions*). This is particularly remarkable because the pre-service teachers only responded to the misconceptions mentioned in a quarter of the cases. When asked how confident they felt in spontaneously reacting to student statements, half of the pre-service teachers responded with *not confident*, three with *confident* and one was not able to assess (Likert scale: *very confident, confident, not confident, not confident at all*). Seven of the eight pre-service teachers rated the usefulness of VR for pre-service teachers as at least high (Likert scale: *very high, high, medium, low*). These results were confirmed by the guided interviews conducted one week after the training. Five of the pre-service teachers once again emphasized the benefits for their own development and the environment's intuitive handling of. However, they would like to have more opportunities to interact with the virtual class, e.g., working together on a blackboard. The interviews also revealed that the pre-service teachers were unsure how to deal with the misconceptions mentioned during the conversation, which is consistent with the results described above.

Discussion and Outlook

Overall, these first results presented are only preliminary. Nevertheless, these results suggest that the pre-service teachers' attitude towards the training in the VR classroom is positive and that the training is considered helpful for professional development (Q2). In addition, the first trial resulted in extensions to the path diagram to enable the coach to react more flexibly to the students' impulses and foster a more fluent classroom conversation. However, it became clear that pre-service teachers rarely visibly respond to the aforementioned misconceptions and still have limited conversation prompts (Q1). Clearly, there is still great potential for developing their conversation skills here, which will be addressed in subsequent seminars together with the per-service teachers.

The next iteration of the study will investigate whether the training leads to improved identification of misconceptions and better dialogue management in class discussions. For this reason, the training will be carried out twice in the following study. In order to achieve improvements in dialogue management, the first training session will be analysed in more detail together with the pre-service teachers and after that, they go through a second training in the VR classroom. In addition, we plan to develop a second VR classroom that deals with the subject of electrochemistry.

Primary Pre-Service Teachers' Professional Identity Development For Teaching Climate Change

Chara Bitsaki[1,2], Lucy Avraamidou[2] and Dimitris Stavrou[1]
[1]Department of Primary Education, University of Crete, Greece
[2]Faculty of Science and Engineering, University of Groningen, Netherlands

Given the complexity of the climate crisis, preparing pre-service teachers to teach Climate Change as a multifaceted topic is essential. However, pre-service teachers are unprepared to integrate this multifacetedness into their teaching. This study investigates how pre-service teachers develop their professional identities during a 12-week seminar on Climate Change Education at a southern European university. The participants in the study were 29 primary pre-service teachers who had participated in activities related to Climate Change content and Climate Change competencies (Normative Competence, Anticipatory Competence, System Thinking, Strategic Competence, and Interpersonal Competence). Simultaneously, the pre-service teachers, divided into seven groups, designed step-by-step teaching materials on Climate Change that included Climate Change competencies. Data were collected through autobiographical texts, teaching materials, reflection journals, and final interviews, and qualitative analysis methods were utilised. The findings indicate that Climate Change Teacher Education should support pre-service teachers by fostering self-awareness and equipping them with teaching strategies to build students' Climate Change Competencies. Participants recognised their competence in teaching Climate Change and explored widely used teaching strategies. Moreover, this process enhanced their self-recognition as competent Climate Change teachers, reinforcing their confidence in integrating Climate Change into their future teaching practices. These findings contribute to the growing discourse on Climate Change Teacher Education, emphasising the benefits of identity-focused approaches that empower pre-service teachers to engage students meaningfully in sustainability and climate action.

Keywords: Science Teacher Identity, Teacher Education, Climate Change

Introduction

Climate Change is a 21st-century challenge that affects the natural environment, society, the economy, and health (IPCC, 2023). Therefore, the climate crisis is not only an ecological threat but also a moral and educational challenge that demands action across all sectors of society. Climate change is a complex system shaped by interacting natural processes and human activities, making it difficult to define, predict, and address with single solutions (Lehtonen et al., 2018; Miani et al., 2025a; Peters & Tarpey, 2019). It is often described as a "super-wicked problem" because interventions can meet resistance or produce unintended consequences. Scientifically, climate change involves non-linear interactions, feedback loops, and uncertainty across interconnected Earth subsystems, which demand an interdisciplinary understanding (Miani et al., 2025a). Socially, it functions as a polarised socioscientific issue, involving ethical dilemmas, justice concerns, and emotional dimensions. These features challenge education, where fragmented curricula and content transmission often fail to support holistic systems thinking and transformative competencies (Eilam, 2022; Sezen-Barrie et al., 2025). Engaging multiple perspectives supports systemic reasoning about drivers and solutions (Cantell et al., 2019; Höhle & Bengtsson, 2023), while future thinking helps learners connect present decisions to uncertain but plausible trajectories (Miani et al., 2025b).

Consequently, addressing the climate crisis requires interdisciplinary and systemic approaches, as well as cooperation among diverse stakeholders (Lehtonen et al., 2018; Miani et al.,2025a).

This makes it vital for Climate Change Education to develop key skills that improve climate literacy and prepare students to be future citizens capable of addressing climate challenges (USGCRP, 2024). These key skills, known as sustainability or climate change competencies, are a) Normative Competence, b) Anticipatory Competence, c) Systems Thinking, d) Strategic Competence, and e) Interpersonal Competence (Wiek et al., 2011), with Scientific Inquiry playing a key role in building and applying these skills (Taurinen et al., 2024).

Building students' key competencies for climate literacy requires teachers who can effectively incorporate them into their teaching. However, teachers encounter various challenges in implementing Climate Change Education. These challenges arise from fragmented knowledge of content and a lack of confidence in managing the inherent uncertainty of climate science (Waldron et al., 2019). Consequently, it becomes difficult to address the complexity of the phenomenon in the classroom and to link scientific content with its societal, ethical, and emotional dimensions (Drewes et al., 2018; Shea et al., 2016). Additionally, several studies indicate that teachers often feel unprepared (Ennes et al., 2021; Waldron et al., 2019) and do not see themselves as competent climate change educators (Ratinen, 2013). This limited professional self-recognition is associated with hesitation in fostering values and agency within their teaching role (Hestness et al., 2014; Timm & Barth, 2021) and is influenced by teachers' personal experiences, attitudes, values, and beliefs regarding climate change (Bascopé et al., 2025; Leite, 2024; McNeal et al., 2017).

Addressing these challenges requires teacher education to move beyond emphasising content knowledge and pedagogical strategies and adopt more comprehensive approaches. Effective Climate Change Teacher Education should not only strengthen teachers' understanding of scientific concepts and ability to design inquiry-based, interdisciplinary learning environments, but also connect this knowledge to the broader social, economic, and ethical dimensions of the climate crisis (Brandt et al., 2019; Cantell et al., 2019). Furthermore, teacher education must offer opportunities for teachers to reflect on their own experiences, values, and beliefs, recognising that positionality fundamentally shapes professional practices and agency. When such elements are integrated, teacher education becomes a transformative space for developing an identity through which teachers see themselves as competent and responsible educators, capable of linking scientific understanding with moral purpose and social engagement (Menon, 2020).

Nevertheless, few studies focus on Climate Change Teacher Education (Rousell & Cutter–Mackenzie–Knowles, 2020), and even fewer invest in teachers' beliefs, values, and attitudes as part of their professional growth. While research highlights the importance of pre-service teacher education beyond scientific content alone (Ennes et al., 2021; Hestness et al., 2014; Waldron et al., 2019; Zangori et al., 2017), there are very few empirical studies that examine teacher training and professional development related to climate change content alongside teachers' beliefs, values and attitudes, and their interaction with environmental, societal, and economic factors (e.g. Brandt et al., 2019; Kriewaldt & Jun Lee, 2023; Waldron et al., 2019).

To address these issues, we propose using the lens of Teacher Identity (Avraamidou, 2014a) in teacher education through the concept of Climate Change Teacher Identity. Climate Change Teacher Identity (CCTI) is crucial for preparing teachers to address the scientific, interdisciplinary, and socio-political demands of Climate Change Education. Teaching climate change requires more than content knowledge and pedagogical techniques: teachers must integrate knowledge, skills, attitudes, and values to help students develop sustainability competencies and navigate complex, uncertain futures (Felix & Clayton, 2025; Howell & Allen, 2019). Building on science teacher identity research (Avraamidou, 2014a), CCTI extends science teacher identity by foregrounding urgency, ethics, emotions, and civic responsibility, positioning

teachers as facilitators of systems thinking, futures thinking, and value-based inquiry (Eilam, 2022; Miani et al., 2025a). Despite growing work on Climate Change Teacher Education, coherent identity-based frameworks, especially in primary education, remain limited.

We conceptualise CCTI through Carlone and Johnson's (2007) three dimensions: competence, performance, and recognition, while recognising that emotions, values, and context shape all three (Avraamidou, 2019; Nation & Feldman, 2022). Competence involves an evidence-based understanding of climate systems and their interactions with the environment, society, the economy, politics, and ethics. Performance refers to how teachers enact this competence through language, representations, and pedagogical tools, including engaging uncertainty and controversy. Recognition concerns seeing oneself, and being seen by others, as a legitimate climate change educator, supported through reflective questions about past, present, and future teacher selves.

Based on the above, this study focuses on the development of the Climate Change Teacher Identity of primary education pre-service teachers as a lens on how pre-service teachers learn and develop during a university seminar on Climate Change Education. The research question that guides this investigation is "How do the dimensions of Primary pre-service teachers' Climate Change Teacher Identity depict during the design of teaching materials on climate change complexity?"

Methods

Research Design And Participants

To address the research question mentioned above, we examined the development of primary pre-service teachers' Climate Change Teacher Identity. All 29 participants took part in a 12-week university seminar on Climate Change Education at the Department of Primary Education in the University of Crete, organised into 7 groups of 4 to 5 students each. In this study, the first author held a double role of a trainer and researcher.

The sessions of this seminar included the following activities:

Reflection on learning experiences in formal and informal environments and values about Climate Change (Session 1): The pre-service teachers had to recall and reflect on their past learning experiences, attitudes, and values related to Climate Change, and share those experiences with their group. Based on their reflections, the participants developed an autobiographical text in which they expressed the aforementioned past experiences in more detail.

Introduction to the scientific content (Session 2): In this session, the pre-service teachers became familiar with Climate Change content by exploring its impacts using real data, hands-on and video experiments, and models and simulations.

Engagement with activities for Climate Change Competencies (Sessions 4-10): The pre-service teachers participated in activities related to the complexity of Climate Change through physics experiments, discussed inclusivity in proposed solutions for Climate Change through a role-playing game, and envisioned themselves in IPCC future scenarios. For these sessions, they wrote three reflection journals and a text in which they imagined themselves as future Climate Change teachers. During this session, they became more familiar with innovative teaching methods proposed by the literature.

Teaching Material Development and Implementation (Sessions 2-12): During these sessions, the pre-service teachers designed, developed, and implemented teaching materials based on climate change competencies, utilising tools such as CoRes (Hume & Berry, 2010) and continuous feedback from the trainer and researcher in this study. The teaching material developed by the

participants was rich, including hands-on experiments, group activities that enhance students' decision-making skills and agency (role-playing games and actions), and artefacts. The implementation took place in the university's science centre.

Data Collection

Data were gathered from autobiographical texts, teaching materials, reflection journals, and a final semi-structured interview. The autobiographical texts offer insights into pre-service teachers' personal experiences, attitudes, and values towards climate change, providing space to express their Self-View as future climate change educators. The reflection journals served both as sources for pre-service teachers' Competence and Self-View. The teaching materials on the other side provided insights into pre-service teachers' Competence and Performance, serving as a means for participants to embody their knowledge and skills related to climate change, as well as their perceptions of a climate change educator's role. Finally, the final interviews served as a form of data triangulation.

Data Analysis

Given the exploratory nature of the study and the small number of participants, we employed qualitative content analysis methods (Mayring, 2014). To answer our research question, we conducted a top-down and bottom-up analysis of autobiographical texts, reflection journals, and teaching materials, focusing on pre-service teachers' Climate Change Teacher Identity. For that, we utilised Carlone & Johnson's framework (2007) to develop a category system for the Climate Change Teacher Identity dimensions. More specifically, Competence was examined through pre-service teachers' knowledge and understanding of Climate Change Complexity (e.g. systems thinking, uncertainty, multiplicity, etc.). Performance was examined in terms of the extent and manner in which PSTs expressed climate change complexity through their designed teaching materials (e.g., representations, tasks, inquiries, decision-making structures). As far as Recognition that regards how the pre-service teachers see themselves and are seen by others, we decided to focus on the first part since the majority of them have not enrolled in practicals yet, and as a result, they haven't yet any reflections on how their students or other teachers are seeing them. Based on that, we focused on pre-service teachers' self-view, which was examined through pre-service teachers' perceptions of themselves and their roles as climate change educators, including how they described their responsibilities, doubts, and ethical/value orientations. Table 1 presents the categories and subcategories derived from this analysis.

Table 1. Categories and Subcategories for Climate Change Teacher Identity

Categories	Subcategories
Competence	Resistance in the nature of complex systems Challenges in managing multiple perspectives Managing Social Aspects Systemic Approaches
Performance	Implement Feedback loop Implement Interactions between subsystems Implement Linear approaches Implement Social/Financial/Ethical implications
Self-View	Activist Optimist Sceptic Inspiring

Results

Across the dataset, participants showed the development of Climate Change Teacher Identity across all three identity dimensions. Below, we present findings organised by Competence, Performance, and Self-View, then highlight interactions among these dimensions.

Competence

Preservice teachers showed developing competence by clearly identifying aspects of climate change complexity and reflecting on the difficulty of communicating those ideas to children. One participant from Group 7 highlighted the challenge of explaining the disproportionate impacts of a seemingly small temperature rise and also recognised personal involvement in the issue:

"I believe the most difficult aspect to negotiate with primary school students will be helping them realise that just a 2-degree increase in temperature can be so destructive and understanding how we, ourselves, contribute to that rise."

This excerpt reflects competence in two ways: (1) recognising that climate change impacts are non-linear and counterintuitive, and (2) linking the scientific phenomenon to human systems and agency.

Another pre-service teacher from Group 1 pointed to the complexity introduced by political-economic structures in sustainability-related practices (in this case, recycling), indicating awareness that climate-related issues cannot be reduced to individual behaviour alone:

"What I think would be the most difficult to explain to students is how recycling works in each region, and why these changes depend on factors like quantity, cost, etc. Because they don't fully understand the political and economic issues that complicate the situation."

Here, competence includes understanding variability across contexts and recognising socio-economic aspects as part of the system.

Pre-service teachers also engaged with uncertainty and epistemic questions about predictability. One excerpt shows a participant from Group 3 negotiating what counts as a scientifically acceptable explanation, resisting embracing the nature of complexity: "Here, even though it's not stated that something supernatural intervenes in the system, chance seems to me as such. So, it doesn't align with my own understanding of science."

While another pre-service teacher from Group 5 reframed unpredictability as a matter of limited means rather than chance in interplay with deterministic laws:

"Perhaps if the conclusion were that we simply can't yet predict its evolution because we don't have the necessary means, it would be easier for me to accept."

This shows increasing skill in distinguishing epistemic uncertainty (limits of measurement and modelling) from non-scientific explanations, which is essential for teaching complexity responsibly. However, it also reveals a strong resistance to embracing the inherent complexity of nonlinear systems and to interpreting their evolution solely through deterministic laws.

Performance

Performance was apparent in how pre-service teachers designed learning sequences and chose phenomena that could act as "entry points" into complex system reasoning. The dataset included teaching materials on ocean acidification, glacier melting, and their implications for biodiversity. Finally, one teaching material approached sustainable mobility as a solution to climate change through hydrogen-powered cars.

In these materials, the pre-service teachers attempted to represent causal chains and feedback relationships (e.g., emissions → ocean chemistry changes → ecological consequences), integrate observable phenomena and modelling and hands-on experimentation, and build decision-making tasks that connect scientific understanding with choices and values.

However, pre-service teachers varied in the degree of sophistication in their teaching materials. While a common pattern was the use of concrete contexts (oceans, glaciers) to support students' reasoning and understanding of climate science, some materials approached these concepts by emphasising only one-way interactions (e.g., the impact of increasing CO2 concentration in the oceans and its effect on ocean biodiversity, without addressing the feedback loop influencing the atmosphere). On the other hand, Groups 1, 2, 6, and 7, which demonstrated greater competence in embracing complexity and managing multiple perspectives in their teaching, succeeded in designing materials that familiarised students with the various drivers of the climate system, as well as the societal aspects that interact with it.

An exception to these two categories is Group 4, which consisted of pre-service teachers facing multiple challenges in scientific content. This group spent time during the seminar familiarising themselves with the scientific content but paid less attention to integrating complexity into it.

Self-View

Self-View appeared in pre-service teachers' reflections on the teacher's role, especially their responsibility to support meaningful action, cultivate values, and serve as role models.

One pre-service teacher described an intention to emphasise practical actions so students can immediately see positive impacts and develop daily environmental awareness:

"Finally, I would like to place greater emphasis on simple and practical actions that students can undertake, so that they can immediately recognise the positive impact of their choices and develop environmental awareness in their daily lives."

This reflects self-recognition through an action-oriented teaching stance, in which the teacher's identity is linked to empowering students.

Another pre-service teacher articulated a deeper tension on how to foster enduring values rather than short-term compliance, and how the teacher's own behaviour and role modelling become part of climate change teaching:

"How can I convey to my students an attitude and a way of life that they will follow throughout their lifetime and not just in the short term? How will they fully embrace the principles and values of a climate-literate citizen? I believe that attitudes and values are matters cultivated daily, not merely through a single educational scenario. What kind of role model do you, as a teacher, provide for your students?"

This excerpt illustrates recognition as a stance of reflective, ethically aware identity. Pre-service teachers are not only asking "Can I teach this content?" but also "Who must I be, and how must I live, to teach this credibly?"

This collection of excerpts represented all groups except again Groups 3 and 5, who appear to be sceptics of certain proposed solutions related to climate change, as well as of the effectiveness of the teacher's role in the current economic status quo.

An example of this scepticism is represented in the excerpt below: "The discussion about green growth doesn't satisfy me, because I see that this plan is also being carried out without a central strategy, and probably not in order to improve our everyday lives."

Interactions Among Climate Change Identity Dimensions

Across the seven cases, the data suggested that competence, performance, and self-view were not isolated. Instead, pre-service teachers' materials and reflections showed interactions consistent with identity scholarship (e.g., Beijaard et al., 2004; Keiler, 2018).

Competence And Performance

Pre-service teachers who clearly expressed complexity and uncertainty tended to design tasks that incorporated system relationships, contextual constraints, or systems thinking rather than simple cause-and-effect narratives.

Performance And Recognition

As pre-service teachers developed and improved teaching materials, recognition was evidenced through responsibility statements (e.g., emphasising daily actions, role modelling, values). Designing for practice prompted reflection on what it means to be a climate change teacher.

Recognition And Competence

Recognition concerns (e.g., wanting to promote values responsibly) sometimes led pre-service teachers to seek more thorough explanations and more careful framing of the concepts of the climate system and the societal drivers within it.

These interactions support the argument that Climate Change Teacher Identity is co-constructed through iterative engagement with content, pedagogy, and professional positioning.

Discussion

This study provides empirical insights into how pre-service teachers learn and develop as they formulate their professional identities by reflecting on their prior experiences, values, and attitudes toward climate change as they learn to teach it. By adapting Carlone and Johnson's (2007) framework, we conceptualised identity not simply as confidence or attitude but as a dynamic interplay of (a) competence in complexity-focused reasoning, (b) performance through designed teaching practices, and (c) self-view through self-positioning and legitimacy.

The findings align with the broader literature, which shows that teachers experience fragmented knowledge and uncertainty as obstacles, struggle to transform climate science into teachable material, and integrate the value-oriented nature of climate change teaching. Yet the results also point to noticeable shifts when the pre-service teachers begin to treat complexity as an opportunity to expand their teaching rather than a reason to avoid the topic. They selected phenomena that enable complexity representations and engaged in reflective recognition of the challenges and obstacles to negotiating these representations with their students.

Our findings highlight the critical role of Climate Change Teacher Education in shaping teachers' positionality and equipping them with the necessary teaching strategies to address complex topics like Climate Change (Nation & Feldman, 2022; Tolppanen & Kärkkäinen, 2022). By fostering self-awareness, pre-service teachers became more confident in teaching Climate Change content, utilising their strengths to integrate diverse pedagogical approaches. This process also enhanced their self-recognition as competent climate change educators prepared to respond to the challenges of the climate crisis. A central implication is that teacher education can support climate change teaching not only by "adding more content" but by designing learning experiences where pre-service teachers engage explicitly with complexity and uncertainty, iteratively translate this into teaching materials, and reflect on positionality, ethics, and the teacher's role.

Implications For Climate Change Teacher Education

Considering that attitudes, values, and personal experiences shape the teaching climate for climate change, it is crucial to examine how teachers' professional identities develop and are reshaped over time (Nation & Feldman, 2022; Tolppanen & Kärkkäinen, 2021). The Climate Change Teacher Identity framework proposed above highlights that competence, performance, and self-view are co-constructed through teachers' biographies and the learning environments

they encounter. Therefore, Climate Change Teacher Education should go beyond disseminating content knowledge and pedagogical strategies to create conditions in which pre-service teachers can reconstruct themselves as climate change educators. Evidence from climate change-focused professional development suggests that identity shifts are strongly supported when teachers are given sustained opportunities to reflect on their positioning, values, and experiences alongside learning about climate change content and pedagogy (e.g., Nation & Feldman, 2022; Tolppanen & Kärkkäinen, 2021; Zen et al., 2024).

Accordingly, climate change teacher education should foreground structured identity work integrated with practice: sustained self-awareness and self-reflection on teaching trajectories through autobiographies, reflective journals, and prompts that engage questions such as "Who am I as a teacher?", "How did I become this kind of teacher?", and "Who do I want to become as a teacher?" (Avraamidou, 2019), so that pre-service teachers can trace changes in their competence, performances, and self-view over time.

These identity-oriented activities should be integrated into opportunities for learning, designing, and experimenting with teaching methods that are common in Climate Change Education. Such methods include investigating local phenomena, engaging in systems-thinking tasks, exploring futures-thinking activities, and participating in value-focused discussions. This allows pre-service teachers to see themselves as climate change educators and to renegotiate their identity claims through tangible classroom practices (Felix & Clayton, 2025; Nation & Feldman, 2022; Sezen-Barrie et al., 2025). Overall, Climate Change Teacher Education should be intentionally designed as a space where pre-service teachers both learn how to teach about climate change and develop into climate change teachers. This can be achieved through combining autobiographical exploration, ongoing reflection, and multimodal self-representations with rich pedagogical experiences. These experiences broaden competencies, enable new ways of performance, and foster recognition as climate change educators.

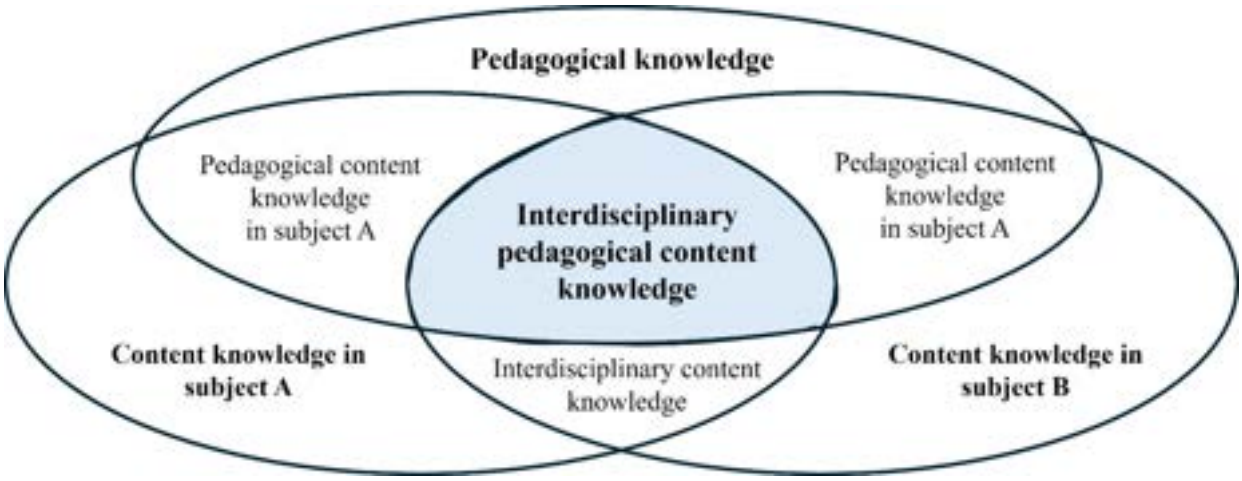
[1] Instituto Politécnico de Setúbal, Escola Superior de Educação, Portugal
[2] UIDEF, Instituto de Educação, Universidade de Lisboa, Portugal
[3] CIEQV, Centro de Investigação em Qualidade de Vida, Portugal

This study examines the interdisciplinary pedagogical content knowledge (IPCK) of pre-service primary teachers enrolled in a two-year master's program in Primary Education (1st to 6th grades), with a specialization in Mathematics and Sciences. The main objective was to investigate changes in their IPCK regarding interdisciplinarity between science and mathematics following participation in a lesson study. Data were collected through an open-ended questionnaire administered in two phases, before and after the lesson study. The questionnaire aimed to capture the specificity of pre-service teachers' understanding of interdisciplinarity by exploring their conceptualizations and the examples of activities they proposed to promote the integration of science and mathematics.

The results indicate that, before the lesson study, pre-service teachers held a limited view of interdisciplinarity, characterized by uneven connections between the two areas. There was a significant emphasis on interdisciplinarity through knowledge to be explored, with less attention given to the processes. Mathematics was mainly integrated through data processing within sciences activities. Furthermore, only a few participants viewed interdisciplinarity as a meaningful integration, where both disciplines collaborate to support one another, thereby enabling unique learning experiences. After the lesson study, the findings suggest that most pre-service primary teachers changed their IPCK towards a more comprehensive perspective on interdisciplinarity in science and mathematics.

Keywords: Interdisciplinarity in science and mathematics; Pre-service primary teachers; Lesson study; Pedagogical content knowledge

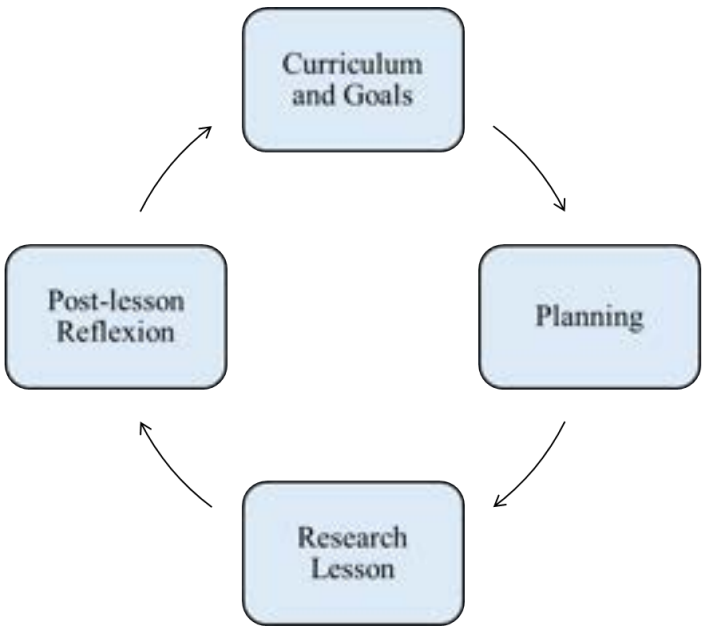
Introduction



Future teachers should be able to make connections between different disciplines. An interdisciplinary approach encourages deeper understanding overtime, inter-relating different topics or subjects (OECD, 2019). That implies careful planning in how and when the topics of each subject will be explored, to promote connections between them.

However, the implementation of interdisciplinarity in schools faces problems of different kinds (e.g. Johnson & Czerniak, 2023). The interdisciplinary work between science and mathematics will always involve the mobilization of disciplinary knowledge from, at least, these two disciplines and depends upon teachers' pedagogical content knowledge (PCK) of each discipline (Ríordáin et al., 2015) and their possible intersections, denominated interdisciplinary pedagogical content knowledge (IPCK) (An, 2017) (Figure 1). According to An (2017),

> interdisciplinary pedagogical content knowledge (IPCK) is the specific capacity for teachers to accomplish the following: (1) work with interdisciplinary considerations that include an understanding of the representation of concepts using themes across curriculum boundaries; (2) apply pedagogical methods and interdisciplinary themed activities in addressing content areas from multiple subjects simultaneously; (3) identify knowledge connections within and between particular subjects, and develop lessons based on such



connections; and (4) employ knowledge of how interdisciplinary explorations can be developed as a part of an instructional process wherein students link existing knowledge across curricula, while presenting that new knowledge through contexts from multiple subjects. (p. 239)

Figure 1. Graphic representation of interdisciplinary pedagogical content knowledge (IPCK) (An, 2017, p. 239).

A way to support teachers practice professional development regarding interdisciplinarity is through lesson study (Lewis, 2009; Murata, 2011; Tomkelski et al., 2022). The central framework of lesson study comprises four key moments: i) characterization of the context and definition of a goal for the development of the research lesson; ii) planning, that is, collaboratively designing a lesson on a specific curriculum topic through multiple sessions with a group of teachers; iii) research lesson, that corresponds to the implementation of the planned lesson in a classroom setting.; and iv) post-lesson reflection, when the group of teachers meets to discuss and reflect on the students' actions in the research lesson, based on observations recorded (Lewis, 2009; Murata, 2011; Tomkelski et al., 2022). Figure 2 presents the lesson study cycle constituted by four phases.

Figure 2. Lesson study cycle of the investigation (Adapted from Lewis, 2009; Murata, 2011; Tomkelski et al., 2022).

Lesson study provides opportunities for pre-service teachers to strengthen their understanding of content, pedagogy, and student learning, namely skills and knowledge in science and

mathematics education (e.g., Kraft et al., 2024; Martins et al., 2023). For instance, Martins et al. (2023) involved mathematics pre-service teachers in a lesson study and concluded that this process allowed them to refine their teaching strategies, leading to improved practice and a better understanding of how to promote students' mathematics reasoning. Kraft et al. (2024) in an extensive review of the literature on lesson studies in science teacher preparation programs concludes that lesson study is a transformative process, enriching pedagogical content knowledge.

This study explores the interdisciplinary pedagogical content knowledge (IPCK) of Portuguese pre-service primary teachers enrolled in a two-year master's program in Primary Education in Sciences and Mathematics. The main aim was to investigate changes in pre-service primary teachers' PCK concerning interdisciplinarity in science and mathematics following their participation in a lesson study. The research is part of a broader project that aims to understand the dynamics of implementing interdisciplinary activities in science and mathematics. It involves pre-service primary teachers from two Portuguese higher education institutions, the Polytechnic Institutes of Setúbal and Lisbon, within the framework of lesson study.

Method

The participants were the whole class of the teaching master programme 2024/25, 11 pre-service primary teachers (8 females and 3 males, aged 22 to 35 years) enrolled in the courses "Didactics of Sciences", "Didactics of Mathematics" and "Teaching Practice in Primary Education". These are annual compulsory subjects in the second-year curriculum of the master's program in Primary Education (1st to 6th grades) with a specialization in Mathematics and Sciences, of the School of Education of Setúbal, Portugal. Prior to this program, the pre-service teachers had completed a three-year degree in Basic Education. The Didactics courses in both areas involved the exploration of different strategies for teaching science and mathematics and were used to support the planification of the research lesson, that was implemented during a seven-week internship in a 5th grade class (Teaching Practice).

During the first semester, the pre-service teachers completed a questionnaire to assess their pedagogical content knowledge of interdisciplinarity in science and mathematics, both before and after the implementation of the lesson study, after informed consent from all participants. The questionnaire was less structured, word-based and open-ended to capture the specificity of the situation analysed in this study (Cohen et al., 2007). This research instrument included four open-ended questions, as follows:

(1) Identify a curricular topic that integrates mathematics and sciences and can be approached interdisciplinarily in primary education (Key Stage 2).

(2) Indicate mathematics and sciences content that can be approached interdisciplinarily in the study of the topic you identified. You may use a diagram to illustrate the relationships between the content (Note: Students were allowed to consult official curriculum documents.).

(3) Provide examples of one or two interdisciplinary activities you would use to explore the topic, incorporating the previously mentioned content from both subjects. Specify the teaching strategies or methodological approach you would adopt in the classroom.

(4) If you have already planned or observed an interdisciplinary activity during previous internships or even during your school years as a student, describe the activity in question, highlighting its relevance.

The analysis of these questions involved content analysis, with the definition of categories and subcategories for analysis for each question, which were formed inductively based on data,

through an iterative process. Tables 1 and 2, which are presented in the results, show the categories and subcategories of questions 1 and 3 of the questionnaire, respectively, which were selected to present in this paper based on their relevance to the study.

For question 1, the following categories of analysis were defined: predominance of the subject area; and nature of the content. Question 2 included two categories: diversity of content; and nature of the content. In order to analyse the scope of responses to question 3, several categories of analysis were defined, namely: predominance of the subject area; curricular alignment; consistency between content and activity; type of activity; organization of work with students; teaching resources; and planned outputs. In the case of question 4, four categories of analysis were created: predominance of the subject area in the planned activity; predominance of the subject area in the activity experienced; relevance of the activity; and justification of the relevance of the activity.

Taking into account all the responses to the questionnaire, we also sought to analyse the concept of interdisciplinarity among students, considering two subcategories: comprehensive view and limited view (Table 3). The comprehensive view is related to the level of complete integration between the two disciplines, with the establishment of relationships between science and mathematics. In the limited view one of the disciplines, Mathematics or Science, predominates, but the other is also present, although in a supporting role.

The categorization of responses to each question was carried out by four researchers, authors of the paper, familiar with the theoretical framework of the study. In a joint meeting, the researchers discussed the main doubts in the categorization of data, and the entire analysis was reviewed. Disagreements were resolved through discussion until consensus was reached.

The lesson study process was structured within a single cycle with four main phases (Figure 2). In the first and second phases, during weeks one to four of the seven-week internship, the pre-service teachers worked collaboratively in groups to define the goals and plan a research lesson centred on an interdisciplinary activity in mathematics and sciences. This work was supported by the four higher education teachers, the researchers, in Didactics sessions. In the third phase, during weeks five to seven of the internship, while the other pre-service teacher from each internship pair taught the research lesson while the other pre-service teacher and one higher education teacher observed the lesson and collected data. The fourth phase, conducted after the internship, involved a group discussion about the planned and implemented lesson and a written reflection (one part produced collaboratively by the internship pair and another part developed individually).

Results and Discussion

Table 1 presents the results for question 1: Identify a curricular topic that integrates mathematics and sciences and can be approached interdisciplinarily in primary education (Key Stage 2), based on the responses of the 11 pre-service teachers (PST), who participated in both the initial and final applications of the questionnaire. The initial questionnaire, applied before the lesson study, shows that PST tended to select topics primarily focused on sciences. In these cases, the science topic served as the context for integrating mathematics, as illustrated by examples such as: “The Terrestrial Materials present in the region (determine the predominant type of terrestrial material in the region)” (PST 1) and “Biodiversity” (PST 3). After the lesson study, the responses reflected a greater emphasis on ensuring that, within the context of science activities, mathematical content is equally explored. The following example shows that situation: “Types of soil, soil properties, and powers of base 10” (PST 7). The absence of change in the category “nature of the contents” suggests that, despite improvements in disciplinary integration, pre-service teachers’ conceptions

of interdisciplinarity remain predominantly knowledge-oriented, possibly reflecting limitations associated with curricular structure and their still limited teaching experience.

Table 2 presents the results for question 3: Provide examples of one or two interdisciplinary activities you would use to explore the topic, incorporating the previously mentioned content from both subjects. Specify the teaching strategies or methodological approach you would adopt in the classroom for three selected categories. The initial questionnaire responses indicate a predominance of focus on the mathematics area. This may reflect the pre-service teachers' effort to make this subject explicit in the activity proposal, despite the curriculum topic focusing on science (as seen in question 1). After the lesson study, there was an increasing concern with integrating both subject areas in the interdisciplinary activity proposals.

Table 1. Pre-service teachers' responses to the question 1 of the initial and final applications of the questionnaire, before and after lesson study.

Categories	Subcategories	Number of PST (n=11)	
		InitialQ	FinalQ
Predominance of the subject area	Science	6	3
	Mathematics	1	0
	Both areas	4	8
Nature of the contents	Focus on knowledge	8	8
	Focus on process	0	0
	Knowledge and process	3	3

Table 2. Pre-service teachers' responses to the question 3 of the initial and final applications of the questionnaire, before and after lesson study.

Categories	Subcategories	Number of PST (n=11)	
		InitialQ	FinalQ
Predominance of the subject area	Science	4	2
	Mathematics	6	2
	Integration of both areas	1	7
Curricular alignment	Total	5	9
	Partial	6	2
	Without	0	0
Coherence between content and activity	Total	4	6
	Partial due to lack of explicitness	0	5
	Excluded due to lack of suitability	7	0
	Without	0	0

The results for the categories "curricular alignment" and "coherence between content and activity" (Table 2) reveal that there was an increased knowledge of the curriculum in the areas of mathematics and sciences, gained through direct involvement in the lesson study, which required an additional effort in a more detailed planning process – including curriculum analysis, task design, and reflection on learning. It is also important to note that this was the pre-service teachers' first teaching practice (internship) in primary education, specifically with 5th and 6th graders, which likely influenced their initial focus and subsequent development of their IPCK.

The results presented in Table 2 reveal a clear qualitative development in pre-service teachers' ability to design interdisciplinary activities. In particular, the disappearance of responses classified as "excluded due to lack of suitability" in the final questionnaire suggests a strengthened capacity to align interdisciplinary intentions with pedagogically coherent activities, an aspect associated with the collaborative planning, implementation, and reflection, characteristics of the lesson study process. At the same time, the increase in activities classified as "partial due to lack of explicitness" should not be interpreted as a regression, but rather as evidence of a growing awareness of the complexity involved in interdisciplinary planning. This pattern indicates that pre-service teachers proposed complex and ambitious integrations of mathematics and sciences, in some cases for the first time, although some proposals still required clearer articulation of the relationships between content and activity.

To illustrate the analysis, the following excerpt presents the activity proposed by one of the pre-service teachers in response to Question 3 of the final questionnaire. This activity demonstrates integration of both subject areas, total curricular alignment, and total coherence between content and the proposed activity:

> Analysis of Bottled Water Labels and Mineral Comparison
>
> Pupils, working in pairs, receive labels from different [and real] brands of bottled water and analyse the chemical information provided.
>
> In Natural Sciences, they discuss the importance of each mineral for human health and debate which type of water is most suitable for different needs (e.g. low-sodium water for people with high blood pressure).
>
> In Mathematics, pupils compare the decimal values shown on the labels, organize them in tables, and represent them on a number line.
>
> The methodological approach focuses on collaborative work and the use of concrete materials, promoting the integration of both subjects.
>
> (*PST 6, Final Questionnaire*)

Analysing the questionnaire responses as a whole, two conceptions of interdisciplinarity were identified: a comprehensive view and a limited view (Table 3). The initial questionnaire, applied before the lesson study, shows that most pre-service teachers (PST) proposed activities that considered an integrative topic, but mathematics supports science. Few PST view interdisciplinarity as a meaningful integration of mathematics and science, when the disciplines interact to support each other, allowing unique learning (An, 2017; Huntley, 1998). In the final questionnaire, evidence of IPCK development was observed. Most PST showed increased attention to balancing the presence of both subject areas, although integration was not always fully achieved, often occurring sequentially. Typically, the topic was selected from the science curriculum, with both areas explored within the activity.

Table 3. Pre-service teachers' conceptions of interdisciplinarity in the initial and final applications of the questionnaire, before and after lesson study.

Categories	Subcategories	Number of PST (n=11)	
		InitialQ	FinalQ
Conceptions of Interdisciplinarity	Comprehensive view (integration)	4	7
	Limited view (partial integration)	7	4

Conclusions

The findings indicate that the majority of pre-service primary teachers developed their interdisciplinary pedagogical content knowledge (IPCK) toward a more comprehensive perspective on interdisciplinarity in science and mathematics. This development was reflected in their increased ability to identify meaningful connections within and between both subjects, to design lessons grounded in these connections, and to deepen their understanding of the curriculum and how it can be coherently managed across subject areas. An initially limited conception of interdisciplinarity evolved into a more integrative perspective that encompasses the PCK of each discipline as well as their potential intersections (An, 2017).

Within the context of the project, the pre-service primary teachers participated in a lesson study, a formative process that emphasizes collaborative work in planning, observing, and reflecting on implemented lessons, with a focus on deepening their IPCK (Lewis, 2009; Murata, 2011). During this process, the pre-service teachers not only designed and implemented interdisciplinary tasks but also engaged in systematic reflection on their teaching experiences, identifying areas for improvement and refinement in their interdisciplinary practices. Across the different stages of the lesson study, reflection on the implemented lesson emerged as a particularly valued component of the training process, highlighting its central role in supporting the development of IPCK.

These findings should be interpreted in light of the study's limitations, namely the small number of participants, the focus on a single lesson study cycle, and the use of self-reported questionnaire data. Nevertheless, the results offer relevant insights into the potential of lesson study to support the development of IPCK in initial teacher education.

Linking Pre-Lesson Content Representations And Post-Lesson Reflections: AI-Based Insights Into Context-Specific PCK Development

Lukas Mientus[1] and Andreas Borowski[2]
[1]Otto von Guericke University Magdeburg, Germany
[2]University of Potsdam, Germany

Understanding pedagogical reasoning across the teaching cycle remains a central challenge in science education research, as lesson planning and retrospective reflection are typically examined using separate instruments and analytic frameworks. This contribution adopts a methodological perspective by linking Content Representations (CoRes) and written reflections as relational artefacts of pedagogical reasoning. Drawing on data from pre-service physics teachers during a teaching internship, embedding-based semantic similarity analyses are used to relate structured planning units from CoRes to segments of unstructured reflective texts. Instead of aggregating similarity scores or applying predefined coding schemes, the analyses retain the full relational structure and explore it using complementary representations, including similarity heatmaps and Principal Component Analysis. Exemplary case analyses illustrate how analytic design choices, such as reflection segmentation or modes of visualization, shape what becomes visible when planning and reflection are analysed in direct relation to one another. The contribution is exploratory and methodological: it demonstrates how relations between planning-related knowledge and retrospective reasoning can be made visible without evaluating teaching or inferring development or change in pedagogical content knowledge.

Keywords: Pedagogical Content Knowledge (PCK); Pedagogical reasoning; Content Representations (CoRes); Written reflection; Embedding-based text analysis

Introduction

Understanding pedagogical reasoning across the teaching cycle remains a central challenge in science education research, particularly because lesson planning and retrospective reflection are typically examined using separate instruments and analytic frameworks. Consequently, empirical research has rarely addressed how knowledge articulated during planning relates to how teachers' reason about their practice after teaching.

Within research on Pedagogical Content Knowledge (PCK), teachers' professional knowledge is understood as person-, topic-, and context-specific. Instruments such as Content Representations (CoRes) make planning-related PCK explicit, whereas written reflections provide access to retrospective pedagogical reasoning. Despite their widespread use, these instruments are rarely analysed in direct relation to one another, limiting insights into how articulated planning-related knowledge is taken up, recontextualized, or omitted in reflective discourse.

Recent advances in natural language processing enable new methodological approaches for exploring such relations. In particular, embedding-based semantic similarity analyses allow heterogeneous text-based artefacts to be related without relying on predefined coding schemes. This makes it possible to examine planning and reflection as relational data while refraining from evaluative or developmental claims.

Against this background, the present study explores how relations between CoRes and written reflections can be made visible by analysing them in direct relation to one another. Using AI-based semantic similarity analyses and focusing on exemplary cases, the study illustrates how different analytic representations foreground different aspects of planning–reflection relations.

The contribution is methodological and PCK-oriented: it demonstrates how planning and reflection can be linked analytically without evaluating teaching or inferring changes in PCK. By doing so, the study positions planning and reflection not as separate data sources, but as relational artefacts of pedagogical reasoning across the teaching cycle.

Theoretical Background

Pedagogical Content Knowledge And Pedagogical Reasoning

Pedagogical Content Knowledge (PCK) is widely regarded as a central component of science teachers' professional knowledge (Shulman, 1986, 1987; Van Driel et al., 1998; Van Driel & Berry, 2012; Loughran et al., 2006; Carlson et al., 2019). The Refined Consensus Model of PCK (RCM) provides a shared theoretical framework that distinguishes between different knowledge bases and emphasizes context-specific, enacted forms of PCK emerging in concrete teaching situations (Carlson et al., 2019).

Within the RCM, pedagogical reasoning is conceptualized as a cyclical process linking planning, teaching, and reflection (Alonzo et al., 2019). Planning and reflection are commonly associated with macro-level pedagogical reasoning, referring to articulated reasoning processes before and after teaching, whereas micro-level reasoning captures in-the-moment, often tacit decision-making during instruction. While macro-level pedagogical reasoning can be accessed through written artefacts such as lesson plans or reflections, micro-level reasoning remains empirically difficult to capture (Mientus et al., 2022).

In teacher education, practical phases are considered particularly relevant for PCK-related pedagogical reasoning, as they require pre-service teachers to articulate knowledge in planning and to retrospectively interpret their teaching experiences in reflection (Brouwer & Korthagen, 2005; Korthagen & Kessels, 1999). Accordingly, analysing artefacts of planning and reflection is a common approach to studying macro-level pedagogical reasoning. However, these artefacts are typically examined in isolation, leaving largely unaddressed how knowledge articulated during planning relates to retrospective reasoning after teaching.

Content Representations As Structured Planning Artifacts

Content Representations (CoRes) are a well-established instrument for capturing context-specific planning-related PCK in science education (Loughran et al., 2004, 2006). They are typically structured as tables in which teachers identify central "Big Ideas" of a topic and elaborate on them using guiding questions addressing different aspects of teaching (Sannert et al., 2025). Following the RCM, CoRes can be interpreted as structured articulations of different PCK facets, such as content knowledge (CK), pedagogical knowledge (PK), knowledge of students (KS), curricular knowledge (CuK), assessment knowledge (AK), and the learning context (Context) (Carlson et al., 2019; Mientus & Borowski, 2024); in the present study, these facets serve only as descriptive reference points rather than analytic coding categories. The PCK articulated in a CoRe is inherently person-, topic-, and context-specific (Chan & Hume, 2019).

In teacher education, CoRes are commonly used to support lesson planning and to externalize planning-related professional knowledge. Analytically, CoRes provide structured access to macro-level pedagogical reasoning before teaching, but do not capture how articulated planning-related knowledge is taken up or reconsidered after instruction.

Written Reflections As Retrospective Reasoning Artefacts

Written reflections are widely used to access retrospective pedagogical reasoning after teaching (Korthagen & Kessels, 1999; Poldner et al., 2014). They are typically unstructured free-text documents combining descriptive, evaluative, and affective elements. Reflective texts are

commonly analysed to study macro-level pedagogical reasoning, using qualitative, quantitative, or automated text-analytic approaches (Buckingham Shum et al., 2017; Ullmann, 2019; Wulff et al., 2022). However, reflective texts are often analysed in isolation, leaving open how retrospective reasoning relates to knowledge articulated during planning.

Linking CoRes and written reflections therefore offers a promising way to examine pedagogical reasoning across the teaching cycle, while posing methodological challenges due to the heterogeneous structure of the two artefacts. Together, CoRes and written reflections provide complementary access to macro-level pedagogical reasoning before and after teaching. Analysing them in relation to one another addresses a largely unexplored perspective in PCK-oriented research.

Methodological Approach

Research Context And Data Corpus

The study is situated in the context of pre-service physics teacher education during the teaching internship (Praxissemester) at the University of Potsdam. Practical phases in teacher education are considered a key setting for PCK-related pedagogical reasoning, as they require pre-service teachers to articulate professional knowledge in planning and to retrospectively interpret their teaching experiences. In this context, students are required to prepare, conduct, and reflect on their own lessons, thereby producing written artefacts associated with different phases of pedagogical reasoning.

Since the winter semester 2019/20, written self-reflections of pre-service physics teachers have been systematically collected as part of the ReFeed project (Mientus et al., 2021). Building on this data infrastructure, an additional preparatory component was introduced in the winter semester 2022/23: prior to teaching, students were asked to create Content Representations (CoRes) using a specially developed online environment. This resulted in paired datasets consisting of a CoRe as a planning artefact and a corresponding written reflection as a post-lesson artefact.

For the present study, data from six pre-service physics teachers were considered. Each participant produced three CoRe–reflection pairs related to self-taught lessons. After excluding incomplete cases, a total of 18 paired artefacts were available in the broader project. The present contribution draws on selected pairs for illustrative analysis. The aim is not statistical generalization, but the exploration of planning–reflection relations in person- and context-specific cases.

Instruments: Cores And Written Reflections

The Content Representation (CoRe) serves as the instrument for capturing planning-related professional knowledge prior to teaching. Following established practice (Loughran et al., 2006), CoRes are structured as tables in which central "Big Ideas" of a topic are elaborated using guiding questions. In the present implementation, these guiding questions were aligned with PCK facets specified in the Refined Consensus Model. Each table field can thus be treated as an articulation of context-specific professional knowledge related to content, pedagogy, students, curriculum, assessment, or learning context.

Written reflections constitute the complementary instrument for capturing retrospective pedagogical reasoning after teaching. Students produced free-text reflections on their lessons without a strict template, resulting in texts that vary in length, structure, and emphasis. The reflections combine descriptive accounts of classroom events with evaluative and affective elements and are consistent with common reflective practices in teacher education.

From a methodological perspective, the two instruments differ substantially in their degree of structure. CoRes provide segmented, planning-oriented representations of professional knowledge, whereas written reflections consist of continuous, unstructured text. Analysing relations between these artefacts therefore requires an approach that can relate heterogeneous text formats without reducing them to predefined categories.

Units Of Analysis And Segmentation

For the CoRes, each table field corresponding to a response to a guiding question is treated as an independent unit of analysis. This follows the internal logic of the instrument, as each field represents a coherent aspect of planning-related professional knowledge.

For written reflections, the default unit of analysis is the sentence. Sentence-level segmentation enables fine-grained mapping between planning units and reflective statements and supports detailed inspection of planning–reflection relations (Ullmann et al., 2019; Wulff et al., 2022). As reflective arguments may extend across multiple sentences, paragraph-level segmentation is additionally explored for illustrative purposes. Segmentation is treated as an analytic design choice, and its implications for interpreting semantic relations are explicitly addressed in the analysis.

Semantic Linking Of Planning And Reflection

To relate CoRes and written reflections, an embedding-based semantic similarity approach is employed. CoRe units and reflection segments are mapped into a shared semantic space using sentence embeddings derived from large language models. Semantic similarity between planning units and reflection segments is calculated using cosine similarity.

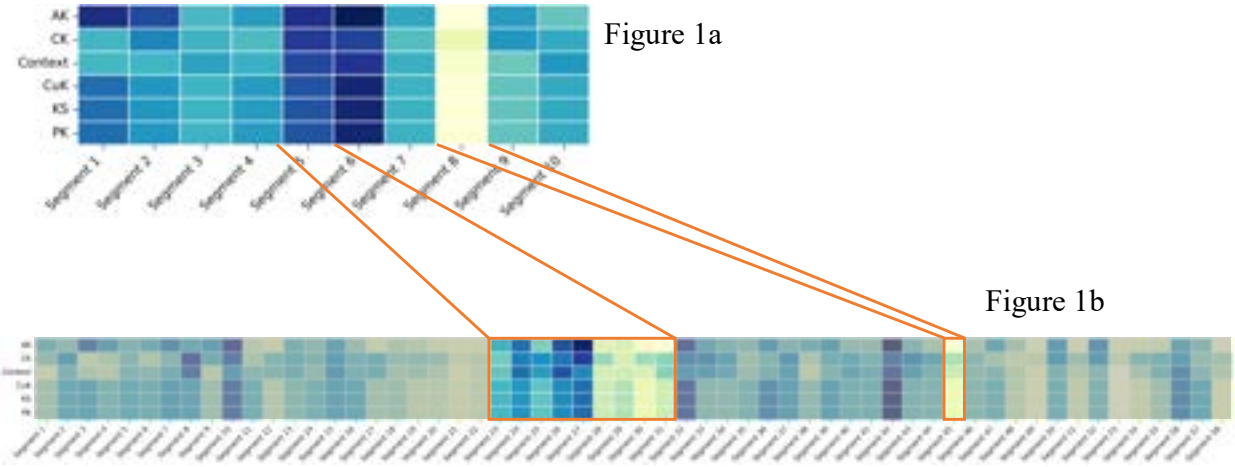
For each CoRe–reflection pair, all planning units are compared with all reflection segments, resulting in a similarity matrix that represents the relational structure between planning and reflection. Rather than aggregating similarity scores, the full similarity structure is retained for analysis and visualization. Heatmaps are used to illustrate local and sequential similarity patterns, while Principal Component Analysis (PCA) is applied to visualize the relative positioning of planning and reflection units in the shared semantic space. These representations serve an illustrative and exploratory purpose.

Analytic Focus And Scope

The analytic focus of the study is explicitly exploratory and methodological; the analyses neither evaluate teaching nor infer changes in PCK. Instead, they demonstrate how relations between planning and reflection can be made visible by analysing CoRes and written reflections in direct relation to one another. Accordingly, the study emphasizes exemplary case analyses rather than aggregate patterns. Selected CoRe–reflection pairs are used to illustrate how different analytic representations foreground different aspects of planning–reflection relations, such as the effects of segmentation choices or differences in global semantic overlap. The analyses are descriptive and intended to support methodological reflection on relational approaches to studying pedagogical reasoning in PCK-oriented research.

Analytic Strategy: Exemplary Case Analyses

The analyses presented in this study follow an exemplary and contrastive logic. Rather than aiming for systematic comparison or representativeness, selected CoRe–reflection pairs are used to illustrate how different analytic representations make different aspects of planning–reflection relations visible. The cases were chosen to highlight methodological contrasts, not to evaluate individual teachers or to establish typologies.



Two complementary analytic representations are employed. First, similarity heatmaps are used to examine local and sequential relations between planning units and reflection segments. These visualizations foreground how specific elements of articulated planning-related knowledge are semantically related to individual segments of the written reflection. Second, Principal Component Analysis (PCA) is used to visualize the global semantic configuration of planning and reflection units within a shared embedding space. This representation shifts the analytic focus from sequential relations to overall patterns of semantic overlap.

The two examples presented below are not intended as comparative cases in a strict sense. Instead, they serve as illustrative contrasts that demonstrate how analytic design choices shape what becomes visible when planning and reflection are analysed relationally.

Example 1: Effects Of Reflection Segmentation On Interpreting Planning–Reflection Relations

Figure 1 illustrates how analytic decisions regarding the segmentation of written reflections influence the interpretation of semantic relations between planning and reflection. Both heatmaps shown in Figure 1a and Figure 1b are based on the same CoRe–reflection pair. The only difference lies in the unit of analysis used for the written reflection: paragraph-level segmentation in Figure 1a and sentence-level segmentation in Figure 1b.

Figure 1. Effects of reflection segmentation on semantic relations between planning and reflection: similarity heatmaps based on paragraph-level (a) and sentence-level (b) segmentation of the same CoRe–reflection pair.

In Figure 1a, the written reflection is segmented into ten paragraphs. The vertical axis represents planning-related units from the CoRe, grouped by PCK-related facets, while the horizontal axis follows the reflection text paragraph by paragraph. At this level of aggregation, the heatmap suggests a relatively homogeneous pattern of semantic alignment. Several planning-related facets appear to co-occur across the same reflective segments, and only one paragraph shows minimal semantic proximity to the planning artefact.

When the same reflection is segmented at the sentence level (Figure 1b), a more differentiated pattern emerges. The reflection is now represented by 58 segments, revealing substantial variation in semantic similarity within paragraphs that previously appeared homogeneous. Sentences focusing on instructional actions and contextual constraints show higher semantic proximity to planning-related units, whereas affective or self-referential statements display markedly lower similarity.

This example demonstrates that segmentation is not a neutral preprocessing step, but a methodological lens that shapes how planning–reflection relations are interpreted. Paragraph-level segmentation foregrounds broader thematic alignment, whereas sentence-level

segmentation makes fine-grained variation within reflective discourse visible. Neither approach is treated as inherently superior; rather, the example illustrates how analytic choices affect what kinds of relations can be observed.

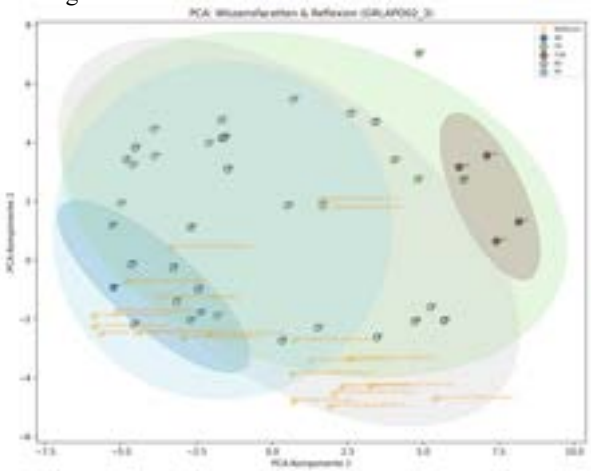
Example 2: Visualizing Semantic Overlap Between Planning And Reflection Using PCA

Figure 2 provides a complementary perspective by visualizing planning and reflection units in a shared semantic space using PCA. Whereas the heatmaps foreground local and sequential relations, the PCA shifts the analytic focus toward global patterns of semantic overlap and distance. Figures 2a and 2b show two illustrative CoRe–reflection pairs. The PCA represents a two-dimensional projection of high-dimensional embedding vectors; the axes themselves have no substantive interpretation and serve only to indicate relative semantic proximity.

In both figures, individual CoRe units are plotted as points and grouped by PCK-related facets, with ovals approximating the semantic regions spanned by each facet. Reflection sentences are plotted in the same space. The visualization highlights the degree to which reflective statements are located within or outside the semantic regions approximated by the planning artefact.

Figure 2. PCA-based visualization of the shared semantic space of CoRe planning units (grouped by PCK facets) and written reflection sentences for two illustrative planning–reflection pairs.

Figure 2a



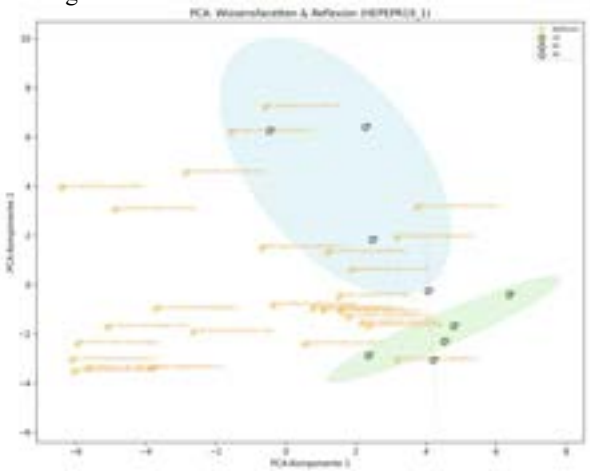


Figure 2b

In Figure 2a, reflection sentences are largely located within the regions spanned by the CoRe units. Descriptively, this configuration indicates a high degree of semantic overlap between planning-related knowledge and retrospective reflection. In Figure 2b, by contrast, several reflection sentences fall outside these regions, suggesting a lower degree of semantic overlap. These observations are reported descriptively and are not interpreted as indicators of teaching quality, completeness of planning, or professional development.

Across both cases, the PCA visualizations also illustrate that the apparent size and shape of planning-related semantic regions depend on properties of the underlying text material, such as length and elaboration. Consequently, PCA-based representations should be understood as heuristic tools for exploring global patterns of semantic overlap rather than as stable characteristics of individuals or artefacts.

Methodological Contribution Of The Exemplary Analyses

Taken together, the exemplary analyses illustrate how linking CoRes and written reflections enables a relational view of pedagogical reasoning that remains inaccessible when planning and reflection are analysed separately. The heatmaps foreground local and sequential relations, while the PCA visualizations provide a global perspective on semantic overlap. Importantly, the

examples show that different analytic representations do not reveal the same aspects of the data but selectively foreground different relations. The purpose of these analyses is not to derive generalizable findings, but to demonstrate the analytic potential and limitations of relational, embedding-based approaches for studying planning–reflection relations in PCK-oriented research.

Discussion

This contribution adopts a methodological perspective on pedagogical reasoning by treating lesson planning and retrospective reflection as relational artefacts situated at different points of the teaching cycle. Linking Content Representations and written reflections makes visible patterns of semantic alignment and non-alignment that remain inaccessible when each artefact is analysed in isolation. In this sense, the study extends instrument-specific approaches by foregrounding relations rather than isolated representations of professional knowledge.

The exemplary analyses resonate with theoretical conceptualizations of pedagogical reasoning as a cyclical process connecting planning, teaching, and reflection. Descriptively, instructional and contextual considerations articulated during planning tend to show higher semantic proximity to reflective statements than affective or self-referential passages. These observations suggest that different modes of retrospective reasoning relate differently to articulated planning-related knowledge. However, in line with the analytic scope outlined above, such patterns are not interpreted as indicators of learning, transformation, or quality of teaching; nor do the analyses provide access to micro-level reasoning processes or changes in PCK.

A central insight of the study is that analytic representations actively shape what becomes visible. Sequential similarity heatmaps foreground local relations along the progression of reflective texts, whereas spatial projections such as PCA highlight global patterns of semantic overlap. These representations are complementary rather than competing and underscore that relational analyses are not neutral windows onto pedagogical reasoning, but methodological lenses that emphasize different aspects of planning–reflection relations.

Limitations

The present study is subject to several limitations. First, the analyses are based on a small number of illustrative cases and are not intended to support generalization across individuals or contexts. The exemplary cases serve to demonstrate analytic possibilities rather than to establish stable empirical patterns.

Second, the observed relations are sensitive to methodological design choices. In particular, segmentation of reflective texts substantially affects the granularity and interpretation of semantic similarity, and PCA-based visualizations depend on properties of the underlying text material such as length, elaboration, and linguistic variation. These dependencies should be understood as characteristics of the analytic approach rather than as sources of measurement error.

Finally, the identified relations describe semantic proximity between planning and reflection, not learning outcomes, instructional effectiveness, or professional development. Developmental or evaluative interpretations would require additional data, triangulation with other methods, and longitudinal designs that are beyond the scope of this contribution.

Implications And Outlook

Despite these limitations, the study points to several implications for future research in science education. Methodologically, it illustrates how planning and reflection can be analysed as relational data without reducing either artefact to predefined categories or evaluative metrics.

This opens up exploratory research designs that focus on pedagogical reasoning across the teaching cycle rather than on isolated knowledge components.

Future work may systematically investigate how analytic decisions, such as segmentation strategies or modes of visualization, influence the interpretation of planning–reflection relations. Longitudinal designs could explore whether characteristic patterns of semantic alignment emerge over time and how they relate to instructional experience. Combining embedding-based analyses with qualitative interpretation may further clarify how different forms of retrospective reasoning connect to articulated planning-related knowledge.

At the same time, the approach should be understood as an analytic tool for making relations visible and inspectable, not as a validated measurement instrument. Its contribution lies in supporting methodological and theoretical reflection on how pedagogical reasoning can be studied relationally within PCK-oriented research, rather than in providing definitive interpretations of teachers' professional knowledge or its development.

Technology And Pedagogy In Science Teacher Education: Promoting Teacher Candidates' Skills In Instructional Design And Learning Management Systems

Mohammed Estaiteyeh and Xavier Fazio
Brock University, Canada

Two main models exist in teacher education programs to advance teacher candidates' (TCs') use of technology in teaching: 1) stand-alone courses on educational technology, and 2) infused model in which digital skills are integrated into teaching methods courses. In this paper, the authors present a collaboration that combines both approaches to promote technology use in science teacher education. We report on an assignment in the educational technology course that requires TCs to capitalize on their skill in science curriculum development to create an online learning module using learning management systems (LMS). This paper aims to analyse the content of TCs' developed online modules and present TCs' experiences in this assignment, with a focus on their skills in using LMS.

The authors adopt a qualitative approach. Participants are 10 TCs enrolled in both the educational technology course and the science methods course in the teacher education program at a university in Canada (secondary division). The authors analyse the online modules developed by the TCs and their reflections.

TCs' work and reflections showcase the positive impact of the training they received and the importance of the online module assignment in promoting their 1) pedagogical skills in science instructional design and 2) technological and pedagogical skills in incorporating digital tools into their lessons and using LMS. The assignment showed the importance of collaboration between educational technology and science education instructors to promote TCs' technological, pedagogical, and content knowledge. This research highlights the successes of professional development practices, especially ones focused on interdisciplinary collaborations in teacher education programs.

Keywords: Science teacher education, learning management systems, instructional design

Introduction and Objectives

Although stand-alone educational technology courses in teacher education allow teacher candidates (TCs) to develop proficiency in using digital tools (Roblyer & Hughes, 2019), they often lack integration with broader content knowledge and pedagogical skills (Estaiteyeh & Rong, 2026; Foulger et al., 2015). Alternatively, teacher educators can infuse technology in subject-specific courses like curriculum and methods courses in science teacher education programs to make technology training more relevant and practically applicable (Koehler et al., 2013). Indeed, Williamson et. al. (2023) emphasize collaboration among educators from different disciplines to foster a multidisciplinary method of technology integration in teacher education. In such infusion models, technology-supported learning strategies are taught, modeled, and practiced throughout the entire preparation program, with all teacher educators assuming responsibility for supporting science TCs' growth in teaching with technology (Sprague et al., 2022). However, time constraints and the need to cover a broad range of topics in science curriculum and methods courses limit science teacher educators from fully incorporating technology in their courses.

In this paper, the authors present a balanced approach that combines the stand-alone and infused approaches to promote technology use in science teacher education. The authors are two teacher

educators in a teacher education program in Canada who collaborated to complement each other's work in their respective courses. The first author teaches the stand-alone educational technology course while the second author teaches the science education course. In the educational technology course, TCs focus on the effective use of digital technologies in the classroom (Estaiteyeh et al., 2025). In the science methods course, TCs are introduced to curriculum design, teaching strategies, and assessment methods in secondary science education. We report on one of the assignments in the educational technology course that requires TCs to capitalize on their skill in science curriculum development to create an online learning module, all while advancing their skills in using learning management systems (LMS). Thus, this paper addresses the following research objectives:

1) Analysing the content of TCs' developed online modules.
2) Presenting TCs' experiences and reflections on this assignment, with a focus on their skills in using LMS.

Literature Review And Theoretical Framework

Preparing Tcs For Online Teaching And Using Learning Management Systems

With the increased prevalence of online learning and as per the lessons learned from teaching during the COVID-19 pandemic, there is a need to better equip TCs for technology-enhanced teaching practices, especially in online environments (DeCoito & Estaiteyeh, 2022; Barbour & Hodges, 2024). Success in online teaching depends on strong course design, appropriate material selection, effective pedagogical strategies, and clear communication with students and families alike (Fernández et al., 2017; Recker et al., 2013). Several studies in Canada have demonstrated the positive impacts of online teaching preparation and training on science TCs' readiness to support this teaching modality (Burns et al., 2020), especially in synchronous learning environments (Estaiteyeh et al., 2024). However, there is a gap in the literature on preparing TCs for asynchronous online teaching and instructional design for virtual environments.

Furthermore, essential to the success of online teaching is the effective use of LMS, which is the platform that is primarily used in online environments. Thus, it is also important that TCs get sufficient training in using LMS, with a focus on student engagement and community building in online settings (Vivolo, 2019) and the use of a variety of interactive virtual resources (Smith et al., 2018). However, despite the importance of LMS, research on their use by TCs is limited. Accordingly, this research aims at advancing TCs' technological and pedagogical skills in using LMS to create effective online learning experiences for the students.

Technological, Pedagogical, and Content Knowledge (TPACK) Framework

This research is informed by the TPACK framework (Koehler et al., 2013). Shulman (1987) defines pedagogical content knowledge (PCK) as the capacity of a teacher to transform their content knowledge into forms that are pedagogically powerful yet adaptive to variations in students' abilities and backgrounds. Koehler et al. (2013) extend Shulman's PCK to integrate technology into teacher's pedagogy. In accordance with the technology infusion framework (Williamson et al., 2023) explained earlier, the authors emphasize how content, pedagogy, and technology interest across different courses in the teacher education program. In doing this work, TCs will capitalize on content and pedagogical knowledge acquired in science education courses to advance their pedagogical and technological knowledge fostered in the education technology course.

Methods

The authors adopt a qualitative approach (Creswell & Creswell, 2018) utilizing document analysis (Stake, 2020) to address the research objectives. Ten TCs (two males and eight females) participated in the study. Participants were enrolled in both the educational technology course and the science methods course in the first year of the two-year teacher education program at a university in Canada (secondary school teacher certification). The science education course ran for 24 weeks (Fall and Winter terms), while the educational technology course ran for 12 weeks in the Winter term.

Assignment Description

As part of the educational technology course, the instructor provided TCs with two workshops on online teaching and LMS features and functionalities. This training included providing relevant resources and tutorials, modelling by the instructor, and direct applications by TCs. Afterwards, the instructor introduced the online learning module assignment. This assignment built on what TCs had learned in the Fall term in the science education course (instructional design using the backward design model, student-centred teaching and assessment strategies). In this assignment, TCs worked individually or in pairs to design and develop an online learning module using Brightspace, the LMS adopted by most district school boards partnered with the University. The module should be developed for students in a class within the and focused on a specific concept within TCs' subject area (e.g., general science, biology, chemistry, physics). The module was planned by TCs to be completed mostly asynchronously by their prospective students. First, TCs completed the instructional design phase of the module. Then, they hosted their module on Brightspace LMS. In addition to developing the modules, TCs submited individual reflections on this assignment.

Data Sources and Analysis

The authors describe and analyse 1) the online modules developed by the TCs (total of seven modules) and 2) the individual reflections submitted by each TC (10 reflections). Sample reflection questions included: What did you benefit the most from this project? What challenges did you face (individual or group challenges)?

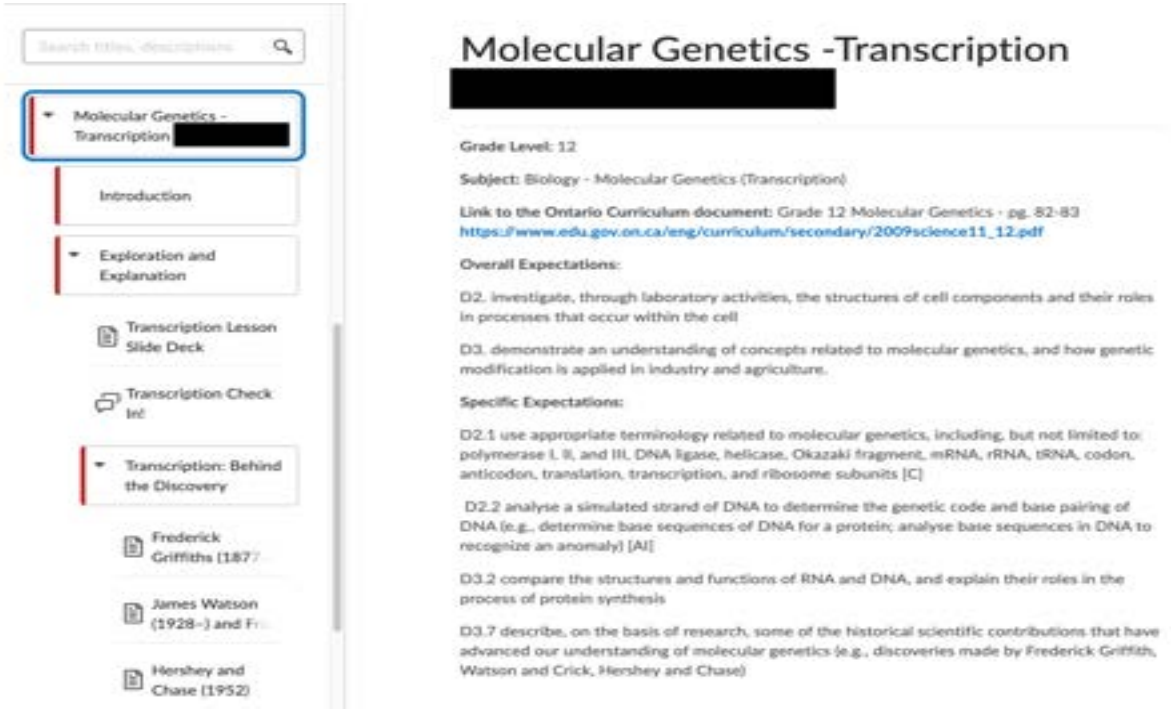
Data analysis adopted a deductive approach (Creswell & Creswell, 2018), using pre-determined themes (e.g., module contents, teaching and assessment staregies, incorporated digital tools, and LMS functionalities). The first author conducted the analysis, and the second author reviewed it by providing corrections. The two authors met to finalize the findings. This process of iterative and collaborative analysis was done to ensure the reliability and validity (Creswell & Creswell, 2018).

Results

Modules' Analysis

As shown in Figures 1 and 2, TCs used several LMS features and functionalities to host their module such as discussion boards, assignments, rubrics, quizzes, and digital publishing while attending to accessibility and inclusion guidelines. TCs were also able to augment their science lesson plans by incorporating digital tools such as multimedia, online simulations, virtual labs, and digital assessments. Although this was the first experience for almost all TCs in using LMS as teachers, their work on the online modules showed the positive impact of the provided training and the relevance of this assignment in preparing them for future use of the LMS software. Equally important, the assignment showed the importance of collaboration between educational technology and science education instructors to promote TCs' TPACK.

Figure 1. Screenshot of a module on DNA transcription showing the structure and flow of the module on Brightspace.



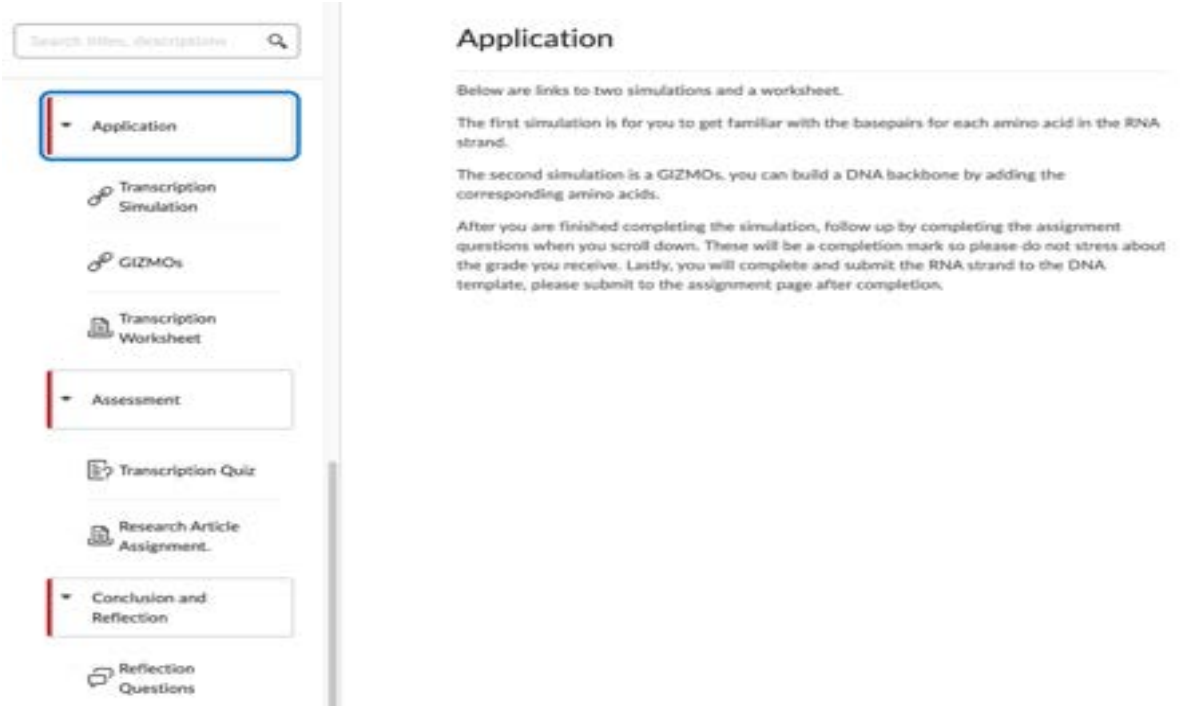


Figure 2. Screenshot of a module on DNA transcription showing the incorporation of digital tools within the module.

Teacher Candidates' Reflections

The reflections of TCs reiterated the positive impact of the training they received and the importance of the online module assignment in promoting their 1) pedagogical skills in science instructional design, 2) technological and pedagogical skills in incorporating digital tools into their lessons and using LMS. For example, TCs said:

> I think that I benefited most from finding new tech tools which can specifically be used within my teachable of science. I was able to find new virtual simulations and tutorials

which I may not have found if I did not take this course. Before taking this course, I did not consider the idea of virtual simulations, virtual field trips, and virtual labs. Having science as one of my teachables, I have realized how useful these virtual tools could be while teaching an online class and needing students to meet the lab-based curriculum expectations. I also benefited from learning how to host a class on Brightspace as this is something I will most likely need to do in the near future either during my teaching placements or within my own class.

This project gave me important insights into instructional design and online module development. Moreover, working on this subject allowed me to improve my ability to organize content effectively and create interesting learning experiences for students. In addition, I learned how to use Brightspace to host online modules, which increased my skills in using learning management systems. Overall, this project provided me with practical experience and knowledge that would be very beneficial in my future teaching career.

Significance of the Study

This research advances knowledge about science teachers' preparation and readiness for technology-enhanced and online teaching. This work informs science teacher educators, educational researchers, and higher education curriculum designers about the successes of professional development practices, especially ones focused on interdisciplinary collaborations in teacher education programs.

ESERA 2025 Copenhagen

Science Teacher Educators: Career Narratives And Life Histories

Peer Daugbjerg
VIA University College, Denmark

A significant notion in science teacher education as in other teacher education is modelling, phrased as 'How I teach is the message'. This is both a professional and a personal stance, or stances as it spreads over several elements for the profession as a teacher educator but also makes it clear that it is the individual teacher educators personal performance applying these elements that is what teacher students meet during their education. This makes teacher education a personal effort for teacher educators and reflects the significance of teacher educators lived experiences in their teaching of coming teachers. This raise the question whether it gives different relations between work and personal life, and furthermore is science teacher educators a unique group here with distinct characteristics in their experience of meaning. My research interest calls for focus on the individual science teacher educator as it is them that do the actual teaching about science teaching. This means that I must learn from individual science teacher educators, what are their life histories, how do they narrate them during life history interviews. My analysis indicates that science teacher educators' careers are influenced by significant professional events in their lives and that second order teaching has a strong position in their professional compass.

Keywords: Science teacher educators, Career Narratives.

Introduction – Context And Background

The recruitment of teacher educators in Denmark has for the last 25 years gone through a structured qualification. This qualification is compulsory for anyone who wants to teach at a University College in Denmark including teacher educators. After 3½ years the teacher educator hands in a maximum 40 pages long written request to become a permanent member of the teacher education staff (Departmental order on teacher educator qualification, 2025). The request must cover teaching of teacher students and teachers including planning and development and implementation of international research aspects in this work. The issue of implementation of research has internationally received attention through the notion of teacher educators' varied researcherly dispositions (Tack, et al 2023). This is especially a concern for researchers from university-based teacher educations. This aspect has also been researched in Denmark (Duch et al, 2021) leading to the formulation of three idealistic types of educators at University Colleges and their relation research and development: 'The profession-oriented educator', 'The research-oriented educator', and 'The educative oriented educator'. The typologies show the spectrum of research interest among Danish university college educators but does not - as all typologies – reveal nuances and personal aspects of the research orientation. A more individualistic approach through life histories can unveil such details (Lorist & Swennen, 2016).

The structured professional development for university college educators in Denmark is not common in other countries. Studies revealed that teacher educators' recruitment is incidental, with no pre-planned policy to form well-balanced teams that provide coherent teacher education programmes (Guberman et al, 2021). It appears that Denmark holds a special position regarding a structured state-run qualification programme for a permanent position in teacher education. However, the Association of Dutch Teacher Educators run a certification programme which includes evaluation of novice teacher educators' products and portfolios (Lunenberg et al, 2014a). This certification is voluntary and does not cover all Dutch teacher educators.

A significant notion in teacher education is modelling, phrased as 'How I teach is the message' by the International Forum for Teacher Education Development (InFo-TED, 2024). This is both a professional and a personal stance, as the forum puts forward 13 building blocks for the profession as a teacher educator but also makes it clear that it is the individual teacher educators personal performance applying these building blocks that is what teacher students meets during their education. This makes teacher education a personal effort for teacher educators and reflects the significance of teacher educators lived experiences in their teaching of coming teachers (ATEE Empowering RDC, 2024).

Research Interest

A firsthand understanding of an insider – my own – is that of a great variation within science teacher educators' professional development and personal practice. The field of science teacher educators is not well researched, however there is an emerging field of international studies on being and becoming a teacher educator as well as on their lives and work (Swennen & White 2021; Jaworski & Woods, 2008; Lorist & Swennen, 2016). These studies bring forward the voices of teacher educators (Swennen & White, 2021) and critical stances to these voices (Holdsworth, 2021). As stated above the Danish qualification of teacher educators might provide a different background for the voices of Danish teacher educators. Does this give different relations between work and personal life, and furthermore is science teacher educators a unique group here with distinct characteristics in their work-life experience. This leads me to my research questions for this presentation.

Research Question

- How is science teacher educators work related to their lives?

Methodological Considerations

My stated research interest calls for focus on the individual science teacher educator as it is them that do the actual teaching about science teaching. This means that I must learn from individual science teacher educators, what are their life histories, how do they narrate them during life history interviews (White & Timmermans, 2021; Swennen & Lorist, 2016).

I can though not only interview science teacher educators. I have also to observe them during their workdays. I must contextualise my science teacher educators' narratives in the teacher educator profession and add a practice perspective on science teacher education to their narratives, so I must do more than interview them. Traianou (2007) emphasises the importance of studying actual practice:

> … the assessment of an individual's knowledge should be based on how this person performs, and not on what this person says about his/her own performance or what he/she can and cannot do in artificial situations (Traianou, 2007, p. 40).

Traianou (2007) puts her finger on the need to study science teacher educators as closely as you can get to real situations. Thus, rather than simply recounting verbatim the science teacher educators' own accounts of their practice, nor confining one's study to their performance in teaching situations, you should apply a research method that brings together diverse observational data and presents science teacher educators in all their complexity. I therefore also make observations of the participating science teacher educators teaching and performing other work functions during entire everyday work.

The Applied Method

The research design departs from the above methodological considerations which is in close alignment with a previous study on school science teachers in Denmark (Daugbjerg, 2013).

1) Life history and career narrative interview of approximately one hour
    i) Art based elements: go-cards and the like, drawing option
2) Two more-or-less whole day (each approximately 6 hours) observations pr. participants with emphasis on teaching practice.
3) Follow-up interview of approximately one hour
    i) Filling identified common aspects not covered by interview and observations
    ii) Validating preliminary interpretations of first individual interview and observations
    iii) Emotional aspects of science teacher education (e.g. joy, anxiety, nervousness)

Conceptual Framing Of The Research

Here I will briefly present research literature that presents and works with the key concepts in my research endeavour.

Second Order Teaching

Teacher educator work can be summarised in six characteristic roles of teacher educators: teacher of teachers, researcher, coach, curriculum developer, gatekeeper and broker (Lunenberg et al, 2014b). Lunenberg et al (2014b) relates in their review of teacher education these roles but especially the 'teaching of teachers' role to the notion of second order teaching. They emphasise the importance of teacher educators ability to articulate tacit knowledge and underlaying theory through explicit modelling (Lunenberg et al, 2014b).

A more recent state of the art research from Denmark puts forward a definition of second order teaching:

> Second order teaching encompasses the educative reflections concerning planning, enactment, analysis, and development of teaching, that actors in the teacher education contexts address, and the praxis they unfold to facilitate coming teachers' ability to future teaching (Ellebæk, Dolin & Daugbjerg, 2022).

Life History

Life history has frequently been used to identify significant events in peoples' lives (Goodson & Sikes, 2001). Also, within teacher education it is a known approach to understand teacher educators lives and work (Lorist & Swennen, 2016; Fisher & Powell, 2023)

Narrative Inquiry

There are several different traditions within narrative inquiry. I subscribe to a seminal work by Clandinin & Connelly (2000). Updated by Horsdal (2011):

> The focus in my approach is not to understand the individual person – how she or he really is beyond the surface – but how the narrator tries to make sense of lived experience through her narration (Horsdal, 2011, p. 108).

Narrative inquiry has also been used to understand teacher educators work e.g. White & Timmermans (2021) study on school-based teacher educators.

Findings

My participants are 8 males and 5 females, an overall cohort of Danish science teacher educators counts 62 whereof 38 are male and 24 are female (Nielsen, 2022). My group of participants is a convenience sample of volunteers, from a field that I have been a member of for nearly 30 years.

That makes my research a bit scarring because some of the participants have been my national colleagues for about a generation.

Table 1. Overview of participants biographic data.

Alias	Birth	Parents	Coming of age	Education	Career
Leif	1979	Vocational trained Ergo therapist	Rural area, scouting	Master in chemistry 2010 PhD Mol. Biophysics 2013	Science Researcher TE 2022: Physics/Chemistry

They represent a geographical distribution in Denmark with participants from all 6 university colleges in Denmark, they represent all the four science subjects in Danish school and teacher education. Biographic data that present the overall life histories are presented in the table below. Interviews and observations were conducted from November 2023 – February 2025.

Comparison of my participants with the overall cohort of Danish Science teacher educators reveals that my sample quite representative for science teacher educators in Denmark in general.

Table 2. Comparison of my participants experience as science teacher educator and a larger cohort of Danish Science teacher educators.

Experience as Science teacher educator	National cohort (N=57) (Nielsen, 2022)	My participants (N=13)
0-4 years	21%	15%
5-9 years	16%	23%
10-14 years	9%	0%
15-19 years	23%	23%
20 years or above	32%	38%

Table 3 Comparison of my participants educational background and a larger cohort of Danish Science teacher educators – several has more than one education e.g. a teacher education and a Master of Science Education or a Master of Science and a PhD degree.

Science teacher educators educational background	National cohort (N=57) (Nielsen, 2022)	My participants (N=13)
Teacher education	36%	46%
Science master	62%	54%
Science education Master	22%	38%
Other master	31%	0%
PhD	31%	31%
Other education	33%	15%

Voices Of Science Teacher Educators

My participants reflect the importance of second order teaching as a way to be a teacher of teachers:

> And then the challenge with second order teaching. That is what I find most interesting (Kia).

Kia has worked with young children at a science centre prior to entering teacher education, here she applied a variety of teaching approaches. These experiences are mirrored in her approach working with science modelling with her science teacher students as a tool to relate to them and make them relate to science.

> And then I work simply with [modelling], rather than sitting and getting frustrated that they can't understand it [the science subject as presented in a text]; I say, that is okay that you do like this [make a model] (Kia).

Kia asks the science teacher students to work with a science phenomenon through different media as they see fit to optimize their learning.

My participants also reflect on specific elements of science education and the duality of teaching and learning.

> Science, aesthetics, and the fascination. Evolution as the red thread and the connection between learning and teaching (Veronika).

Veronika also reflects on the relation between science education research and science teacher education and its options for double synergies. Veronika has been a science researcher prior to entering teacher education.

> Because I research into teaching, and that must be anchored. So, I anchor it in my own [teacher education] praxis. I try to include it [research] and try to use the synergies (Veronika).

My participants also refer to significant events in their career

> I had these two supervisors … who also were Danish language teachers. They had a lot of focus on language … and then ever since I have had a lot of focus on language in science and mathematics (Sten).

Sten also narrates another significant event from a stay abroad, where he met a science supervisor who encouraged him to work extensively with practical work in the science lab. He recalls the instruction he was given:

> '*When you think you have investigated it sufficiently, then you make a report and then you take the next'*. So, there was much more freedom. And there were much in the teaching that dealt with experimental methods, contrary to what I was used to back at University in Denmark (Sten).

Stens work with coming physics teachers is based on a lot of practical experimental work in the science lab, so Sten has implemented his own experience with lab work in his praxis. He emphasizes the importance of his science teacher students to be comfortable working with experiments themselves and together with students in school.

Some of my participants work with in-service training of school science teachers and how their former career as a school science teacher eases them in their role as a broker for school science teachers in their professional development.

> Well, I love to do continuous education for teachers, but that is also because I have been doing it for so many years. And I have been a colleague with them. I can see that some of the new young ones [science teacher educator colleagues] that come the university way, they hurt themselves on them [school teachers]. Really schoolteachers are the most critical race you can teach, but that is because they sit in it [teaching] daily themselves (Lars).

Table 4. Summary of how work and life relate in science teacher educator roles seen in my participants career narratives.

Teacher of teachers	Broker	Researcher
Commitment in the relation to teacher students using own teacher experience.	Relation to teachers - Own experience as a teacher.	Experience with research: - Prior to entering teacher education

Focus on making science teacher students comfortable with doing practical experimental work with school students based on own experience with science lab work.		- As a part of being a teacher educator

Conclusion

The presented voices indicate that science teacher educators' careers are influenced by significant professional events in their lives and that second order teaching has a strong position in their professional compass. There are general teacher educator aspects in the narratives e.g. relating to teacher students and schoolteachers, but there are also references to science education elements such as science modelling or experimental work and grand narratives of science like evolution as a red thread.

Examining Pre-Service Chemistry Teachers' Perceptions About Their Interactions With Mentors And Peers During The COVID-19 Pandemic

Paulo A. C. Loureiro[1], Luciane Goes[2] and Carmen Fernandez[2]
[1]University of Georgia (UGA), USA
[2]University of São Paulo (USP), Brazil

This study explores the pre-service chemistry teachers' perception of mentoring relationships within the context of the Brazilian Pedagogical Residency Program (PRP), focusing particularly on the challenges posed by the COVID-19 pandemic and the shift to remote learning. The PRP, a public policy designed to enhance teacher training, pairs pre-service teachers with experienced in-service mentors and fosters peer mentoring to develop practical teaching skills. This study investigates how these mentoring relationships contributed to the development of pre-service teachers' teaching practices, especially considering challenges posed by the pandemic. Two key research questions were addressed: the role of in-service mentors and peers in shaping teaching practices, and how the pandemic affected these mentoring relationships. Data were collected through interviews, experience reports, and audiovisual recordings from six pre-service teachers who participated in the PRP between 2020 and 2022. The findings emphasize the essential role of in-service mentors in providing guidance; however, communication barriers were enhanced by the remote learning context. Although peer mentoring emerged as a valuable source of emotional and professional support, the physical absence of mentors led to more superficial mentor-mentee interactions. The study underscores the importance of strong communication and deeper engagement in mentoring relationships, particularly during times of crisis. It also suggests that future improvements in mentoring training and program design could enhance the effectiveness of teacher training programs. The research contributes to understanding how mentoring dynamics influence pre-service teacher development and provides insights for refining educational policies in Brazil and beyond.

Keywords: Pre-service teacher education, Professional development, Educational Policy

Introduction

Mentoring is discussed in the literature from different perspectives. More traditional and classical views of mentoring consider it as a process where knowledge is transferred from the mentor to the mentee in a more hierarchical manner (Spooner-Lane, 2017). In contrast, more modern views emphasize a collaborative and mutually beneficial approach to educational mentoring (Larsen et al., 2023).

Regardless of which perspective researchers align with, they consistently highlight the importance of the relationship between mentors and mentees in the mentoring process. In this context, Brazil has recently implemented public policies that describe mentoring programs for pre-service teachers, such as the Brazilian Pedagogical Residency Program (PRP). Science pre-service teachers have been a primary focus of educational policies, particularly due to alarming university dropout rates. Research attributes this high rate the absence of active and interdisciplinary teaching and learning strategies (Silva & Figueiredo, 2018).

Additionally, pre-service teachers in Brazil have a highly demand coursework that requires them to take pedagogical core courses while also taking content-specific pedagogical courses and content-specific courses, contributing to these rates. Previous studies indicate that challenges in mathematics-related coursework may contribute to science pre-service teachers drop-out rates (Heusel et al., 2023). With that said, it is important to have a deep understanding of how these

new policies, focused on mentoring programs, are influencing student-teachers to persist in and complete their degrees.

Since the onset of the COVID-19 pandemic in 2020, much has been discussed about its impact on fields such as education and pre-service teacher training. However, little is known about how it may have hindered mentoring programs like PRP. This investigation draws on data from this period, which adds uniqueness and importance to understanding whether and to what extent the pandemic may have affected pre-service teachers' experiences in a mentoring program.

This study aims to identify aspects of the relationship between mentors (in-service teachers) and mentees (pre-service teachers) that may have provided support to the mentees as they began their teaching practices, according to their perspectives. Two research questions are posed:

RQ1: According to pre-service chemistry teachers' perceptions, what role did in-service teacher mentors and peers play in helping them develop better teacher practices?

RQ2: According to pre-service chemistry teachers' perceptions, how did the pandemic and the remote learning context hinder their relationships with peers and in-service teacher mentors?

Framing

Teacher Perception

In Science Education literature, studies frequently draw on teachers' and students' perceptions to analyse experiences, practices, and learning environments. However, despite its widespread use, the concept of perception is often taken for granted and remains theoretically underdefined. In this study, perception is understood not as a passive registration of events, but as an active cognitive process through which individuals interpret, organize, and attribute meaning to their experiences.

From a cognitive perspective, perception is grounded in prior experiences and embodied interactions with the world. According to Kiefer and Trumpp (2012), perception and cognition are inseparable, as cognitive processes are rooted in sensorimotor experiences accumulated over time. This embodied view suggests that individuals do not merely perceive situations as they are, but rather reconstruct them based on previous experiences, actions, emotions, and contextual cues. Thus, what pre-service teachers perceive in mentoring relationships is shaped by their trajectories, expectations, and the specific conditions under which those interactions occur.

Goldstone et al. (2010) further argue that perception is not limited to what is immediately visible or apparent. Instead, perception is educable and adaptable, evolving as individuals learn to attend to features of situations while ignoring others. In educational contexts, this means that learners and teachers develop perceptual frameworks that guide how they interpret complex environments, such as classrooms, professional relationships, or collaborative practices.

Importantly, this perspective challenges the idea that perception is superficial or opposed to deeper understanding. As Goldstone et al. (2010) demonstrate, perceptual processes can be aligned with conceptual reasoning, allowing individuals to make sense of abstract or complex phenomena through learned interpretive lenses. In teacher education, this implies that pre-service teachers' perceptions of mentoring and peer interactions are not merely subjective impressions, but meaningful constructions that reflect how they make sense of professional learning experiences.

Literature Review

Mentoring Relationships

As previously stated, mentoring relationships are extremely important to determine the efficacy of a mentoring program. In science teacher education, these relationships are even more important, because teachers need to envision classrooms as communities of practice. Teachers need to envision science classrooms that engage students with learning science as communities. Mentor-mentee effective relationships can help pre-service teachers to develop the skills they need to build such classroom environments (Abed & Abd-El-Khalick, 2015).

The literature on mentoring in teacher education presents both traditional and contemporary perspectives that reflect different assumptions about learning, professional development, and the roles of mentors and mentees. More traditional views conceptualize mentoring as a hierarchical process in which knowledge, norms, and practices are transmitted from a more experienced teacher to a novice in a largely unidirectional manner (Spooner-Lane, 2017). In this model, the mentor is positioned as an expert whose primary role is to guide, evaluate, and support the mentee's adaptation to the profession.

In contrast, more recent approaches frame mentoring as a collaborative and mutually beneficial process, emphasizing dialogue, shared reflection, and co-construction of professional knowledge (Larsen et al., 2023). From this perspective, mentoring is understood as a relational practice in which both mentors and mentees actively negotiate meanings, roles, and expectations. Rather than focusing solely on transmission of established practices, contemporary mentoring models highlight reciprocity, trust, and professional learning for all participants involved.

Despite differences in conceptualization, researches indicates that mentored teaching practice can be a powerful component of initial teacher education. Studies have shown that mentoring by experienced teachers can support pre-service teachers in developing pedagogical skills, professional confidence, and a sense of belonging to the teaching profession (Spooner-Lane, 2017). However, the literature also cautions that mentoring is not inherently beneficial. Ineffective mentoring relationships, characterized by poor communication, limited feedback, or misaligned expectations, can negatively impact teacher development and, in some cases, be more detrimental than the absence of mentoring altogether (Tuma et al., 2021).

Effective communication emerges as a central element in productive mentor–mentee relationships. Roehrig et al. (2008) emphasize that frequent and meaningful interactions between mentors and mentees enable pre-service teachers to reflect on practice, receive targeted feedback, and emulate effective teaching strategies. Communication that is dialogic rather than prescriptive allows mentees to engage more deeply with their professional learning and to critically examine their instructional choices.

In the context of science teacher education, mentoring relationships assume particular importance. Preparing science teachers involves more than developing general pedagogical skills; it requires helping future teachers envision science classrooms as communities of practice in which students actively engage in inquiry, modelling, argumentation, and collaborative knowledge construction. Abed and Abd-El-Khalick (2015) argue that effective mentoring can support pre-service science teachers in developing the pedagogical and epistemic skills necessary to foster such classroom environments. Through observation, modelling, and reflective dialogue, mentors can help mentees align their teaching practices with contemporary goals of science education.

COVID-19 And Science Teacher Education

The COVID-19 pandemic profoundly disrupted science teacher education worldwide, challenging established assumptions about teaching, learning, and mentoring. Central to these challenges was the difficulty of enacting science-as-practice approaches, widely emphasized in contemporary science curricula, which rely on classroom interaction, inquiry, collaboration, and situated engagement with scientific practices. In remote and hybrid learning contexts, ensuring meaningful engagement with science practices became particularly challenging for both in-service and pre-service teachers (Haidusek-Niazy et al., 2023).

Scholars have raised critical questions about whether online and remote experiences can effectively support the development of pre-service science teachers' capacity to enact core instructional practices. Campbell et al. (2021) argue that practice-based approaches to science teacher education, such as rehearsals, approximations of practice, and clinical experiences, were significantly constrained during the pandemic. The abrupt shift to remote instruction limited opportunities for pre-service teachers to engage in authentic classroom environments and to interact with students in ways aligned with inquiry-oriented and justice-informed science teaching.

In Brazil, the pandemic had a particularly strong impact on pre-service teachers enrolled in programs that relied on school-based experiences. Student teachers who were expected to be physically present in schools were suddenly removed from classroom contexts, restricting their opportunities to familiarize themselves with school routines, student interactions, and the social dynamics of teaching. As a result, mentoring relationships, traditionally grounded in shared physical spaces and *in situ* observation, were reshaped by the hinderances of remote interaction.

At the same time, the pandemic context gave rise to new forms of mentoring and professional support. Haidusek-Niazy et al. (2023) document the emergence of peer mentoring and reverse mentoring practices during the COVID-19 crisis, particularly in technologically mediated environments. In many cases, pre-service and early-career teachers supported more experienced mentors in navigating digital tools and online teaching platforms, temporarily reversing traditional hierarchical roles. Additionally, peer mentoring among teachers became a critical source of emotional, pedagogical, and technological support, often compensating for weakened or disrupted formal mentoring structures.

Understanding pre-service teachers' perceptions of mentoring and peer interactions during this period is therefore essential for capturing how science teacher education was reconfigured under pandemic conditions. By examining these perceptions, this study contributes to ongoing discussions about the possibilities and limitations of mentoring in times of crisis and offers insights into how alternative mentoring arrangements may inform future models of science teacher education.

Methodology

The Brazilian Pedagogical Residency Program (PRP) is a public policy in Brazil aimed at enhancing pre-service teacher training by immersing participants in the teaching routine during the final three semesters of their undergraduate studies, as part of their student teaching. Participants collaborate with experienced in-service teacher mentors at designated schools, engaging in tasks such as observations, lesson planning, and reflective practice. A unique feature of the PRP is its emphasis on collaboration, where pre-service teachers also act as peer mentors,

discussing and criticizing each other's lesson plans to foster critical reflection and practical skill development.

This study involved six pre-service chemistry teachers with no prior teaching experience who participated in the PRP between 2020 and 2022. Part of the program took place during the COVID-19 pandemic, when activities were conducted through emergency remote learning. This context required a nuanced analysis, as mentoring relationships and teaching practices were shaped by the constraints of remote interaction.

Data were collected through audiovisual recordings, written experience reports, and semi-structured interviews. All ethical procedures were followed, including the signing of informed consent forms granting permission for data use. To ensure anonymity, participants' names were replaced with pseudonyms throughout the analysis.

The data were coded focusing on pre-service teachers' perceptions of their relationships with mentors and peers (Saldaña, 2025). Coding was conducted inductively, allowing categories to emerge from the data in alignment with the research questions. This process supported an in-depth examination of how participants interpreted their mentoring experiences.

From this, we looked for themes that described the codes through thematic analysis (Clark & Braun, 2017). Initial coding was conducted individually, with categories refined through iterative revisions of the dataset. Two researchers independently analysed the data and subsequently discussed the findings to reach consensus, ensuring rigor, reliability, and validity in the qualitative analysis (Kuckartz, 2014).

From this process, three main themes emerged: (i) Navigating Support in Relationships with In-Service Mentors; (ii) COVID-19 Enhanced Challenges; and (iii) Peer Mentoring as a "Safe Space".

Findings And Discussion

Navigating Support In Relationships With In-Service Mentors

Pre-service teachers recognized the value of in-service mentors, particularly for lesson planning and for understanding the constraints and possibilities of the school context. Mendeleev emphasizes that mentors' classroom experience and familiarity with school routines were crucial for planning intervention activities. This support helped pre-service teachers situate their proposals within the realities of the school environment.

In addition to practical guidance, mentors were perceived as open and supportive in their interactions. According to Oppenheimer, "I always felt that the preceptors were present and interested, and were willing to help, you know?!" (Oppenheimer, Interview 1). At the same time, the pre-service teacher highlights that this support was accompanied by freedom to innovate, as mentors encouraged discussion and autonomy in planning activities: "[...] they [in-service teachers] were willing to discuss, I felt this freedom for us to come up with whatever we wanted" (Oppenheimer, Interview 1).

Together, these perceptions suggest that mentors played an important role by balancing guidance with autonomy. Even within a remote or hybrid context, pre-service teachers valued mentors' contributions to planning and decision-making, particularly when these interactions allowed space for dialogue and creative pedagogical choices.

COVID-19 Enhanced Challenges

Despite recognizing the importance of mentors, pre-service teachers pointed out two main concerns that hindered their experience in the PRP: communication and superficiality in

relationships. Communication issues were especially evident in the early stages of the program, when the teachers were often absent from weekly group meetings. According to the participants, this absence negatively affected coordination and planning processes.

Oppenheimer recalls a specific situation in which communication failures directly impacted the development of activities: “I remember one of the preceptors did not respond to one of my colleagues, I don't remember who it was. The person sent him an audio message, and he never listened to it, so there was a communication failure in the planning” (Oppenheimer, Interview 1). Such episodes reinforced the perception that maintaining open communication channels was particularly challenging during remote interactions.

In addition to communication barriers, pre-service teachers described their relationships with mentors as superficial. Enrico explains that his contact with the teachers was largely restricted to PRP-related activities, which limited deeper interaction and integration. He acknowledges that failures occurred on both sides, particularly regarding communication, which contributed to this sense of distance.

This superficiality, however, does not appear to be identified as the core problem, but rather because of communication challenges and contextual constraints. Marie reflects on the organization of the subproject’s weekly meetings, noting that greater participation from the teachers could have strengthened relationships with the undergraduates. Pre-service teachers also demonstrated understanding of the broader context, recognizing that the pandemic and emergency remote teaching likely reduced in-service teachers’ availability. As Enrico reflects, “I don't think I pursued enough, and I say this also because I already thought the teachers were too overwhelmed with the pandemic” (Enrico, Interview 1).

Marie further elaborates on these challenges in her supervised internship report, acknowledging that access to mentor teachers was compromised by remote and hybrid teaching conditions. However, she suggests that the issue extended beyond availability alone: “The remote teaching thing is really bad. [...] I had no direction, but so did the teachers, because the Department of Education wanted something every time” (Marie, Report).

Previous studies indicate that mentoring by experienced teachers can be a valuable component of initial teacher education (Can-Kucuk et al., 2022), while ineffective mentoring can hinder mentees’ experiences (Tuma et al., 2021). In line with these findings, the results of this study reveal how disrupted communication and limited interaction constrained mentoring relationships during the pandemic. Even so, pre-service teachers continued to recognize the importance of mentors, while acknowledging that the lack of physical presence and sustained interaction hindered the development of deeper professional relationships.

Peer Mentoring As A “Safe Space”

In contrast to the challenges experienced with in-service mentors, pre-service teachers consistently described peer interactions as supportive and meaningful. Boyle highlights the contribution of peers to lesson planning during weekly meetings, which he viewed as particularly positive. According to him, collaborative planning enabled exposure to different perspectives and enriched decision-making: “planning a group teaching sequence was interesting, because the conversation between the three of us [pre-service teachers] during the process of preparing the classes allowed for contrasting views on the same subject in favor of student learning” (Boyle, Report).

Peer meetings were also described as safe spaces for discussion and reflection. Mendeleev explains that videoconferences with other participants in the subproject felt comfortable because

the group members were already familiar with one another. This sense of familiarity fostered openness and trust, encouraging participants to share ideas and concerns freely.

Marie reinforces this perception, emphasizing the collaborative nature of peer discussions: “We [pre-service teachers] brought the ideas we had, the other colleagues discussed them, I thought it was really good, really positive” (Marie, Interview 1). The longevity of their relationships and shared experiences within the program contributed to a sense of safety that supported reflection and mutual learning.

These findings align with previous research suggesting that informal mentors, such as peers, can provide important emotional and professional support during teacher preparation (Desimone et al., 2014). While in-service teachers offered practical knowledge about school contexts and constraints, peers played a complementary role by creating spaces for dialogue, emotional support, and collaborative sense-making. Together, these different forms of mentoring contributed to pre-service teachers’ professional learning during a particularly challenging period.

The findings of this study highlight the importance of informal mentoring, particularly among peers, as participants reported feeling safe to express their opinions about lesson plans and teaching activities developed by others. This sense of safety appears to be central to peer mentoring interactions, enabling open dialogue, critical reflection, and mutual support during the planning process. The idea of a safe space for discussing pedagogical ideas is not limited to peer mentoring but is fundamental to mentoring relationships more broadly, as previously emphasized by Luft et al. (2022).

Although the emergence of peer and reverse mentoring during the COVID-19 pandemic has been discussed in the literature (Haidusek-Niazy et al., 2023), these forms of mentoring have been primarily examined among in-service teachers. The findings of the present study extend this discussion by showing that peer mentoring also played a central role among pre-service teachers, functioning as a critical source of pedagogical and emotional support during emergency remote teaching.

These results also reaffirm that teachers’ autonomy was significantly constrained during the pandemic by institutional, technological, and regulatory demands (Campbell et al., 2021). In this context, older educators, who traditionally served as mentors, were often overwhelmed by the need to adapt to new technologies, limiting their capacity to provide sustained support to novice teachers (Kraft et al., 2020). As a result, peer mentoring among pre-service teachers emerged not only as complementary practice but as a necessary space for professional learning and sense-making in a period of crisis.

Conclusions

Overall, the pre-service teachers recognized the value of both in-service mentors and peers in their professional development. Mentors contributed primarily through professional guidance, offering feedback on lesson planning and classroom activities that supported reflection on pedagogical practices. These interactions helped pre-service teachers identify strengths and areas for improvement, reinforcing the importance of experienced teachers in initial teacher education.

This appreciation underscores the role of mentoring programs such as the Brazilian Pedagogical Residency Program (PRP) in strengthening the connection between universities and schools. By immersing pre-service teachers in school contexts, the PRP provides opportunities for situated learning, collaborative reflection, and engagement with the realities of teaching. At the same time,

the findings suggest that mentoring relationships are central to how pre-service teachers make sense of these experiences and adjust their practices.

The COVID-19 pandemic, however, significantly reshaped mentoring dynamics within the program. Communication difficulties and limited interaction hindered the development of deeper mentor–mentee relationships, often resulting in more superficial exchanges. These challenges were largely attributed to emergency remote teaching conditions, institutional demands, and the overload experienced by in-service teachers during the pandemic.

Despite these constraints, peer mentoring emerged as a strong and consistent source of support. Pre-service teachers described peer interactions as safe spaces for sharing ideas, expressing concerns, and collaboratively reflecting on teaching practices. Even in a context marked by uncertainty and disruption, peer relationships helped sustain professional learning and emotional support, highlighting the relevance of informal mentoring structures in teacher education.

Taken together, these findings point to the need for future research and program design to place greater emphasis on mentoring skills, particularly communication and expectation-setting. Further studies should expand the scope of analysis to explore the broader mentoring context in teacher education programs and investigate how peer mentoring can be intentionally fostered among pre-service teachers. Strengthening mentoring practices, both formal and informal, may enhance the quality of science teacher education and contribute to the long-term success of public policies such as the PRP.

ESERA 2025 Copenhagen

Physics as Culture: Dialogues for a Critical and Sustainable Teacher Education

Jéssica dos Reis Belíssimo, Roberto Nardi and Geovana dos Reis Belíssimo
São Paulo State University, Brazil

The progress toward a sustainable society, focused on building a viable and equitable future, has become a key issue on the international stage. According to research in the field, tackling this difficulty requires a focus on culture as well as the development of critical, reflective educators. In the context of physics teacher preparation, it is critical that potential educators get an in-depth comprehension of physics as both, a scientific subject and a cultural construct. This study sought to investigate the fundamental components involved in the foundational training of physics educators, with the goal of suggesting methods that promote sustainable scientific education rooted in the recognition of physics as a vital part of culture. We examined the discourses of undergraduate physics students, gathered through a questionnaire, to accomplish this. The analysis was conducted using Pêcheux's Discourse Analysis, with the assistance of theoretical frameworks in physics pedagogy and teacher education. The attendees mainly view physics to elucidate natural occurrences, largely overlooking the historical, social, ideological, and philosophical dimensions that shape the discipline. This viewpoint highlights an absence of thoughtful consideration among upcoming educators. The arrangement of the undergraduate curriculum, frequently divided into distinct sections, could play a role in these patterns, and impede the cultivation of critical thinking skills. As a result, the research emphasizes the necessity of developing curricular strategies in the early training of physics educators that foster critical, transformative, and sustainable scientific education.

Keywords: Physics as culture, sustainable development, teacher training.

Introduction

The development of a sustainable society, committed to constructing a feasible and equitable future, has emerged as one of the foremost global imperatives. Inspired by the need to tackle complex sustainability issues spanning economic, social, environmental, and ethical domains, the United Nations (UN) drafted a landmark report titled "The 2030 Agenda for Sustainable Development" (UN, 2015).

In this sense, the exploration of culture's influence in promoting an engaged, sustainability-focused community has garnered significant academic attention and discussion. Viesba-Garcia et al. (2019) argue that sustainability education helps society move from its existing state to a more desired reality based on sustainable principles. Culture emerges as a critical component in this process, given its essential function in facilitating societal adaptability, stimulating the production of new knowledge, and consolidating values and traditions aligned with sustainability. Thus, achieving sustainable development is deeply connected to the cultural evolution and appreciation of communities—a process facilitated through education.

The initial education of physics teachers, grounded in the principles of cultural integration and sustainable development, is predicated upon the practice of critical reflection. Freire (2020) asserts that critical reflection enables educators to engage in a deeply meaningful process of professional self-recognition, which is actualized through the integration of cultural elements. When looking at how to train physics teachers using critical reflection as a framework, Nardi & Castiblanco (2018) emphasize that the teaching of Physics Didactics must develop methodologies capable of addressing content in ways that cultivate undergraduates' critical thinking skills, thereby empowering them to construct independent understandings of teaching practices. Lima

& Bozelli (2024) further argue that critical reflection positions teachers as intellectual agents who fulfill a vital social role by creating, promoting, and disseminating cultural knowledge.

Given these considerations, the present study seeks to investigate key aspects of the initial education of physics teachers, with the aim of delineating strategies conducive to a sustainable scientific education framework that is deeply rooted in the conceptualization of physics as culture.

Physics As Culture In The Education Of Critical Intellectual Teachers

One of the pioneers in Brazil to explore the importance of critical reflection in teacher education was the educator Paulo Freire. In several of his works (Freire, 2019; 2020), he expressed that the transformation of the contemporary world occurs through the critical reflection and action of men and women upon the world. In dialogue with these perspectives, Giroux (1997) argues that educational practice grounded in critical reflection provides educators with greater autonomy, in favor of an education rooted in the struggle for the transformation of social reality, aiming to overcome economic, social, and political injustices. Contreras (2002), in turn, when considering a model of teacher education grounded in critical reflection, conceives the teacher as a transformative intellectual, whose pedagogical action is intrinsically connected to the promotion of social equity through the construction of a more democratic and sustainable society.

Thus, in deliberations regarding the inclusion of Physics as culture in the education of critically reflective teachers, the imperative emerges to conceive a Physics teaching process that incorporates a dynamic and active scientific culture, in accordance with the Freirean perspective, that is, one that seeks the transformation of the contemporary world toward a sustainable world. As observed by Zanetic (1990), this purpose implies consideration of certain conditions, including: (1) the improvement of teaching and learning processes so that students become capable of solving theoretical problems both in Physics and in everyday life; (2) the deconstruction of the veneration of the traditional scientific method that currently prevails; (3) the conceptualization of Physics as a component of social history, that is, Physics as it developed alongside historical events; and (5) the presentation of contemporary Physics and the explicit discussion of its relevance in the contemporary global context, since only through this approach is it possible to foster the perception of Physics as a cultural element.

In this context, the need emerges to attribute significance to the development of Physics and to its capacity to influence social transformation. Zanetic (1990) expresses concern regarding the economic, political, religious, and cultural aspects that make up the History of Physics. This is especially relevant, since, about culture, Science, particularly Physics, often remains invisible. From this perspective, culture is frequently restricted to literary works and artistic expressions such as painting, dance, and music, a direct consequence of the educational system, which does not contemplate the teaching of science as culture and thus contributes to alienating Physics from people’s everyday lived experience.

The deficiency in the development of a scientific culture is not a problem restricted to Brazil, but rather a reality observable in several countries, due to the promotion of a culture that becomes disconnected from reality. The connection between science and economic and social foundations is of great importance for understanding its role in the cultural context. It is through this interrelation that the construction of a Physics education that is both critical and pragmatic becomes possible.

For Zanetic (1990), the conception of Physics as culture requires the inclusion of externalist components, namely: influences of a socioeconomic nature, ideological approaches, formulations of scientific methods, the dynamic history of Physics, experimentation, scientific theories, and their practical applications. The integration of these elements is fundamental to confer concrete

relevance to Physics in the education of citizens. Another important aspect in considering Physics as a cultural component is interdisciplinarity, as it enables the integration of Physics with other fields of knowledge and with the world more broadly. Thus, as discussed by Nardi and Castiblanco (2018), it becomes necessary for teachers of this discipline to draw on other forms of knowledge beyond the specific Physics content learned at university, incorporating externalist components into their teaching practices.

Theoretical And Methodological Foundation

The foundation of this study's theoretical and methodological framework is rooted in Pêcheux's Discourse Analysis (DA), as described by Orlandi (2015), and is further enriched by insights from a theory of teacher education with a critical stance, as outlined by Freire (2020). Additionally, we integrated contributions from the physics education domain, drawing on the works of Nardi & Castiblanco (2018) and Zanetic (1990).

We collected the research data by administering a questionnaire with ten open-ended essay questions in a didactic-pedagogical course to final-year students enrolled in a physics degree program at a Brazilian public university. The data analysis was carried out by developing an analytical framework based on the theoretical and methodological principles discussed thus far. As highlighted by Orlandi (2015), the construction of an analytical framework enables the researcher to navigate the boundaries of interpretation and to delineate the research object with precision.

A total of 14 undergraduate students enrolled in the course participated in the study. Owing to space constraints, this research selected the discourses of four participants for dissemination. The selection was based on the representativeness of their responses in relation to the broader group of participants.

The principles of Discourse Analysis (DA) guided the construction of the corpus for analysis, aligning it with the objectives of this research. Orlandi (2015) emphasizes that theoretical, not empirical, criteria determine the selection of the corpus. This approach reflects the foundational premise of DA, which does not aim to encompass all empirical elements associated with the object of study but rather focuses on those elements that align with the specific analytical objectives at hand.

Discourse Analysis Of The Undergraduate Students

We developed two collaborative gatherings in this context. The first one sought to examine undergraduate students' understanding of the concept of physics, employing the following question as a point of departure: "How would you explain to a high school student what physics is?" Table 1 systematically organizes the responses provided by the undergraduate participants.

Table 1. Undergraduates (with fictitious names) give speeches about physics

NAMES	GRADUATES' RESPONSES TO THE QUESTION
Gisele	I would explain that physics is the ability to explain why "things" move.
Luana	I would explain that physics is a natural science that aids in our understanding of the world around us.
Marcos	Physics is a way of experiencing things.
Mario	I would explain that physics is the science that explains how the universe works based on energy transformations.

Undergraduate students' writings show that they think of physics mainly in terms of how it explains natural events, with its historical, philosophical, ideological, and social aspects being less important. This comprehension is intrinsically linked to the imaginative formations of physics and scientific knowledge that undergraduate students have developed because of their production experiences. Most students point to their initial exposure to physics during high school as predominantly instrumental, emphasizing the resolution of mathematical exercises and the memorization of concepts.

These findings are consistent with existing literature in the field. Undergraduates, according to Nardi and Castiblanco (2018), tend to look back on their high school experiences when reflecting on their basic education, particularly in cases when critical reflection is not effectively addressed in teacher preparation programs. Zanetic (1990) further highlights that the dissociation of Physics from its cultural dimensions can be attributed to the way the subject is taught in high schools. This teaching approach is typically focused on the "teaching/learning" process of solving exercises and problems, with limited attention given to experimentation, theoretical analysis, and the exploration of the historical and conceptual development of Physics as a field of knowledge.

Moreover, the discourses produced by undergraduate students reveal a noticeable gap in their engagement with an educational-critical approach, as these discourses fail to incorporate the historical, social, and political elements that influence the construction of scientific knowledge.

Building upon these considerations, we designed the second collaborative gathering to explore in greater depth how undergraduate students conceptualize the relationship between physics and culture. To this end, we presented the following question: "In your opinion, what is the relationship between Physics and culture? Please explain." Table 2 below systematically organizes the responses provided by the undergraduate students.

Table 2. Speeches by undergraduates (fictitious names) about physics as a culture

NAMES	GRADUATES' RESPONSES TO THE QUESTION
Gisele	I believe that every area of knowledge is a form of culture. This includes physics.
Luana	I believe that Physics is culture, as it is part of the knowledge produced by civilizations historically.
Marcos	In the same way that science and society are collaborative with each other, Physics and culture are too.
Mario	Physics explains sound and music… It explains the climate that governed the establishment of peoples in different regions, transforming customs and cultures.

Examining the discursive outputs of undergraduate students shows that they express their ideas through unique imaginary constructs, which can be generally categorized into two projection types. The initial category, as expressed by the perspectives of all undergraduate students aside from Gisele and Luana, perceives physics and culture as distinct realms, where one either influences or enhances the other. The second category, as articulated by Gisele and Luana, views physics as a manifestation of culture—an inseparable and inherent phenomenon It is necessary to acknowledge that physics reflects society to conceptualize it as culture. According to Zanetic (1990), the knowledge we acquire in science emerges from social interactions and reflects the cultural context in which it is developed. Scientific knowledge is an integral component of this culture, and it is both influenced by other fields of knowledge. Therefore, perceiving physics as culture implies recognizing it as a product of social dynamics.

In light of these considerations, it is evident that the imaginary formations which suggest a division between physics and culture align with the discussions outlined in our first collaborative gathering. Basic education, which primarily emphasizes the resolution of mathematical exercises, and the undergraduate physics curriculum, which organizes knowledge according to segmentation and the reflective teacher model, both influence these representations—and these educational structures may shape the way undergraduates perceive physics as a cultural element.

Consequently, it is understandable that, despite two undergraduates establishing a direct connection between physics and culture, the prevailing educational conditions do not provide sufficient opportunities to foster a comprehensive understanding of the social, historical, ideological, and political dimensions of science. Zanetic (1990) argues that Physics, as culture, cannot be divorced from "external" factors, such as socioeconomic influences, ideological frameworks, the "definitions" of scientific methods, and the dynamic history of physics. These elements are essential for supporting experimentation, scientific theories, and their applications. Thus, physics assumes a pivotal role as a fundamental cultural component in the formation of individuals in contemporary society.

Final Considerations

Overall, this study aimed to explore key elements related to the initial training of physics educators, with the goal of outlining guidelines that facilitate sustainable scientific education based on the understanding of physics as culture.

The discourse analysis revealed two distinct projections within the imaginaries of undergraduate students: one sees physics and culture as distinct entities, while the other regards physics as an integral and indivisible component of culture.

The first viewpoint’s key conceptions, which separates physics from cultural contexts, clearly support discussions about the impact of basic education, which frequently concentrates solely on mathematical exercises, as well as the structure of the undergraduate physics program, which divides knowledge into different components.

This fragmentation leads to an understanding of physics as culture within the initial training of physics teachers, but that is incomplete and devoid of its essential cultural dimensions. Although two students managed to link physics with culture in the second projection, their training conditions fall short of offering a solid basis for cultivating a complete awareness of the diverse contexts that influence physics.

Finally, based on the premise that critical reflection offers a promising approach for the appropriation of physics as culture, there arises a need to reconsider the organizational structure of undergraduate programs. Such a reevaluation is essential to create educational environments that foster discussions and critical reflections on the historical, social, philosophical, and ideological contexts of physics as a cultural subject. Critical, transformative, and sustainable scientific education must be a part of physics teacher preparation programs from the start.

Beyond Human Mentors – Exploring AI-Driven Reflection In Teacher Training

Jens Damköhler, Wolfgang Lutz and Thomas Trefzger
University of Würzburg, Germany

This paper reports on integrating AI-based reflection coaches into a Physics Teaching & Learning Lab in pre-service teacher education and examines how students relate this support to supervision. The intervention provided structured experience with generative AI while scaffolding reflection across cycles of preparation, school-class visits, reflection, and adaptation. We conducted guided end-of-course interviews with 12 of 13 participants and analysed the data using content-structuring qualitative content analysis complemented by a deductive marker analysis of relationship-relevant qualities. Students largely reported little to no direct impact of chatbot use on their supervisory relationships with the course lecturers and predominantly conceptualized the chatbot as a tool rather than an independent supervisor. At the same time, their accounts invoked relationship-relevant qualities, especially closeness (limited by boundary-setting and restricted availability), relatedness (a low-pressure space enabling reassurance before approaching lecturers), and genuineness (overly validating interaction styles perceived as inauthentic). Overall, chatbots may support reflection and indirectly shape relational dynamics, but do not substitute authentic human experience in supervision.

Keywords: Teacher education, Generative AI, Teacher-student relationships

Introduction

Generative AI tools such as chatbots are rapidly becoming part of educational practice and, consequently, a relevant topic for teacher education (OECD, 2026). However, early evidence from our context suggests that many pre-service teachers still gain little systematic experience with AI tools in their university courses, and that this lack of experience matters: students without prior use tend to report lower perceived competence/self-efficacy and a more cautious attitude toward AI, whereas experience with AI use is associated with greater confidence and a higher likelihood of future use (Lutz et al., 2025).

Against this background, we designed the present course innovation with the intention to first, provide physics teacher trainees with the opportunity to engage with AI tools in a didactically meaningful, structured way; and second, to explore whether such tools can productively support processes that are known to be central for teacher professional learning, most notably reflection on practice. Reflection is a core component of many practice-based formats, yet it is also resource-intensive: it requires time, individual attention, and sustained guidance, which is difficult to provide consistently in university courses.

Our intervention is embedded in an iterative Teaching & Learning Lab course format in which students design and realize experimental learning stations and repeatedly revise them across several school-class visits (see **Figure** 1 for the overall sequence).

To strengthen the reflection phases within this cycle, we integrated AI-based reflection coaches (custom GPTs) intended to guide students through structured reflective dialogues and to support concrete adaptations for subsequent realizations.

While research and public discourse often focus on performance, ethics, or learning gains, an equally important – yet less frequently examined – dimension concerns relationships in teacher education. Mentoring and supervision are inherently relational, and introducing an AI tool into

reflective support raises a subtle question: even if students only perceive the chatbot as a tool, might their descriptions still reveal relationship-relevant qualities (e.g., perceived closeness, relatedness, or genuineness) that shape how supervision is experienced? Prior work in our project suggests precisely such a pattern: students tend to report little direct change in their relationship with human mentors, yet they also articulate relationally meaningful experiences with the chatbot interaction (e.g., neutrality, emotional relief, and authenticity as a boundary) (Damköhler et al., 2025).

This paper addresses the following research questions:

- RQ1: How do physics student teachers describe the impact of chatbot-based reflection coaching on their supervisory relationship(s) with course lecturers?
- RQ2: How do students conceptualize the chatbot as an interaction partner (e.g., human-likeness and underlying conceptions of AI)?
- RQ3: Which relationship-relevant qualities do students invoke, explicitly or implicitly, when describing chatbot-supported reflection and supervision?

To answer these questions, we conducted guided interviews with course participants and analysed the data using content-structuring qualitative content analysis complemented by a deductive marker analysis of relationship-relevant qualities.

Theory

AI Literacy

As suggested by Lutz et al. (2025), guided and targeted engagement with AI tools and the positive experiences that may result from such engagement can contribute to students' confidence in their own capability to use AI effectively. To describe these competencies more precisely, the concept of AI literacy has been developed in analogy to established literacy frameworks; e.g., digital literacy, computational literacy, data literacy, scientific literacy (Long & Magerko, 2020). In this view, AI literacy captures not only functional use, but also the understanding and critical evaluation of AI systems in educational contexts.

One operationalization of this construct is provided by the Meta AI Literacy Scale MAILS (Carolus et al., 2023), which conceptualizes AI literacy as a set of competencies related to using and applying AI, understanding AI, detecting AI, and reflecting on ethical implications of AI use. Furthermore, it contains a concept of AI self-efficacy (which includes aspects of AI problem solving and AI learning) and AI self-competency (which is based on AI persuasion literacy and AI emotion regulation). In the present study, this framework served primarily as a basis for designing interview prompts that elicit students' experiences with chatbot-supported reflection.

Teacher-Student Relationships

While AI literacy provides a useful framework for understanding competencies needed for responsible and effective AI use, the present paper additionally draws on research on teacher-student relationships and related constructs. This is because chatbot-supported reflection may be experienced not only as a functional tool interaction, but also in terms of relationship-relevant qualities such as perceived closeness, relatedness, and genuineness that can shape how reflective support and supervision are approached. This relational lens is further supported by the 'Computers Are Social Actors' (CASA) perspective, which suggests that people may respond to computer-based interaction using social scripts and expectations, even when they are fully aware that they are interacting with a machine (Nass et al., 1994). Importantly, meta-analytic findings indicate that both positive and negative teacher-student relationships show medium-to-large

associations with students' engagement (and smaller but still significant links to achievement), underscoring why relational quality is central for learning processes (Roorda et al., 2011).

Attachment Theory

From an attachment perspective, relationships with significant adults can function as a secure base that enables exploration and learning. In educational contexts, this is often operationalized via dimensions such as closeness (warmth and openness), conflict, and dependency; closeness captures whether an interaction climate supports trustful, open communication (Pianta, 1999, 2001). In our context, this lens helps interpret students' answers regarding boundaries, availability, and interpersonal nuance as conditions that may limit or enable closeness – regardless of whether the interaction partner is framed as a tool or a person.

Self-System Theory / Self-Determination Theory

Drawing on the Self-Determination Theory, the satisfaction of three basic psychological needs – autonomy, competence, and relatedness – is considered fundamental for the development of supportive relationships (Ryan & Deci, 2000). In supportive educational relationships, relatedness is fostered when learners feel accepted and psychologically safe; autonomy is supported when guidance is non-controlling; and competence is supported through structure and feedback that enables progress. Applied to reflective support, SDT helps capture why students might value a "low-pressure" space (relatedness/safety), benefit from structured prompts (competence support), yet still insist on human mentoring for authenticity and situated judgement (Roorda et al., 2011).

Learner-Centred Teacher-Student Relationship

Research on teacher-student relationships highlights that relational quality is not a "nice-to-have" but a robust correlate of students' engagement and learning. Meta-analytic work shows that affective relationship qualities – especially warmth and support – are consistently associated with students' engagement and, to a smaller extent, achievement (Cornelius-White, 2007). For this paper, TSR provides a vocabulary for describing how supportive interactions are experienced which includes empathy, warmth, genuineness, nondirectivity, higher order thinking, encouraging learning/challenge, adapting to individual and social differences (Cornelius-White, 2007).

Course Design

Course Sequence Of The Teaching & Learning Lab

As previously described, the Physics Teaching & Learning Lab (TLL) at the University of Würzburg is organized as an iterative course format that connects university-based preparation with authentic teaching-related experiences in a secure framework (Damköhler et al., 2025; Völker & Trefzger, 2011). Over the semester, students design and run their own experimental learning station and accompany small groups of school students working on hands-on physics tasks. The course follows a recurring cycle of preparation (preparatory phase) – visits by school classes – reflection – adaptation (see Figure 1).

Figure 1. Structure of the TLL

During the preparatory phase, students develop an inquiry-oriented station including materials, instructions, and prompts that are suitable for a short, self-contained learning unit. The station is

then implemented during a visit by a school class, where the TLL is operated in a station-based format: each station is typically completed in 30 minutes by small groups of school students, and each student tutor runs their station about four times across the visit.

After each class visit, the teacher trainees enter a reflection phase in which experiences from implementation are documented, discussed, and analytically processed. This reflection is typically supported by the two lecturers, who provide feedback and help connect observations to instructional goals and design principles. Based on these reflections, students adapt their stations in a targeted way before the next implementation. This cycle is repeated across three class visits, with exactly two weeks between visits, allowing students to iteratively refine their station design and their instructional practice across successive realizations.

Implementing AI-Based Reflection Coaches

The AI-based reflection coaching was integrated into the reflection and adaptation phases of the TLL cycle. After each visit by a school class, the course provides a structured opportunity to analyse the previous run and to derive concrete improvements for the next implementation. The revised format was supported by individual dialogue-based coaching from two AI reflection coaches, while the overall course structure (reflection followed by targeted adaptation) remained unchanged.

These sessions with the AI-based reflection coaches took place in the two scheduled reflection/adaptation sessions following the first and second class visits. The chatbot-led dialogues were designed to (a) structure students' retrospective analysis of their station realization, (b) prompt justification and elaboration to deepen reflection, and (c) support the development of feasible adaptations for the next class visit. The two coaches were used with different focal points: one coach emphasized an analytic reflection on the quality of the implementation, while the other coach additionally promoted the deliberate evaluation of alternative options and encouraged a critical stance toward AI-generated suggestions.

Following the individual coaching dialogues, reflections were brought back to the course context: students summarized and contextualized their insights and planned changes, and these were then discussed regarding their suitability for the course structure and supported by the lecturers. In addition to the AI use for coaching purposes, the implementation also included a meta-level engagement with the technology in which students exchanged experiences and reflected on further effects of the technology (e.g., perceived boundaries of AI support, ethical considerations, and potential implications for supervision in the TLL).

Design And Development Of The Reflection Coaches

The reflection coaches were developed as customized chatbots based on GPT-4 using the GPT development environment within ChatGPT. Their design followed a principle of aligning coaching prompts with clearly specified theoretical foundations and with an anticipated structure of productive reflection dialogues. For both coaches, relevant background materials were provided and integrated so that the chatbots could explicitly draw on them during the conversation. The first coach was based on the framework of basic dimensions of teaching quality (Praetorius et al., 2018), while the second coach was based on Korthagen's onion model (Korthagen, 2004), a framework addressing teacher personality and professional development.

For each coach, the team first anticipated the course of a plausible coaching conversation based on the underlying theory and then decomposed it into smaller conversation blocks (i.e., coherent phases with specific functions such as eliciting a description of the implementation, probing for explanations, generating alternatives, or consolidating an action plan). The chatbots' behaviour was then specified through a combination of (1) the integrated theoretical background materials

and (2) systematic prompting: a precise role description (reflection coach), a set of general behavioural rules (e.g., guiding the dialogue, asking follow-up questions, supporting structured reflection), and block-specific instructions defining the intended interactional moves and goals within each phase of the dialogue.

Before student use, both coaches were subjected to pre-testing in simulated coaching conversations across different scenarios by several test persons. This iterative testing served to check whether the chatbots' guidance reliably instantiated the intended coaching structure, whether follow-up questions supported depth rather than superficial agreement, and whether the dialogue design consistently led to the intended outcome – namely, a justified reflection and a concrete plan for adaptation before the next class visit.

Method

Course Context And Sample

The study was conducted in the summer semester of 2024 in a Physics TLL at the University of Würzburg. The course was attended by 13 pre-service teachers; N = 12 of them participated in the evaluation study. Participation in the interviews was voluntary.

Data Collection

Data were collected through guided, semi-structured interviews which lasted approximately 10 to 15 minutes and were conducted at the end of the semester by the two course lecturers. The interview guide was developed with reference to the previously described MAILS framework (Carolus et al., 2023) and adapted to the specific course context. Rather than administering MAILS as a test, selected item formulations were used as prompts to recall students' experiences and perspectives regarding chatbot-supported reflection, including perceived differences between human and AI interaction and the perceived influence of chatbot use on their supervision-related conversations. For example, the MAILS item "I can distinguish if I interact with an AI or a 'real human'" was contextualized into an interview question about differences between a chatbot conversation and a conversation with a real person.

All interviews were audio-recorded and transcribed. Transcripts were lightly edited for readability (e.g., reducing fillers) without changing the intended meaning of statements.

Content-Structuring Qualitative Content Analysis

The material was analysed using content-structuring qualitative content analysis following Kuckartz und Rädiker (2022). As recommended in this approach, we defined the coding unit as a single sentence (i.e., the smallest textual unit to be assigned to a category), while consecutive sentences belonging together contextually served as the context unit. In line with Kuckartz, multiple coding was allowed.

To address the aims of the present paper, analysis proceeded in two coding passes.

First Coding Pass: Explicit Topical Categories (Guide-Based, Inductively Refined).

In the first pass, we organized students' explicit statements using a set of deductive top-level categories derived from the interview guide. These top-level categories captured the main topics addressed by the students and provided a structured overview of how students articulated their views. The deductive top-level categories were: (1) "Independent supervisor?", (2) "Differences to a real conversation?", (3) "Influence on conversations with lecturers?", and (4) "Changed relevance of lecturers?". Following the logic of content-structuring analysis, these categories were then refined inductively: subcategories were developed from the interview material to

capture the diversity of students' perspectives. Given the relatively small number of interviews and the high thematic variety, the category system was developed based on the entire dataset.

Second Coding Pass: Deductive Marker Analysis Of Relationship-Relevant Qualities.

A second coding pass focused on relationship-relevant qualities that students referred to implicitly or explicitly, even when they did not explicitly frame their statements as 'relationship' talk. This step was motivated by the observation that students often stated that chatbot use had little or no direct impact on their supervisory relationships, while simultaneously describing interaction qualities that are central to theories of teacher-student relationships. For this reason, we conducted a deductive marker analysis using a set of relationship-quality markers derived from three theoretical perspectives: attachment theory, learner-centred teacher-student relationship research, and self-system theory. Based on these frameworks, we developed a formalized codebook containing short definitions and anchor examples for each marker (e.g., closeness, relatedness, genuineness, higher-order thinking, encouraging learning). The codebook was used to identify segments indicating these qualities across the interviews.

Importantly, we did not build separate category families for different "targets" (e.g., student-chatbot vs. student-mentor). Instead, the same marker set was applied to segments referring to the chatbot, to lecturers, and to statements that remained unspecific with respect to a relationship partner. This approach reflects our analytic interest in students' relational expectations and interaction qualities in the context of reflective support, which can be articulated without explicitly naming the relationship partner.

Coding was conducted primarily by one researcher. Selected segments and ambiguous cases were discussed within the two-person research team until a shared interpretation was reached.

Results

All interview quotes were translated from German by the authors for publication. The translations aim to preserve meaning and tone.

RQ1 Described Impact On Supervisory Relationships

Most students described little to no direct impact of the chatbot conversations on their supervisory relationships and conversations with the course lecturers. When asked about changes in the lecturers' relevance, nine of twelve students reported no (n = 7) or only minor (n = 2) changes and highlighted the continuing value of human supervisors *("I see the AI as a helpful tool, but your practical experience is hard to match – especially in the Teaching & Learning Lab setting. So, overall, I wouldn't say it changed much."* – Patrick). Students often framed chatbot use and lecturer conversations as serving different functions: chatbot dialogues supported individual reflection on one's own station, whereas lecturer conversations were described as more situational, experience-based, and oriented toward practical problem solving *("What I talked about with you was something completely different from what I talked about with the AI."* – Caro).

A smaller group reported indirect links between chatbot use and lecturer interaction. Three participants described the chatbot sessions as providing conversation triggers (*"[...] it didn't really influence things, but it did provide new input for topics to talk about [...]"* – Martina) and two described a pre-relief effect – using the chatbot to voice uncertainties or "stupid questions" without embarrassment before approaching lecturers *("I think I was more likely to ask the AI a few 'stupid questions'[...]"* – Saph). One participant explicitly reported a more relaxed relationship with lecturers *("I think I would have felt a bit more under observation if I had the entire conversation with you."* – Emily).

Several students also noted practical constraints, particularly limited time to implement or discuss chatbot suggestions with lecturers *("[…] it didn't feel like we truly had enough time afterwards to implement what came out of the AI session"* – Caro]), and a few preferred more direct human exchange (e.g., small-group discussions) *("I actually would have preferred a conversation with you in a small group of four."* – Franka).

RQ2 Conceptualization Of The Chatbot

Overall, students predominantly conceptualized the chatbot as a tool-like technology rather than an independent 'person'. Typical descriptions framed it as a programmed system, a machine, a search-engine-like resource, a tool, a digital extension of the lecturers, or a neutral instance for thinking through one's own practice. At the same time, a small number of accounts portrayed the chatbot interaction as a relatively separate field of support – notably because students engaged with it without involving the lecturers – while still emphasizing that this did not generally apply to all situations and could not replace the interpersonal qualities of human supervision (*"[...] in the sense that you're texting it, it is something of its own, because we didn't involve you [the lecturers] at all. […] In this case, it worked well."* – Annika). A frequently mentioned difference to 'real' conversation concerned the chatbot's interaction style: although it had been instructed not to evaluate or provide feedback, students experienced it as overly validating and often strongly praising, and thus as qualitatively distinct from human feedback.

RQ3 Relationship-Relevant Qualities

Across the interviews, students' remarks frequently invoked relationship-relevant qualities, most prominently closeness, relatedness, and genuineness. Regarding closeness (warmth and openness), several students emphasized a clear boundary between interacting with a machine and with a person, which for them limited the degree of relational openness (e.g., *"You still must distinguish. You're talking to a machine, not to a human being. That difference must remain."* – Alexa). Beyond the human-machine boundary, some students link limited closeness to the chatbot's restricted availability. As one student noted, the AI could only be used *"for a very limited period of time,"* which did not necessarily coincide with moments when questions emerged, and they explicitly wondered how the experience might differ if it were *"permanently available"* (Saph). Others pointed to missing interpersonal nuances such as implicit undertones in communication (e.g., *"What the AI can't do is capture what's implicit. The undertone you pick up when people talk to each other. I don't think AI can do that."* – Annika), while only very few suggested that the interaction could, in specific moments, resemble communication with a person (e.g., *"No. In the end, it could just as well have been a human I was communicating with"* – Peter).

With respect to relatedness, students described the chatbot interaction as a safe, low-risk environment that could provide emotional reassurance, particularly in phases of uncertainty (e.g., *"At the beginning I was really lost about how to implement things, and the AI did give me a bit of emotional reassurance."* – Franka).

Finally, genuineness emerged as a salient boundary condition: some students criticized the interaction style as overly validating and strongly praising, which they experienced as inauthentic (e.g. *"Yes, because of the excessive praise. I found that really irritating at times"* – Peter).

In addition, students also mentioned that chatbot use could support higher-order thinking (e.g., by prompting reflection and critical evaluation of outputs) and encouraging learning (e.g., through structuring and guiding the reflective process), even though these aspects were typically described as complementary rather than substituting human support.

Discussion

Overall, the findings suggest that the chatbots functioned primarily as supportive tools for reflection, rather than being perceived as an independent supervisory figure. At the same time, students' answers contained multiple relationship-relevant cues – even when participants explicitly stated that chatbot use had little impact on supervisory relationships. In particular, students' references to closeness, relatedness, and genuineness indicate that chatbot-supported reflection can intersect with relational dynamics in teacher education in subtle ways: restricted availability and a clear human-machine boundary limited perceived closeness; the chatbot could still provide a low-pressure space for articulating uncertainty; and interaction styles perceived as overly validating highlighted genuineness as a decisive boundary condition. Overall, these patterns suggest that it is worthwhile looking beyond direct claims of 'relationship change' and pay attention to the relational qualities students mention when describing reflective support.

These insights translate into concrete implications for course design. First, availability is not only relevant for relational reasons but also pragmatically: if reflective tasks emerge outside narrow time windows, restricted access may prevent students from using the tool in a moment of need and may thereby limit closeness. In a subsequent iteration of the course, we therefore reduced constraints on availability. Initial feedback from students in that follow-up project (Herz et al., 2025) points in the direction that more flexible access can support meaningful use. Second, our results underline the importance of combining chatbot reflection with human supervision. Several students described the two support formats as operating "either-or," with too little time to discuss and implement insights. Future designs should therefore create structured opportunities to jointly discuss, validate, and translate chatbot outputs into concrete adaptations – for instance in small-group debriefings with lecturers – so that AI support complements rather than competes with human mentoring.

Finally, the results also call for a brief cautionary note regarding students' conceptions of AI. While many students framed the chatbot as a programmed tool, one described it as a "neutral instance." Even if meant in the sense of "non-judgmental," such framing may unintentionally reduce vigilance toward potential biases or limitations of AI-generated suggestions. This reinforces the need to embed chatbot use in explicit AI literacy work – particularly around critical evaluation of outputs and an awareness that 'helpful' and 'neutral' are not the same. Importantly, students themselves strongly emphasized that, for complex real-world teaching problems, chatbot suggestions require careful examination and cannot substitute the authenticity and experience-based judgement of human supervisors. In this sense, chatbots may scaffold reflective processes, but they do not replace what students perceive as uniquely valuable in supervision: authentic human experience.

Conclusion And Outlook

The present study suggests that our chatbot-based reflection coaching was primarily experienced as supportive scaffolding rather than an independent form of supervision, while students' accounts nevertheless contained relationship-relevant statements. At the same time, conclusions are constrained by several limitations: the study draws on a small sample from a single course (N=12), relies on end-of-course self-reports, and the interviews were conducted by the course lecturers, which may have shaped how openly participants discussed critical views. In addition, coding was conducted primarily by one researcher.

Future work will therefore extend beyond interview accounts by **analys**ing students' recorded reflection products given immediately after teaching-related experiences, allowing us to examine whether chatbot use is associated with changes in the structure and depth of reflection and in the

specificity of subsequent adaptations. Further iterations should also systematically change key design parameters – most notably availability and the structured integration of chatbot reflection with lecturer-led small-group debriefs – to identify configurations that support meaningful use without weakening human supervision. Finally, triangulating interviews, reflection products, and (where available) chatbot interaction traces in a longitudinal design can clarify how relational expectations and AI literacy practices (including critical evaluation and assumptions of "neutrality") develop through repeated, guided use.

Analysis Of Physics And Chemistry Pre-Service Teachers' Perceptions About Their Teaching Identity And Professional Development

Liliana López-López and Cristina García-Ruiz
Science Education, Universidad de Málaga, Spain

Developing a Teaching Professional Identity (TPI) is crucial for effective teaching practice, particularly during initial teacher education. This study explores the perceptions of eight preservice secondary science teachers (PSSTs) about their professional development during their Master's in Education program (MEd), specifically examining how self-reflection on teaching competencies contributes to their identity construction. Through a qualitative case study approach, we analysed PSSTs' responses to an ad-hoc survey, focusing on nine teaching competencies and their relationship with five key factors affecting TPI (teaching experience, motivation, self-image, Master's expectations, and task perception). In general, the analysis reveals that PSSTs showed a balanced awareness of their strengths and challenges. Findings suggest that PSSTs' identity formation is significantly influenced by their practical teaching experiences and self-image, revealing the important role of initial teaching education programs in supporting their transition into teaching careers. Hence, while teaching experience plays a crucial role in shaping their confidence and competencies, there is a clear recognition of the need for continuous self-assessment, positive attitudes, and the development of both personal and social skills to foster a harmonious and effective learning environment. In short, these results highlight the need for a more comprehensive approach in initial teacher education programs, where the development of both professional skills and personal identity is nurtured through reflection, experience, and positive engagement with the teaching profession.

Keywords: Pre-service teacher education, teacher identity, professional development

Introduction

The International Teaching and Learning Survey (TALIS) (Organisation for Economic Co-operation and Development [OECD], 2025) reveals that teachers who have recently graduated report feeling insufficiently prepared, both in terms of subject-matter knowledge, pedagogical and practical aspects, to teach the subjects for which they are responsible. Additionally, the growing demands for equity and inclusion (Karousiou et al., 2019) and the educational shift towards personalised and student-centred pedagogies (Schleicher, 2018) represent a challenge in defining teachers' roles, leading to graduated teachers reporting high levels of stressed in their early years (OECD, 2025). This situation leads some in the secondary teaching workforce to perceive themselves not as subject teachers but rather as graduates in a scientific discipline who transmit content. As a result, a spontaneous approach to teaching predominates, grounded in prior experience as learners, directly impacting the construction of their teaching identity, their instructional practices, and their professionalism (Imbernón, 2019).

Research on teacher identity is therefore essential because, as Wenger (1998) explains, it examines "how learning changes who we are" (p. 5). Moreover, the concept of identity enables teachers to reflect on the relationship between the individual and the world, thereby addressing the role of context and valuing the sociocultural nature of learning (Gee, 2000). Nevertheless, despite the existence of review studies on teacher identity, further research is required to ensure a specific focus on the identity of science teachers (Avraamidou, 2014), particularly during their initial training period. This interest is grounded in the idea that, in order to make the transition from student to teacher, pre-service science teachers (PSSTs) must not only acquire a set of skills,

knowledge, and an understanding of pedagogical approaches, but also create and recreate their self-image as active members of a professional community—an aspect that is directly related to the construction of their teacher identity (Sutherland et al., 2010).

In light of the above, promoting and fostering the development of strong teacher identities is essential for teachers themselves, the research community, and educational policy. The benefits of analysing the professional identity of science teachers (TPI) are directly linked to students' learning success, the strengthening of teachers' self-image, and the assurance of the development of effective educational policies (Suárez & McGrawth, 2022).

Theoretical Framework

In the teaching-learning process, teachers are a key agent with a direct impact on students' learning and development (Jennings & Greenberg, 2009), leading both society and educational systems to revalue the teaching profession in a context characterised by constant change and fluctuation (Nias, 2014). As a consequence, in recent years, there has been growing interest in understanding teachers' professional lives through the study of their TPI and its influence on teaching quality, motivation to teach, commitment to the profession, good pedagogical practices, and decision-making in school contexts (Beauchamp & Thomas, 2009; Buchanan, 2015). For teachers, understanding their TPI can strengthen teaching practice insofar as it aligns with fundamental questions such as "who am I?" or "what should I do?" (Mockler, 2020), which directly influence pedagogical decision-making and teacher–student relationships.

TPI encompasses teachers' perceptions, beliefs, and attitudes about their professional role (Cordingley et al., 2019), significantly influencing classroom practices and policy implementation (Karousiou et al., 2019). Although, over the years, researchers have approached TPI from different theoretical perspectives and proposed various definitions, there are some commonalities widely acknowledged, such as its complexity and multidimensionality, its evolution with personal and professional experiences, and its variation across individuals and cultures (Hanna et al., 2019).

Within the context of teacher education, the sociocultural approach results particularly valuable, as it allows for a broader understanding of professional development that goes beyond the acquisition of knowledge and technical skills (Gee, 2000). Furthermore, this approach has facilitated analysis of how teachers perceive themselves, how they are recognized by others, and how factors such as gender, personal histories, and prior experiences influence the construction of their professional identity (Avraamidou, 2014).

Nevertheless, research on pre-service teachers' TPI remains at an early stage in understanding how these identities are constructed, which factors influence their transformation, and what role they play in motivating both teachers and students to learn (Schutz et al., 2018). This gap highlights the need for more integrative frameworks that connect teacher identity with key dimensions of professional practice, development, and effectiveness across changing educational contexts.

In an era characterized by rapid change and uncertainty, teachers face diverse expectations from multiple stakeholders while navigating complex educational transformations (Nias, 2014), making essential to promote ever since teacher education the construction of a robust TPI to respond to these challenges while maintaining high-quality instructional practices effectively ensuring in this way educational quality and successful teaching careers.

For doing so, it becomes fundamental to research into key factors and domains shaping TPI from teacher education program, analysing, among others, the influence of motivation (drive to be or

become a teacher), self-image (how individuals view and feel as teachers), self-efficacy (belief in their capability to perform their teaching activities effectively) or task perception (beliefs about what a teacher considers to be good teaching) (Suárez & McGrath, 2022).

These TPI elements intersect with teachers' competencies, affecting their professional development and classroom effectiveness. Hence, the relationship between teaching competencies and TPI becomes particularly relevant when examining how teachers negotiate their professional roles and responsibilities. Studies suggest that teachers with well-developed professional identities demonstrate a greater capacity to implement educational innovations and maintain a commitment to their practice (Sachs, 2016). This interplay between competencies and identity formation provides a crucial framework for understanding teacher professional development and effectiveness in contemporary educational settings.

Aims And Research Questions

With the purpose of contributing to the growing body of research on TPI while offering insights into effective teacher preparation and professional development strategies, this study explores the interconnection between teaching competencies and TPI development. Focusing on how PSSTs' experiences and initial teacher education influence their professional identity formation, we aim to answer the following research question: What are the perceptions of PSSTs about their teaching professional development during their initial training stage, and how does self-reflection on teaching competencies contribute to the construction of teachers' identity?

Methodology

Participants

This research was developed as a case study design with 8 PSSTs of the MEd from the University of Málaga, from the speciality of "Physics and Chemistry". All participants held a bachelor's or a master's degree in either science or engineering, which is a requisite to enroll in the MEd. The demographic composition of the group included three males and five females, with ages ranging from 25 to 35 years.

Research Instrument, Data Collection And Analysis

Through an *ad-hoc* survey-type task, PSSTs were asked to identify and justify their professional development level for the teaching competencies (TC) promoted during the MEd, related to curriculum assessment (TC1), professional communication (TC2), social climate (TC3), reflection innovation (TC4), institutional culture (TC5), collaborative decision-making (TC6), instructional design

We collected data through an online survey during the 2022/2023 (PSST1-PSST4) and 2023/2024 (PSST5-PSST8) academic years. We then proceeded to develop a qualitative analysis of PSSTs' responses individually using coding techniques performed with the Atlas.ti software (version 25.0.1). Thus, the researchers and co-authors of this communication read the individual responses and co-related them to factors linked to TPI development, particularly the previous experiences of the teachers and their initial teacher education, following the Suárez and McGrath (2022) framework. Hence, based on common patterns and key aspects found in the PSSTs' responses, we then coded and categorised data independently within domains and factors most affecting TPI in teacher education (teaching experience [TE], motivation [MO], self-image [SI], MEd expectations (instead of job satisfaction) [ME] and task perception [TP]), finally negotiating the coding consensus (Creswell, 2013).

Findings

Table 1 illustrates how PSSTs' responses were classified each teaching competencies described in the survey and the subsequent categorisation according to the main factors affecting TPI, also providing an example of response.

Table 1. Examples of the categorization of PSSTs' responses within each teaching competence and TPI factor.

PSST	TEACHING COMPETENCIES AND FACTORS AFFECTING TPI
PSST 5	**Teaching competence:** *Affective interaction (TC8)*
	TPI Factor: *MEd expectations (ME)*
	Response: *"I believe this attitude is developed through practice and experience, so I hope to improve in the best possible way during the remaining months of my master's."*
PSST 6	**Teaching competence:** *Reflection innovation (TC4)*
	TPI Factor: *Motivation (MO)*
	Response: *"Although I am not very familiar with the subject, I think I can manage to give feedback and try to improve the proposal when necessary."*
PSST 8	**Teaching competence:** *Professional communication (TC2)*
	TPI Factor: *Self-image (SI)*
	Response: *"I do consider that I have this competence more developed since although I have not yet worked as a teacher, I have given many talks and workshops to secondary school students, and I have some practice expressing myself in writing and orally with them."*
PSST 7	**Teaching competence:** *Social climate (TC3)*
	TPI Factor: *Teaching experience (TE)*
	Response: *"I believe it is important to have social skills to create a positive learning environment and promote coexistence in the classroom. It is something I don't have much experience in, but I believe it can improve over time."*
PSST2	**Teaching competence:** *Curriculum assessment (TC1)*
	TPI Factor: *Task perception (TP)*
	Response: *"Regarding the evaluation, I consider it one of the most difficult points to carry out, since we not only have to take into account the grade of an exam, but also their previous level, the student's performance in class, their proactivity, etc."*

Table 2. Relationship between the nine teaching competencies and the factors influencing TPI.

TEACHING COMPETENCIES	FACTORS AFFECTING TPI					TOTAL (per TC)
	TE	**MO**	**SI**	**ME**	**TP**	
TC1 Curriculum assessment	5	1	6	2	3	17
TC2 Professional communication	6	2	6	0	2	16
TC3 Social climate	2	4	4	0	6	16
TC4 Reflection innovation	3	2	4	3	2	14
TC5 Institutional culture	5	2	3	1	0	11
TC6 Collaborative decision-making	2	0	4	0	8	14
TC7 Instructional design	2	6	2	3	0	13
TC8 Affective interaction	3	5	2	1	2	13
TC9 Evidence-based improvement	3	0	4	1	8	16
***TOTAL** (per factor)*	**31**	**22**	**35**	**11**	**31**	130

Table 2 provides an overview of the relationship between the nine teaching competencies and the factors influencing TPI as perceived by the eight PSSTs, relating the number of mentions of each factor within each teaching competence. Notably, collaborative decision-making (TC6) and evidence-based improvement (TC9) show strong connections to task perception (TP) (8 mentions

each), while professional communication (TC2) has strong links to both teaching experience (TE) and self-image (SI) (6 mentions each), and instructional design (TC7) shows a strong connection to motivation (MO) (6 mentions). This distribution also suggests that specific competencies, particularly those related to curriculum and assessment (TC1), tend to engage multiple identity factors simultaneously.

In total, PSSTs included up to 130 mentions in their survey responses about the teaching competencies (Table 3), mainly concerning self-image (35), teaching experience (31) and task perception (31). On the other hand, motivation (22) and MEd expectations (11), were the less mentioned competencies in the study, respectively.

Table 3. Frequency of mentions emerged from the analysis per PSST.

FACTORS AFFECTING TPI	PPSTs								TOTAL (per category)
	1	2	3	4	5	6	7	8	
MEd EXPECTATIONS (ME)	**0**	**5**	**0**	**1**	**1**	**1**	**3**	**0**	**11**
Educational methodologies	0	2	0	1	1	0	0	0	4
Teaching work	0	0	0	0	0	1	2	0	3
Functioning of the educational institution	0	1	0	0	0	0	1	0	2
Observation	0	1	0	0	0	0	0	0	1
Participation	0	1	0	0	0	0	0	0	1
MOTIVATION (MO)	**4**	**2**	**3**	**3**	**3**	**1**	**5**	**1**	**22**
Intention to improve	2	1	2	0	3	1	5	1	15
Interests	0	1	1	3	0	0	0	0	5
Teaching professional capacity	2	0	0	0	0	0	0	0	2
SELF-IMAGE (SI)	**8**	**0**	**3**	**5**	**2**	**7**	**1**	**9**	**35**
Self-assessment	3	0	2	4	2	5	1	9	26
Personality	2	0	1	1	0	2	0	0	6
Curricular aspects	1	0	0	0	0	0	0	0	1
Oral expression	1	0	0	0	0	0	0	0	1
Written expression	1	0	0	0	0	0	0	0	1
TEACHING EXPERIENCE (TE)	**2**	**3**	**4**	**3**	**3**	**7**	**3**	**6**	**31**
Lack of teaching experience	2	1	1	0	1	3	2	4	14
Previous teaching experience	0	1	3	3	2	4	1	2	16
Teaching resources	0	1	0	0	0	0	0	0	1

Teacher-student relationship	0	1	0	1	0	0	0	0	2
Pedagogical methods	0	1	0	1	0	0	1	0	3
TOTAL (per PPST)	19	19	12	18	11	16	17	18	130

With reference to the five main factors affecting TPI, Table 3 shows the different subcategories encompassed within each of these factors. Regarding **self-image**, 'self-assessment' stands out as the main subcategory (26 mentions), highlighting the value of self-awareness and personal reflection in the construction of their professional identity. Concerning **teaching experience**, the results reveal a closely balanced division of opinions between 'Lack of experience' (17 mentions) and ‘Previous teaching experience' (16 mentions), reflecting the contrast between initial insecurity and the importance attributed to prior non-formal experiences in the development of their competencies. In terms of **task perception**, most responses highlight the attitude with which

PSSTs approach the teaching profession (9 mentions), emphasising a positive attitude toward overcoming challenges, followed by 'Classroom management' and 'Teacher collaboration' (6 mentions each), which indicates that the PSSTs acknowledge the importance of fostering a structured and collaborative environment that promotes active learning. Subsequently, with respect to **motivation**, the PSSTs highlight their intention to improve (15 mentions) their personal skills to ensure the success of the teaching-learning process, as well as their social skills, in a way that guarantees harmony in the classroom environment. Finally, the PSSTs express, as **expectations of the MEd**, the need to improve their training regarding new educational methodologies (4 mentions) and teaching practices (3 mentions), in order to adapt to new educational needs and ensure the success of the learning process.

Conclusions And Implications

This study examines PSSTs' perceptions of their professional development through a qualitative analysis, correlating teaching competencies and five key factors defining Teaching Professional Identity (TPI): teaching experience, motivation, self-image, MEd expectations, and task perception. The findings of this study lead us to make the following conclusions, which should be considered with caution due to the reduced number of participants in this case study.

Results show that PSSTs believe self-reflection, particularly through self-assessment, is crucial for building their professional identity. Likewise, the study highlights the value that PSSTs attribute to their own capabilities, limitations, and progress, revealing that the construction of professional identity is not solely the result of the accumulation of experience, but rather a continuous process of renegotiating their self-perception as teachers in relation to their competencies, expectations, and emotions. In this sense, reflection on one’s own teaching self-image emerges as a key mechanism for the development of TPI.

Teaching experience plays a key role, as PSSTs experience tension between initial insecurity due to lack of experience and the value they place on prior experiences. In this context, offering early, guided, and diverse teaching practice opportunities within initial teacher education programs is essential to help PSSTs connect theoretical content with classroom realities, thereby progressively strengthening their sense of professional competence and belonging.

Regarding task perception, a positive attitude toward challenges, classroom management, and teacher collaboration are key elements in shaping their identity. PSSTs also emphasize their motivation to improve both personal and social skills, highlighting the importance of comprehensive training that covers both professional and personal competencies.

Overall, this study underscores that reflection on teaching competencies and fostering an educational environment that allows PSSTs to assess and develop their abilities are essential for building a strong professional identity. In this regard, initial teacher education programs should create spaces for self-reflection and competency development, facilitating a successful transition into teaching practice and long-term professional success. This approach has important implications for the design of teacher training programs, which should integrate both technical competencies and the personal and reflective development of future teachers. Along these lines, such programs should adopt an integrated approach to professional development, articulating teaching competencies with factors linked to TPI and providing structured spaces for reflection, the promotion of teaching experiences, and attention to the socioemotional dimension, thus contributing to the development of a solid TPI. In this regard, the identification of key domains of professional identity can be used as a practical framework to guide assessment processes, course design, and reflective practices in initial teacher education, reinforcing the intentional development of TPI (Hanna et al., 2019).

Finally, despite the limitations derived from the reduced sample size, this research offers a competency-based perspective on the development of TPI during the initial training of science teachers. Future studies could extend this work through larger and more diverse samples, as well as comparative studies across disciplines and/or educational contexts. Such approaches would allow for a deeper understanding of how teaching competencies and professional identity construction interact, contributing to the design of teacher education programs that foster competent, reflective, and professionally committed teachers.

Pre-Service Physics Teachers' Conceptions About What It Means To Understand Physics: A Phenomenographic Study

Gregory P. Thomas
University of Alberta, Canada

The development of conceptual understanding is a long-standing goal of science education. However, a gap exists in the literature regarding what pre-service physics teachers' conceptions are of what it means to understand physics. Given the importance of teachers' epistemic conceptions for shaping their pedagogy, this gap is surprising. This study employed phenomenography to determine the qualitatively various ways that pre-service physics teachers conceptualize what it means to understand physics. Phenomenography is a second-order approach to research in which conceptions, (a) are viewed as being the product of interactions between humans and the world around them, and (b) arise from a human being's thinking about their external world. Fourteen pre-service physics teachers were interviewed individually for around thirty minutes each regarding their experiences as physics majors and their thoughts about what they considered it meant to understand physics. Five categories of description emerged from the analysis: (1) feeling, (2) applying, (3) making meaning, (4) communicating, and (5) accumulating. The first four categories occupy a higher level in the outcome space than the 'accumulating' category, as students reported that 'applying' and 'making meaning' were contingent on processes represented by the two sub-categories of 'accumulating.' The potential value of these findings is outlined.

Keywords: Phenomenography, physics, understanding.

Literature and Study Rationale

The understanding of concepts is closely related to high quality and/or in-depth learning. In science education there has been consistent attention to conceptual understanding and its development (e.g., Driver et al., 1994; Potvin et al., 2020) and conceptual change (e.g., Duit & Treagust, 2012; Lin et al., 2019). In this paper, however, the attention is on individuals' conceptions of understanding, itself, rather than on what it means to understand any particular science concept.

Previous research seeking individuals' views on what it means to understand has been reported. These studies employed phenomenography. The concept of understanding was identified by Marton et al. (1993), and Säljö (1982) as one of six conceptions of learning. Irving and Sayre (2012) investigated eighteen university physics students' conceptions of understanding and reported, similar to Waterhouse and Prosser (2000), that individuals understanding was when one could use and apply knowledge, and that one's level of understanding was determined according to different levels of task requirement and context complexity.

In phenomenographic research in science education, Zhao (2015) explored mainland Chinese students' conceptions of learning science. Lukie (2021) explored and compared high school physics students,' high school physics teachers,' and university physics professors' conceptions of what it means to understand physics. He reported five non-hierarchical categories: feelings, achievement, communication, making meaning, and application. The variations between the groups of participants related to their levels of knowledge, domain expertise, experience, and roles.

There is little, if any, research regarding pre-service science teachers' conceptions of what they consider understanding to be. Given that conceptions of understanding can be linked to teacher pedagogy, curriculum interpretation, learning processes, and domain expertise, the research reported in this paper is timely. It is important that teachers and their students have a shared, consistent view of what it means to understand science subjects. There should be a common epistemic foundation that can be shared and communicated between them. Otherwise, the purposes of teaching and learning might not be similar or identical between classroom participants. This study investigated pre-service physics teachers' conceptions of what it means to understand physics.

Research Design

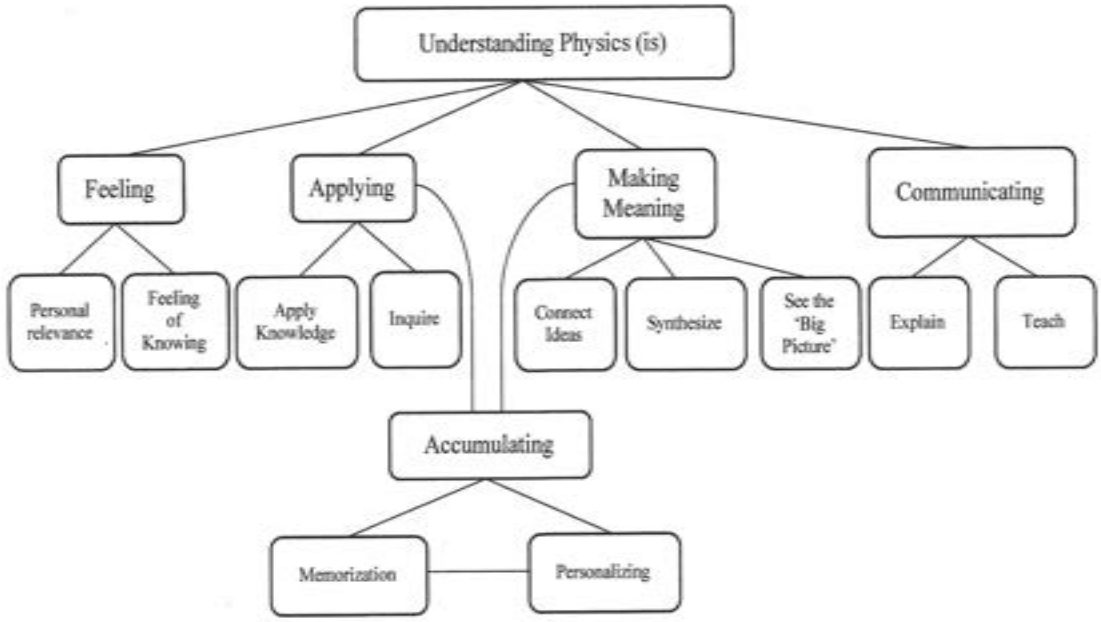
Phenomenography: An Overview

Phenomenography is a "research method for mapping the qualitatively different ways in which people experience, conceptualize, perceive, and understand various aspects of, and phenomena in, the world around them" (Marton, 1986, p. 31). Phenomenographers adopt a second-order approach to research; their description of a phenomenon is based on the experience/s of that phenomenon as described by others (Marton & Booth, 1997; Trigwell, 2006). Marton (1986) suggests that "each phenomenon, concept, or principle can be understood in a limited number of qualitatively different ways" (p. 30). Phenomenographers attempt to identify and categorize the various, multiple conceptions that a population might have for a phenomenon and describe the variations in those conceptions. These categories of conceptions are presented as the 'outcome space' that represents the minimum number of categories that explain all the variations in the data. The outcome space should, (a) reveal something distinct about how the phenomenon is experienced, (b) present each category in its logical relationship with other categories, and (c) present the fewest number of categories that can represent the data and its analysis (Marton & Booth, 1997). This study aimed to determine, represent, and explain the outcome space representing pre-service physics teachers' conceptions of what it means to understand physics.

Participants, Data Collection, And Analysis

Fourteen pre-service teachers, physics majors enrolled in a Bachelors of Education degree at a large North American comprehensive university, consented to participate. Data were collected using semi-structured interviews of around 30 minutes each during which the participants answered open-ended questions (Dunkin, 2000, Bowden, 2005, Åkerlind, 2005a) about what they considered it meant to understand physics and about their experiences as physics learners. The interviews were transcribed and analysis began with the transcripts being read numerous times while listening to the audiotape in "to clarify what the participant meant" when responding to the questions (Åkerlind, 2005b, p. 328). The phenomenon in question, i.e., understanding physics, was then "narrowed down to and interpreted in terms of selected quotes" (Marton, 1986, p. 42). The selected quotes and their interpreted meanings were compared to identify sources of variation and agreement, and to ascertain which could be grouped together and which could remain separate. After these processes had been undertaken several times, labels for the categories of conceptions were determined and the categories were arranged (in the outcome space) in a way that respected and reflected the pre-service teachers' self-reports regarding what they considered it meant to understand physics.

Results and Discussion



Five conceptions of understanding physics are evident: Feeling, Applying, Making Meaning, Communicating, and Accumulating. Eleven sub-categories emerged: Personal Relevance,

Feeling of Knowing, Apply Knowledge, Inquire, Connect Ideas, Synthesize, See the 'Big Picture,' Explain, Teach, Memorization, and Personalization. The structure of the outcome space (Figure 1) is hierarchical. This is in contrast to the outcome spaces reported by Lukie (2021) and Zhao (2015) who both reported circular outcome spaces. However, it is consistent with those outcome spaces reported by Irving and Sayre (2012) and Waterhouse and Prosser (2000). In outlining these conceptions, examples of students' interview comments are provided to illustrate the researcher's interpretations.

Accumulating

The participants said that what it means to understand Physics was to accumulate information and memory elements via *Memorization*, which involved conscious attention to information retention, often at a surface level, as exemplified by comments such as "understanding involves…taking notes of the key terms, doing definitions of those terms, writing down formulas, and trying to draw diagrams…if I can't remember, then I'm just trying to write it down and I'll try to figure it out later," and *Personalizing* information that involved rewording, e.g. "…putting what a lecturer is saying into my own words," or creating visualizations of the materials and ideas provided by teachers and instructors. Students stated clearly that 'Accumulating' was a key and necessary component of understanding physics; a precursor to applying and making meaning. However, they were unanimous that Accumulating, by itself, constituted a lower, subordinate level of understanding than applying and making meaning. Hence it is placed in a lower area in the outcome space. In what follows, the four other, superordinate conceptions are briefly explained.

Figure 1. The Outcome Space Representing Pre-service Physics Teachers' Conceptions of Understanding Physics.-

Feeling

The participants said that what it means to understand physics was to experience a feeling; a positive emotional response. Two sub-categories were identified: A feeling of *Personal Relevance* referring to when students saw physics as directly relatable to their lives, as exemplified by comments such as, "I like being able to look at things around me and know how they work…it's just fun," and a *Feeling of Knowing*, which meant that they could understand the material intuitively. This is exemplified by students' comments such as, "understanding physics

means it kind of (sic) just makes sense…an intuitive thing." Scholarship on feelings of knowing is highly visible in the literature, especially that which is related to metacognition (e.g., Efklides, 2006). Further, the importance of emotions for learning and understanding science is gaining increasing attention (e.g., Bellocchi & Ritchie, 2015).

Applying

The participants said that what it means to understand physics was to apply the physics one knows. Two sub-categories were identified: *Applying Knowledge* as using knowledge to solve problems and pass exams, as exemplified by comments such as, "I know I understand if I can do the questions,' and applying knowledge in the pursuit of *Inquiring* as being able to inquire and think critically about information and ask research questions in the field of physics, as exemplified by comments such as, "If I understand physics I can…develop my own procedure that makes sense…set up my own problem [to investigate] as thoroughly as I can." The sub-category of applying knowledge has been reported in previous studies (e.g., Irving & Sayre 2012; Lukie, 2021; Waterhouse & Prosser 2000). The second sub-category of *Inquiring* has not previously been reported to this researcher's knowledge.

Making Meaning

The participants said that what it means to understand Physics was to make meaning. Three sub-categories were identified: *Connecting Ideas* that involves seeing connections between physics concepts and ideas as exemplified by comments such as, "understanding involves…seeing how what we're learning fits into what I already know about a topic," *Seeing the 'Big Picture'* as being able to see physics as a field of study that can be connected to everyday life, often through the lens of mathematics and other areas of science, for example, "I see a car drive down the street, and I think of all the moving parts, and the mechanical engineering, and the thermodynamics…that's the basis of what physics is," and *Synthesizing*, as being able to deconstruct, reconstruct and revise concepts in potentially new ways, as suggested for example in, "[understanding physics is] seeking and finding patterns and logical structures in the world…mathematics is the main tool used to do that…[it's about] finding out how 'puzzle pieces' like, for example, energy, kilometres, hours, and formulas, fit together." To this researcher's knowledge, this subtle distinction between categories of making meaning has not previously been reported.

Communicating

The participants said that what it means to understand Physics was to communicate what one knows with others. Two sub-categories were identified: *Explaining*, meaning being able to explain physics to someone else, for example, "…being able to explain a difficult concept to somebody in layman's (sic) terms," and *Teaching*, meaning communicating with the intention of facilitating learning, for example being able to, "…tutor at university…to teach physics to somebody." The distinction between explaining and teaching is consistent that noted in past studies (e.g., Lukie, 2021; Irving & Sayre, 2012, Waterhouse & Prosser, 2000).

Conclusion And Implications

The significance of these findings relates to considering the everyday classroom event of a physics teacher asking their students, "Do you understand?" When they ask this question, what is it that are they really asking? Further, do teacher/s and students share similar epistemic positions on what it means to understand physics? The findings of this research suggest that a variety of conceptions of what it means to understand physics are possible for pre-service physics

teachers. Lukie (2021) reported similar variations between high school physics students and between high school physics teachers. The conceptions identified in this paper can be used, and are being used by this researcher, for initiating discussions with pre-service and practicing science teachers about what it means for individuals to understand physics. The outcome space shown in Figure 1 can be and is being used as a template for structuring such discussions. Further phenomenographic studies across science subject specialisms with pre-service and practicing teachers is required to expand the literature and potential use of such findings across teacher education.

Acknowledgement

This paper draws on research was part of the project 'Using audio podcasts and supporting text materials to stimulate metacognitive experiences in pre-service science teachers regarding metacognition and its development' supported by the Social Sciences and Humanities Research Council of Canada.

ESERA 2025 Copenhagen

Fostering An Understanding Of The Significance Of Insect Care In Pre-Service Teacher Training

Karen Onodera
Faculty of Education, Okayama University, Japan

This study investigates the effectiveness of a teaching intervention designed to enhance pre-service teachers' understanding of "thinking from the animal's perspective" in Living Environment Studies. A six-session intervention was integrated into a Living Environment Studies course for 24 pre-service teachers at a private women's university in Japan. Through discussions, lesson planning, and reflective activities focused on insect care, they explored the pedagogical value of perspective-taking in animal care. Post-intervention data from questionnaires and lesson plan analyses indicated that 83.3% of the pre-service teachers understood the importance of perspective-taking, with 66.7% linking it to fostering respect for life. Findings suggest that structured interventions can effectively equip pre-service teachers with strategies to cultivate empathy and a biocentric worldview in the children they will teach. Future research should explore integrating the coexistence of nature and humans and strengthening connections between Living Environment Studies and science education to enhance holistic animal care.

Keywords: Living Environment Studies, Insect Care, Thinking from the Animal's Perspective

Introduction

Living Environment Studies And The Educational Significance Of Animal Care

Animal care has been an integral part of Japanese primary education since the Meiji era. Initially rooted in science education, it has since become one of the core learning activities within Living Environment Studies (LES), as noted by Saito and Yoshimura (2023). This subject was established following the revision of the national curriculum guidelines in 1989 and fully implemented in primary schools in 1992 as part of Japan's educational reform. Taught in the first and second grades, LES helps children learn how to navigate their daily lives and grow through direct, hands-on experiences with people, their community, and the natural world. By exploring these connections, children begin to understand their place in the world and learn to interact responsibly with others and the natural environment. A primary goal of LES is to help children realize that nature is a vital part of their own lives. It encourages them to reflect independently on how humans and the environment can coexist harmoniously. In this way, the subject builds a foundation for a lifetime of harmony with the world. Within these lessons, caring for animals is especially important; it helps children develop a meaningful connection with other living beings, reflect on animal–human relationships, and cultivate empathy and respect for all life. The current national curriculum guidelines emphasize that animal care should involve observation and interaction that enable children to understand animals' needs and perspectives (MEXT, 2018).

This educational orientation is consistent with the natural tendencies of humans to understand and respond to animals, as indicated by psychological research. Fujisaki (2002) reported that humans naturally perceive emotions in animals and adjust their interactions accordingly, while Fujisaki (2004) emphasized that this ability is present from early development. Yamada (2012) noted that attributing emotions to animals is a general human characteristic. However, previous studies in LES have indicated that merely providing opportunities for children to interact with animals is insufficient for learning, and that structured learning experiences are necessary to help children shift from a human-centred perspective toward an understanding that incorporates animals' natural habitats, life processes, and ecological contexts (Onodera & Fujii, 2023).

Educational Value Of Insect Care In Living Environment Studies

When focusing on the types of animals kept in Japanese primary schools, recent studies indicate a clear shift in school-based animal care practices. The keeping of birds and mammals such as chickens and rabbits has declined due to concerns about infectious diseases and management burdens, whereas the keeping of relatively low-maintenance animals, including fish, amphibians, and insects, has increased (Nakajima, 2021). Among these animals, insects occupy a particularly significant position in LES. Insects are regarded as one of the most accessible materials through which children can experience and feel connected to nature in their everyday lives (Yamashita & Shuto, 2008). Previous research has demonstrated that even insects that children tend to find less appealing, such as crickets, can become objects of care and concern through sustained rearing and observation, leading to changes in children's perceptions and the development of attitudes that value and protect living beings (Saeki & Tsuchiya, 2012). Furthermore, the Science Council of Japan (2011) has emphasized the educational value of insects as school teaching materials, highlighting their manageable size, ease of rearing, species diversity, and suitability for learning about ecological roles and life processes. Because of these characteristics, insects serve as engaging hands-on examples of how life and ecosystems work, reinforcing why they are so highly recommended for school activities.

Given these characteristics and current educational contexts, insect care represents a particularly appropriate and meaningful focus for examining how children can be guided to think from the animal's perspective within animal care in LES.

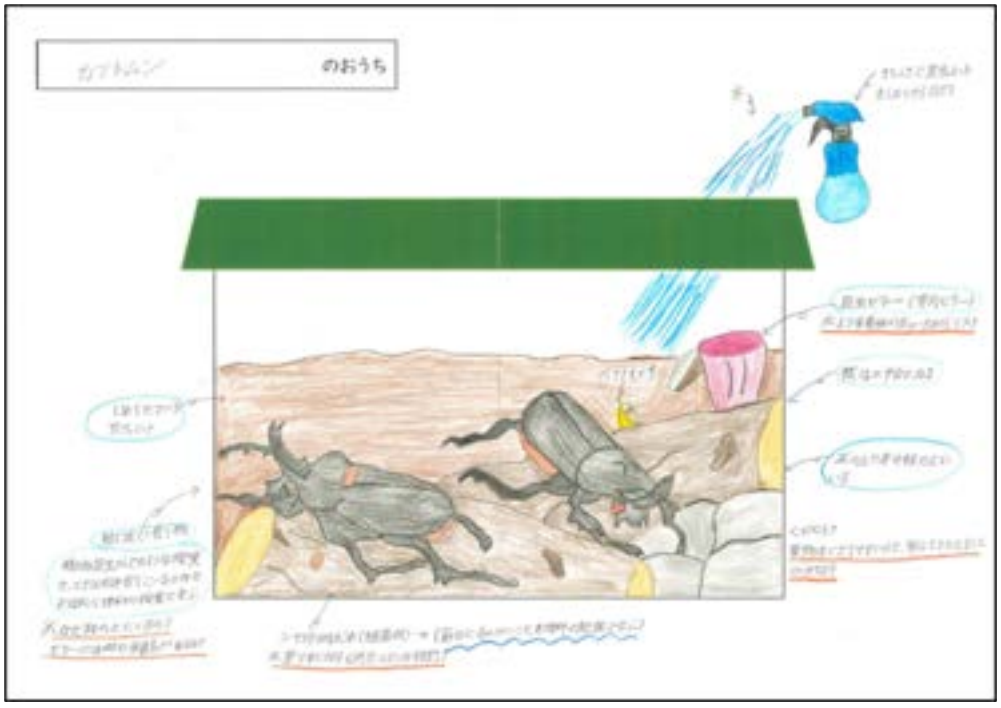
Challenges In Teacher Education For Perspective-Taking In Animal Care

In classroom practice, facilitating this shift requires teachers to intentionally design learning situations that encourage children to think from the animal's perspective. Such situations may include activities in which children imagine animals' living environments, compare natural habitats with rearing cases, and reflect on how human actions influence animals' lives. Through these processes, children can begin to connect emotional engagement with cognitive understanding, thereby forming foundational perspectives related to respect for life and coexistence between nature and humans. Despite the recognized importance of these pedagogical approaches, existing research on teacher education for animal care in LES has largely focused on technical and managerial aspects, such as appropriate species selection and daily care routines (Miyazono & Miyagawa, 2012; Suzuki, 2006). While these studies provide valuable practical guidance, they have paid limited attention to how teachers can support children in thinking from the animal's perspective and linking such perspective-taking to ethical attitudes, including empathy and respect for living beings. Moreover, although research on teacher education in LES has accumulated since the subject's introduction, much of this work has emphasized understanding the subject's philosophy or improving general lesson design skills. As a result, there remains a notable lack of empirical studies examining how pre-service teachers learn to design animal care lessons that intentionally cultivate children's ability to consider animals' perspectives as a foundation for humane and responsible relationships with animals.

Purpose Of The Study

This gap in teacher training highlights the need for interventions specifically designed to enhance pre-service teachers' understanding of the importance of "thinking from the animal's perspective" in animal care. Accordingly, this study aims to investigate the effectiveness of such a teaching intervention implemented within a mandatory LES course for pre-service teachers. By developing and implementing this intervention, the study examines whether it can promote a deeper understanding of this concept and better equip future educators to foster empathy and

respect for animals in the children they will teach, thereby contributing to more comprehensive and compassionate animal care practices in Japanese primary schools.



Method

Participants

The participants in this study were 24 second-year undergraduate pre-service teachers enrolled in a mandatory LES course at the faculty of education of a private women's university in Japan. The course constituted a core component of their pre-service teacher education program for obtaining primary school teaching certification. Before taking part in this study, they had already completed their foundational coursework in LES. Specifically, they studied the national curriculum standards issued by the Japanese Ministry of Education (MEXT), which are known as the Course of Study. This ensured that they were generally familiar with the government's official goals, core content, and the specific learning objectives required for primary schools across Japan. In addition to theoretical instruction, they engaged in experiential learning activities that mirrored those undertaken by primary school children, allowing them to examine LES from both learner and teacher perspectives. The course also addressed the continuity between LES and the rest of the curriculum. It emphasized how LES serves as an essential bridge to more specialized subjects including science and social studies, which children begin to study in the third grade.

Prior to the intervention, they had engaged in learning activities related to animal care. As part of this learning, they participated in an activity in which they designed a "home for insects" (Figure 1), focusing primarily on identifying and arranging the elements necessary for maintaining an appropriate rearing environment. This activity encouraged pre-service teachers to consider basic requirements for insect care, such as shelter and materials, from the perspective of preparing a suitable living space. However, these prior learning experiences provided limited opportunities for them to explicitly reconsider animal care from the animal's perspective or to examine how such perspective-taking could be intentionally integrated into lesson goals and instructional structures. Therefore, the instructional intervention in this study was designed to build upon pre-service teachers' existing knowledge of LES and animal care, while explicitly addressing this pedagogical gap by focusing on the educational significance of "thinking from the animal's perspective" and its incorporation into lesson design.

Figure 1. Worksheet used in the pre-intervention "home for insects" activity.

This study was reviewed and approved by the ethics committee of the university at which the author was affiliated at the time of data collection. Participation was voluntary, and informed consent was obtained from all pre-service teachers. They were informed that their decision to participate or not would not affect their course evaluation, and all data were anonymized and used solely for research purposes.

Intervention Lessons

A six-session intervention was designed to enhance pre-service teachers' understanding of the importance of “thinking from the animal's perspective” in animal care practice. The intervention was integrated into a 15-session LES course and focused on insect care as a concrete context for examining this concept. The intervention combined short lectures, guided discussions, and lesson design activities to support pre-service teachers in linking theoretical perspectives with practical lesson planning. An overview of the six intervention sessions is presented in Table 1.

In Sessions 10 and 11, pre-service teachers were introduced to the concept of “thinking from the insect’s perspective” through research findings on lower primary school children’s perceptions of insects and participated in facilitated discussions on its ethical and educational significance. In Sessions 12 and 13, pre-service teachers developed LES lesson plans on animal care, with explicit instructions to incorporate opportunities for children to consider insects’ perspectives within learning objectives, activities, and worksheets. Sessions 14 and 15 focused on peer review, revision, and reflection, enabling pre-service teachers to critically examine how effectively their lesson designs embodied the intended pedagogical focus.

Table 1. Intervention Lessons-

Session	Session Content
10	Introduction to the concept of "*thinking from the insect's perspective*" and its relevance to LES. This included a presentation of research findings regarding lower primary school children's perceptions of insects and their perspectives.
11	Facilitated discussion on the significance of incorporating "thinking from the animal's perspective" in animal care, prompting pre-service teachers to consider the ethical implications and potential benefits.
12-13	Pre-service teachers developed LES lesson plans focusing on animal care with an emphasis on "thinking from the animal's perspective". This included the design and creation of accompanying worksheets for primary school children to encourage engagement with the concept.
14	Peer review and constructive feedback sessions on the developed lesson plans and worksheets. Pre-service teachers revised and refined their teaching materials based on this feedback.
15	Pre-service teachers presented their final lesson plans and worksheets. A facilitated group discussion followed, focusing on the learning outcomes of the intervention, challenges encountered in the lesson planning process, and the overall significance of "thinking from the animal's perspective" in animal care.

Data Collection And Analysis

To evaluate the effectiveness of the instructional intervention in promoting pre-service teachers’ understanding of "thinking from the animal’s perspective," a post-intervention questionnaire was administered in July 2023. This took place following a 15-session LES course that incorporated a targeted six-session intervention. The questionnaire was designed to capture a comprehensive view of how pre-service teachers understood lesson design through a single open-ended question.

They were asked to describe, in bullet points, their primary takeaways regarding animal care lessons and the underlying rationale for their views. This single integrative prompt encouraged them to articulate their learning in their own words without being influenced by leading terminology. To safeguard the internal validity of the study, specific concepts such as "thinking from the animal's perspective" were not explicitly presented in the question. This design allowed for an examination of whether such ideas had been inductively internalized and prioritized by pre-service teachers.

The primary dataset consisted of the free-response text obtained from these questionnaires. To enable a more careful interpretation and bolster construct validity, the study employed data triangulation by analysing lesson plans and worksheets created during the intervention alongside the questionnaire responses. This cross-referencing served to verify whether the understandings expressed in written reflections were consistently reflected in pre-service teachers' actual lesson designs and learning activities. The qualitative analysis utilized a process of inductive coding, beginning with an exhaustive reading of the data to identify initial themes grounded in the pre-service teachers' own language. Through the method of constant comparison, these codes were iteratively tested against the entire dataset to ensure categorical consistency.

To mitigate researcher bias and achieve interpretive rigor, codes were refined into overarching themes over multiple rounds of review until thematic saturation was reached. Each theme was corroborated by representative excerpts to provide a clear evidence trail, ensuring the results remained firmly anchored in the raw data and demonstrated the plausibility of the emerging findings.

Findings

Learning Processes During The Intervention Lessons

During Sessions 10 to 15, gradual developments were observed in pre-service teachers' understanding of animal care, particularly regarding the importance of thinking from the insect's perspective, as reflected in their discussions, lesson planning processes, and reflective activities conducted during the intervention lessons.

Session 10 focused on establishing the goals of animal care activities in LES and introducing research findings on how children perceive the feelings of reared insects. Through individual worksheet writing and peer discussions, pre-service teachers articulated various reasons for the importance of adopting an insect-centred perspective, including fostering respect for life, helping children recognize their own anthropocentric assumptions, and promoting coexistence with other living beings. Overall, they came to view the cultivation of an insect-centred perspective as essential for respecting life and living together with insects in LES.

In Session 11, discussions centred on how lessons and activities could support a shift from human-centred to insect-centred thinking among children. Pre-service teachers proposed experiential activities such as role-playing insects confined in rearing cases or imagining changes to their own school environment and applying those feelings to insects. Notably, some who initially believed that simple observation was sufficient to foster perspective-taking reconsidered their views after listening to peers and began to emphasize the importance of embodied and expressive activities, such as dramatization, to support deeper understanding.

During Sessions 12 and 13, pre-service teachers developed lesson plans for the first time. Many plans set learning objectives related to imagining insects' feelings and designing appropriate rearing environments. The plans frequently incorporated experiential learning methods valued in LES, including simulated environments, role-play, and prediction activities. By creating

worksheets and anticipating children's responses, they repeatedly revised their lesson plans, reflecting on the alignment between learning goals, activities, and the intended perspective-taking.

In the final sessions (14 and 15), pre-service teachers evaluated and presented their lesson plans and reflected on the broader educational significance of animal care. Discussions highlighted the necessity of teachers intentionally designing activities that prompt children to think from an insect's perspective, while also cautioning against the imposition of fixed interpretations regarding an insect's feelings. They further explored the continuity between LES and science education, noting that the perspectives and skills cultivated through insect care, such as comparison, prediction, and respect for living environments, could be transferred to later science learning. These reflections indicate that pre-service teachers not only deepened their understanding of perspective-taking but also began to situate animal care within broader educational goals, including coexistence between nature and humans.

Analysis Of Questionnaires

The following excerpts (Table 2) from the questionnaires further illustrate pre-service teachers' understanding of the significance of "thinking from the animal's perspective" in animal care education. The qualitative analysis focused on identifying recurring ideas and patterns across pre-service teachers' free-response answers through repeated reading and comparison of responses.

Table 2. Emerging Themes from the Questionnaire Analysis

Theme	Example Quotes
Empathy and Perspective-Taking	• "It is crucial to design lessons that enable children to consider the needs of animals from the animal's perspective." • "It is important to encourage children to step into the shoes of animals." • "Through animal care activities, children can begin to think from the standpoint of living beings different from themselves." • "In LES, it is important to engage with various feelings, including those of oneself, others, and animals, without assuming a single correct answer."
Recognizing the Value of Life	• "It is also crucial to help children understand that animals, like humans, have lives that deserve to be valued and protected." • "I believe it is important for children to understand that animals, like humans, have lives and must be treated with care." • "By learning about the preciousness of life, children's attitudes toward animals may change."
Shifting from an Anthropocentric to a Biocentric Perspective	• "This can lead to a more life-centred and ecological perspective, allowing children to empathize not only with animals but with all living beings." • "This can help them shift from a human-centred viewpoint to an animal-centred viewpoint, leading to a deeper understanding of the value of life." • "By considering animals' feelings from multiple perspectives, children can shift from self-centred thinking to a life-centred way of thinking." • "Children need to recognize that animals play roles in nature and that these roles are connected to human life."
Fostering Responsible Behaviour	• "They may become more careful in their handling of animals and more likely to return them to their natural habitats after observation." • "Children may begin to handle animals more gently and return insects to their original environments after observation."

	• "Understanding the differences between natural environments and rearing cases can encourage children to act responsibly toward animals." • "It is important to care for animals responsibly by providing environments suited to their specific needs."

Analysis of the post-intervention questionnaires indicated that 83.3% (20 out of 24) of the pre-service teachers explicitly stated that incorporating "thinking from the animal's perspective" was crucial in LES animal care lessons. Further analysis of these 20 responses revealed that the majority (66.7%, or 16 pre-service teachers) associated this approach with raising children's awareness of life and fostering an attitude of respect for all living beings. They highlighted that encouraging children to consider the animal's perspective could lead to a deeper understanding of the value of life, promoting a shift from an anthropocentric viewpoint to a more biocentric perspective. The percentages reported here are used to indicate the relative prevalence of these themes among pre-service teachers and to complement the qualitative interpretation, rather than to provide statistical generalization. This suggests that the intervention successfully enabled pre-service teachers to understand the pedagogical value of "thinking from the animal's perspective" within LES.

Reflection in Lesson Plans

This understanding was further reflected in the lesson plans developed by the pre-service teachers. Many of these plans incorporated activities specifically designed to encourage children to empathize with animals. These lesson plans were examined to explore how the understandings expressed in the questionnaire responses were translated into concrete instructional ideas, with attention to features that appeared across multiple pre-service teachers' plans. Examples include having children enter a cardboard box designed to represent a rearing case to encourage them to imagine the feelings of an insect within, and role-playing activities where children take on the roles of both the "carer" (human) and the "cared for" (insect) to promote a deeper understanding of both perspectives. These findings demonstrate that the intervention was effective in not only enhancing pre-service teachers' theoretical understanding of "thinking from the animal's perspective" but also in equipping them with practical strategies to incorporate this approach into their future teaching. The emphasis on empathy and respect for life aligns with the broader aims of LES and reflects a growing recognition of the importance of fostering these values in primary education.

Discussion

Implications Of Key Findings

This research aimed to develop and implement a teaching intervention within a mandatory "Living Environment Studies" course for pre-service teachers to enhance their understanding of the significance of "thinking from the animal's perspective" in animal care. The findings suggest that the intervention was successful in achieving this aim. The majority of the pre-service teachers (83.3%) understood the importance of incorporating "thinking from the animal's perspective" in LES animal care lessons. Furthermore, most of them (66.7%) understood this pedagogical approach as a means to cultivate children's awareness of life and foster an attitude of respect for all living beings.

This positive outcome can be attributed to the design of the intervention, which provided opportunities for pre-service teachers to actively engage with the concept. By developing lesson plans and discussing the rationale behind "thinking from the animal's perspective," they were able to grapple with key questions, such as:

- What are the core goals of animal care education in LES?
- What does it mean to think from an animal's perspective?
- How can this approach be effectively incorporated into LES lessons?

This process of active engagement and reflection appears to have been crucial in deepening pre-service teachers understanding of the significance of this pedagogical approach. While previous studies in LES have highlighted the importance of children's experiential learning with animals, the present study extends this line of research by demonstrating how pre-service teachers can be supported in intentionally designing animal care lessons that foreground animals' perspectives as an educational goal. The intervention successfully highlighted the potential of "thinking from the animal's perspective" to not only enhance children's understanding of animal care but also to foster broader values such as empathy, respect for life, and a biocentric worldview.

Future Directions

Building on the findings and limitations of this study, two key areas for future development were identified:

1. Incorporating the concept of coexistence between nature and humans: While this study focused on fostering empathy towards animals, it is important to expand this concept to encompass a broader understanding of the interconnectedness between humans, animals, and the natural world (Matsumoto & Noda, 2009). Future interventions could explore ways to incorporate this concept of coexistence into LES animal care lessons, thereby encouraging pre-service teachers to consider the relationship between wildlife and humans, as well as the impact of human actions on the environment.
2. Exploring the connection between animal care in LES and science education: This study primarily focused on the role of animal care within LES. However, the values of respecting life and understanding living beings are also central to science education. Future interventions could explore the connection between animal care in LES and science, helping pre-service teachers design learning experiences that build a foundation for future scientific exploration while fostering ethical considerations regarding animals and the natural world.

By addressing these areas for future development, this research can contribute to more holistic and effective animal care in Japanese primary schools, fostering in children a deep understanding of and respect for animals and the environment. These efforts may also help pre-service teachers translate the pedagogical principles of LES into broader educational practices.

Limitations

This study has several limitations that should be considered when interpreting the findings. First, the pre-service teachers were drawn from a single private women's university in Japan, and the sample size was relatively small. Therefore, the findings cannot be readily generalized to all pre-service teachers or teacher education contexts. Second, the study relied primarily on self-reported data collected through a post-intervention questionnaire. Although the questionnaire was designed to encourage reflective and descriptive responses, the findings represent pre-service teachers' perceived learning rather than direct evidence of changes in teaching practice or long-term instructional outcomes. In addition, because no pre-intervention questionnaire was administered, it was not possible to quantitatively compare changes in pre-service teachers' understanding before and after the intervention. Third, all qualitative data were analysed by a single researcher. While a transparent and systematic analytic procedure was employed to enhance the trustworthiness of the analysis, alternative interpretations of the data may be possible.

Future studies could strengthen analytic rigor by involving multiple researchers or employing additional validation strategies, such as member checking or inter-rater discussion.

Finally, this study focused on pre-service teachers' understanding immediately following the completion of the course, including the instructional intervention. As a result, it did not examine how this understanding may develop over time or be enacted in actual classroom practice. Longitudinal research following pre-service teachers into their teaching careers would provide further insight into the sustained impact of learning to "think from the animal's perspective" in animal care.

Note

This paper is an expanded and revised version of part of the author's doctoral dissertation.

Acknowledgement

The author would like to express sincere gratitude to all those who cooperated in this research, as well as to the colleagues who provided invaluable guidance and support. This study was supported by JSPS KAKENHI Grant Number 24KK0048.

ESERA 2025 Copenhagen

Exploring The Attention Dimension Of Plant Awareness Through Drawing: From Stereotypes To Detailed Observations

Marcia Eugenio-Gozalbo[1], Inés Ortega-Cubero[1] and Rafael Suárez-López[2]
[1]Faculty of Education of Soria, University of Valladolid, Spain
[2]Faculty of Education, University of Salamanca, Spain

The construct 'plant awareness' emphasizes the importance of improving individuals' understanding, appreciation, and attention towards plants. This study explores the role of naturalistic drawing as a strategy to foster plant awareness, focusing on how pre-service teachers represent plants graphically without instruction. Both drawings and text notes were qualitatively analysed through the constant comparison method to classify them into conceptual categories (drawings) and based on information richness (text notes). We observed that students often struggle with representing the volume of plants -especially of those with dense foliage-, and that they tend to use stereotypes to represent plant parts and even whole plants, thus avoiding drawing difficulties. A main identified barrier was plant elements' overlapping, a trait that was not adequately captured in most drawings, which can be attributed to the natural evolution of graphic expression in most adult population lacking art training. Our findings support the idea that drawing is a useful strategy to promote observation and attention towards plants. However, instruction should focus on certain aspects that are particularly challenging for learners, so initial barriers can be overcome, and the observations of plant structures and traits can be refined.

Keywords: attention, naturalistic drawing, plant awareness, pre-service teachers

Introduction

The term 'plant blindness' (Wandersee & Schusler, 1999) describes how people tend to overlook plants. Since then, reversing this phenomenon has become a major goal of biological education. A recent conceptualization links 'plant awareness disparity' to a lack of attention, interest, positive attitudes, and knowledge about plants (Parsley, 2020). Pany et al. (2022) proposed using 'plant awareness' instead, emphasizing positive engagement. Recently, this theoretical construct was defined as "a multidimensional construct that reflects the level of an individuals' perception, understanding, and valuation of plants" (Dünser et al., 2024).

A key challenge in fostering plant awareness is enhancing individuals' attention to plants. One effective strategy to improve plant awareness could be promoting their observation through drawing (Eugenio-Gozalbo & Ortega-Cubero, 2022). Drawing deepens scientific understanding by stimulating intense observation and aiding effective data recording for subsequent study (Katz, 2017). Several theoretical frameworks address the role of drawing in learning. Dual coding theory states that integrating verbal and non-verbal information facilitates the construction of a coherent mental representation and recall (Paivio, 2014). The later theory of generative learning considers that drawing connects previous knowledge with new content, contributing to building mental models and enhancing understanding and recall (Fiorella & Mayer, 2016). However, drawing is a difficult task for many people, requiring spatial abilities that are hard to develop, and is time-consuming and cognitively demanding (Fiorella & Zhang, 2018).

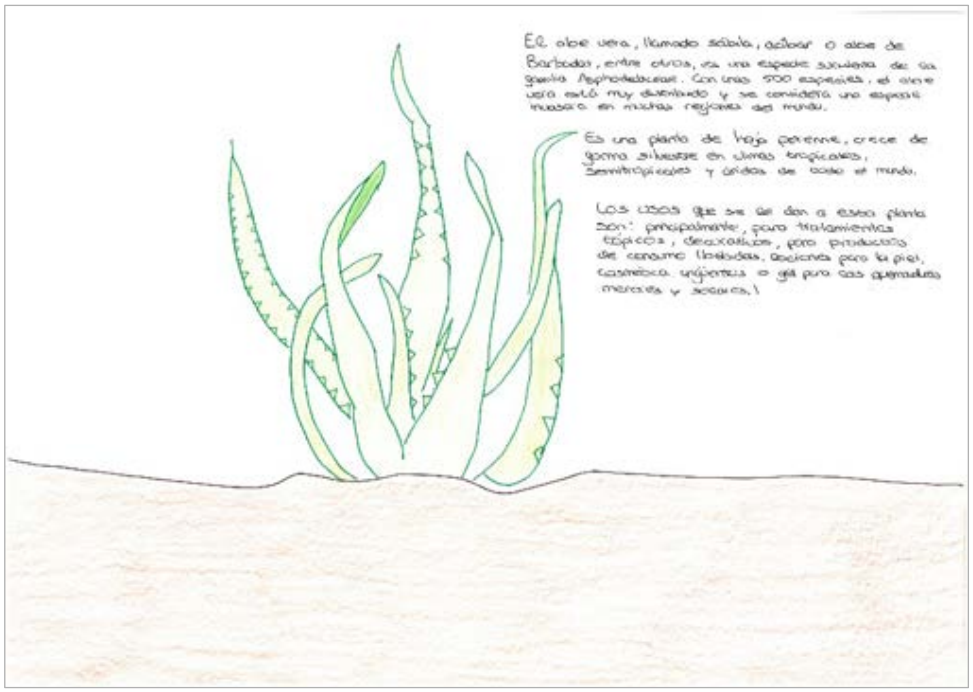
Classical treatises on children's drawing emphasize that children tend to place each element in drawings in its own space, avoiding overlap. Objects in front of another are usually drawn next to, rather than partially overlapping, each other (Lowenfeld & Brittain, 2008; Martínez, 2004; Matthews, 2002). This trait persists in adults who have not advanced beyond the developmental

stages of childhood graphic language, which applies to most people. It leads to unconscious resistance, causing moments of creative block during demanding drawing exercises. To avoid this, most people use stereotypes—simple images as communicative symbols. The tree stereotype is particularly widespread, often depicted with a rectangular trunk supporting a rounded or fan-shaped canopy spread out on a single plane (Parini, 2002). Stereotypes are typically drawn with firm, inexpressive lines. Parini (2002) recommends using 'trembling, sharp, unpredictable, piercing, curved, or tortuous lines, or inventing one's own' to effectively depict different types of plants, emphasizing that these strokes 'are highly appealing for overcoming stereotypical representations' (p. 188).

In this research, we aimed at posing a naturalistic drawing exercise to pre-service teachers (PSTs) to be conducted without any artistical or biological instruction; to unveil the difficulties they faced in drawing and perceiving plant structure and traits. The exercise was conducted outdoors, with students free to choose any plant specimen, as we were also interested in such choices themselves.

Materials And Methods

The study involved third-year 39 PSTs in the compulsory subject 'Natural Sciences', of the Degree in Pre-School Education at the Faculty of Education of Soria (University of Valladolid, Spain). A teaching-learning sequence designed to promote plant awareness, published elsewhere (Eugenio-Gozalbo et al., 2024), combined artistic and scientific activities, both theoretical and practical, some conducted outdoors at an organic garden. The artistic part focused on observation-based drawing, particularly botanical illustration, to help students understand plant morphology, thus laying the foundation for effective learning of basic plant classification. One of the initial activities of such sequence was the naturalistic drawing exercise, whose results are presented here.



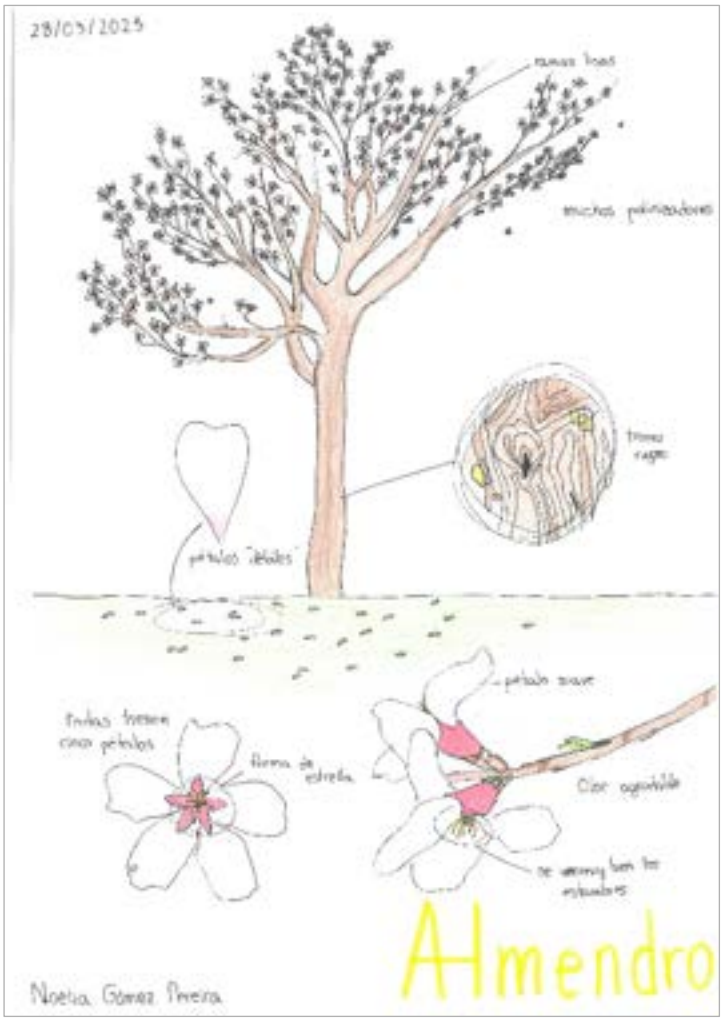
Students' drawings and text notes were qualitatively analysed by two researchers using Grounded Theory, through the constant comparison method. This approach involved systematically and iteratively examining the sample to identify emerging categories and subcategories of graphic representations, rather than using predefined classifications. The drawings were analysed together to detect recurring patterns and establish a more robust categorization. Text notes were categorised into three complexity levels (low, medium and high), based on the type and richness of information. The final categorization was reached through consensus between the researchers, who discussed all cases, particularly those with ambiguities.

Results

Drawing Analysis

Of the 39 drawings analysed, most students chose to depict trees (23), followed by herbaceous plants (12), and shrubs (4). A strong preference for flowering plants was observed, with 28 drawings featuring plants with flowers and only 11 without. Thus, trees were the plant form most frequently drawn, with 17 featuring flowers. Almond trees (Prunus dulcis) dominated this category, with 15 representations, while a pear tree (Pyrus communis) and a cherry tree (Prunus avium) were also included. The remaining six tree drawings depicted non-flowering species. Shrubs were less common, with an equal distribution between flowering and non-flowering species. Herbaceous plants accounted for 12 drawings, nine of which had flowers. Notably, three students selected Aloe vera, likely due to its simple appearance, though its thick, sculptural leaves posed unexpected challenges in conveying the sense of volume (Figure 1).

Figure 1. Example of an *Aloe vera* drawing with an inaccurate three-dimensional representation.



Students faced significant difficulties in tree representation, often lacking spatial awareness, resulting in flat, fan-like depictions with all elements displayed on the same plane (Figure 2). When drawing trunks, eight students failed to depict the gradual tapering of trunks, creating structures that widened and narrowed arbitrarily. In contrast, nine students correctly showed this transition, with six achieving a sense of volume. However, three avoided the challenge by focusing on small details like branches or saplings. Non-flowering trees exhibited similar issues, with half of the students' making distortions. For canopies, three students struggled to convey volume, instead outlining individual elements uniformly, thus avoiding overlapping. This approach resulted in rigid, repetitive patterns, reinforcing the flat, schematic nature of their drawings. Some added excessive leaves to conceal structural difficulties, as seen in an olive tree drawing. Few students included trunk textures, with only four drawings (poplar, olive, cherry, and almond trees) showing this detail. Similarly, leaf details were rare, appearing in a few cases (holm oak, two olive trees, one cherry, and one pear tree). Notably, the absence of leaves in almond trees at the time of observation likely influenced this.

A clear correlation between the quality of trunk and flower representations was observed. PSTs who depicted tree structures well also rendered flowers more accurately. The biggest challenge was capturing petal perspective, especially in non-frontal views, where some petals appear smaller. Six students successfully created recognizable flowers (five almond flowers, one pear flower), with most belonging to the group that achieved better tree representations. Common difficulties included simplification or exaggeration of petal shapes, the latter indicating effort despite inaccuracies. A strong example of expressive floral drawing was an almond flower drawing (Figure 3), where she used a loose, irregular stroke to capture petal fragility. When depicting flowers in tree canopies, students tended to repeat the same graphic symbol uniformly instead of creating texture, further reinforcing the fan-like canopy representation (see Figure 2).

Figure 2. Example of an almond tree (*Prunus dulcis*) representation in a single plane.

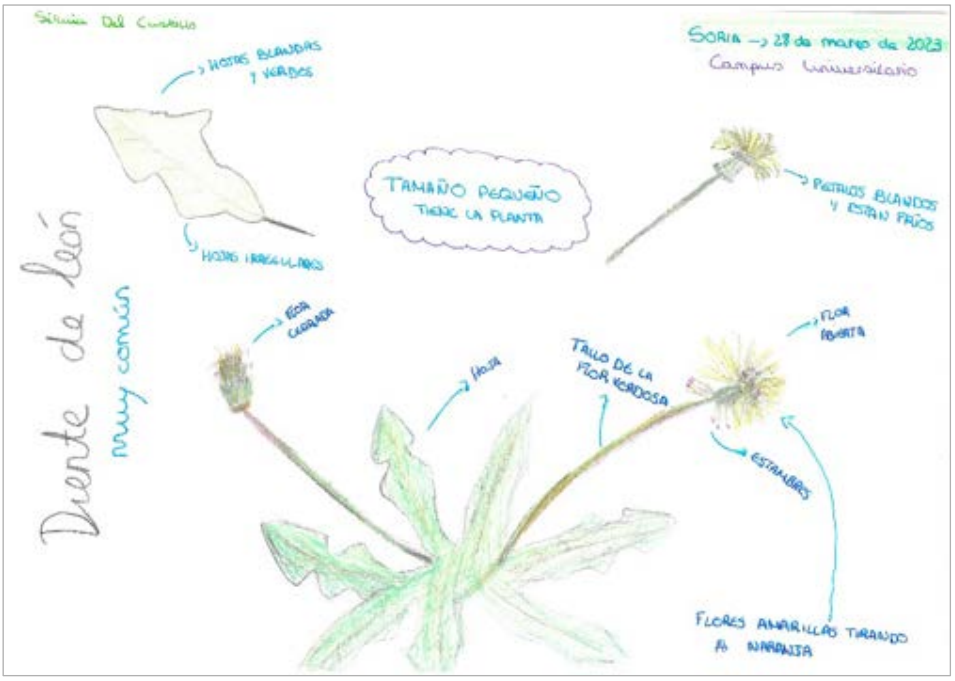


Figure 3. Example of an accurate representation of an almond flower (*Prunus dulcis*).

Students also encountered similar difficulties in representing volume with herbaceous plants, particularly tulips and *Aloe vera*, struggling to distinguish spatial relationships. In Asteraceae,

such as *Taraxacum* sp. and *Bellis perennis*, basal rosettes were depicted as undifferentiated masses rather than distinct leaves (Figure 4). Overall, students found it challenging to represent depth and spatial layering, indicating a broader struggle with volume perception in plant drawing.

Figure 4. Example of an inaccurate representation of a basal rosette.

Text Notes Analysis

Students' textual descriptions categorized at the low level (7 cases) typically reflected personal opinions or inaccurate observations, such as noting ‘much resistance’ or ‘irregular petals’ in the case of forget-me-not flowers (*Myosotis* sp.). This level also included information copied from the internet, such as descriptions of absent *Aloe vera* flowers. At the medium level (15 cases), students provided more concise and accurate labels. These included simple descriptions consisting of one or two adjectives (4 cases), such as “dark green stem,” or more specific, yet general, observations (11) like “petals flying in the wind” and “presence of many pollinators,” particularly for almond trees. While these descriptions lacked the richness found in higher-level texts, they still reflected the students' direct observations and were more consistent. The high level (10) included the most detailed and accurate descriptions. One student provided a long passage that described both the plant's context and its features, indicating a thorough awareness of the plant's environment. Other nine students used text notes that correspond to sensory details, such as the ‘lighter brown branches’ or ‘yellow stamens with anthers.’ In some cases, students acknowledged the limitations of their drawings and supplemented their observations with additional information.

Discussion And Conclusions

Students’ naturalistic drawings often focused on trees and flowering plants, likely influenced by their aesthetic appeal rather than other criteria. A minority chose specimens seemingly easier to draw, such as Aloe vera. In general, capturing the volume of plants proved challenging, as it was easier to depict the linear, less dense structure of herbaceous plants (with few leaves and one or more long stems, but not overlapping). This difficulty arises from the conflict between vegetal density, which is not a solid mass of leaves, and the tendency to avoid overlapping in graphic representation (Lowenfeld & Brittain, 2008; Martínez, 2004; Matthews, 2002). Thus, drawing details was easier than depicting the whole plant.

To address this challenge, it is important to provide students with strategies that focus on capturing the essence of plant forms, particularly volume and density. Emphasizing observation techniques that focus on textures, light, and shadow can help represent complex plant structures, including dense leaves or branches (Parini, 2002). Encouraging practice in both detailed and holistic representations will help them balance the intricate features of plants with their overall form. This approach encourages students to notice, reflect on, and appreciate plant morphology and complexity, ultimately improving plant awareness (Eugenio-Gozalbo et al., 2024).

Further discussion and research should address how drawing exercises can be effectively integrated into plant biology education to enhance students' observation skills. One key area of research is how to support students in moving beyond stereotypical representations of plants. Additionally, assessing the effectiveness of these educational strategies remains an important aspect for further development. The poster session will feature visual examples of the results, with an interactive component inviting participants to discuss these questions and exploring how drawing can serve as a valuable tool for improving plant awareness.

Agile In Academia: Assessing Scrum's Potential For University Teaching

Dirk Brockmann-Behnsen
Leibniz University Hannover, Germany

This study explores the integration of the Scrum concept into university-level teacher training, specifically within a physics teaching internship preparatory course at Leibniz University Hannover. Originally developed for agile software development, Scrum promotes self-directed learning and iterative improvement, aligning well with modern educational approaches. The study investigates the effectiveness of Scrum in fostering pre-service teachers' competence development through a structured, team-based lesson planning process. A longitudinal study was conducted to examine changes in students' competence self-assessment. Data were collected at three points: before the preparatory course, after the course, and after the following school internship. Results indicate a significant increase in competence self-assessment during the course, attributed to the iterative, feedback-driven structure of Scrum. However, a stagnation or slight decline was observed during the school internship, likely due to real-world challenges in lesson implementation. Findings suggest that Scrum is a viable framework for teacher education, enhancing competence development through structured teamwork and reflective practice.

Keywords: Pre-Service Teacher Education, Professional Development, Learning Environments

Theoretical Framework

At the Physics Working Group at Leibniz University Hannover, students train to become secondary school teachers, with the module "Physics Teaching Internship" ("Fachpraktikum") playing a key role in their preparation. This module consists of a preparatory course at the university (1.5 hours per week over 14 weeks) and a five-week internship at grammar or vocational schools. The course aims to develop practical teaching competences through both subject-specific and pedagogical training. It encourages students to explore professional teaching approaches and to critically reflect on their actions based on educational research.

Previously, the preparatory course followed a traditional, lecturer-led format, focusing on lesson planning and execution. However, in the winter semester of 2022/2023, a paradigm shift toward more student-centred learning was implemented. Research indicates that self-directed learning enhances intrinsic motivation (Dignath & Büttner, 2008; Stone, Deci, & Ryan, 2009). This principle is integral to the Scrum methodology (Schwaber & Sutherland, 2020), which originates from agile software development, but is now used in many other areas. In the school sector, it was first adopted by Willy Wijnands in the Netherlands in 2011 as "eduScrum".

In the revised course format, students work in teams of three to five, with one member serving as team captain responsible for coordinating the group's workflow. Teams create lesson plans on assigned topics within three course sessions. They organize their tasks using a backlog, a tabular overview that lists specific work steps and tracks progress via mobile graphical elements. Completed lesson plans are uploaded to an online platform, where they undergo peer review. This review process provides critical feedback, which students use to refine their lesson plans. Regular team discussions allow members to assess their collaboration, identify strengths and weaknesses, and make improvements. This iterative approach ensures continuous enhancement of lesson plans and contributes to the development of a cohesive teaching unit.

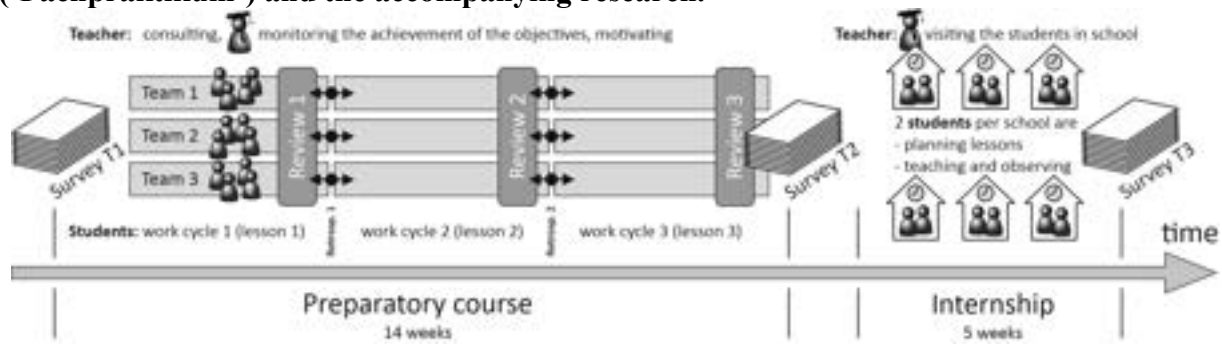
The effectiveness of this Scrum implementation in academic teaching is investigated in an accompanying study, which examines its impact on student competences. The study already found that Scrum was well-suited for university-level education. Students particularly valued the small team structure and the lecturer's advisory role (Brockmann-Behnsen, 2024).

This report specifically examines the development of the students' competence self-assessment during the preparatory course and the internship. Competence, as a theoretical construct, is complex and lacks a universal definition (Weinert, 2001, p. 46). One relevant framework is "action competence", which includes problem-solving skills, critical thinking, social skills, and domain-specific strategies. In the school context, the German Conference of Ministers of Education and Cultural Affairs (Kultusministerkonferenz, 2004) defines key competence areas as *"teaching"* (instructional design, learning facilitation, differentiation, etc.), *"educating"* (values education, social development, conflict management, etc.), *"assessing"* (diagnostic assessment, performance evaluation, feedback, etc.) and *"innovating"* (professional development, reflective practice, school improvement, etc.). These domains are the focus of the current study on the effectiveness of Scrum-based learning in teacher training.

Research Questions

As the competence self-assessment is to be examined during the preparatory course and internship, a longitudinal study is appropriate. The research questions therefore focus on the developmental stages occurring throughout these two phases:

[Q1] How does the students' competence self-assessment represented by the above-mentioned areas 'teaching', 'educating', 'assessing' and 'innovating' change during the preparatory course?



[Q2] How does the students' competence self-assessment change during the school internship?

Hypotheses:
It is to be expected that the competence self-assessment will improve during the preparatory course, as the iterative, incremental approach of the Scrum concept leads to a noticeable improvement in the lesson planning and corresponding feedback. During the block internship in the schools, on the other hand, students often experience that a good lesson plan does not necessarily lead to a good lesson. It can therefore be assumed that during this phase the competence self-assessment does not increase further or even decreases.

Methodology

Since the study is intended to examine the students' competence self-assessment in the course of the preparatory course and the internship, three measurement points were determined at which written surveys were conducted with the participants: at the beginning of the preparatory course (T1), between the preparatory course and the school internship (T2) and at the end of the internship (T3). Figure 1 provides an overview of the overall course of the module. In the preparatory course, the participants were introduced to the Scrum concept and then worked within the framework of this concept. The aim of this phase was to learn professional lesson planning. These skills were then applied during the block internship in a real school context. The scientific investigations reported in this article focus on effects of this innovative approach onto the students' competence self-assessment. Therefore, the research results presented here refer to the measurement points T1 vs. T2 and T2 vs. T3 respectively.

Figure 1: Overview of the courses in the "Physics Teaching Internship" module ('Fachpraktikum') and the accompanying research.

Instrument

The survey instrument consists of three questionnaires, which are used at the respective measurement times T1, T2 and T3 (see table 1). Scales from the KLiP study (Gröschner, & Schmitt, 2012; Gröschner, Schmitt, & Seidel, 2013) were used for all three measurement points to analyse the students' competence self-assessment. The items formulated there are based on the above-mentioned educational science standards of the German Conference of Ministers for Education. Six to eleven items each relate to the four areas of competence that are important for teacher professionalization: *"teaching"*, *"educating"*, *"assessing"* and *"innovating"*. The competence self-assessment is inquired by a seven-point Likert scale ("1" corresponds to "not at all competent", "7" corresponds to "fully competent"). The items are introduced by: "The teacher is capable of ..." ("Die Lehrperson kann …"). The Likert scale formulation and the initial sentence are intended to prevent the students' overestimation of their competences and tendencies towards socially desired response behaviour (see Gröschner et al., 2013, p. 81). In order to examine the development of the participants' competence self-assessment during the preparatory course (research question [Q1]) and during the block internship (research question [Q2]), the results from the questionnaires of the survey are used at points in time T1 vs. T2 and T2 vs. T3 respectively. The central tendencies of the two pairs of data sets were examined using Wilcoxon sign rank tests.

Sample

The sample consists of N = 39 students from courses in the summer semester 2023, winter semester 2023/2024, summer semester 2024 and winter semester 2024/2025; complete data was available from 32 participants (82% cohort utilization). The course participants were on average M = 24,13 (SD = 1,87) years old. The age ranges from 22 to 30 years. The reduced sample includes 24 males, 7 female and one with diverse gender. All of them are enrolled in the course of study for a teaching degree at grammar schools.

Results

Table 1 shows the median values (M) and interquartile ranges (IQR) of the students' competence self-assessments in the four areas "teaching", "educating", "assessing" and "innovating" at the three survey times. Cronbach's α was determined to examine the internal consistency of the scales. For the areas "teaching", "educating" and "assessing" the competence self-assessment increase is significant ($p < 0{,}001$) in between timepoints T1 and T2 with median increases of 1. Between timepoints T2 and T3 only the area of 'teaching' shows a significant increase in competence ($p < 0{,}01$).

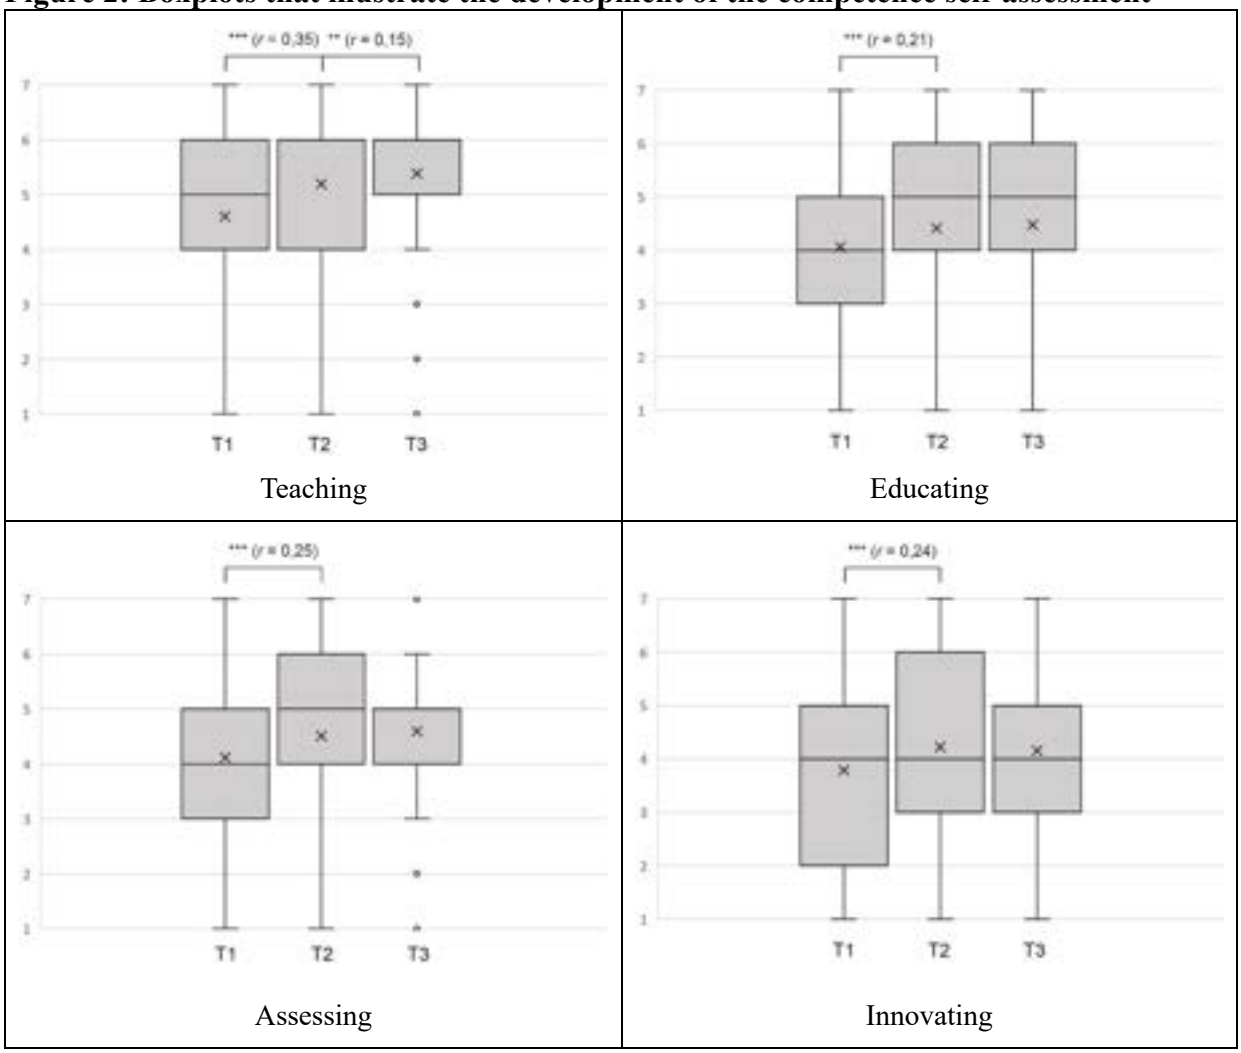


Figure 2 shows the distributions of the students' responses as box plots. The increase in self-assessments of competence between the time points T1 and T2 and the stagnation or decline

between the time points T2 and T3 can clearly be seen. The determination of the effect sizes shows small effects for all areas between the time points T1 and T2 (Pearson's r [0.21; 0.35]) and also a small effect for the 'Teaching' area between the time points T2 and T3 (r = 0.15).

		T1		T2		T3	
Scale	Items	*α*	*M (IQR)*	*α*	*M (IQR)*	*α*	*M (IQR)*
Teaching	11	0,82	5 (2)	0,85	6 (2)	0,86	6 (1)
Educating	9	0,76	4 (2)	0,89	5 (2)	0,81	5 (2)
Assessing	7	0,74	4 (2)	0,85	5 (2)	0,82	5 (1)
Innovating	6	0,81	4 (2,5)	0,78	4 (3)	0,87	4 (2)

Figure 2: Boxplots that illustrate the development of the competence self-assessment

Discussion

Testing innovative concepts is of great importance for research in university teaching. The iterative and student-led approach of Scrum is a very innovative concept. It is therefore an important finding that this concept led to significant increases in the students' competence self-assessment in three of the four scales analysed during the preparatory course. This was to be expected, as the students experience themselves as very effective when working in small teams and generally receive a lot of praise and constructive feedback in the regular reviews. Due to the high frequency of the work loops, they also experience a rapid improvement in their lesson planning. This apparently also leads to an increase in self-perceived competence. It is interesting that the increase in competence self-assessment does not only refer to the area of *"teaching"*,

which is particularly addressed in the preparatory course, but is apparently also transferred to the areas of *"educating"* and *"assessing"*. It is unexpected that the preparatory seminar on the Scrum methodology does not have a significant impact on "innovation", as this methodology places particular emphasis on regular introspection and reflection with the aim of optimisation.

The stagnation or decline in the self-assessment of competences during the practical phase following the preparatory course is noteworthy. Here, the students are no longer in the familiar surroundings of their teams and the academic environment but have to implement their lesson plans into the reality of the school. They learn that not every lesson plan that is promising in theory will prove successful in everyday school life. This experience obviously manifests itself in a decline in self-assessment of competence. In this context, it is interesting to note that Gröschner et al. (2013), who developed the questionnaire used here to investigate the self-assessment of competences during a practical semester, came to different conclusions. There, the self-assessment of competence increases with the degree of perceived learning support during the practical phase. The practical phase described here does not extend over an entire semester, but only over a period of five weeks. For organisational reasons, it is also only possible to visit the students once during this time. It can be assumed that the learning support is therefore perceived as rather low. There is clear potential for improvement in this regard, particularly with respect to the duration of the practical phase. Empirical studies, such as those by Gröscher et al., demonstrate that an extended practical semester can be highly effective when accompanied by structured and high-quality supervision. In the study presented here, lesson plans were regularly reviewed and refined through systematic, collaborative critique within the preparatory seminar. Extending this iterative process into the practical phase would allow for continuous further development of instructional design. Such sustained optimisation of teaching practice is likely not only to enhance instructional quality but also to positively influence students' self-perceived teaching competence.

Introduction

The papers gathered in strand 16 address one of the central challenges currently facing science education: how to support teachers' professional learning in a period marked simultaneously by ecological urgency, rapid digital transformation, and growing demands for more equitable, interdisciplinary and socially relevant science education. The ESERA 2025 conference themes of sustainability and digital advances are therefore not peripheral to this collection; they form a central axis around which many of the contributions are organised. Sustainability is approached not only as scientific content to be taught, but also as a multidimensional educational orientation involving values, systems thinking, future-oriented reasoning, responsible action, nature connectedness and socio-environmental engagement. Digital advances, in turn, are considered not merely as tools to be adopted, but as developments that reshape the conditions, practices and purposes of science teaching, raising questions of teacher competence, professional identity, equity, accessibility, ethical use, pedagogical quality and institutional support.

The strand "In-service Science Teacher Education and Professional Development" focuses on the continuing professional learning of science teachers and science teacher educators across different educational levels, institutional settings and national contexts. It encompasses in-service teacher education programmes and policies, teachers as lifelong learners, professional development models, innovation and reform in science teaching, reflective practice, teachers as researchers, lesson study, action research, professional learning communities, and the evaluation of professional development practices. At its core, the strand is concerned with how teachers learn, how they transform their knowledge, beliefs, practices and identities, and how professional development can be designed so that it is meaningful, sustainable and connected to the realities of classrooms, schools and wider educational systems.

Taken together, the contributions show a field that is moving beyond short, decontextualised training events towards richer, more situated forms of professional learning. Across the papers, professional development is frequently conceptualised as collaborative, inquiry-oriented, design-based and practice-embedded. Teachers are positioned not simply as recipients of expert knowledge, but as active interpreters, designers, facilitators, reflective practitioners and co-constructors of innovation. This is visible in studies centred on lesson study, professional learning communities, design-based research, co-design, out-of-school laboratories, teacher learning communities, classroom implementation cycles and reflective inquiry. The emphasis falls on the dynamic relationship between professional development design and teachers' actual possibilities for action in specific school, curricular, technological and cultural contexts.

Several major thematic clusters emerge across the strand. One concerns sustainability and socio-environmental education, including professional development for sustainability competences, climate-change education, nature connection, aesthetic engagement with the natural world, and interdisciplinary STEM or STEAM approaches to complex real-world problems. A second cluster addresses digitalisation and emerging technologies, including ICT-related professional

development, interactive experimental videos, adaptive gamification, artificial intelligence and ChatGPT-supported teacher learning, digital inequalities, and the use of digital tools in laboratory and inquiry contexts. A third cluster focuses on teacher knowledge, beliefs, self-efficacy, professional identity and competencies, showing how professional learning involves cognitive, affective, epistemic and practical dimensions. A fourth cluster examines organisational and systemic conditions for sustainable professional development, including transfer pathways, scaling-up, professional learning networks, institutional routines, resources, time, leadership, policy support and cross-institutional collaboration.

The most prevalent trend across the papers is the search for professional development models that are both pedagogically ambitious and practically viable. Many contributions recognise that teachers are expected to address complex and rapidly changing demands, but often do so under constraints of time, resources, curriculum structure, assessment regimes and uneven institutional support. Consequently, the question is no longer only what teachers need to learn, but how professional learning opportunities can be organised so that they are coherent, sustained, context-sensitive and capable of supporting actual classroom change. Another strong trend is the integration of content, pedagogy and technology, particularly through approaches aligned with TPACK and related frameworks. Digital innovation is treated as productive when it is connected to disciplinary learning, inquiry, experimentation, feedback, inclusion and student agency, rather than when it is used as an isolated technical add-on.

A further trend is the broadening of science teacher professional development towards interdisciplinarity and societal relevance. Integrated STEM and STEAM, sustainability education, climate education and real-world problem solving require teachers to cross disciplinary boundaries, work collaboratively, tolerate uncertainty and develop new professional identities. The papers also reveal a growing concern with equity and accessibility: digital inequalities, inclusive STEAM environments, access to technological infrastructure, and the need to avoid reinforcing existing divides all appear as important issues. Finally, there is a clear methodological tendency towards research designs that make professional learning processes visible, including qualitative case studies, mixed-methods evaluations, systematic reviews, design-based research, lesson study analysis, reflective journals, observations, interviews, surveys and studies linking teacher learning to student outcomes.

Within the wider field of science education research, this set of papers contributes to a more complex understanding of teacher professional development as a systemic, relational and transformative process. It reinforces the idea that improving science education depends not only on producing new curricula, technologies or resources, but on understanding the conditions under which teachers appropriate, adapt, question and sustain innovation. The strand also strengthens the connection between science teacher education research and current educational challenges: preparing learners for sustainability, supporting scientifically informed action, responding critically to digital transformation, and developing inclusive, practice-based and evidence-informed forms of professional learning. In this sense, the collection illustrates a mature and evolving field, attentive both to the micro-processes of teacher learning and to the broader institutional, technological and societal conditions that shape science education today.

Digital Inequalities In The Context Of Teaching And Learning Of Science And Technology In Secondary School

Diane Gauthier[1], Marie Alexandre[2], Annie Côté[3] and Séverine Parent[2]
[1]Université du Québec à Chicoutimi, Canada,
[2]Université du Québec à Rimouski, Canada
[3]Cégep de Rivière-du-Loup, Canada

In Quebec, since the implementation of the Education Reform, the teaching and learning of science and technology (S&T) at the secondary level has raised several questions. Initially, developing the interdisciplinary component proved challenging, and adolescents' motivation towards this pairing of disciplines, despite concrete focus, has not improved. Additionally, the place of digital technology in the classroom can no longer be ignored, as digital inequalities negatively impact S&T teaching and learning. Furthermore, access to digital technology varies significantly between educational institutions.

In 2015, the Organisation for Economic Co-operation and Development came out in favor of access to digital technology in the school environment. Digital inequalities are then considered a complex problem arising from an authentic situation in the school environment, mobilizing different resources in an imperfectly predictable and difficult to break down function.

To describe the problem of digital inequalities in the school environment, a research initiative involving university researchers and school stakeholders was realised between 2022 and 2024. Led by a facilitator, a group was mobilized to address the problem of digital inequalities. This article explores the meeting dynamics (5 meetings) and the facilitator's role (convene, observe, reflect, act and harvest) in solution co-creation.

The facilitation role can be effectively undertaken by science teachers, enabling them to bridge digital gaps and enhance the teaching of science to secondary school students. This approach empowers educators to integrate interdisciplinary and technological elements into their pedagogy more effectively.

Keywords: Facilitation, U theory, digital inequalities

Introduction

The purpose of this text is to identify and describe the role of facilitator agents in the context of the activities of a co-creation group that is inspired by design thinking and is part of a living laboratory. Thus, participants from various fields, occupying different professional functions and expressing sometimes divergent opinions participate in the co-development of solutions to counter digital inequalities in science and technology (S&T) courses at the secondary level (12 to 17 years old). The approach used by the facilitator agent to support the participants and allow the expression of their perceptions of the situation is design thinking. One of the main challenges of the function of facilitator agents, during these meetings of the co-creation group lies in the ability to listen and be open to the expression of divergent opinions. The challenge of facilitating these meetings is to create an environment of trust and respect that encourages participants to express their thoughts and propose solutions that could produce tangible societal repercussions on digital inequalities in the school environment. During the meetings held, in person and remotely, a facilitator led the group's discussions. The role of this person proved to be important, which led the research team associated with the project to take an interest in their actions and posture. It is by taking these conditions into account that the team of researchers decided to look at the professional action of its facilitator agents to describe and validate their potential for the

co-development of solutions. A question also raises the interest of researchers: What is the role of facilitator agents in a co-creation group of a living laboratory in education? The general objective of the project is to establish a living laboratory for innovation in education (LaVIE) in order to co-create, with stakeholders and users, innovative solutions that promote the adaptation of educational and pedagogical practices to combat educational and digital inequalities exacerbated by the pandemic.

Indeed, although digital inequalities in the school context are recognized and manifest in the manner in which courses are delivered and learning is generated, particularly in S&T teaching where the abstract side of concepts is often dominant, the complexity of the situation precludes a single, simple solution to this problem. That is, the problem is one with no possible definitive resolution (Rittel and Webber, 1973).

Conceptual Framework

According to Stewart and Sampsa (2008), facilitation is defined as the provision of opportunities for various actors affected by a social problem. For them, these opportunities include the provision of information, the establishment of connections, and the allocation of resources. The purpose of these opportunities is to enable these actors to identify and implement remedies for the social problem. Johnson (2018) adds to this definition that the facilitator is a person whose responsibility in research is to help teams conduct and learn innovation work from ongoing projects, without however directing or managing the work themselves.

Facilitation emerged in the early 1960s in the United States. During this decade, there were major debates against the Vietnam War, racism and poverty (Gauthier, Bibaud & Roy-Baillargeon, 2011). Twenty years later, it is mainly returning in the environmental protection and sustainable development awareness movements (Doelle & Sinclair 2006). In this context, facilitation responds to a need for modifications and accommodations of social objectives.

"The term facilitation can be approached in two ways: either interchangeably with the notions of mediation, conciliation and consultation or comparatively with mediation and negotiation." (Gauthier et al., 2011) Facilitation is oriented towards prevention where the discussion methods are fair and open. It contributes through its logistics to the proper conduct of meetings. It promotes active listening and the identification of opportunities for consensus between participants (Dorcey and McDaniels, 2001). Through public debate, it helps to raise awareness among participants so that they can increase their involvement and better coordinate their actions with their community (Thomassian, 2009).

An important part of the facilitators' task is to guide participants toward an agreement by creating a climate of trust and transparency that is conducive to verbalizing needs, sharing information, and analysing all proposed options in order to identify and develop an integrated, equitable, and sustainable solution to the problem under study (Beuret 2006; Milburn 2006). The interactive dimension of facilitation involves seeking an agreement. It is directed toward transforming the conflict by establishing a dialogue between project participants. The interactive dimension also leads them to change their perceptions of the situation and develop an openness to negotiation. Facilitation thus contributes to improving collective understanding of the issues, empowering the parties, and managing emotions (de Carlo 2004a). Balancing emotions is achieved by setting limits on interactions between participants. Facilitation thus generates avenues for compromise or solutions on the relevance of the project in order to facilitate integration into its environment. Therefore, facilitation through its function with participants is oriented towards i) collective decision-making (de Carlo 2004a and 2004b; Kaufman 2009), ii) the ability to prevent conflicts, iii) the social acceptability of projects (Karjalainen & Järvikoski 2010; Peltonen & Sairinen 2010,

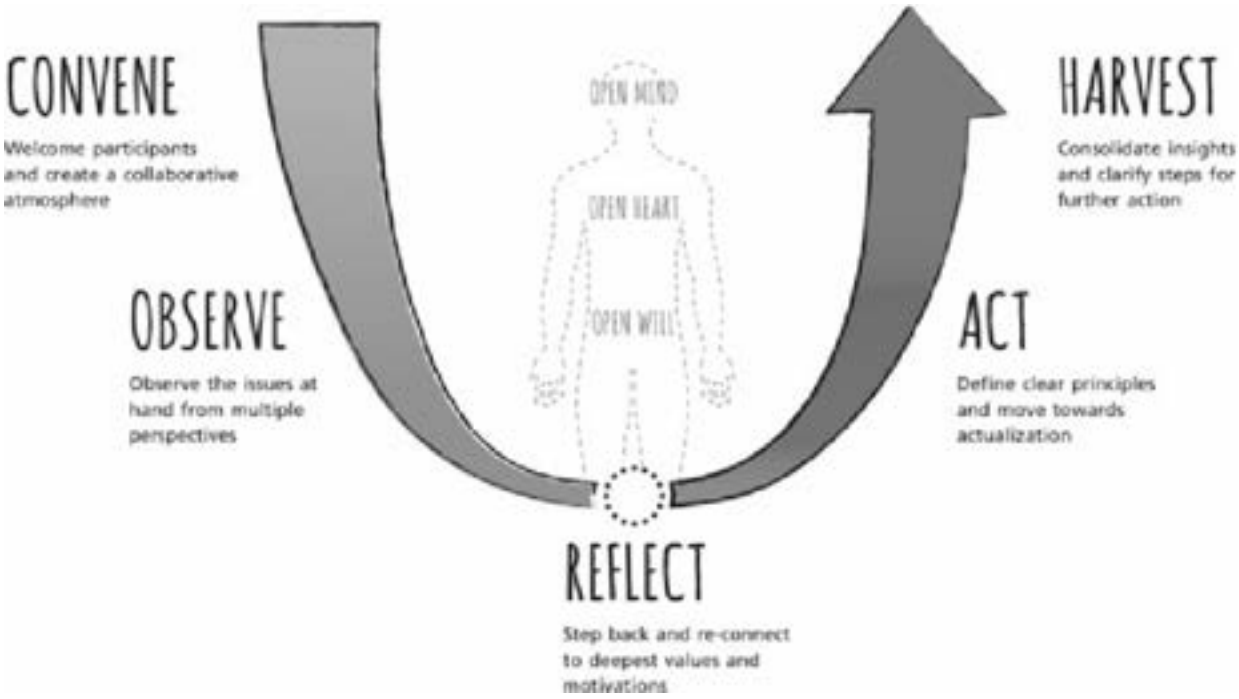
and iv) the manifestation of collective intelligence and social cohesion (Fortin, 2009; Kaufman 2009). In addition, being a facilitator agent implies understanding a problem in order to determine its limits and constraints (Glen, Suciu & Baughn 2014). This is manifested by the ability to frame and reframe the problematic situation from different angles, from microscopic and macroscopic levels, and this, at all stages of the targeted project. Framing is linked to the development of critical thinking. It consists of undoing the unconscious biases generated by life experiences, appropriating systems of thought, understanding the main ideas which guide the choices and opinions of the participants.

The objective of the meetings was twofold: first, to assist educational stakeholders and participants in comprehending the issue of digital inequalities in the school environment, with a particular focus on science and technology education, and second, to facilitate the conception and evaluation of innovative solutions.. The support or action of educational stakeholders in the face of digital inequalities constitutes a lever. Facilitators also prevent situations of tension by promoting interaction between the different stakeholders so that they produce common solutions while having initially expressed divergent interests and opinions (Dorcey and McDaniels 2001; de Carlo (2004a); Pereira, Drimie, Zgambo & Biggs (2020)) the primary responsibility of the facilitator lies in their ability to adequately interpret the meaning of the words of the different stakeholders so that it is understood by all and used as a basis in the development of a new social message.

Duhigg (2024) mentions that when a discussion group feels positively guided and respected by a facilitator, few participants are aware of the real influence it has on the evolution of their thinking and their membership in the group. The facilitator then plays an essential role in sharing thoughts and in the evolution of opinions on the situation of digital inequalities.

Design Thinking

Design thinking, centred on the human, requires taking a step back from actions in order to ensure an optimal understanding of the problem to be addressed by the participants, before focusing on the solutions to be explored. In addition, this approach implies, in its implementation, that the shared reflections take into account the experience of the participants. For Brown & Wyatt (2010) a research project conducted according to the design thinking approach is made up of several stages where each is linked to an objective, results and diagrams. Furthermore, these stages do not necessarily occur successively; they can coexist in their implementation.



The design thinking model, as used for the project, is made up of two phases and six stages. The phases represent the problem space and the solution space. The steps in the problem space phase, for their part, require defining the problem, understanding it by consulting the people who experience and know it, and then, if necessary, redefining it more precisely. The subsequent step in the process is to envision multiple solutions, prototype them, make them tangible, and test them with the intended users. This method is called collaborative because all participants must be involved in the process.

Methodology

The authors Pearson et al. (2018) and Scharmer (2016, 2009) proposed a modelling of the change process through reflection and sharing of perceptions. The goal of this model is to present an evolving sequence of meetings (in workshops) in order to lead participants to design a common solution to improve a situation that has become socially difficult. Called the U theory, this model is used as a co-design tool. It is easy to understand for the facilitators and provides essential time for individual reflection followed by sharing. It thus marks the duration of the different stages of

the meetings. According to Pearson (2021), the stability and predictability of this framework contribute to facilitating the engagement of the participants. The U theory explicitly aims to open up spaces of possibilities.

Figure 1. Theory U The Theory U process of co-sensing and co-creating[1].

The application of the Pearson et al. model. (2018) can be summed up in five stages: a) the gathering (convene) where a climate of collaboration is created, b) the observation (observe) of the different facets of the problem to be solved, c) the reflection (reflect) on the values and principles inherent in the problem and the motivation of the actors to modify elements, d) the action (act) redefine the principles retained and update e) the harvest (harvest) clarification and consolidation of the possible stages to be put in place.

To analyse the meetings held between 2022 and 2024, based on these stages, their content was transcribed in verbatim form. A sequenced thematic analysis was applied to part of the verbatims (4 pages of verbatim from the first meeting) by the authors of the text. After this exercise conducted independently, an inter-judge validation meeting was held to consolidate the analysis grid. Subsequently, an author analysed all of the identified verbatims.

The Results

The facilitator's professional actions, including her invitation to engage in the discussion and her openness to diverse opinions, fostered an environment conducive to the expression of individual perspectives while respecting the divergent ideas of others. The quality of her facilitation made it possible to define the constitutive parameters of digital inequalities, information whose nature is linked to the professional status of the different participants and the relationship they have with the use of digital technology.

The U-model appeared operational and can be used as a tool for the expression and analysis of design thinking in the context of the living laboratory. The five stages of the U-model were

[1] Source: Pearson et al. (2018) as adapted from Scharmer (2009) Creative Commons Attribution 4.0 International

manifested. However, nuances must be made, particularly on the succession of stages in an iteration (back and forth) where several stages of the model are likely to manifest themselves during the same meeting. It should be mentioned that the different stages of the model are associated with reflections and the expression of these reflections. In addition, everyone has their own way of creating links between the comments made by the participants and the realities as they perceive them on digital inequalities in the school environment.

The facilitation role can be effectively undertaken by science teachers, enabling them to bridge digital gaps and enhance the teaching of science to secondary school students. This approach empowers educators to integrate interdisciplinary and technological elements into their pedagogy more effectively.

Adaptive Gamification In Primary Science Education: Teacher Implementation

Alkinoos Ioannis Zourmpakis and Michail Kalogiannakis
Department of Special Education, University of Thessaly, Greece

Implementing adaptive gamification in science education, supported by teacher training, is vital to enhance students' engagement and learning. This study examined how teachers trained in a TPASK-based program integrated and utilized an adaptive gamification application in teaching science concepts related to the water cycle with 3rd-grade students. using observational checklists. This study examines the training of teachers regarding the use of an adaptive gamification application, in the teaching of science education concepts in elementary education. The main point of interest was collecting first-hand data on the degree of effective utilization and pedagogical integration of the adaptive gamification environment by in-service teachers. The data were collected through the use of observational checklists based on the TPASK dimensions after the implementation. Results revealed two teacher profiles based on TPASK proficiency and diverse application strategies. The findings highlight the potential of such practices in early and primary education and emphasize the need for teacher training to utilize adaptive learning digital application and ongoing support to address implementation challenges.

Keywords: Adaptive education, Teacher implementation, TPASK framework, motivational aspects, science education

Theoretical Framework

In recent years, due to new challenges and demands, education has been in a process of reconfiguration, especially after the coronavirus period (Shehaj, 2022). In general, the role of the teacher has changed over the years, as the teacher is now expected to provide strategic support to students to help them become self-directed learners (UNESCO, 2008). However, this requires the redefinition of teachers' professional skills (Torrance & Forde, 2017) and the enhancement of their training to enable and facilitate the development of essential skills such as collaboration, critical thinking, problem-solving, scientific and digital literacy in today's world (Dede, 2010; Torrance & Forde, 2017). Enabling students to acquire modern skills such as scientific and digital literacy requires teachers to use and/or create appropriate classroom scenarios that inspire, motivate, and engage students in learning (Mee et al., 2020). One of the current trends that is attracting the interest and attention of teachers and students alike is that of gamification (Statti & Torres, 2020).

Several researchers have focused on applying gamification in science education due to its familiarity with students (Kalogiannakis et al., 2021). Additionally, it can facilitate the development of scientific thinking (Tsai, 2018), and it is compatible with scientific theories, methods, and learning strategies related to the teaching of science concepts (Tsai, 2018). Providing motivation and enjoyment is not common to all people, so there is a need to understand the characteristics and techniques responsible, taking into account the different needs, values, and interests of each individual (Böckle et al., 2017). Adaptive gamification, i.e. the adaptation of different gaming mechanisms and features based on each learner's actions, preferences, and characteristics, is a rapidly developing method that enhances the traditional gamification approach (Klock et al., 2020). Inherently, it is a more personalized, learner-centred method of teaching, using a specific set of elements that respond to the characteristics of each learner.

However, although teachers recognize the value of technology, they often fail to use it as a learning tool (UNESCO, 2017). Therefore, in order for teachers to be able to effectively integrate ICT in education in the context of new pedagogical changes, they should be exposed to new models and trained to apply them (Zourmpakis et al., 2022).

Furthermore, a training program following the Technological Pedagogical Science Knowledge (TPASK) model as a design framework (Jimoyiannis, 2010) has been developed to train teachers to effectively teach science concepts using an adaptive gamification environment in authentic classroom settings. The present study aims to investigate the extent to which practicing teachers use adaptive gamification environments to teach science relating to the water cycle, following their participation in a training program designed according to the TPASK model.

Consequently, after the in-service teachers conducted the instructional implementation and analysed the observational checklists and motivational questionnaires of the students, we will respond to the following research question:

RQ: What is the degree of effective utilization and pedagogical integration of adaptive gamification environments in science teaching by practicing teachers?

The Adaptive Gamification Application: “The Water Cycle”

For the needs of this study, the adaptive gamification application “The Water Cycle” was created. This open-world role-play simulation was built with the Unity3D engine. The theoretical framework that the application was based was Self-Determination Theory (SDT) and Marczewski’s Hexad typology, allowing dynamic tailoring game elements and mechanics to each student’s needs and motivational priorities. More specifically, upon entry, students complete a 24-item questionnaire to identify their dominant player type (e.g., Philanthropist, Achiever, Socializer) but also their two more adjacent ones. Based on this profile, the system configures the game environment by activating specific game mechanics that align with the user's main type, while also incorporating elements from their two adjacent types traits to ensure a balanced experience (Zourmpakis et al., 2023).

The application further personalized the educational process by integrating two distinct pedagogical strategies: Problem-Based Learning (PBL) and Inquiry-Based Learning (IBL). The PBL approach focused more on narrative driven mystery where students act as detective assistants. On the other hand, IBL positions them as university research assistants focused on structured experimentation, limiting the story side. To maintain engagement, a continuous adaptation mechanism monitors student progress and feedback through in-game dialogues, in order to adjust difficulty and provide real-time scaffolding if necessary, ensuring the learning curve remains appropriate for each user.

Methods & Context

The main interest of this study was to investigate how teachers will integrate and utilize the adaptive gamification application after completing a professional training program based on the TPASK methodology.

This study was conducted in a Mediterranean country in southwestern Europe. Data were collected using observation checklists by the researcher. The educational application included 5 teaching hours, one to prepare the students to use the application and one for each of the 4 scientific concepts taught, coagulation, melting, evaporation, and boiling. Overall, 6 in-service elementary 3rd grade teachers participated in this study. The implementation took place in their school's computer labs. Data were collected using observation checklists by the researcher. An observation checklist was completed for each teaching session. The researcher was present during

these sessions to observe, fill the observation checklist and provide technical support only when strictly necessary (e.g., if students found "bugs" or ways to break the game boundaries), ensuring the teachers remained the primary facilitators. The observation checklists were analysed qualitatively. Additionally, this research followed all formal national and international rules for ethics in research, including obtaining written consent from parents and from students.

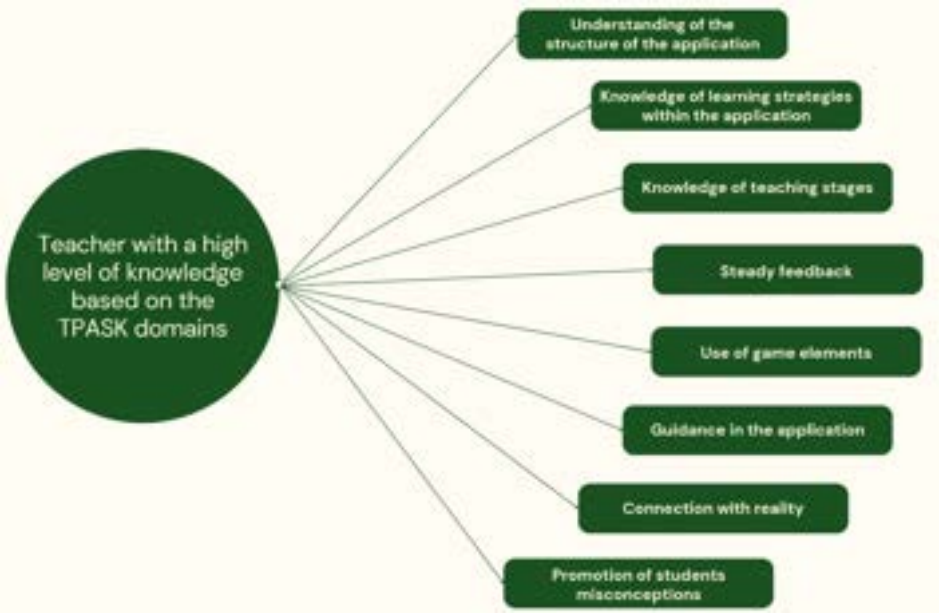
Albeit the small sample of teachers, we followed a semi-experimental design with a convenience sample, following a robust ethical protocol through the following:

(a) observational checklists were checked by external researchers to verify clarity and connection to the TPASK model

(b) to ensure the validity of this study, all data could be accessed and reviewed by external researchers

(c) data were analysed through the use of ATLAS.ti software.

This approach allowed for first-hand data collection where teachers' interaction with students occurred naturally, as opposed to relying on secondary reports that could be obtained through interviews. The process involved completing an observation method which involved having a comprehensive checklist with detailed explanations in each TPASK domain, providing a thorough description of each teaching case. In addition, increasing student motivation is the direct purpose of gamification. Thus, it was deemed necessary also to measure student motivation in order to be able to ascertain whether the practical application is influenced by student motivation.



Findings

Based on our findings two main categories of teachers were identified. The primary criterion for this categorization was the actual utilization of the application during teaching, as the effective pedagogical integration of technology is the ultimate goal of the TPASK framework.

The first type, which consisted of half the sample size, appeared to have considerable knowledge of the application. applied appropriate teaching strategies, and incorporated game elements to enhance student motivation. To be more specific, these teachers demonstrated a comprehensive understanding of the structure of the application and were well-prepared, possessing specific knowledge of the learning strategies embedded within the software and how to identify them. They applied appropriate teaching strategies and knew the specific teaching stages required to help students at every step. Moreover, they were distinguished by their ability to relate the application to reality and to support students' conceptual understanding by highlighting alternative conceptions and guiding them toward conceptual change. An important factor of their teaching was their provision of steady feedback during experiments and review discussions. Furthermore, they consistently incorporated game elements and mechanics to enhance student motivation and engagement.

However, their performance was not high from the start, as almost all had some initial difficulties in the first lesson implementation, but showed gradual improvement, especially in areas such as guidance within the application and the integration of gamified elements. Also, even though they showed high levels of TPASK knowledge, they faced some difficulties with technical issues that came up during the lesson implementation in all lessons.

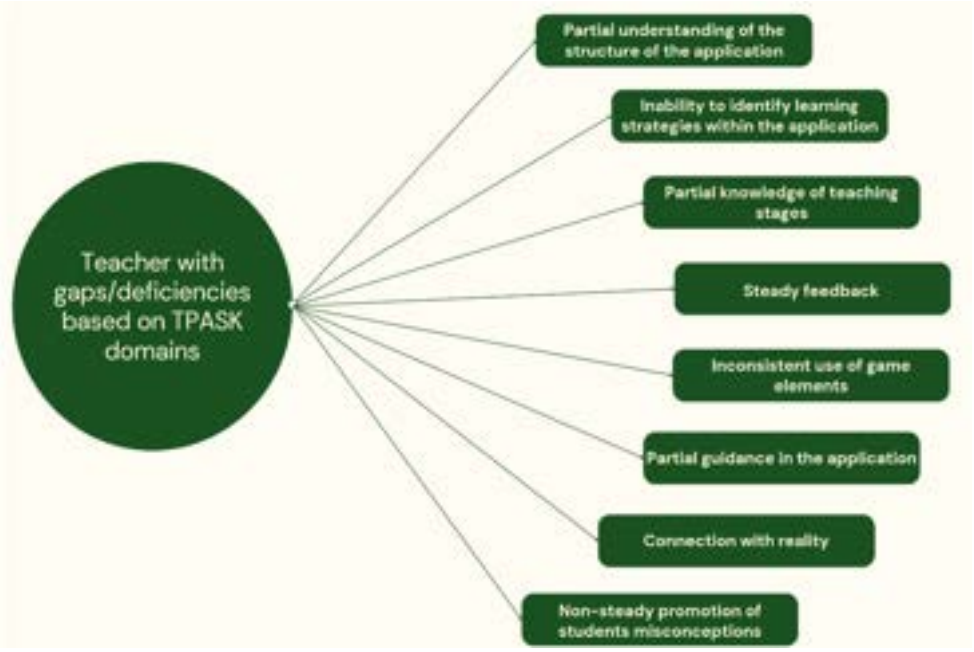


Figure 1. The specific characteristics of type 1: Teacher with a high level of knowledge based on the TPASK domains.

The second type included the rest of the sample size and showed deficiencies in the preparation and use of the app, as well as in the management of learning strategies. This group was characterized by a partial understanding of the application's structure and a lack of full integration of the scientific inquiry process through the digital tool.

In particular, although they made an effort to support students, they exhibited an inability to identify specific learning strategies within the application and had only partial knowledge of the necessary teaching stages. They struggled with linking technological knowledge with pedagogical and scientific knowledge, resulting in a failure to consistently integrate experiments and game elements into the educational process. Despite these gaps, they did attempt to provide steady feedback to students during the explanation of phenomena. However, their promotion of student misconceptions and reflection was non-steady and inconsistent. They also had similar problems in solving technical issues and reported more significant concerns regarding time constraints and classroom management.

Figure 2. The specific characteristics of type 2: Teacher with gap/deficiencies based on TPASK domains.

Importance

The findings of this study, though they can't be generalized due to the small sample, show the importance of training teachers in the use of adaptive gamification environments through specialized professional development programs based on the TPACK framework, particularly adapted for teaching science education (TPASK) and applying it practice. Additionally, based on students' engagement during the implementation, of it can be suggested that applying adaptive gamification environments in teaching can have a positive impact on students' motivation, even in cases where the teacher shows deficiencies regarding implementation. This could become clearer later with the analysis of the students' motivational questionnaire and teachers interviews in a later stage. Integrating technologies into education through TPASK requires balanced knowledge and skills development, with a focus on practical application and reducing the complexity of tools (Rochintaniawati et al., 2018).

Taking into account the role of the teacher in the learning process and their impact on students' learning experiences, especially when integrating technological tools into teaching (Kalogiannakis et al., 2021), it is important to design and provide appropriate training programs for current and future teachers. Based on the differentiations found from the utilization of classroom instruction (teacher types), we propose the creation of education/training programs where teachers' training is tailored based on their specific characteristics and needs. Additionally, the advantages of adaptive environments are not limited to primary and secondary education.

In addition, we propose the use of methodologies that are specialized both in the content of teaching and in the integration of technologies in teaching. By its nature, TPACK requires pedagogical methods and technologies tailored to specific topics (Voogt et al., 2013). Each subject has specific characteristics (e.g. learning strategies), which are sometimes specific to that subject (Jimoyiannis, 2010). Also, each technological tool has different capabilities and weaknesses. Treating technological tools in a generic way may result in not offering appropriate guidelines to improve teachers' professional development based on their abilities and weaknesses (Hsu et al., 2015). Creating a personalized learning system driven by the TPACK methodology would facilitate teachers' professional development (Chaipidech et al., 2022), while combining it with gamification could enhance their motivation and engagement.

ESERA 2025 Copenhagen

Developing Sustainable Professionalization Programs For STEM Teachers By Systematically Reflecting On Transfer Pathways

Silke Rönnebeck[1,2], Andrea Bernholt[1,2], Carolin Flerlage[1], Stefanie Lenzer[1,4], Torben Bennink[3] and Marc Reid[1,2,4]
[1]IPN Leibniz-Institute for Science and Mathematics Education, Germany,
[2]Institute for Quality Development in Schools Schleswig-Holstein, Germany,
[3]University of Potsdam, Germany,
[4]Kiel University, Germany

Digitalization offers great potential for teaching and learning. To unfold this potential and support pre- and in-service teachers as well as students in schools to develop the competences needed for teaching and learning in a culture shaped by the digital transformation, a statewide program was initiated in the German federal state of Schleswig-Holstein. The program aims at developing and implementing innovative support structures on a personal, material and systemic level, thus addressing multiple target groups with the ultimate goal to implement the program at scale throughout the state. With its long-term orientation, its integration of all phases of teacher education and its approach to institutionalize the collaboration between the different institutions involved in teacher education, the program offers unique opportunities to systematically investigate transfer processes. Research in this field shows that enabling successful transfer is challenging - and often fails - because of the complex nature of factors influencing it. This paper will present findings from a systematic analysis of transfer pathways within the program based on a process model that accounts for the complexity of the program, conditions and interactions, using STEM subjects as an example. It will show the models' potential for the monitoring and synoptic reflection of transfer processes in large-scale intervention programs that can not only feed back into the program but may contribute to a better understanding of transfer in education in general.

Keywords: transfer processes, digitalization, teacher professionalization

Introduction And Background

Today's personal, social, and professional lives are shaped by digitalization (Stalder, 2016). Living in a culture of digital transformation is also affecting teaching and learning in many ways. Digital media have the potential to support teaching and learning processes and promote the acquisition of subject-specific and interdisciplinary competences and skills. At the same time, however, if you look e.g. at the opportunities arising from the use of artificial intelligence (AI) and big data, the subjects and disciplines themselves are changing as a result of increasing digitalization. From the perspective of important cross-cutting issues such as inclusion, heterogeneity and differentiation, or assessment, digital media enable new approaches of support for and design of learning processes. They pose, however, also challenges with generative AI being a prominent example: It opens up new possibilities for individual, formative support through intelligent tutoring and automated feedback systems, but at the same time poses challenges for traditional learning and examination formats. Moreover, thinking e.g. of fake news, it brings new aspects into traditional classroom instruction that need to be addressed. Ultimately, living in a culture of digital transformation requires digital and media-related skills, the acquisition of which is a cross-cutting task to which all subjects and disciplines must contribute (Redecker, 2017). Consequently, digital transformation also requires innovative formats for education and the way that we teach and learn. This does not only include the content or formats but also the conditions and actors that shape educational (systems).

However, across countries and educational systems, it can be observed that sustainably bringing educational innovations into practice is a widespread challenge leading to a limited impact of educational research on schools and teaching practice (e.g., Penuel et al., 2020). Research in this area faces the additional challenge that the process of "bringing into practice" incorporates not only different phases ranging from the development of an innovation, to its implementation, dissemination, and scaling-up, but also different concepts such as e.g. research-practice partnerships or teacher professionalization (e.g., Schrader et al., 2020). However, throughout different research fields these aspects and concepts are not consistently defined (e.g., implementation processes, innovations in school, school improvement, knowledge transfer) and sometimes used synonymously. In the last years, in the German-speaking literature, most of these aspects and research fields are summarized under the term transfer (e.g., Schrader et al., 2020). Therefore, in this contribution, we try to unify these existing aspects and constructs and define the interplay of development, implementation, and scaling-up as transfer processes.

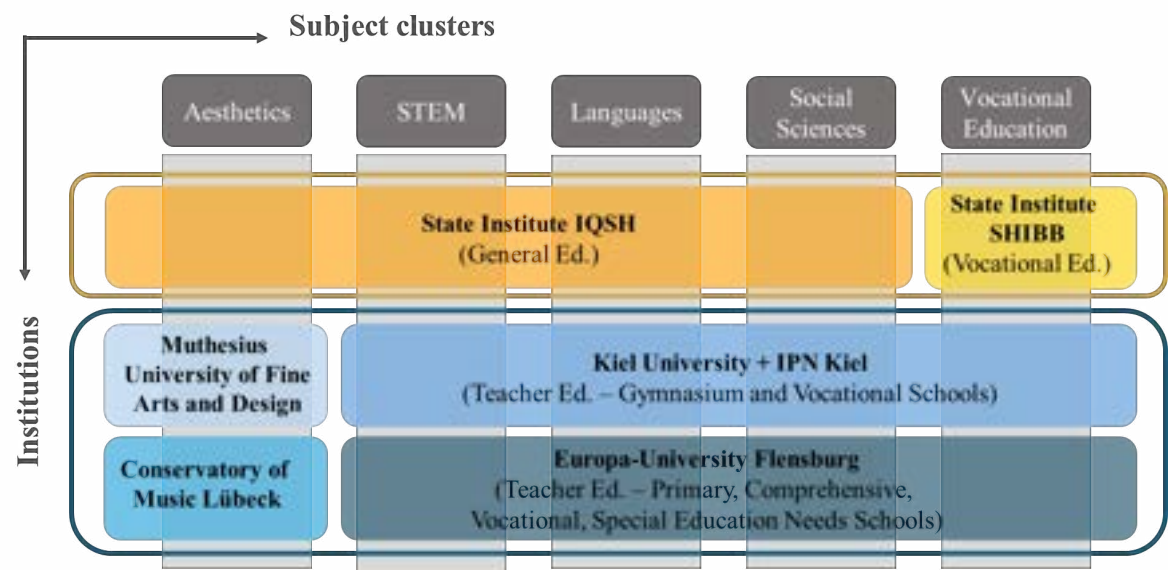
Due to the great importance of transfer processes for the transformation of education, research in this area has increased over the last years. In a review study, Schrader and colleagues (2020) investigated factors supporting or hindering such transfer processes with a specific focus on the implementation phase. In total, they found 194 factors that are either related to the intervention itself (e.g., quality of material, fit to existing curricula) or the social environment of the learners (e.g., support, acceptance) as well as to institutional and organizational (e.g., autonomy, support, cooperation) or personal conditions (e.g., beliefs, self-efficacy). In their research, the authors used a utilization of learning opportunities model that allows not only for looking at different levels of context factors but also for taking the role of the target group as the ultimate user of transfer endeavors into account – a perspective often neglected in existing transfer models. One reason for this might be that for a long time a unidirectional understanding of transfer – with research being the provider and practice being the recipient – prevailed (e.g., Penuel et al., 2021; Tseng, 2012). More recent approaches, however, advocate for understanding transfer as bi-directional or co-constructive processes in which actors from research and practice bring in their respective expertise and collaboratively work together to enable educational transformation (Farley-Ripple et al., 2018; Penuel et al., 2021). Investigations in this field, however, are still scarce which might be due to a lack of models allowing to investigate this kind of transfer processes.

The growing importance of transfer within educational research is also reflected in educational policy and practice. Over the last years, a number of projects that explicitly aim at supporting transfer processes (in Germany e.g. the project lernen:digital[2]) have been funded. However, these projects often face the challenge that they are of limited duration. The successful transfer of innovations, though, requires longer time spans due its complexity but also a certain inertia of educational systems (e.g. Otto, Bieber, & Heinrich, 2019).

In this contribution, we present an investigation of bi-directional and co-constructive transfer processes in a long-term, statewide program aiming at the sustainable professionalization of teachers for teaching and learning in a culture shaped by the digital transformation. The findings from this investigation can make an important contribution to the development of sustainable programs for the transformation of education.

A Statewide Program For Fostering Digital Competences As A Context For Investigating Transfer Processes

As a response to the increasing demand by schools, teachers and teacher educators for support in addressing the challenges of the digital transformation but also harnessing its potential for



[2] https://lernen.digital/

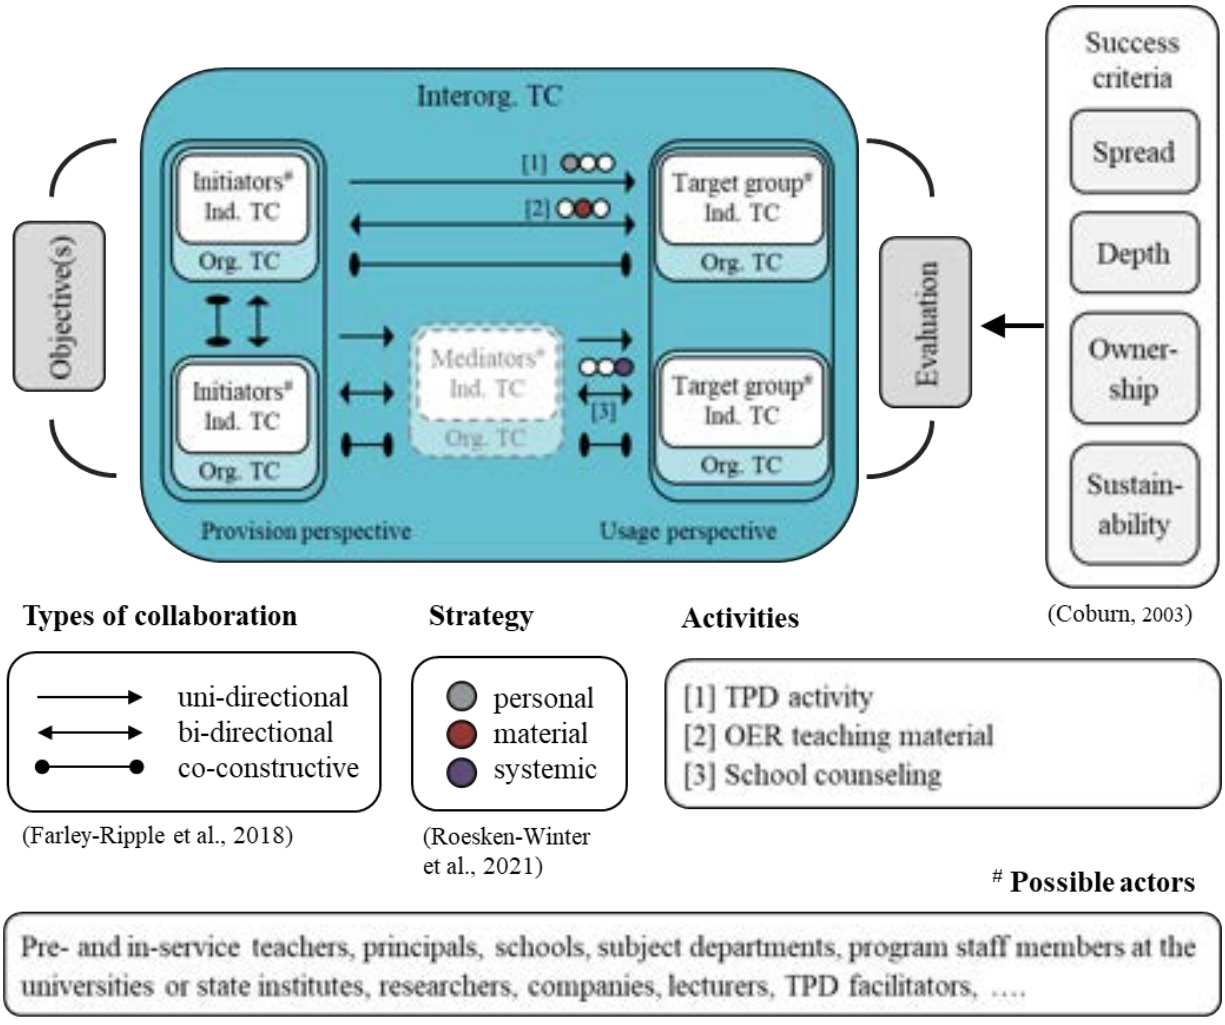
enhancing student learning, a statewide program was established in the German federal state of Schleswig-Holstein. The program *Zukunft Schule im digitalen Zeitalter* (*Future School in the digital age*) aims at sustainably promoting the competence development of students and pre- and in-service teachers through a future-oriented approach to the potentials and challenges of an increasingly digitalized living and working environment. For addressing these aims, it

- … is conceptualized as a long-term, permanent support and intervention project,
- … addresses all subjects and all phases of teacher education (university/phase 1, teacher training/phase 2 ("Vorbereitungsdienst (VD)"), TPD/phase 3) and, ultimately, the competences of students, and
- … brings together all institutions involved in teacher education, namely the four universities offering teacher education programs in Schleswig-Holstein, the IPN Leibniz-Institute for Science and Mathematics Education, the two state institutes (for general and vocational education) responsible for VD and TPD and the Schleswig-Holstein Ministry of Education.

The program focuses on fostering general digital competences (such as media and technological competences) as well as subject-specific (e.g., the potential of microcontrollers in science education) and transdisciplinary competences (e.g., education for sustainable development). This is reflected in its organizational structure that builds upon two pillars. The media competence pillar consists of four regional media labs and media consultants who offer school counseling and TPD activities regionally in the different state districts. Within the subject cluster pillar, teacher educators at the state institutes (called *Regional Subject Consultants, RSC*) and the universities (called *Educational Engineers, EE*) collaboratively develop and implement support activities for pre- and in-service teachers in five subject clusters, thus bringing together expertise and perspectives from research and practice (see Figure 1).

Figure 1. Research-practice collaboration within the organizational structure of the state program.

Their activities include e.g. university, TPD and self-study courses; school development days; lecture series; exhibitions; digital work shadowing; OER teaching and learning materials or courses for teacher trainers but also supporting curriculum development at schools and universities.



The concept and structure of the state program thus not only address the challenges and opportunities of the digital transformation but explicitly acknowledges what is known about

successful transfer. It thus provides promising conditions for investigating transfer processes with a specific focus on bi-directional and co-constructive collaboration.

A Model To Monitor And Reflect On Transfer In Projects

The model presented in this section (see Figure 2) understands transfer initiatives as projects with a clear focus on transfer (flerlage et al., in press). While building on existing models of transfer, this model differs in its explicit focus on the processes and actors involved, allowing for the identification and pursuit of specific transfer pathways tailored to project goals. With this focus, the model is particularly suited for monitoring and reflecting on transfer in complex large-scale projects, in which many contributors with potentially different goals are involved.

Figure 2: Model For The Systematic Reflection On Transfer (Adapted From Flerlage Et Al., In Press).

Note: TC = Transfer Conditions, Interorg. = Interorganizational, Org. = Organizational, Ind. = Individual

The model represents transfer scenarios within a project as structured around three core elements: the definition of objectives (left grey box in Figure 2), the transfer process (big blue box in figure 2), and the evaluation of outcomes (right grey box in Figure 2). It can be used to investigate various pathways leading from the objective to the outcome. Larger projects as the presented state program may consist of multiple interrelated transfer scenarios including various pathways from the defined objective to the outcome. The evaluation of outcomes related to the objectives is conducted using suitable indicators, which may conclude the transfer scenario or function as an intermediate checkpoint to inform adjustments to objectives, actor involvement, and/or strategy.

A key feature of the model is its focus on the actors involved. From a provision perspective, transfer processes are set up by initiators, while from a usage perspective, they address specific target groups. Mediators may also be involved to facilitate the process. Actors can be individuals, groups, or institutions within educational contexts, such as teachers, principals, students, TPD facilitators, subject departments, researchers, companies, or schools. Importantly, actors can assume different roles depending on the transfer process, for example as initiators, mediators, or target groups. While initiators and target groups are essential components of any transfer process, the inclusion of mediators depends on the specific objectives and design of the transfer process. The actions of all actors are shaped by individual, organizational, and interorganizational conditions. Individual conditions include beliefs, motivation, self-efficacy, and competencies. Organizational conditions encompass factors such as institutional size, available resources, and incentive structures. Inter-organizational conditions involve aspects such as frequency of contact, trust, mutual recognition of expertise, and geographic or cultural proximity, all of which can influence collaboration and transfer effectiveness (Schrader et al. 2020, 27 f.).

The model also accounts for the variety of collaboration forms between actors. Depending on the objectives pursued, collaboration may be uni-directional, bi-directional, or co-constructive (Farley-Ripple, et al., 2018). Furthermore, different transfer strategies can be applied individually or in combination, including personal strategies (e.g., professional development activities), material strategies (e.g., provision of teaching materials), and systemic strategies (e.g., development of policy or strategy documents; Roesken-Winter et al., 2021). These strategies and forms of collaboration may vary across actors within a single transfer process, allowing objectives to be pursued through tailored combinations of approaches.

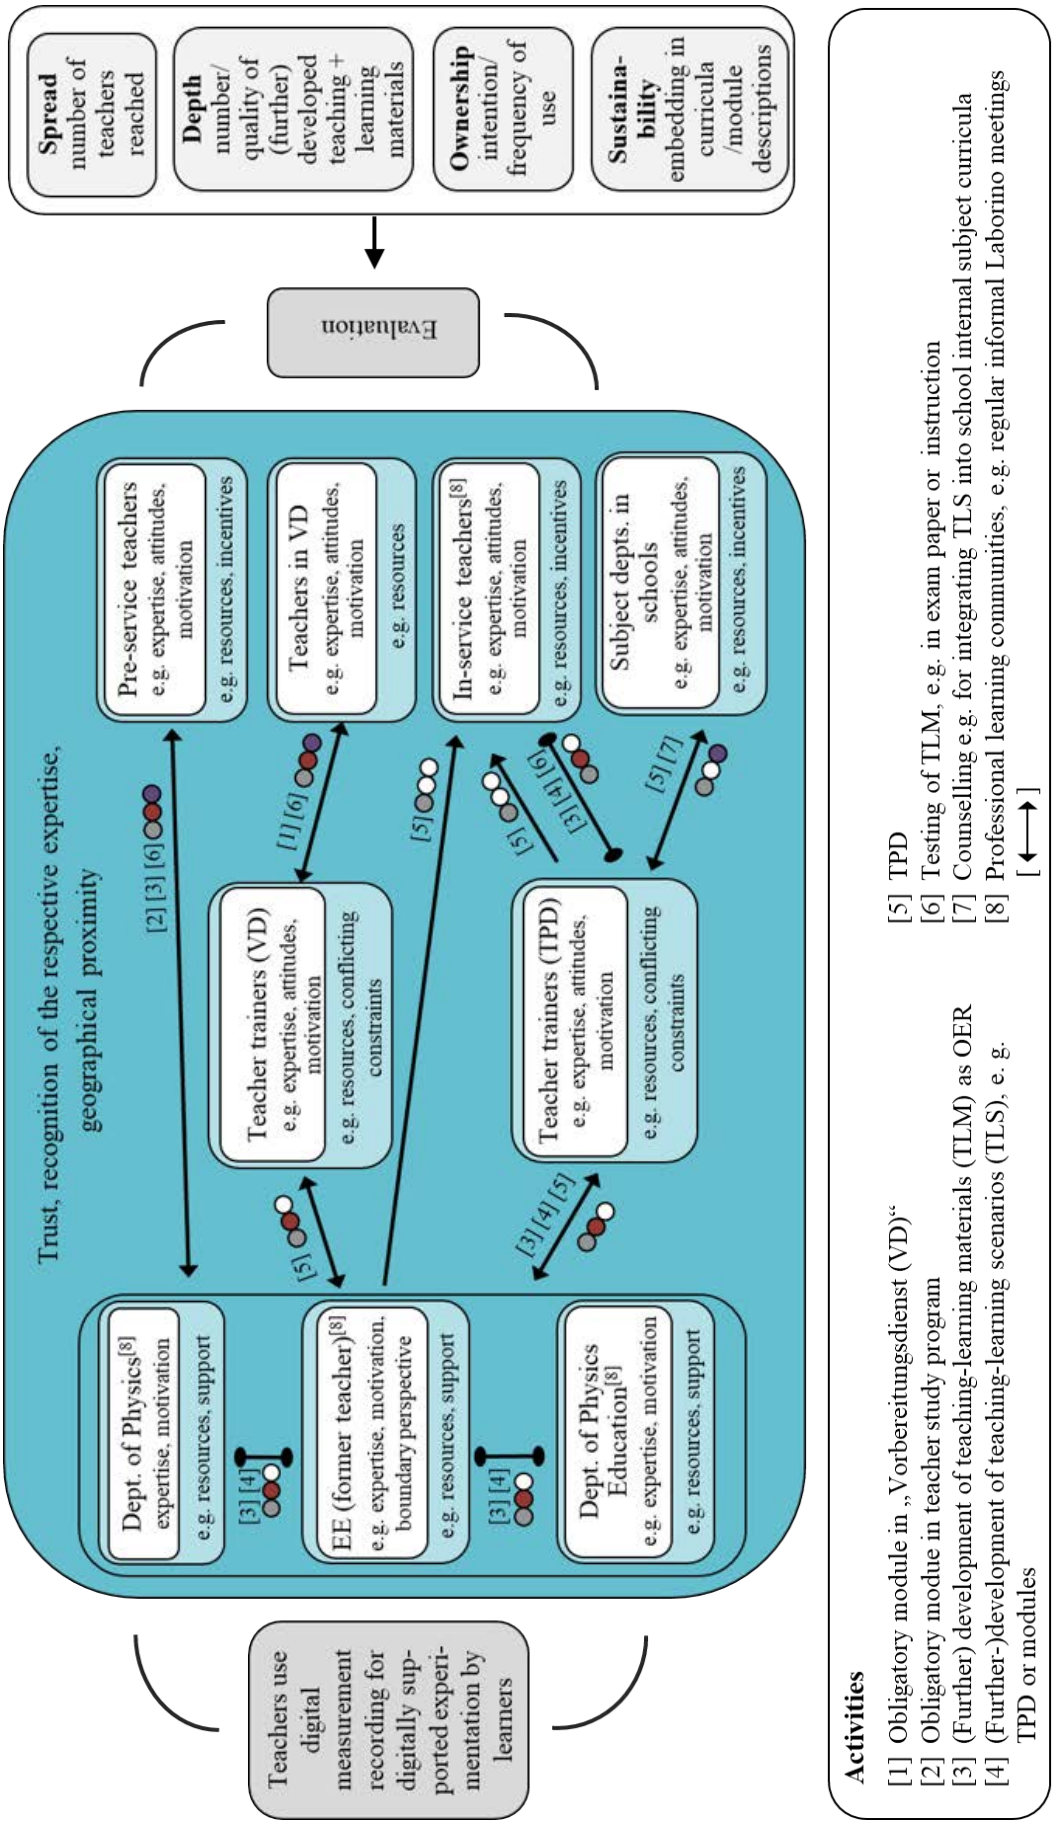
Finally, the model supports the systematic evaluation of transfer outcomes through goal-aligned indicators. For example, the four criteria proposed by Coburn (2003) can be used: reach (the involvement of multiple institutions and actors), depth (changes in beliefs and practices), ownership (identification with and responsibility for the transfer product), and sustainability (continuation beyond initial funding phases). These criteria provide a flexible foundation for operationalizing indicators that are adapted to the objectives of each transfer initiative.

Overall, the model's strength lies in its flexibility, capturing the dynamics of actors, collaboration forms, and transfer strategies across different phases of transfer processes. Rather than depicting prototypical processes, it provides a framework for the systematic analysis and of diverse transfer initiatives within a project. In this way, it supports both the scientific analysis and the informed design and optimization of transfer processes in educational research and practice.

Investigating Transfer Pathways

The complex conceptualization of the state program and its broad and all-encompassing overarching objectives provide opportunities but also challenges for transfer, among others, the multitude of formats, content, target groups, strategies and actors. To counteract this complexity and make beliefs about expected effects, decisions and related actions visible, the model presented in the previous paragraph is used to exemplarily map, describe and analyse different transfer scenarios – and the corresponding transfer pathways – pursued within the program. The underlying assumption is that looking into the specific transfer pathways from a program perspective will not only provide insights into objectives, beliefs and how these influence the decision for e.g. specific target groups, contents or formats, but also into the nature of interactions that hinder or support transfer at different stages of the process. On the individual level, visualizing one's own cooperations, formats, target group(s), etc. and explicitly describing objectives and outcomes of different transfer scenarios might support and lead to a more strategic and reflective process of planning one's own work. Thus, applying the model in the program

potentially serves two purposes: 1) giving an overview about different transfer pathways within specific transfer scenarios already "implemented" for further systematic and strategic decisions and, by fostering self-reflection, 2) acting as a systematic tool for planning and reflecting on transfer scenarios in a more holistic way.



To address these purposes, the model was presented to the program staff working in the five subject clusters. Thereafter, they were asked to use it to describe and visualize examples of transfer pathways within one or two transfer scenarios from their clusters. The resulting graphical representations were then discussed with two of the authors and, if necessary, revised. In addition, the providers of the examples were asked about their experience of working with the model and their feedback was collected.

In the following, one example of a transfer scenario from the stem subject cluster including various pathways will be described in detail to illustrate the analysis approach and the work with the model. The example was chosen because it represents a rather complex scenario initiative, thus showing the potential of the model to visualize complex transfer pathways including several target groups such as pre- and in-service teachers.

Example Of A STEM Transfer Scenario

The chosen example is from the field of physics education (see Figure 3) and acknowledges the potential of digital measurement recording for science teaching and learning (e.g. Abdiakhmetova et al., 2024; Papadimitropoulos, & Pavlatou, 2023). The overall objective is to increase teachers' use of these systems in student experiments. To support teachers in developing the necessary competences, beliefs and attitudes to reach this objective, a transfer process integrating different actors from all phases of teacher education is used. This not only enables a coherent acquisition of competences but also acknowledges that beliefs tend to be robust and difficult to change (e.g. Tillema, 1998; Fives & Buehl, 2015). With the Educational Engineer acting as the central initiator, researchers and educators from physics and physics education co-constructively develop teaching and learning materials and scenarios. In order to provide teachers with the necessary digital measurement technology, a digital sensor box was developed and is made available as an open educational resource. Its further development is an important part of the co-constructive transfer process. The teaching and learning materials form the foundation for subsequent support measures for pre- and in-service teachers (e.g. modules in the teacher study program or TPD courses) but also for teacher trainers working at the state institute or at schools in teacher training and TPD. In the context of the model, these teacher trainers act as mediators between the initiators and specific target groups. Introducing mediators in the transfer process allows to increase the spread by using them as multipliers but also contributes to the other indicators of successful transfer, e.g. by embedding the topic as an obligatory module into VD (increasing sustainability) or by counselling subject departments in schools (increasing ownership). In addition to these formal learning opportunities, the transfer process also incorporates professional learning communities as informal settings to encourage and support collaboration and exchange among teachers and between research and practice. As far as transfer conditions are concerned, from an individual perspective expertise and motivation play an important role. However, the expertise of the respective actors differs. On the initiators' side, researchers in the physics department contribute primarily technical and physics-specific expertise to the development and use of digital measuring devices as open educational resources, while researchers in the department of physics education contribute expertise in systematic integration into teaching and lesson plans. On the user side, in-service teachers contribute their expertise and experience to the co-constructive process, sharing what has worked well in their teaching and what is still needed.

Figure 3. Exemplary transfer scenario from physics education (for legend see Figure 2).

From an organizational perspective available resources, possible incentives and support are important transfer conditions. At the interorganizational level, the success of the transfer process depends on trust and appreciation of the respective expertise and perspective; it is supported by

a spatial proximity, e.g. all initiators and institutions involved are located in the same city and the teacher trainers are working regionally with schools and teachers in VD.

Conclusion: Challenges And Opportunities Of Working With The Model In The Program

Reaching the objectives of the state program requires successful transfer. The overarching aim of looking at transfer through the lens of the presented model thus is to support transfer at the program level by systematically analysing the different transfer scenarios that are pursued. Applying the model to examples from the STEM cluster but also across subject clusters showed the model's potential to systematically describe, analyse, and reflect on transfer pathways of varying complexity ranging from processes involving multiple initiators, target groups, collaborations and formats to simple ones like e.g. the development and implementation of a single module within a teacher education program. The graphical representations thereby visualize important factors influencing transfer like e.g. individual and organizational conditions, types of collaboration and transfer strategies as well as criteria to evaluate whether the outcomes are in line with the objectives. For example, it can be observed that truly co-constructive collaboration (Farley-Ripple, et al., 2018) is rare but is supported if contributors have the same subject background. Moreover, initiators usually pursue more than one transfer strategy to reach their objectives; they often combine material and personal strategies but yet seldom address the systematic level (Roesken-Winter et al., 2021). Overall, it became obvious that a lack of learning scenarios addressing the systematic level exists (e.g., teach-the-trainer workshops, multipliers, professional learning communities) which might give hints for strategic management and planning in the future.

In terms of evaluation and effects of transfer scenarios it can be observed that working with and discussing the model enables the visualization of the criteria and measurements of effects that are actually applied (Coburn, 2003). However, it also became obvious that an important target group stated in the program's objectives, namely school students, is only very seldom directly addressed by support measures. These focus almost entirely on pre- and in-service teachers as well as teacher educators in all phases of teacher education assuming that supporting and professionalizing these groups will have a positive effect on student learning.

Working with the (science) educators in the state program on describing and reflecting on transfer pathways related to the support measures they are developing and implementing revealed challenges but also opportunities at different levels. From a transfer perspective, formulating objectives in a way that they can guide a transfer process proved to be vary daring. Objectives tended to be very broad (e.g., fostering digital competences or supporting collaboration) or format- rather than content-related (e.g., developing a TPD activity or support). In addition, only limited attention was paid to evaluation criteria leading to the use of standard questionnaires that were often not aligned with the stated objectives and transfer getting confused with related concepts like effective TPD or the development of teachers' professional competence. Looking at challenges related to the specific use of the model, a tendency could be observed to report only on complex processes and consider any type of collaboration as co-constructive. The analysis, however, also revealed that the initiators of support activities often focus on the development and implementation of a specific format rather than regarding it as a transfer scenario and seldom included ideas for scaling up. Working with the model and trying to apply it to their own work, however, made them aware of this, thus making the model a valuable resource for self-reflection at an individual level, too.

Outlook

Overall, it can be summarized that applying the transfer process model to the program has been helpful in two ways. From a program point of view, analysing transfer through the lens of the model enables the investigation and visualization of transfer pathways that lead from an objective, over transfer processes of various complexity to outcomes. At an individual level, the contributors considered the model very valuable in guiding and structuring their work because it encourages and supports self-reflection. However, the model might not only be helpful in retrospective. It could also be used as a planning tool to guide transfer initiatives and design effective and detailed scenarios when initiating new projects or programs (Ward, 2019).

These first results are exemplary and have to be supported by further analyses in order to learn from comparing the different transfer scenarios and address questions like: How do objectives align with target group, content and formats? What beliefs exist regarding expected and expectable effects and how do these influence the decision for specific transfer pathways? What are individual and group-specific conditions for successful transfer of individual support measures? Moreover, additional analyses like e.g. social network analyses could provide information whether the collaboration structure envisioned in the conceptualization of the program – and in parts visualized in the transfer pathways – is reflected in the resulting networks. Answering these questions may not only feed back into the program to inform its further development but may also provide valuable insights for similar projects and programs and enhance the existing knowledge base on transfer.

Acknowledgement

The state program „Zukunft Schule im digitalen Zeitalter“ is being implemented on behalf of the Schleswig-Holstein Ministry of Education in cooperation with the teacher training universities (Kiel University, Europa University Flensburg, Conservatory of Music Lübeck, Muthesius University of Fine Arts and Design), the IPN Leibniz-Institute for Science and Mathematics Education, the Schleswig-Holstein Institute for Vocational Education (SHIBB) and the managing Institute for Quality Development in Schools Schleswig-Holstein (IQSH).

Research shows that teachers need to feel a degree of instructional autonomy, i.e., a sense of ownership, and self-efficacy to implement reform-based instructional practices learned in professional development (PD) courses. Certainly, PD has been shown to be crucial for teacher professionalisation and engagement. Criteria for effective PD, such as content-focused, collaboration, or activity-based approaches, have been elaborated. However, there is a great deal of variation between countries in how PD is organised, what topics are offered, who participates (voluntarily) and what the outcomes regarding teachers' (Information and Communication Technology, ICT) skills are. Accordingly, it is challenging to empirically identify what works best in PD courses, i.e., to identify examples of best practice that work in and for different teaching and school contexts. Our current Ministry-funded research and development project LFB-Labs-digital focuses on Science, Technology, Engineering, and Mathematics out-of-school laboratories as spaces for PD in teachers' ICT skills. Therefore, good practice within PD is being identified through questionnaires, interviews, and observations. We see great potential in a cross-country exchange of good, next and ideally best practices to improve PD provision. In this exploratory seminar, we discussed with international PD providers and researchers what examples of best practice look like, what data and criteria are used to identify them, how evidence-based approaches can be scaled up and implemented in different countries, and what recommendations can be derived for PD providers, researchers, and policymakers. To structure the exchange, we applied the placemat method, in which participants recorded and reflected their ideas and experiences.

Keywords: professional development, teacher education, digital learning

Introduction

Professional development (PD) is a central component of teachers' professional learning and an important lever for improving teaching and learning in schools (Drossel & Eickelmann, 2017; Priebe et al., 2019). In recent years, expectations on PD have further increased, particularly with regard to supporting teachers in responding to ongoing digitalisation and changing educational demands (Kultusministerkonferenz, 2020; European Commission, 2021; West & Leary, 2024). Although a growing body of research has outlined characteristics of effective PD (e.g. Desimone & Garet, 2015), its specific design and implementation continue to vary widely across educational systems, institutions, and national contexts. As a result, practices that are considered successful in one setting are often difficult to transfer to another.

This contribution is situated within this field of tension between established research knowledge and context-specific practice. It draws on an international exploratory seminar that brought together researchers, professional development providers, and practitioners from Germany and the United States. The exploratory seminar offered an opportunity for shared reflection on PD

focusing on teachers' ICT-related competences and on the conditions under which good or best practices can be meaningfully adapted and disseminated. By examining different perspectives and experiences, we seek to illuminate challenges and opportunities related to scaling PD across diverse educational contexts.

Theory And State Of Research

Beyond supporting individual growth, PD plays a central role in school and instructional development and ultimately affects the quality of student learning opportunities (Kultusministerkonferenz, 2020; European Commission, 2021; West & Leary, 2024). Against this backdrop, research has identified several core features that contribute to the effectiveness of PD initiatives. For example, Desimone and Garet (2015) highlight content focus, active learning, coherence, sustained duration, and collective participation as central criteria. Similarly, Lipowsky and Rzejak (2021) propose an adapted offer-and-use model, which outlines ten features of effective PD, including the quality of instructional design, the organisation of learning activities, and the professional expertise of the facilitators. These frameworks emphasise that PD must go beyond isolated workshops and be embedded in sustained, collaborative, and practice-oriented formats.

However, there is still considerable variation in how PD is structured and delivered across countries and even within regions of the same country (OECD, 2020). This includes differences in the topics addressed, the degree of voluntary participation, the resources allocated, and the resulting outcomes for teachers and students. Such diversity poses challenges for identifying universally applicable best practices for PD, as their success often depends on local educational traditions, systemic conditions, and teacher needs (Hayes et al., 2025). Recent studies also stress the importance of organisational factors, such as school culture and leadership support, alongside teachers' individual characteristics for successful PD implementation (Beavers, 2009; Hayes et al., 2025).

A key area of current concern is the integration of digital technologies into teaching and thus into PD. Despite investments in digital infrastructure, the actual use of information and communication technology (ICT) in classrooms remains limited (Eickelmann et al., 2024, Gil-Flores et al., 2017). This highlights the importance of PD that not only strengthens teachers' ICT skills but also supports the development of digital pedagogical competence, as described by frameworks such as TPACK (Mishra & Koehler, 2006) and DigCompEdu (Redecker, 2017). PD programmes in this field must enable teachers to critically reflect on their own beliefs about digitalisation, integrate technological tools meaningfully with subject content and pedagogy, and prepare students for participation in a digitally mediated world (Ertmer et al., 2012; Vogelsang et al., 2019).

Out-of-school learning environments, such as out-of-school labs, provide a promising yet under-explored context for teacher PD. Traditionally designed for students, these laboratories, often located at universities or research centres, offer authentic insights into scientific practice and experimentation (Kirchhoff et al., 2023). More recently, they have also been used as spaces for teacher learning, including the development of ICT-related skills (Martens et al., 2022; Martens & Schwarzer, 2023). Preliminary results of our joint project *LFB-Labs-digital* (see Kirchhoff, Schwedler et al., 2024) highlight the importance of collaboration and sufficient PD duration, while challenges remain regarding sustainable implementation and broad participation (Lüsse et al., 2025), which aligns with international findings (Popova et al., 2022).

Aim And Subject Matter Of The Exploratory Seminar

Despite the findings of several recent studies, the question of how to scale-up and generalise good practices remains a pressing concern. The diversity of educational contexts in different countries necessitates a careful consideration of how best practices can be adapted to meet the unique needs of different teacher populations. For example, PD programmes designed for urban schools with access to advanced technological infrastructure may not be directly applicable to rural schools with limited resources. Similarly, cultural differences in teaching philosophies and student-teacher dynamics must be accounted for when designing and implementing PD initiatives.

Given these complexities, a cross-country exchange of best practices was conducted within the exploratory seminar as a means of improving PD provision internationally. The aim was to provide an overview of PD practices for teachers' ICT skills across different countries, with a particular focus on identifying and scaling up best practice examples, while also establishing international collaborations to evaluate and disseminate these practices. The key question was: How can we scale-up our best practice examples in PD?

Figure 1. Overview of the placemat and the guiding questions within that was used in the exploratory seminar. The questions were enlarged for better readability.

In the exploratory seminar several interrelated themes were examined: the identification of best practice in PD from a cross-country perspective, the data and criteria used to identify best practice, strategies for scaling and adapting successful approaches across contexts, and recommendations for PD courses. Participants were asked to share specific examples of best practice, to reflect on the influence of policy guidelines, and to discuss how research evidence can be balanced with practitioners' experience. The exploratory seminar also considered factors contributing to successful scaling, including both achievements and challenges, and examined recommendations from multiple perspectives: for PD providers, on combining evidence-based approaches with practical classroom applicability; for researchers, on suitable designs and methods to capture long-term impact; for policymakers, on structural and financial conditions required to sustain PD; and across all roles, on fostering effective collaboration.

We used the placemat method enabling participants to individually record and reflect their ideas and contribute to a collective dialogue around these guiding themes (Figure 1). The placemat method is a cooperative learning strategy with a graphical layout, implemented in this context in groups of four. It first allows for the individual documentation of participants' ideas, solution approaches, and responses to a given question, and subsequently supports the negotiation and recording of shared group results, which are then discussed with the whole group.

To structure and enrich the exchange, the seminar followed four main steps.

1. Collecting Individual Thoughts: Each wrote their own experiences and perspectives
2. regarding the guiding questions into the placemat while rotating the placemat after each round (5 min).
3. **Breakout Group Discussions:** Participants discussed in smaller groups the general conditions, data collection, criteria, and evidence regarding best practice PD examples.
4. **Group Reports and Open Discussion:** The group results were summarised and compared in a plenary discussion, allowing for reflection on similarities and differences across contexts.
5. **Conclusion and Follow-Up Plans:** The seminar concluded with outlining next steps, including the definition of work packages, future seminars or workshops, and potential collaborative projects.

Results Of The Exploratory Seminar

The following section presents the results from the group discussions within two groups, which were documented using the placemat method. Participants (N =8) from Germany and the United States took part, providing a comparative perspective on the topics discussed. Due to the focus of the participants on PD in general, it was not possible in this case to compare experiences regarding teacher PD in out-of-school labs or with a focus on teachers' ICT skills in different countries.

Defining Best Practice In International PD

The discussions emphasized several recurring elements that contribute to defining best practice in PD from a cross-country perspective. Clarity and structure were identified as essential characteristics ("clear program", "clear guidelines", participants group 1). Programmes with clear guidelines enable teachers and school leaders to estimate the required workload and time commitment, thereby increasing feasibility at the school level. In contrast, the absence of sufficient hands-on opportunities was noted as a weakness in many PD formats. Opportunities for dialogue among teachers, students, and school leadership were considered necessary to ensure relevance and applicability in practice ("have conversations with teachers, students, and head of school", participant group 2). A second theme concerned the transferability of international examples ("International examples must be translated to a common language, what sometimes is difficult to achieve", "They [PD] depend on national/regional learning objectives", participants group 2). Participants highlighted the challenge of translating practices into a common conceptual and linguistic framework, particularly when aligning them with diverse national and regional learning objectives. The consideration of teachers' needs emerged as another defining feature of best practice ("Ask teacher what they need/expect for these PD courses → hands on + practical material", participant group 2). Effective PD should be designed in consultation with teachers, incorporating hands-on activities, practical materials (including possibilities for borrowing resources), and systematic evaluation through mixed methods. The integration of digital tools was also considered important. PD initiatives should prepare participants to work with a range of devices and hardware. At the same time, policy guidelines were often perceived as insufficiently

supportive, with limited autonomy reported as a barrier ("policy guidelines did not help; too much top dow[n], too less autonomy"; "I generally find policy to be limiting", participants group 2). In several cases, practitioners chose to move beyond restrictive policy frameworks in order to pursue what they considered most effective. Another point was the role of collaborative structures and action research in large-scale PD projects ("In a very large PD project we developed three different collaboration groups and did Action Research. Each group had a unique facilitator and PI. Each had a slightly different focus depending on their [teachers'] interest", participant group 1). Establishing multiple working groups with differentiated focuses, supported by targeted facilitation, was seen as a productive strategy for accommodating diverse professional interests while ensuring sustained engagement.

Data And Criteria For Identifying Best Practice

Concerning the data and criteria used to identify best practice in PD from a cross-country perspective, participants emphasized the importance of engaging in conversations about plans and results, collaborative planning between teachers and researchers, and producing practically oriented publications. School visits were highlighted as valuable opportunities to experience local practices firsthand and understand the contextual possibilities ("learn from practitioners + listen to them", participant group 1; "visit schools to experience their work and their possibilities", participant group 2). A crucial starting point, according to participants, is the practitioner's own experience, which helps to establish initial expectations while also introducing them to new models and approaches. Collaborative approaches, such as design-based research, were seen as effective ways to share ideas, experiences, and evidence ("development of a shared views", "compare actions and research", participant group 1). Mixed methods – including interviews and questionnaires – were recommended to compare evidence with practitioner experience. The development of a shared understanding and the comparison of action research with research-based interventions were also highlighted as important strategies ("I include classroom teachers in the design, implementation, and assessment process. This is done through Participatory Action Research, Collaborative Action Research, and a lot of formative Assessment/Evaluation", participant group 1)", participant group 1). In addition, participants stressed the need to include classroom teachers in the design, implementation, and evaluation of professional development. This is often achieved through participatory, collaborative action research and formative assessment, using research instruments not only to collect data but also as reflective tools for teacher learning.

Scaling And Adapting Best Practice Across Contexts

Regarding scaling and adapting best practice across different contexts, participants noted that dissemination rarely happens directly; instead, it is often carried out through multiple platforms, including digital networks, websites, and professional development institutes ("I suppose that dissemination through several platforms (web, network, institute of PD) could be positive", participant group 2). Therefore, the idea of a best practice handbook or "how-to" guide, combining digital and analog formats for both providers and researchers, was suggested and discussed within the exploratory seminar as a potential tool. German participants emphasized the challenge of coordinating communication with a larger number of participants and schools, particularly when crossing regional or federal boundaries with differing curricula for PD ("Expanded to more schools – lead to higher time commitment of coaches. Also, more organization", participant group 1). Effective communication was highlighted by all participants as essential to ensure that both practitioners and researchers feel acknowledged and heard. Commitment from PD providers and additional organizational support were also seen as necessary, alongside collaboration with specific teachers (find a way to have a good conversation

to make sure that both (providers and researchers) feel ‘good and heard’”, participant group 2). Teachers can act as multipliers, engaging their colleagues at their own schools. Long-term cooperation with laboratory schools was described as particularly effective, often yielding more substantial outcomes than initially expected, despite the understanding that teachers have a mind of their own.

Recommendations And Take-Away Of Own PD Courses

As last aspect, recommendations and key takeaways for designing effective PD courses were discussed. Regarding the role of PD providers, participants suggested using design-based research in collaboration with teachers, visiting schools to gain firsthand experience, and including assessments on specific topics as well as sufficient time for reflection. For researchers, longitudinal and cross-sectional studies as well as mixed-methods approaches were recommended to gain deeper insights, with a particular emphasis on qualitative research. From a policy perspective, participants highlighted the need for sufficient funding, clear communication, blended formats combining digital and in-person elements, and overall commitment to make PD feasible and sustainable. It was noted that in the United States, teachers are often paid for participating in PD programmes, which appears to serve as a strong incentive for engagement. Participants discussed that implementing a similar approach in Germany could likewise enhance participation, but can hardly be implemented in the current system as PD is seen in Germany as part of the duties of a teacher. Across all roles, effective collaboration was seen as essential, with participants emphasizing discussion and action on equal footing. Inviting policymakers to PD courses was also suggested to strengthen mutual understanding and engagement. Additional recommendations included involving various stakeholders, integrating action and community action research, providing coaching throughout the planning and implementation phases, conducting interview-based studies, designing programmes with sufficient duration, establishing long-term cooperation, and ensuring ongoing communication (e.g., “programmes with enough ‘time’ might impact sustainability”, “long lasting cooperations”, participants group 2).

Discussion And Conclusion

The results of the exploratory seminar indicate that the dissemination of PD is a non-linear process that depends on structural clarity, participatory design, and sustained communication. PD programs with transparent structures regarding workload, time commitment and outcomes are more likely to be taken up and disseminated at the school level, whereas formats lacking hands-on components limit practical transfer. Hereby, the results underline former results in the context of teacher PD (Drossel & Eickelmann, 2017; Lüsse et al., 2025; Lipowsky & Rzejak, 2021).

The dissemination of PD content across contexts requires careful adaptation rather than direct replication. The discussions between participants from the United States and Germany have shown that national best practices cannot be replicated in other countries but must be translated into shared conceptual and linguistic frameworks and aligned with local curricula, policy conditions, and teachers’ needs. By doing so, this might be a chance to improve policies regarding teacher PD in different countries.

Teachers play a key role as multipliers in the dissemination process. PD initiatives that actively involve teachers in design, implementation and evaluation (e.g. through participatory action research or design-based research) support sustainable dissemination within and across schools. Collaborative working structures and long-term partnerships with schools further strengthen ownership and professional learning communities.

Dissemination typically occurs through multiple channels, including digital networks, institutional platforms, professional development institutes and school visits. Hybrid

dissemination tools, such as digital and print-based best practice guides, can support both practitioners and researchers. Effective communication across platforms is essential to ensure engagement and recognition of all stakeholders.

Finally, sustainable dissemination depends on supportive organizational and policy frameworks, including adequate funding, institutional commitment, and blended PD formats. Incentives for participation – as described by the participants from the United States in contrast to the opportunities in Germany where PD are part of the job as teacher – and ongoing collaboration among teachers, PD providers, researchers, and policymakers are crucial for ensuring that PD content is not only disseminated but also sustained over time. This exploratory seminar facilitated a cross-country exchange about individual experiences in the context of teacher PD. As it was not possible in this case to compare experiences regarding teacher PD in out-of-school labs or with a focus on teachers' ICT skills in different countries, further exchange or research would be of interest.

ESERA 2025 Copenhagen

Understanding In-Service Stem Teacher Professional Development Needs: A Literature Review

Kārlis Greitāns, Ergi Bufasi and Inese Dudareva
University of Latvia, Faculty of Science and Technology, The Interdisciplinary Center for Educational Innovation, Latvia

As the global demand and importance for up-to-date STEM professionals increases, STEM education should flexibly follow the trends. One mechanism, how STEM teachers can stay up to date with changes in the STEM field is in-service teacher professional development (PD). In the last decades, there have been numerous reports about various STEM teacher PD solutions in various contexts. Also, the number of publications regarded STEM teacher PD needs is growing, therefore the present study aims to provide an overview of the complexity of this topic. As a result, a systematic study was carried out to identify STEM PD teacher needs both in terms of PD contents and approaches to PD. The selected 17 peer-reviewed publications were published between 2010 and 2024 in Scopus, Web of Science, and EBSCOhost databases. A comprehensive review of these empirical articles produced a total of 16 subthemes under the main PD content and approach themes.

The results exhibited that the dominant STEM teacher PD needs in terms of contents are the use of ICT in STEM teaching and learning and the teacher's deeper understanding of STEM subject contents; in terms of PD approaches – practice-based PD and systemic support. Finally, several recommendations for STEM PD sustainability and future research references are presented.

Keywords: STEM, In-service teacher professional development

Introduction

In-service STEM teacher professional development (PD) is a cornerstone for fostering high-quality STEM education. As scientific knowledge and instructional methodologies advance, it is crucial that practising STEM teachers continuously enhance their content knowledge, pedagogical skills, and practical classroom strategies. Effective professional development experiences not only support teacher growth but also translate into enriched learning environments for students and enhanced student results – the goal of STEM education (Surahman & Wang, 2023). Several scholars agree that recognizing and addressing in-service STEM teacher PD needs is central to designing meaningful PD programs, as adults learn according to their needs. Still, often the STEM teacher PD is built top-down – the contents and approaches to teacher learning within PD are dictated by higher authorities (Cooper et al., 2020). The investigation of various teacher PD needs has been ongoing for some time in research articles as well as in international studies (i.e., OCED TALIS), still to this date there is an empirical gap about the in-service STEM teacher PD needs. At the same time, the perspective from which teacher PD needs are defined (and simultaneously the teacher PD needs definitions) vary.

Conducting a literature review in this area is vital for several reasons. First, it provides a comprehensive overview of existing research, enabling educators, policymakers, and PD providers to discern models and strategies for in-service STEM teacher PD. Second, it can help to identify persistent gaps and future research avenues.

Aim Of The Study

The study aims to investigate the intricacies of in-service STEM teacher PD needs (in terms of PD contents and approaches), which can guide further research and practice development. More particular, we aim to answer the following research questions:

RQ1: From what perspectives (teacher, school leader, policymaker etc.) are in-service STEM teachers' professional development needs addressed and how are they defined in recent studies?

RQ2: What are the in-service STEM teacher needs in terms of PD contents and approaches?

It is worth mentioning, that in the present review, the authors themselves do not define what STEM teacher PD needs are; we aim to obtain an overarching view about STEM teacher PD needs, the definitions and perspectives from which STEM teacher PD needs are defined.

Method

This study investigates the PD and training needs of in-service STEM teachers through a systematic literature review guided by the PRISMA checklist (Moher et al., 2009). The review followed key stages: (a) eligibility and exclusion criteria, (b) identification review, (c) screening, (d) eligibility, and (e) data abstraction and analysis. The process began with identifying relevant keywords and creating search strings for Scopus, Web of Science, EBSCOhost, and Google Scholar, as detailed in Table 1. Articles were then screened based on inclusion and exclusion criteria (Table 2), with automatic sorting functions used to streamline the process. The overall selection process is illustrated in the PRISMA flow diagram (Figure 1). Out of 85 initially screened papers, 43 articles were assessed for eligibility, and 21 were excluded for reasons such as including both pre-service and in-service teacher participants or lacking direct relevance to STEM PD needs. The final selection of studies was critically analysed to synthesize key findings, ensuring a rigorous and focused review aligned with PRISMA principles.

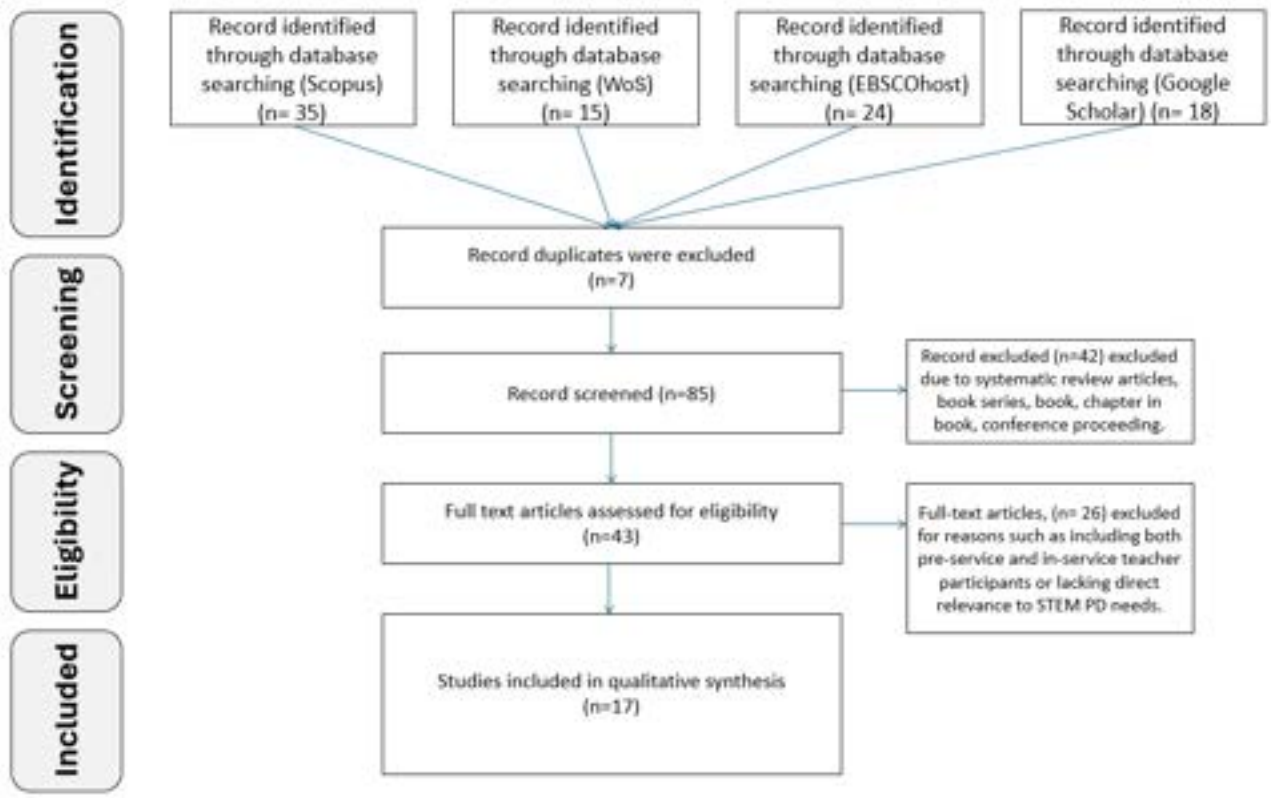

Table 1. Strings used during the search.

Databases	Search String
Scopus	TITLE-ABS-KEY(('STEM professional development' OR 'teacher professional development') AND ('In-service teacher' OR 'PD needs' OR 'Teacher needs' OR 'Teacher training needs'))
WoS	TS=(('STEM professional development' OR 'teacher professional development') AND ('In-service teacher' OR 'PD needs' OR 'Teacher needs' OR 'Teacher training needs'))
EBSCOhost	(('STEM professional development' OR 'teacher professional development') AND ('In-service teacher' OR 'PD needs' OR 'Teacher needs' OR 'Teacher training needs'))
Google Scholar	"STEM professional development" OR "teacher professional development" AND "In-service teacher" OR "PD needs" OR "Teacher needs" OR "Teacher training needs"

Table 2. The inclusion and exclusion criteria.

Inclusion Criteria	Exclusion Criteria
Studies focusing on in-service STEM teachers (science, technology, engineering, and mathematics).	Studies focusing on pre-service teachers or teacher candidates.
Articles that explicitly address professional development needs or teacher training needs.	Articles that do not explicitly mention STEM disciplines.
Peer-reviewed journal articles, conference papers, and reputable reports published in the last 15 years (2010-2025).	Opinion pieces, editorials, and non-peer-reviewed sources.
Research was conducted in diverse educational contexts, including primary, and secondary contexts.	Studies published in languages other than English (due to resource constraints).
Studies employing qualitative, quantitative, or mixed methods approaches.	

Figure 1. PRISMA flow diagram.

Findings

The reviewed studies span multiple continents, providing a comprehensive view of in-service STEM teacher PD needs. The research was conducted across North America (USA), Europe (Lithuania, Northern Ireland, Greece, Portugal, and Germany), and Asia (Taiwan, Malaysia, Turkey, Israel, and the Philippines), showcasing diverse educational contexts and priorities. Sample sizes ranged widely, from small-scale studies with as few as 5 participants in Lithuania to extensive surveys involving up to 4,957 teachers in the USA, offering both localized insights and broader comparative analyses. The studies employed various research methodologies,

including quantitative, qualitative, and mixed methods approaches. Quantitative studies, such as those conducted in the USA, utilized structured questionnaires for systematic data collection. Mixed methods approaches, combining surveys and interviews, were used in studies from Taiwan, Malaysia, and the Philippines, enabling both statistical analysis and nuanced qualitative insights. Meanwhile, qualitative methods, including case studies, interviews, and teacher reflections, were prominent in studies from Israel, Turkey, and Greece, offering a deeper contextual understanding of PD needs. This methodological diversity enriches the overall findings and highlights the complexity of STEM teacher PD globally.

In terms of in-service STEM teacher PD needs definitions, only one of the reviewed studies (Zakaria & Daud, 2009) included a definition of needs (still not in the context of STEM teacher professional development needs): “need is defined in terms of want or preferences of an individual or a group of people. Need in this context is seen as a want (which implies interest or motivation), felt by an individual or group to eliminate a lack (Queeney, 1995).” Nevertheless, many of the reviewed studies include the perspective from which STEM teacher PD needs are viewed. For example, the study by Shernoff et al. (2017) includes the perspective in the study research questions: “What are the greatest challenges [for STEM teachers] to effectively implement integrated approaches to STEM education? What supports would be most helpful to overcome these challenges?”. Overall, all of the reviewed studies view STEM teacher PD needs from the teacher's perspective and define STEM teacher PD needs as challenges that STEM teachers face in their practice.

In the table below the identified 16 subthemes under the two main themes: 1) STEM teacher PD content and 2) approach needs are outlined.

Table 3. The themes and subthemes of in-Service STEM teacher PD needs identified in the present review (For the list of references of the reviewed articles, please use this LINK).

Discussion

All the research articles view teacher-perceived needs and are based on teacher opinions. There is a lack of studies, where PD needs are viewed from other perspectives (school leaders, external experts).

There are noticeable similarities between the results of this review and the large-scale OECD TALIS 2018 survey (OECD, 2019), which identified teacher PD needs on a large scale: use of ICT in lessons; assessment; and classroom management are some aspects which converge and are STEM teachers' top priorities in terms of PD content needs. Teaching students with special needs differs - none of the reviewed articles in the present research, still it is one of the top needs in OECD TALIS. A deeper understanding of STEM concepts could be highlighted as a unique PD need for STEM teachers. The rationale for such a need is clear - as few of the reviewed studies uncover – STEM teachers are usually specialists in one of the STEM subjects. When STEM is taught as an integrated subject it is objective to lack knowledge about other aspects.

Systemic support, ready-to-use materials and practice-based approaches are the top PD needs from the perspective of PD approaches; such needs appear not only in small-scale qualitative studies but also in large-scale quantitative studies.

There aren’t a lot of differences between the PD needs of STEM teachers in countries from various regions. For example, studies by Oztay in Turkey (Oztay et al., 2022) and Shernoff in the

USA (Shernoff et al., 2017) outline quite similar STEM teacher PD needs both in terms of approaches and contents. This could be possibly explained by the comparatively recent popularity of integrated STEM worldwide.

ESERA 2025 Copenhagen

Aesthetic Learning Processes In Science Education – Cultivating Empathy And Curiosity For Nature In Primary And Middle School Science

Sonja Heinrich, Anna-Vera Meidell Sigsgaard and Peter Mikael Hansen
University College Copenhagen, Danmark

This paper examines how Danish primary and middle school science teachers can develop and implement aesthetic learning processes to foster students' empathy and curiosity for nature. The study focuses on integrating authentic macro photography and observational drawing within a science-didactic framework that encompasses Education for Sustainable Development (ESD), the Danish concept of "naturdannelse", i.e. nature connectedness. By incorporating these visual tools, teachers can create engaging science lessons that deepen students' understanding of natural phenomena and promote sustainable development. Data collected from both in-service and pre-service teacher training programs demonstrates the effectiveness of these didactic approaches in engaging both teachers and students.

Keywords: professional development, student engagement, sustainability

Introduction

Research indicates that children develop deeper understanding and retention of natural phenomena when they engage with them through sensory experiences (Shouse et al., 2007; Zinkernagel 2017, 2022). However, studies also show a declining trend in curiosity and empathy for nature (Shouse et al., 2007), an observation supported by our experiences as teacher educators at the University College of Copenhagen. While direct contact with nature is crucial for fostering curiosity, this presents a challenge given the limited weekly hours allocated to science lessons in Danish public schools (Bentsen & Jensen, 2012).

This work contributes to Education for Sustainable Development (ESD, e.g. UNESCO 2017) by exploring how aesthetic engagement with nature might foster the emotional connection and curiosity that underpin environmental care and stewardship. To address the constraint of limited classroom time and foster students' curiosity and engagement with nature, we propose bringing nature into the classroom' through the use of macro photographs and aesthetic learning processes. This paper presents our work incorporating instructor-captured photographs and observational drawing activities in pre-service and in-service teacher education. This approach aligns with outdoor didactics theory by complementing classroom teaching with indoor nature experiences (Jordet, 2002). This method provides teachers with didactic tools that promote student co-ownership and engagement, potentially leading to increased motivation and stronger connections to nature (Jordet 2002; Bentsen & Jensen, 2012).

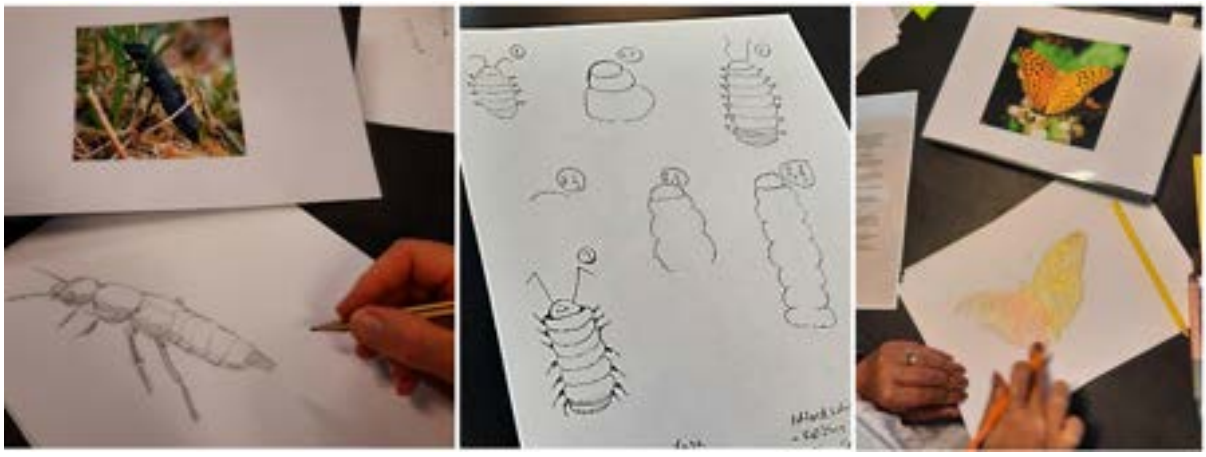
Photographs and observational drawings serve as powerful tools for creating aesthetic experiences of nature in science education. Visual representations help students grasp complex concepts while creating engaging learning experiences (Alenezi, 2015; Andersen, 2022). By using authentic macro photographs and guiding students through iterative observational drawing and discussion, teachers facilitate direct engagement with scientific phenomena through nature's aesthetics. This approach enables students to develop deeper connections with their subjects of observation while enhancing their understanding of nature's complexity and biodiversity – essential foundations for sustainable development (Zinkernagel, 2017, 2022).

Methodology

Our methodological approach is grounded in Iskov's (2020) concept of "det dobbeltdidaktiske blik", i.e.. the double didactic lens and the pedagogic principle of modelling. This framework emphasizes the importance of having teachers experience learning activities as learners themselves, while also reflecting on how to implement these activities in their own teaching practice. By engaging teachers in the same type of aesthetic learning processes which they later can be expected to facilitate with their students, we as teacher educators create opportunities for both experiential learning and pedagogic (didactic) reflection.

The study reported here was conducted at the University College of Copenhagen (Københavns Professionshøjskole, KP), which offers both pre-service teacher education and in-service professional development programs. Pre-service teachers at KP complete a four-year bachelor's degree in teaching, with those specializing in science education receiving comprehensive training in both scientific content and pedagogic/didactic approaches. The in-service program offers already practicing teachers the opportunity to become science supervisors through a professional development degree which combines two modules focusing on pedagogical knowledge and research with three science education courses and a final independently determined capstone project.

In one of the in-service modules, we introduced macro-photography in science teaching implementing the double didactic lens. Participants first experienced the learning process as students by examining authentic macro photographs of insects, flowers, and other natural subjects. These photographs were taken by one of the authors, who is a successful amateur photographer, highlighting subjects such as local flora and fauna. Using these photographs as models, in-service teachers were then asked to create detailed observational drawings of the organisms (Figure1). The process included peer feedback sessions and refining their drawings based on the feedback received. This was followed by presentations of their work to the whole class, with a subsequent reflection session, shifting to the teacher perspective. In the reflection session, participants engaged in whole-class discussions analysing the pedagogic potential of this approach. The lesson finished with time allotted for the in-service teachers to plan implementation of the approach in their own practice.



The lesson described for in-service teachers above was replicated with in-service teachers participating in a NAFA (Danish Academy of Science Education) project and with two cohorts of pre-service teachers in their first and third years of study, maintaining the dual focus (the double didactic lens) on personal experience and professional application.

Data

This paper draws on practitioner inquiry conducted within teacher education courses at the University College of Copenhagen. As course instructors, we implemented the macro photography and observational drawing approach described above with both pre-service teachers (1st and 3rd year cohorts) and in-service teachers within the context of the science supervisor program and NAFA´s professional development. Following their experience with these activities, some participating pre- and in-service teachers chose to implement similar approaches and were observed in their own classrooms (in grades ranging from Kindergarden to year -6, with students aged approximately 6-12).

Data presented here includes observations from our own teaching, teachers' created artifacts, and feedback collected through classroom discussions with pre- and in-service teachers. Figure 1 below shows examples of teachers' observational drawings.

Figure 1. Teachers´ observational drawings.

The subsequent classroom implementations provided additional observational data, including students' drawings and unstructured reflections with the participating teachers. Figure 2 below shows examples of observational drawings made by students and students, taking their own photos of insects found near their school.

Figure 2. Students' Observational Drawings And Taking Photos.

Finally, we conducted a survey-questionnaire with the teachers who implemented the approach with their students. The questionnaire includes four different themes according to our research interest in fostering students' empathy and curiosity for nature:

1. Empathy and Affection for Nature
2. Curiosity and Engagement
3. Understanding of and Communication about Natural Phenomena
4. Developing Nature Connectedness

Theory

The theoretical framework integrates multiple perspectives on learning and nature connection (e.g. Shouse et al., 2007). Beginning with aesthetic learning processes, research demonstrates how aesthetic experiences enhance motivation and engagement in science education (Zinkernagel, 2022). Visual learning theory supports the use of photography and drawing in

science education, showing how visual tools facilitate understanding of complex scientific concepts (Alenezi, 2015; Feldman & Lee, 2014).

Studies specifically examining macro photography and observational drawing highlight their effectiveness in fostering creativity and engagement (Antal et al., 2020). This visual approach aligns with the Danish concept of "udeskole" (outdoor education), which emphasizes the importance of bridging indoor and outdoor learning experiences (Jordet 2002; Bentsen & Jensen, 2012).

The Danish Outdoor Council further enriches this framework by identifying five essential dimensions for fostering children's nature connection (Hartmeyer & Præstholm, 2021):

1. Experiential Learning and Sensory Engagement: Macro photography and observational drawing enable detailed sensory interaction with nature in the classroom, allowing students to discover overlooked details and patterns.

2. Cognitive Development and Knowledge Acquisition: The process of careful observation and documentation through drawing promotes scientific investigation skills and deeper understanding of natural phenomena.

3. Emotional Connection and Appreciation: Visual engagement with nature through photographs and drawing cultivates emotional responses and empathy, fostering environmental stewardship.

4. Philosophical Reflection: The documentation process encourages reflection on humanity's role in ecosystems and environmental impact.

5. Material Engagement and Sustainability: Direct engagement with natural subjects through visual observation and documentation creates tangible connections to nature and environmental responsibility.

This theoretical framework supports our approach of using macro photography and observational drawing as tools for ‘bringing the outdoors in;’ when direct outdoor experiences are limited by time constraints, such aesthetic methods provide meaningful alternatives that maintain the essential connection to nature while also developing scientific observation skills.

Results And Findings

Our experiences implementing this approach in teacher education, combined with observations and feedback from teachers who subsequently tried it with their students, revealed patterns at two levels: first, the experiences of pre-service and in-service teachers as they engaged in the observational drawing process themselves; and second, their observations when implementing the approach with their own students in classrooms. Analysis of teachers' observational drawings, reflections, and feedback from course and classroom activities revealed insights about teachers' own learning experiences and patterns within four areas we had identified as central to our research interest: empathy and affection for nature, curiosity and engagement, understanding of and communication about natural phenomena, and developing nature connectedness. Below we present findings from both teacher learning experiences and classroom implementation, demonstrating how the double didactic approach functioned in practice

Teacher Experiences With Observational Drawing

When pre-service and in-service teachers engaged in the macro photography and observational drawing activities as learners, they consistently reported deep immersion in the observation process. As one teacher noted, "I became completely immersed in the task and forgot about time

while working."[3] This absorption appeared to stem from the detailed visual information provided by macro photographs, which revealed features that participants had previously overlooked. One teacher expressed surprise: "I was surprised by how little I actually knew about what the animal looks like."

The extended observation required by drawing facilitated what teachers characterized as slow and deep learning: "Working slowly gave me time to really notice details I would otherwise have missed," one participant reflected. This deliberate pace appeared to transform not only participants' understanding but also their emotional responses to their subjects: "An animal I initially found unpleasant became fascinating to explore."

Teachers acknowledged that the drawing process demanded perseverance, particularly at the outset. However, participants emphasized that success was more about technique than innate ability: "Drawing turned out not to be about talent, but about learning a technique." The scaffolding provided through video demonstrations and peer feedback proved essential, with one teacher noting, "The video and the feedback partner made it easier to get started."

The collaborative dimension emerged as particularly valuable, both for skill development and for generating science-related discussions. Through peer feedback and shared observation, teachers found themselves naturally engaging with scientific concepts and vocabulary. As one participant observed, "Talking about the animal helped me become more confident in using scientific terms." Teachers reflected that experiencing these challenges and discoveries firsthand enhanced their pedagogical understanding of how to implement the approach with their own students.

Student Implementation Findings

When teachers implemented these approaches in their classrooms with students ranging from kindergarten through 6th grade, four key themes emerged that illuminated how the aesthetic learning process functioned across different age groups.

Empathy And Affection For Nature

The most striking finding across multiple classroom implementations was a transformation in students' emotional responses to organisms they previously found unappealing or frightening. One 6th grade teacher observed: "The students saw the beauty of nature. Before, they screamed when they saw a spider in the classroom, but after these lessons, they went looking for spiders in nature and in the vicinity, just to look at them!" This shift from fear to fascination was echoed by another 6th grade teacher who reported being, "surprised that the students became so eager and affected to go out after the class session to find animals they previously found disgusting!"

Teachers attributed this change to the detailed visual access provided by macro photography. A 3rd grade teacher noted that, "especially the macro photos that allowed them to see all the many details up close gave the students enhanced joy and fascination of nature, something I don't usually see daily." The magnified perspective appeared to reveal aesthetic qualities in familiar organisms that students had previously overlooked or dismissed.

Curiosity And Engagement

The combination of viewing macro photographs and creating observational drawings generated sustained student engagement across all age groups. A 4th grade teacher reported that the approach, "created curiosity and motivation for further investigation into butterflies." This motivation extended beyond passive observation to active participation: "When the students were

[3] All teacher quotes have been translated from the original Danish to English by the authors of this article.

sent out, there was great engagement as they thought it was fun to take pictures themselves. The students were very curious when they were out taking pictures. It was very motivating to take pictures themselves."

The drawing process itself facilitated deep concentration, with one 6th grade teacher expressing surprise at observing students, "sit and immerse themselves in drawings of different species," a level of focused attention they had not previously witnessed in their science lessons.

Understanding Of And Communication About Natural Phenomena

Teachers observed that the detailed observation required for accurate drawing supported students' development of more precise descriptions and a need for related scientific vocabulary. A 6th grade teacher noted: "The students were able to name the animals and use technical terms such as horns, wings, hind legs, tail, etc. In addition, they learned to be concrete in their language." The iterative process of observing, drawing, and receiving peer feedback appeared to refine both students' visual discrimination and their ability to articulate what they observed using more appropriate scientific terminology.

Developing Nature Connectedness

Perhaps most significantly for long-term environmental engagement, participating students developed enhanced awareness of local biodiversity and their relationship to nearby nature. A 4th grade teacher reported that her students were, "especially surprised by how many different butterflies there actually were. 'They don't all look alike' – and 'do they really exist here!'." This discovery of diversity in familiar surroundings led to deeper connections: "The pictures opened up the butterfly-world more to the students, as they observed things that require the butterfly to sit still for a longer period of time. They became aware of the diversity, also in appearance. So, it created a desire to learn more about the butterfly."

A 3rd grade teacher emphasized the importance of using students' own nature experiences and photographs: "The students became more aware of what nature is and their local nature... Since it was their own nature-experiences and nature-images that we used, they also had to relate to their own experiences." Multiple teachers reported that students expressed "a desire to continue working with butterflies" and other natural subjects beyond the planned lessons. We see this as a solid foundation for further developing students' empathy and interest in nature.

Discussion And Conclusion

The implementation of macro photography and observational drawing in science education presents both opportunities and challenges that warrant careful consideration. Teacher reflections from both their own learning experiences and classroom implementations consistently highlighted several key requirements for successful practice. First, students require scaffolding and support in developing both observational awareness and drawing skills. As one teacher noted, success is, "not about talent, but about learning a technique." Second, what the teachers characterized as 'slow' and 'deep' learning facilitated by this approach demands dedicated time worth prioritizing even though it may conflict with curriculum pressures and the limited hours allocated to science instruction. Third, teachers need a clear pedagogical framework to guide implementation effectively, particularly in balancing aesthetic engagement with scientific learning objectives. These considerations are not limitations of the approach itself but rather indicate areas where teacher preparation and institutional support are essential for successful implementation.

Despite these implementation requirements, our findings demonstrate significant potential for this approach to address contemporary challenges in science education. While the four areas we

examined were informed by the five dimensions of nature connection identified by the Danish Outdoor Council (Hartmeyer & Præstholm, 2021), our findings validate this theoretical framework as a useful lens for understanding how aesthetic engagement supports nature connection.

The deep immersion and curiosity reported by both teachers and students reflects experiential learning through detailed sensory interaction. The transformation in students' emotional responses, from fear and disgust to fascination and care, embodies emotional connection and appreciation for nature. Students' awareness of local biodiversity and desire to continue exploring represents material engagement with their environment. Notably, several teachers reported students raising questions about ecosystems and biodiversity during the drawing process, touching on the dimension of philosophical reflection about humanity's relationship with nature. Students' use of more precise descriptive language and scientific vocabulary in articulating observations suggests cognitive development and knowledge acquisition. The iterative process of observing, drawing, and discussing appeared to create contexts where more precise language became useful for communication, an observation that warrants further investigation.

The convergence between our findings and established theoretical frameworks suggests that macro photography and observational drawing offer a viable pedagogical strategy for achieving the goals of "naturforbundethed" (in English: nature connectedness) even within the time constraints of contemporary schooling. Where Bentsen and Jensen (2012) and Jordet (2002) emphasize the importance of outdoor education for developing nature connection, our approach demonstrates how carefully selected visual materials can ’bring the outdoors in’, creating meaningful nature experiences when direct outdoor access is limited. The authentic macro photographs function as what we might call ‘windows to nature' providing the detailed, extended observation opportunities that are often difficult to achieve in traditional outdoor settings where organisms are small, mobile, or ephemeral. We believe that through providing such windows to nature in science lessons, students will become more curious and more motived to engage with nature outside the classroom. Teachers’ reflections on students’ wanting to take their own pictures of organisms reflect this.

The effectiveness of aesthetic engagement in generating scientific curiosity aligns with Zinkernagel's (2017, 2022) arguments for the role of aesthetics in science education. Teachers' observations that students discovered beauty in previously feared or ignored organisms suggest that aesthetic appreciation can serve as a gateway to scientific inquiry. This finding has particular relevance for Education for Sustainable Development (ESD), where fostering emotional connection to nature is recognized as foundational for developing environmental care and stewardship. The emotional and cognitive shifts we observed in both teachers and students represent important precursors to the deeper environmental engagement that ESD seeks to cultivate.

Our use of the double didactic approach (Iskov, 2020) in teacher education proved particularly valuable. Teachers who experienced the learning process themselves, engaging with photographs, creating observational drawings, giving and receiving peer feedback, developed both experiential understanding of the approach's power and practical insight into potential student challenges. This embodied knowledge appeared to translate directly into more effective classroom implementation, as evidenced by teachers' reports of increased confidence and their ability to anticipate difficulties and design appropriate scaffolding. The voluntary nature of classroom implementations further underscores teachers' genuine conviction in the value of this approach; those who chose to try it with their students did so based on their own transformative learning experiences.

Our findings across both pre-service and in-service teacher contexts suggest that the approach presented here is viable for teachers at different stages of professional development. These findings point toward broader implications for science teacher education. Traditional science methods courses often emphasize content knowledge and inquiry processes while giving limited attention to aesthetic dimensions of science learning. Our results suggest that explicitly addressing how visual tools and aesthetic experiences can support both affective and cognitive learning goals in science, have a valid place in teacher education programs. This is particularly important given the documented decline in children's connection to nature (Shouse et al., 2007) and the increasing recognition that environmental education must engage both head and heart. The double didactic approach offers a practical model for how teacher educators can prepare future teachers to use aesthetic engagement effectively, not as a supplement to science education, but rather as an integral component.

The success of this approach with students ranging from kindergarten through 6th grade, as reported by teachers across several implementations, suggests its adaptability across developmental stages. While the specific scaffolding varied by age group, with younger students requiring more support and older students capable of more sophisticated scientific engagement, the core process of careful observation, aesthetic appreciation and refining drawings proved engaging across the age range included.

The practitioner inquiry reported here demonstrates that macro photography and observational drawing offer a practical approach for cultivating both scientific understanding and emotional connection to nature within the constraints of contemporary classroom settings. By bringing nature indoors through aesthetic engagement, teachers can address the documented decline in children's nature connection while simultaneously developing essential scientific observation skills. This represents a contribution that aligns with both scientific literacy goals and the Education for Sustainable Development agenda.

While our findings demonstrate the potential of aesthetic learning processes for developing empathy and curiosity for nature, they also reveal opportunities for deeper investigation into how such approaches can support scientific literacy development. Our observations from both lessons with pre- and in-service teachers and with K-6 classrooms suggest significant potential for working more closely with subject-specific language and disciplinary dialogue. Teachers noted that students naturally sought more precise terminology as they attempted to describe and compare their observations. These finding warrants development and further investigation.

We hypothesize that through slow, attentive observation combined with structured collaborative discussion, learners can be scaffolded from everyday descriptions toward increasingly precise scientific understanding (Heinrich et al., 2024; Polias 2016). The need to accurately represent and communicate about organisms in their drawings appears to create authentic motivation for acquiring scientific vocabulary and engaging with disciplinary explanations. In this way, aesthetic engagement may serve as a dual function: deepening conceptual understanding while simultaneously motivating meaningful scientific communication.

While this practitioner inquiry establishes the viability of using macro photography and observational drawing to cultivate both emotional connection to nature and scientific observation skills, the approach warrants further development in two key areas. First, more systematic investigation is needed to understand how best to leverage aesthetic engagement for sustained nature connectedness and environmental stewardship. Second, future research should examine how this approach can be refined to more intentionally support scientific knowledge and science literacy development. Such investigations, conducted through more structured research designs across diverse educational contexts, will help establish the generalizability of our findings and

develop pedagogical frameworks that maximize the dual potential we have observed: fostering both affective engagement with nature and developing scientific literacy and understandings.

Acknowledgement

The authors would like to express their sincere gratitude to the teachers and students who contributed to this project.

Empowering STEM Teacher Professional Development Through AI Integration

Ergi Bufasi, Kārlis Greitāns and Inese Dudareva
University of Latvia, Faculty of Science and Technology, The Interdisciplinary Center for Educational Innovation, Latvia

Artificial intelligence (AI) has revolutionized education by offering scalable, personalized, and interactive tools for teachers. This study investigates the potential of ChatGPT, an AI-powered platform, to enhance PD for primary school teachers, focusing on improving instruction in spatial ability—a critical skill for success in STEM disciplines. Grounded in constructivist learning theory, spatial cognition theory, and the TPACK framework, the research adopts a design-based research (DBR) approach to iteratively develop and evaluate a ChatGPT-supported PD program. The study utilizes a four-phase methodology: exploratory interviews, program design, classroom implementation, and program evaluation. Teachers integrate ChatGPT to design spatial ability tasks, generate lesson plans, and provide differentiated instruction aligned with STEM curricula. Data collection includes pre- and post-intervention assessments, reflective journals, focus groups, and lesson observations, analysed through the TPACK framework to assess the program's impact on teaching practices and student outcomes. This study highlights the potential of AI to transform teacher PD, offering insights into best practices for integrating AI tools into education while addressing challenges related to ethical use and overreliance. The findings aim to inform future PD initiatives and enhance STEM education at the primary level.

Keywords: Teacher professional development, spatial ability, ChatGPT, STEM

Introduction

Artificial intelligence (AI) is transforming education by offering innovative tools to enhance teaching and learning, particularly in professional development (PD) for educators. AI-powered platforms like ChatGPT provide unique opportunities to support teachers in designing, implementing, and refining strategies to foster critical skills such as spatial ability. Spatial ability—the capacity to visualize and manipulate objects in space—is a foundational skill for success in STEM disciplines, as it underpins problem-solving and conceptual understanding in subjects like mathematics, physics, and engineering (Uttal et al., 2013). Developing these skills in primary education is crucial, as early spatial reasoning correlates strongly with later academic achievement in STEM fields (Newcombe, 2010). Professional development plays a pivotal role in equipping teachers with the knowledge and tools needed to integrate spatial skills into their classroom practices effectively. Traditional PD models, while valuable, often face limitations in scalability, personalization, and real-time applicability. Here, AI emerges as a game-changer. Tools like ChatGPT can personalize PD experiences by tailoring content to individual teacher needs, providing immediate feedback, and generating diverse examples and instructional strategies (Holmes et al., 2022). Additionally, the accessibility of AI-driven PD solutions makes advanced methodologies more attainable for teachers, especially in under-resourced settings, ultimately enhancing both teaching practices and student outcomes. This study explores how AI can bridge gaps in traditional PD models, focusing on its potential to revolutionize the teaching of spatial ability in primary education. Still, every AI solution has its limitations and also can produce insufficient and/or biased answers.

Theoretical Framework

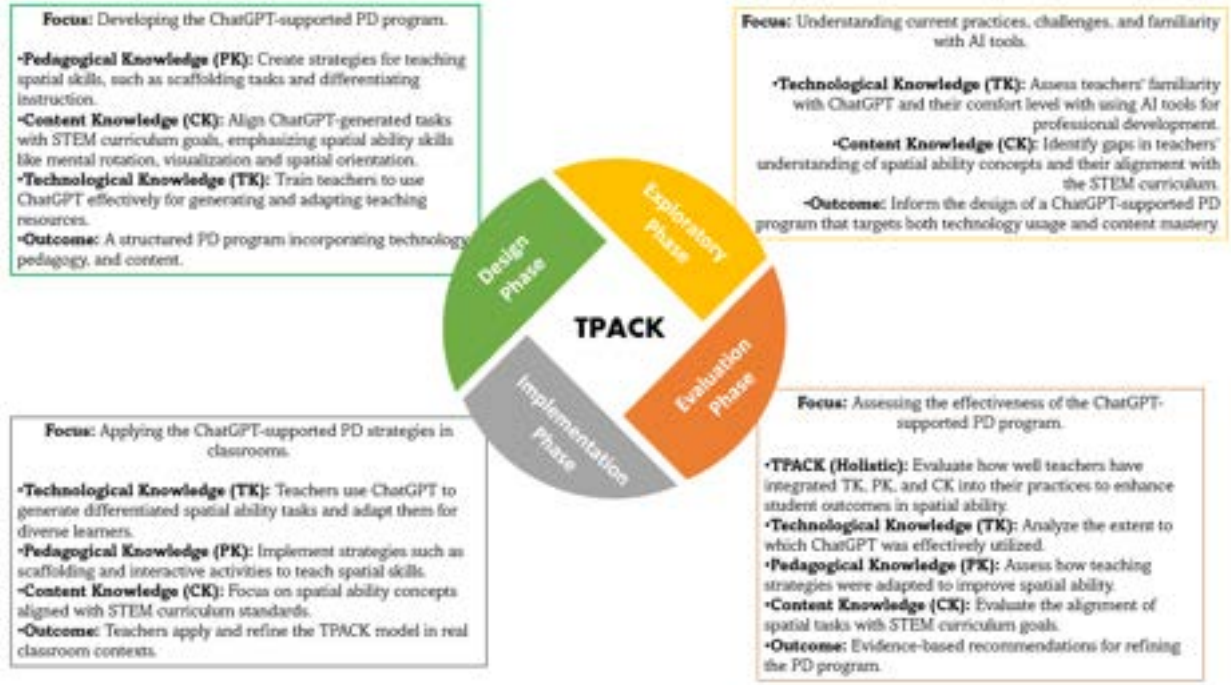
This study draws on two important frameworks for teaching & learning: the spatial cognition theory, and the TPACK framework. Spatial cognition theory (Uttal et al., 2013) underscores the malleability of spatial skills and their significance for STEM success. This study leverages these principles to enhance students' spatial skills through targeted teacher PD. The TPACK framework (Mishra & Koehler, 2006) integrates technology, pedagogy, and content knowledge, guiding the use of ChatGPT to align spatial skills strategies with STEM curricula. Grounded in design-based research (DBR) (Anderson & Shattuck, 2012), this study emphasizes iterative cycles to refine AI-supported PD, ensuring both theoretical rigour and practical relevance.

Aim Of The Study

The study aims to investigate the use of ChatGPT in enhancing PD for primary school teachers to improve spatial ability instruction. To achieve this, the study addresses the following objectives:

1. Investigate how ChatGPT can support teacher PD in improving spatial ability in STEM lessons.
2. Identify teachers' perceptions, challenges, and opportunities when integrating AI tools like ChatGPT into their PD.
3. Assess the effectiveness of ChatGPT-assisted PD compared to traditional PD methods.

Method



This study adopts a DBR approach, grounded in the TPACK and spatial cognition frameworks, to iteratively develop and evaluate a ChatGPT-supported PD program for primary school STEM teachers. The integration of ChatGPT serves as both a technological scaffold and a tool for aligning pedagogical strategies with spatial reasoning content. The DBR approach enables the refinement of the intervention through cycles of design, implementation, and reflection, ensuring both practical relevance and theoretical rigour (Anderson & Shattuck, 2012). The study involves 15 primary school teachers, selected through purposive sampling, who have diverse levels of experience in teaching STEM subjects. Their students (ages 8–10) are indirectly involved, with pre-and post-intervention assessments used to measure the impact of teacher PD on student spatial ability.

Phases Of Research

The study is structured into four key phases. In the exploratory phase, semi-structured interviews with teachers are conducted to understand their current practices, challenges, and familiarity with AI tools in their PD practices. These insights inform the design of a ChatGPT-supported PD program aligned with the TPACK framework, addressing gaps in technological knowledge (TK), identifying pedagogical strategies (PK) for teaching spatial ability and focusing on specific spatial skills such as mental rotation, spatial visualization and spatial orientation (CK). The intervention design phase involves developing a PD program consisting of workshops to train teachers on ChatGPT use, guided practice for aligning tasks with curriculum goals and adapting them for diverse student needs, and iterative reflections to refine their ChatGPT application. In the implementation phase, teachers integrate ChatGPT-supported strategies into their classrooms over six weeks. ChatGPT is utilized to generate differentiated spatial ability tasks, provide real-time feedback, and enhance lesson plans aligned with STEM curricula and developmental requirements. Finally, in the evaluation phase, both quantitative and qualitative data are collected through pre- and post-intervention tests, reflective journals, focus groups, and lesson

observations. These data are analysed using the TPACK framework to evaluate the integration of ChatGPT into teaching (TK, PK, CK), the alignment of spatial tasks with curriculum goals (TCK, PCK), and the overall effectiveness of ChatGPT in enhancing pedagogy and improving student outcomes (TPK, TPACK). In other words, to ensure that this phased approach ensures a comprehensive and iterative evaluation of the intervention, we set the TPACK elements as criteria for designing an effective STEM teacher PD solution that promotes teaching that supports student spatial ability. Figure 1 provides a visual representation of the DBR phases within the TPACK framework, illustrating how each phase is interconnected and aligned to enhance teacher development and student learning outcomes.

Figure 1. The DBR phases aligned with the TPACK framework, highlighting the integration of technological, pedagogical, and content knowledge in teacher PD for enhancing student's spatial ability.

The table below outlines how the TPACK framework was applied in the design and implementation of the ChatGPT-supported PD program. Each component of TPACK was strategically addressed throughout the various phases of the program's development and execution.

Findings

As this study is currently in its first cycle, findings are not yet available. The intervention is being implemented, and data collection will continue throughout the semester. By the time of the conference, the research will have completed all phases, including data analysis. Preliminary findings are expected to provide insights into how effectively ChatGPT supports teacher professional development for enhancing spatial reasoning skills and its impact on student outcomes. The conference presentation will focus on sharing these findings, discussing key themes from the qualitative data, and presenting implications for practice based on the quantitative results.

Table 1. Research phases aligned with TPACK components as design principles.

Phases	Component	Focus on PD Design	Annotation
Exploratory Phase	TK CK	Understanding current practices, challenges, and familiarity with AI tools.	**Activity:** Semi-structured interviews to assess teachers' current technological and content knowledge levels. **TPACK Focus:** Exploration highlights gaps in TK and CK, laying the groundwork for integrating these with PK in subsequent phases.
Design Phase	PK CK TK	Developing the ChatGPT-supported PD program.	**Activity:** Workshops for training on ChatGPT functionalities (TK), designing scaffolded spatial tasks (PK), and aligning them with curriculum goals (CK). **TPACK Focus:** The design integrates TK, PK, and CK to create a holistic program that fosters spatial reasoning.
Implementation Phase	TK PK CK	Applying the ChatGPT-supported PD strategies in classrooms.	**Activity:** Teachers integrate ChatGPT to design and implement lesson plans, aligning technology and pedagogy with STEM content. **TPACK Focus:** Real-time application of TPACK, enabling iterative refinement of teaching practices.
Evaluation Phase	TPACK (Holistic) TK PK CK	Assessing the effectiveness of the ChatGPT-supported PD program.	**Activity:** Analyse pre-and post-tests, focus groups, and reflective journals to assess TPACK integration. **TPACK Focus:** Evaluation synthesizes insights into how well TK, PK, and CK were integrated to improve teaching and learning outcomes.

Discussion

The TPACK framework, introduced by Mishra and Koehler in 2006, emphasizes the integration of technology, pedagogy, and content knowledge for effective teaching. Several studies have applied the TPACK framework to PD programs, demonstrating its effectiveness in enhancing

teachers' abilities to incorporate technology into their instruction. For instance, Bos (2011) highlights the integration of the TPACK framework in PD for elementary teachers, emphasizing its effectiveness in enhancing teachers' ability to incorporate technology into instruction. Through workshops and guided practice, teachers developed instructional units utilizing Web 2.0 tools and mathematical objects, aligning with TPACK principles. The study demonstrated that such professional development initiatives significantly improved teachers' technological, pedagogical, and content knowledge, enabling more effective technology integration in the classroom.

Moreover, recent studies have explored the integration of ChatGPT into educational settings, highlighting both its potential benefits and challenges. A systematic review by Mai et al. (2024) examined the strengths and weaknesses of using ChatGPT in teaching and learning, discussing opportunities and threats associated with its implementation. Additionally, a study conducted by Gill et al. (2024) analysed ChatGPT's capabilities and its impact on the education sector, identifying potential concerns and challenges. These studies collectively suggest that while ChatGPT can enhance personalized learning and provide immediate feedback, there are concerns regarding academic integrity, potential overreliance, and the need for educators to guide its ethical use.

Bridging The Gaps In STEAM Education: Voices Of Educators

Natalia Spyropoulou, Konstantinos Mathiopoulos and Achilles Kameas
Hellenic Open University, School of Science and Technology, Greece

STEAM education is widely recognised as a key approach for developing 21st-century skills through the integration of science, technology, engineering, arts, and mathematics. However, its implementation remains challenging due to limited resources, insufficient professional development, and weak systemic support for interdisciplinary teaching. This study, conducted within an EU Horizon project, examines the needs of in-service educators through a large-scale mixed-methods survey involving more than 600 participants from more than 25 countries. The analysis focuses on five areas: preparation, implementation, coordination, collaboration, and professional development. The findings highlight financial constraints, lack of preparation time, and limited training opportunities as major barriers. Educators also emphasised the need for real-world learning, improved technological infrastructure, and assessment approaches aligned with interdisciplinary goals. The study points to the importance of policy support, sustained funding, and structured professional development to enable effective and inclusive STEAM education.

Keywords: STEAM Education, Teachers professional development, teacher perceptions

Introduction

STEAM education integrates multiple disciplines to provide learners with a holistic learning experience that supports the development of 21st-century skills. By integrating science, technology, engineering, the arts, and mathematics (STEAM), STEAM promotes inquiry-driven, project-based, and problem-solving learning activities that reflect real-world challenges (Amanova et al., 2025; Leavy et al., 2023). Research shows that interdisciplinary and experiential learning approaches enhance student engagement and better prepare learners for changing labour market and societal demands (Erol, Erol, & Başaran, 2023; Harris & de Bruin, 2017).

The integration of diverse disciplines within STEAM education responds to the growing need for a workforce capable of combining technical knowledge with creativity, critical thinking, and collaboration. Across Europe, industries increasingly seek professionals with strong digital competences, sustainability awareness, and innovation-oriented problem-solving skills (Colucci et al., 2017). In this context, STEAM education plays a key role in supporting future generations to address complex global challenges, including technological transformation and sustainable development (Yeomans et al., 2025; Yim et al., 2025).

Despite its widely recognised benefits, the effective implementation of STEAM education largely depends on educators' ability to design and deliver interdisciplinary teaching (Spyropoulou, Mathiopoulos & Kameas, 2025). This requires not only subject knowledge but also pedagogical approaches that support collaboration across disciplines, real-world learning, and innovative assessment practices (Firmansyah & Aslan, 2025). However, many education systems continue to prioritise traditional, discipline-based structures, limiting opportunities for integrated teaching and learning.

As a result, educators often face structural, organisational, and professional barriers when attempting to implement STEAM approaches in practice (Ariza, J. Á., & Olatunde-Aiyedun, 2023). Limited access to targeted professional development, lack of institutional support, and insufficient time and resources further constrain their capacity to adopt interdisciplinary methods effectively.

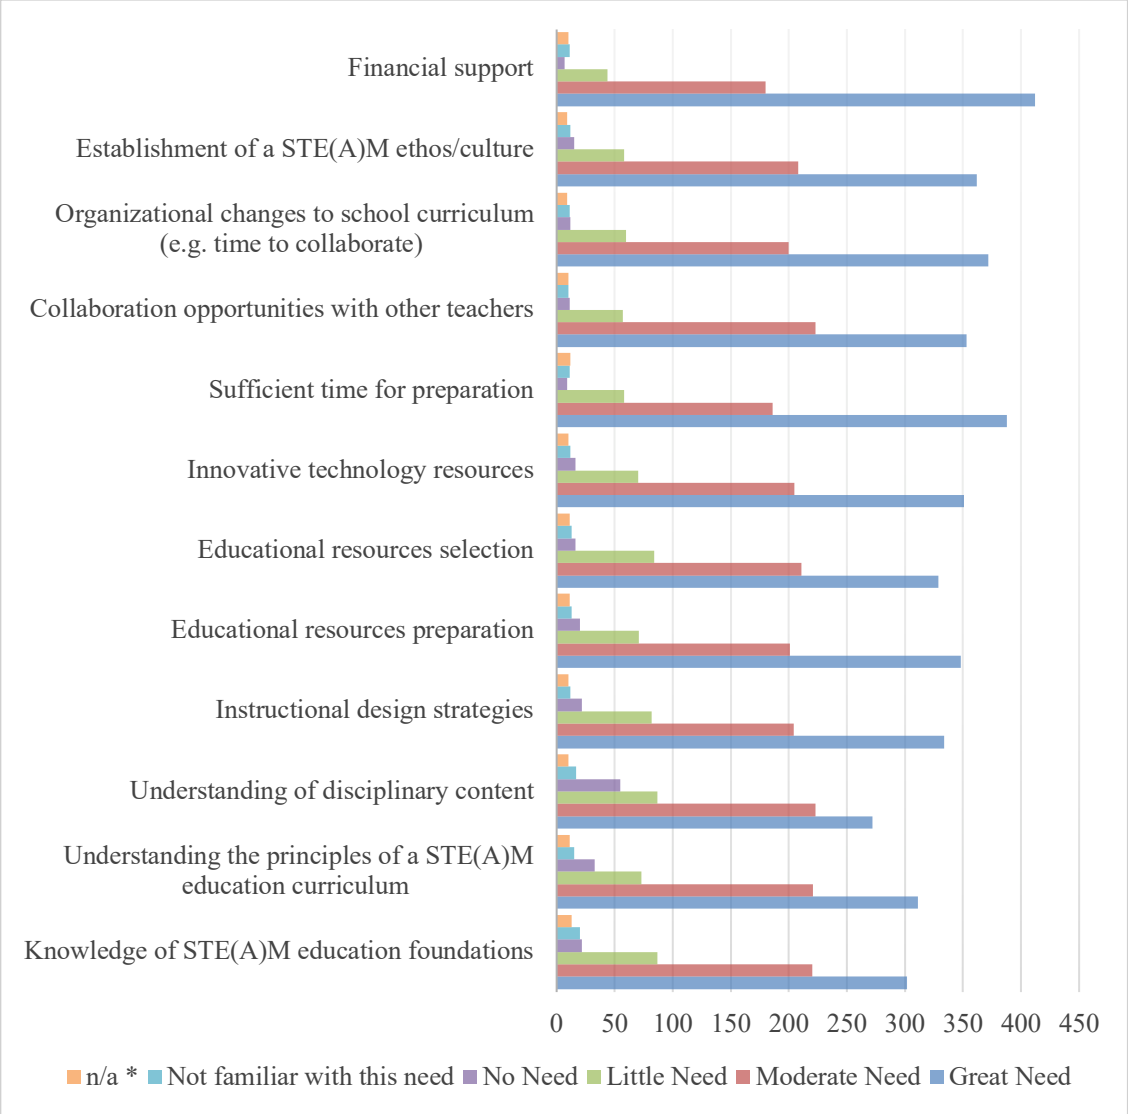
This study aims to identify the specific needs and gaps of in-service teachers in relation to the implementation of STEAM education. By examining current challenges in teachers' preparation, support structures, and working conditions, the study provides evidence-based insights to inform strategies that can strengthen STEAM teaching and learning across Europe.

Methods

For this study, we employed a survey-based approach to gather quantitative and qualitative data on the needs of in-service educators in STEAM education. A structured questionnaire was developed to capture various aspects of educators' experiences, competences, and challenges during the different roles of educators during preparing, design, implementing and coordinating STEAM education projects and activities. The questionnaire was designed based on existing research in STEAM education and the competence framework (Spyropoulou & Kameas, 2024). It included demographic questions, Likert-scale items, and open-ended responses to ensure the following five core dimensions:

- Preparation and Development: Understanding of STEAM foundations, curricular standards, disciplinary content, instructional design strategies, and more.
- Implementation: Needs for resources and support to implement pedagogical strategies, content knowledge of specific STEAM disciplines, instructional time, assessment methods, etc.
- Coordination: Support needs for coordinating and managing the educational process, resource and lab management, handling of students/teachers, and school organization/administration.
- Collaboration and Community Building: How to foster cooperation with other educators, institutions, parents, local communities, and industries.
- Professional Development: Understanding of STEAM instructional practices, student motivation strategies, assessment tools, teamwork techniques, classroom organization, and the use of emerging technologies.

The survey targeted 664 in-service educators from 28 countries. The professional roles of participants varied, with secondary teachers comprising the largest group (45.5%), followed by primary teachers (20.7%), secondary principals/directors/education managers (8.5%), and pre-primary teachers (7.0%). Other roles included vocational school teachers and teacher trainers/adult educators. While the overall survey addressed all five dimensions, this paper concentrates on the first dimension, Preparation and Development. This focus enables a detailed examination of the foundational conditions necessary for effective STEAM education and provides insights into the early-stage challenges educators face in designing and planning interdisciplinary learning experiences.



Findings And Discussion

The survey results reveal substantial needs and structural gaps in the preparation and development of STEAM education programmes for in-service teachers. Figure 1 presents an overview of the results for the survey questions. The most prominent finding concerns financial support, which emerged as the highest-ranked need. More than 62% of respondents reported a strong need for funding, while an additional 27% indicated a moderate need. This clearly shows that many schools lack the financial capacity to support teachers and STEAM implementation, including the purchase of materials, technological equipment, laboratory resources, and digital tools.

Closely linked to funding constraints is the issue of time for preparation, which nearly 58% of respondents identified as a major need. STEAM education requires careful planning, coordination across subjects, and the design of interdisciplinary learning activities. The findings indicate that current school schedules do not adequately support these demands, leaving teachers to prepare STEAM activities outside formal working hours. The data also indicate the need for organizational changes within school curricula, with 56% of respondents emphasizing the importance of structural flexibility, underscoring the need for curricular arrangements that enable collaboration, co-teaching, and interdisciplinary planning.

Another important finding relates to the establishment of a STEAM ethos and culture within schools. More than half of respondents indicated that institutional support, shared vision, and leadership commitment are essential for successful STEAM implementation. In addition, teachers reported significant needs related to the preparation of educational resources and access to innovative technologies. More than half of the respondents identified the preparation of STEAM-specific teaching materials and the integration of digital and technological resources as critical. Finally, the development of instructional design strategies tailored to STEAM was identified as a key gap. Teachers expressed the need for guidance on designing interdisciplinary learning activities that align learning objectives, teaching methods, and assessment practices.

Figure 1. Questions result from STEAM educators' needs.

The open-ended responses provided additional insights into the challenges and needs of educators in STEAM education. The thematic analysis revealed four key themes, as outlined in the table below (Table 1):

Table 1. Themes and key findings from open-ended questions.

Theme	Key Findings
Infrastructure and Resources	Lack of modern facilities, need for dedicated STEAM labs, and increased financial support
Curriculum and Assessment	Demand for innovative assessment methods, continuous curriculum feedback
Cultural and Systemic Changes	Resistance to change, calls for reduced bureaucracy, public awareness initiatives
Inclusivity and Accessibility	Need for inclusive learning environments ensuring equal access to STEAM education

Infrastructure and resources emerged as a central concern. Educators frequently referred to the lack of modern facilities, the absence of dedicated STEAM laboratories, and limited access to equipment and digital tools. These constraints were closely linked to insufficient financial support and were seen as a major barrier to implementing hands-on and inquiry-based STEAM activities. Curriculum and assessment challenges were also strongly represented in the responses. Participants highlighted the need for more flexible curricula that support interdisciplinary learning, as well as assessment approaches better aligned with STEAM pedagogy. In particular, educators called for project-based assessment, peer review, and formative feedback mechanisms that reflect collaboration and problem-solving rather than traditional testing practices. A third theme concerned cultural and systemic changes within education systems. Educators reported resistance to change at institutional and administrative levels, alongside excessive bureaucracy that limits innovation. Several respondents stressed the need for stronger leadership support, reduced administrative burden, and broader public awareness initiatives to legitimise and promote STEAM education within schools and communities. Finally, inclusivity and accessibility were identified as critical considerations. Respondents emphasised the importance of inclusive learning environments that ensure equal access to STEAM education for all learners, regardless of gender, socio-economic background, or learning needs. This includes accessible infrastructure, inclusive pedagogical approaches, and targeted support measures to avoid reinforcing existing inequalities.

Discussion And Conclusion

The findings of this study highlight a clear and consistent message: the effective implementation of STEAM education depends on systemic support for educators, extending beyond individual professional development to include financial investment, curriculum flexibility, and strong institutional backing.

Financial support emerged as the most critical need, confirming previous research that identifies funding as a prerequisite for meaningful STEAM implementation (Harris & de Bruin, 2017). STEAM education relies heavily on access to materials, digital tools, laboratories, and flexible learning spaces. Without sustained financial investment, STEAM practices risk remaining

fragmented, project-based, or dependent on short-term initiatives rather than being embedded within school systems.

In parallel, the strong demand for time and professional development reflects broader challenges in teacher preparation and working conditions (Ariza & Olatunde-Aiyedun, 2024). STEAM education requires educators to collaborate across disciplines, design interdisciplinary learning activities, and adopt innovative pedagogical and assessment approaches (Amanova et al., 2025). However, existing school structures often limit opportunities for joint planning and peer learning (Spyropoulou et al., 2025). Consistent with earlier studies, the findings show that targeted professional development, combined with protected time for collaboration, is essential for building educators' interdisciplinary competences and confidence (Conradty & Bogner, 2020).

Rigid subject-based timetables and assessment structures were perceived as major barriers, strengthening the view that STEAM education cannot be effectively implemented without systemic adjustments at the school and policy level (Spyropoulou, Ioannou & Kameas, 2025).

The results also point to curriculum and organisational barriers as major constraints. Rigid subject-based curricula, standardised assessment practices, and limited flexibility in scheduling were perceived as incompatible with interdisciplinary teaching. These findings align with the literature emphasising the need for curriculum innovation and adaptive assessment models to support inquiry-based and project-based learning in STEAM contexts (Shernoff et al., 2017). Addressing these barriers requires policy-level action to allow schools greater autonomy in curriculum design and assessment practices.

Insights from the open-ended responses further illustrate the multifaceted nature of educators' challenges. Infrastructure and resource limitations were repeatedly mentioned, reinforcing the quantitative findings and highlighting the importance of modern learning environments and dedicated STEAM spaces. Educators also called for assessment approaches that better reflect collaboration, creativity, and problem-solving, such as project-based and peer-reviewed methods (Firmansyah, & Aslan, 2025). These findings suggest a mismatch between STEAM pedagogical goals and existing evaluation systems. Cultural and systemic resistance to change emerged as another significant challenge. Educators reported bureaucratic constraints and limited institutional openness to interdisciplinary innovation. Overcoming these barriers requires a cultural shift within education systems, supported by leadership commitment, reduced administrative burden, and increased awareness of the value of STEAM education among policy makers, school leaders, and the wider community. Finally, inclusivity and accessibility were identified as essential dimensions of sustainable STEAM education. Respondents stressed that STEAM initiatives must ensure equal access for all learners, avoiding the reinforcement of existing social, gender, or digital divides. Inclusive pedagogical approaches, accessible infrastructure, and targeted support measures are therefore central to ensuring that STEAM education contributes to both equity and innovation (Weisberg et al., 2025).

In conclusion, the study demonstrates that advancing STEAM education requires coordinated action across multiple levels of the education system. Targeted policy reforms, increased and sustained funding, innovations in curriculum and assessment, and structured professional development are all necessary to support educators effectively. By addressing both structural and cultural barriers, education systems can move towards more inclusive, coherent, and sustainable STEAM learning environments. Such environments are essential for preparing learners to navigate complex societal and technological challenges and to participate actively in an increasingly interdisciplinary and digital world.

Building Knowledge Together: How Collaborative Professional Development Fostered New Learning Opportunities For Secondary Physics Teachers

Rebecca Harrop and Deepa Chand
Te Herenga Waka – Victoria University of Wellington, New Zealand

This paper, guided by transformative learning theory, presents how new learning opportunities emerged during three topic-specific collaborative senior physics workshops. We identified structured activities and participant interactions that created opportunities for transformative learning and examined the barriers limiting these opportunities. Using a multiple case study approach, audio recordings during and reflective interviews after the workshops were collected from six participants teaching Year 12 (Grade 11) physics in New Zealand. Qualitative analysis revealed that the CoRe framework's structure and prompts together with the collaborative dialogue created disorienting dilemmas and opportunities for critical reflection, the initial phases of transformative learning. The findings suggest that professional development designed to make teacher thinking visible combined with collaborative conditions that encourage questioning and uncertainty-sharing can systematically create opportunities for transformative learning if teachers have sufficient content knowledge and are willing and ready to engage in alternative perspectives. The study provides facilitators with practical insights for designing collaborative professional learning that may contribute to meaningful shifts in how teachers plan their practice.

Keywords: Physics, Professional Development, Transformative Learning Theory

Introduction

Collaborative Content Representation (CoRe) workshops have been shown to contribute to the development of teachers' pedagogical content knowledge for pre-service and in-service science teachers at both secondary and primary levels (Carpendale, 2018; Eames & Birdsall, 2019; Hume & Berry, 2013; Williams et al., 2012). In these studies, there has been less focus on the specific mechanisms that create learning opportunities within these workshops. Previous studies have instead focussed on learning outcomes, with less exploration of how structured activities and participant interaction created opportunities for learning. This paper examines these approaches through the lens of transformative learning theory (Mezirow, 2003) by answering these questions: How were learning opportunities created in the collaborative-CoRe physics PLD, and in what ways do these learning opportunities align with the initial phases of Mezirow's TLT?

In this study we use "learning opportunities" to refer to moments within the workshops where conditions emerged that could facilitate transformative learning. We focus on opportunities characterised by disorienting dilemmas and critical reflection, the initial phases of Mezirow's transformative learning process. We recognise that while these opportunities create the potential for transformation, whether individual teachers experienced actual transformation in their frames of reference require longer-term investigation that was beyond the scope of this study.

This study focuses on two aspects of TLT: disorienting dilemmas and critical reflection through dialogic interaction. When participants experience disorienting dilemmas, they question their assumptions and consider alternative perspectives. In literature, disorienting dilemmas have been explored in a professional development setting with beginning teachers (Laros & Košinár, 2019) and through the self-reflection of an experienced teacher-educator (Berry, 2010). These studies

show how disorienting dilemmas can disrupt their thinking and act as catalysts for adults to become critically conscious (Mezirow, 1991) and transform their learning.

Critical reflection supports teachers to understand "what they do and why they do it" (Cranton & King, 2003, p. 35). According to Liu (2015), critical reflection incorporates processes (e.g. analysis, questioning), content (e.g. assumptions about teaching), and goals (e.g. improved student outcomes). Despite there not being consensus about whether critical reflection is necessary for new learning, (Fleming, 2018; Mezirow, 2003) it is still one aspect that could lead to transformative practices. Philp-Clark & Grieshaber's (2024) meta-aggregative qualitative evidence synthesis identified that teachers use critical incidents, such as disorienting dilemmas, to reflect and identified that collaborative critical reflection embedded in professional learning and connected to clear objectives appeared to be a successful strategy for supporting a change in teachers' thinking.

Another key aspect of Mezirow's (2003) TLT is the critical role dialogue and dialectic discourse play in learning, which is especially relevant to collaborative professional learning. Mezirow emphasises that transformative learning occurs through dialectic dialogue, where adults critically examine their assumptions and engage with alternative perspectives. Richman et al. (2019) claimed that collaborative professional learning can facilitate changes to science teachers' practice with the New Generation Science Standards. Similarly, while not at secondary level, Nolan and Molla (2018) demonstrated that early childhood teachers learn best when they engage in thorough and thoughtful analysis through social collaboration, suggesting that this collaborative approach may be beneficial for teachers regardless of age groups taught.

Method

This qualitative study employed a multiple case study approach to examine how new learning opportunities occurred during collaborative professional learning. The design was useful because it enabled us to explore deeply how teachers created opportunities for new learning through dialogue in their experiences of disorienting dilemmas. Full ethical approval was obtained from the Human Ethics Committee at Victoria University of Wellington (VUW) (0000030762), and the research process was conducted in accordance with the NZARE (2010) guidelines.

Six fully informed and consenting participants teaching senior physics in New Zealand participated in this study. All participants had more than five years of teaching experience and worked in English-medium schools following New Zealand's national curriculum. Their schools represented diverse socio-economic backgrounds. Participants were recruited through convenience sampling, replying to an email seeking expressions of interest.

Three audio recordings and six interviews were analysed using Johnson and Christensen's (2020) analytical approach. First, it was transcribed before being segmented during preliminary reading. Deductive coding identified instances of learning opportunities, and inductive coding identified patterns in the new learning opportunities and themes were created. A hierarchical coding system and network diagram helped us to explore the relationships between the codes and themes. Intercoder reliability checks were completed once themes had been established and themes were linked to specific approaches of TLT.

The study centred around three four-hour workshops based on Loughran et al.'s (2008) Content Representations (CoRe) which were operationalised in collaborative settings for pre-service secondary chemistry teachers (Hume & Berry, 2011, 2013) and in-service secondary science (Carpendale & Hume, 2020; Eames & Birdsall, 2019) and primary science teachers (Hume, 2016). The workshop utilised a bottom-up approach (Timperley, 2011) to develop individuals' teaching and learning knowledge and skills related, in this study, to a physics topic. The

workshops aligned with the participants' upcoming physics topic, the New Zealand Curriculum (Ministry of Education, 2007), and the relevant Physics Achievement Standards from the New Zealand Qualifications Authority (NZQA, 2014a, 2014b, 2014c). Participants met in groups of between two and four to collaboratively create a CoRe-design. They identified the key concepts and big ideas in the topic and, using the prompts discussed for each big idea, the importance of the concepts, the teaching strategies, the difficulties, misconceptions, and associated models and representations that could be used to teach the big ideas, and strategies to assess the big ideas.

Teachers attended between one and two workshops which were spaced two months apart. This spacing reflected the need to schedule topics before teachers began teaching them. They were facilitated by the first author, an experienced physics teacher, who intentionally avoided providing content explanations. Direct facilitator interventions offering content support or pedagogical solutions were excluded from the data analysis, however, procedural facilitation was included as this formed part of the workshop structure and did not pre-determine participant responses. The semi-structured one-on-one interviews exploring teachers' perceptions of learning, reflections of changes in their thinking about physics content and pedagogy were completed within two weeks of the workshops and lasted between 45 and 60 minutes, these were conducted in person or online by the first author.

Results And Discussion

Structure and Prompts

Opportunities for new learning occurred when teachers articulated their uncertainty into a shared space which allowed others to offer alternate perspectives. The structure and prompts of CoRe seemed to support teachers to discuss topic-level PCK in a more nuanced way than when they first considered it. This progression can be identified in the following example. Initially teachers' thoughts around assessment were relatively undifferentiated.

> P1: "Assessments for different concepts, we can just put the same approach can't we?"
>
> P2: "I mean just walking around and asking students about the work"
>
> P3: "Really? Like what, more quizzes?"

After further exploration of the big ideas through the CoRe prompts, one teacher articulated a more sophisticated understanding of assessment:

> I'll still go round and talk to students and ask them questions, but actually, you could build circuits and get students to check their understanding with me… That way they start to understand some of the practical [skills], concepts, and how they go together.

This shift towards a more nuanced understanding suggests that the prompts and structure of the CoRe contributed to deepening this teachers' understanding of assessment strategies in this topic.

The collaborative aspect supported by CoRe prompts appeared to encourage teachers to experience disorienting dilemmas. Sorting key concepts into groups provided opportunities for teachers to question and disagree with each other, which served as a productive tool for deepening their understanding. In the following example, three teachers explored what "nuclear stability" meant to them and whether it is an appropriate term to use.

> P1: "we have atomic structure, so could another big idea be nuclear stability?"
>
> P2: "what do you mean by stability and why would you use it?"
>
> P1: "because those are released when we undergo nuclear decay."

P2: "Does that make it more stable? … for me this is not stability, because it just goes ting, ting, ting, ting, ting (indicates transformation of atomic nuclear by decay)…

P3: "are you looking at the fundamental forces when you mean stability?""

P1: "some atoms are more stable than others… in using the term 'stability' I'm describing a measure of how stable a particular atom is… The forces are a bit beyond what is needed I think.

P3: Those are covered at year 13, perhaps we could use reaction.

P1: Stability is good for half-life though

P2: I think you're talking about two different things. We should look at each idea first before grouping them.

Through these interactions, P1's initial vague notion of nuclear stability was challenged and refined. P2's questioning revealed a conceptual ambiguity which resulted in the group collectively recognising that they needed to clarify the individual concepts thoroughly before organising them. When multiple interpretations were shared and disagreement created, participants were able to experience disorienting dilemmas.

The structure of the collaborative CoRe also encouraged opportunities for critical reflection. When discussing why it was important to teach and understand the history of the atom, the teachers initially began with surface level justifications, including "teaching vocabulary" and "it's required content." When the facilitator contextualised one of the prompts, "why is it important to know about this general atomic model changes over time?", one teacher began to examine their underlying assumption that they "teach it because I'm required to" and recognised this framing as problematic to students' deep understanding of science as an ever changing body of knowledge and appeared to shift her perspective.

> The biggest thing for me is that they need to realise that when I start with an atom, I'm like 'ohh this is an atom, the nucleus is in middle and electrons outside,' but now this is not how it looks like anymore. Then they go, 'why didn't we learn that in year 9?'. That [progression] is helpful as it shows them that ideas change, and this change is because of technology and changes over time.

Building on this insight, a second teacher extended this critical reflection by suggesting another historical example from different scientific domains to demonstrate how scientific understanding evolves and highlighting the importance of students gaining this epistemological understanding of science: "if you can get access to the medical texts from the 16th century. [you'd see] 'He has a headache, so we're going to drill a hole into his head through his skull to relieve the pressure.'" This example illustrated the teachers understanding that the history of atomic models helps students see science not as a collection of facts, but as a field where mistakes have been made and corrected, making it important to learn from past errors and essential for developing students' critical awareness.

This example illustrates Mezirow's (1981, 2003) concept of critical reflection in action and demonstrates how the CoRe prompts facilitated critical reflection which then contributed to transform teachers' understanding from viewing content as something that needs to be covered to recognising its role in developing students' epistemological understanding of science.

Barriers To Learning

Two barriers were identified that did not appear to encourage these opportunities to be created. The first, was teachers' self-reported understanding of the content and concepts being taught in

the topics. These included one teacher who was new to teaching physics and suggested he "didn't have enough content knowledge." This teacher reported being "a passive observer," did not participate a lot in discussions, and reported during workshops that "this is just going over my head." This teacher was sometimes dismissive of other teachers' desire to explore concepts in more detail stating, "kids' don't need that" and "do we want to make physics boring for them?" Another teacher also made minimal contributions in some sections, they reported during the workshop and in the follow up interview that "to be honest I don't know a lot about it." Discussions about concepts and pedagogy were unable to progress when teachers were unable to participate or explain more fully.

The second barrier identified was teachers' willingness or unwillingness to consider alternative approaches and ideas. Beyond the teachers already identified, a third teacher demonstrated an unwillingness to engage with alternative perspectives. They expressed boredom "I'm so bored… I feel like we're trudging through the same thing again," showed resistance to probing concepts further "I hadn't intended to [discuss fundamental forces], do you [the facilitator] want us to?" and were content with their teaching methods "for level 2 I just have a booklet that I made and the students go through the booklet. it's the same each year… and I know it works because I wrote it." These types of interactions not only reduced their own opportunities to engage with new ideas but also other teachers' opportunities to explore new concepts and approaches.

These instances showcase how teachers' content knowledge limitations and unwillingness to engage not only reduced their participation in the conversations but also appeared to reduce the chances of them experiencing disorienting dilemmas and critical reflection. Whether these conversations created an opportunity for these processes to occur internally was not captured in the data and cannot be discounted. The evidence, however, suggests that for transformative learning to occur, teachers need both sufficient content knowledge to recognise challenges to their existing frameworks and an openness to engage with alternative perspectives. It should be noted though, that these less open-minded behaviours not only did not progress conversations for others, but may have deterred others sharing when the comments seemed dismissive. These barriers emerged despite the facilitators' repeated attempts to prompt reflection and create opportunities for deeper engagement, suggesting that structural factors alone, such as collaborative time and prompting questions, may be insufficient when teachers lack content knowledge or appear unwilling to engage in learning.

Discussion

This study demonstrates that structured collaborative professional development can systematically create the conditions for transformative learning as described by Mezirow's theory (2003). The CoRe framework's prompts and collaborative structure facilitated the initial phases of transformative learning: disorienting dilemmas and critical reflection, by creating spaces where teachers were able to articulate their uncertainties and experience alternative perspectives through discussion. When teachers engaged in productive disagreement, they were prompted to reconsider their understanding when other teachers challenged their ideas and assumptions. Similarly prompts pushed teachers beyond surface-level responses and allowed them to examine their underlying pedagogical assumptions and shift their thinking. These findings align with previous research showing how disorienting dilemmas can catalyse transformative learning in professional development settings (Berry, 2010; Laros & Košinár, 201) and support Philip-Clark and Grieshaber's (2024) conclusion that collaborative critical reflection that is embedded in professional development can contribute to changing teachers' thinking.

Fewer opportunities for new learning were identified for teachers with limited content knowledge. Mezirow (2003) defined transformative learning as "learning that transforms

problematic frames of reference" to make them "more inclusive, discriminating, open, reflective, and emotionally able to change" (p. 58). For transformation to occur, adults must first have an existing frame of reference that can be challenged. Teachers who lacked experience teaching the content and confidence in their content knowledge may not have yet established conceptual and teaching frameworks for the topics behind discussed that could be disrupted or transformed. This finding suggests that transformative learning opportunities may be inappropriate for teachers in the early stages of developing their content knowledge or pedagogical content knowledge. Instead, of this collaborative approach, they may require professional learning that focusses on acquiring new knowledge and skills rather than transforming existing perspectives. Furthermore, the "not knowing" about content prevented teachers from engaging in what Mezirow describes as "critical dielectric discourse involving the assessment of assumptions and expectations supported by beliefs, values, and feelings" (p. 60). In these cases, it appeared the teachers had not yet formed assumptions about what these concepts were and how to teach them.

Teachers' dispositions did not sometimes appear to suit to this type of professional learning. Mezirow (2003) emphasises that participating in critical dialectical discourse requires "having an open mind, learning to listen empathetically, 'bracketing' premature judgement, and seeking common ground" (p. 60) as well as emotional intelligence including "empathy and social deftness" (p. 60). Participants who were unwilling seemed resistant to exploring deeper, appeared satisfied with their existing understanding of concepts and practices, which suggests they held a frame of reference that was not "open, reflective, and emotionally able to change" (p. 58). Despite having access to potential disorienting dilemmas, such as the debate about nuclear stability, this teacher appeared to actively avoid engaging with these challenges, suggesting they were not actively engaging in learning.

Whether these conversations that are supported by the CoRe framework created opportunities for internal disorienting dilemmas and critical reflection that were not verbalised could not be discounted. Mezirow (2003) states that adult educator's role is "to help learners acquire the skills, sensitivities, and understandings essential to become critically reflective of assumptions and to participate more fully and freely in critical-dialectical discourse" (p. 62). This assumes that providing such help will be effective, and that learners are willing and able to develop these capacities. These findings challenge this assumption and reveal that transformative learning requires both sufficient content knowledge as well as a dispositional openness to engage with alternative perspectives. When these prerequisites are not present, even appropriate facilitation and structures may not be sufficient to create conditions for transformative learning. Furthermore, in collaborative professional learning settings, individual resistance may compromise the conditions required for discourse for themselves and other group members.

Conclusion

To create learning opportunities that support transformative learning, these findings suggest PLD providers consider including structured activities where teachers are required to make their thinking visible, create collaborative conditions where teachers feel comfortable sharing uncertainties and questioning their teaching practice to enable authentic dialogue, and find strategies to identify whether teachers are ready to learn, both with their content knowledge and dispositions. While the study provides insight into collaborative professional development, several limitations exist. The small sample size, while useful for gathering rich and in-depth data, limits generalisability. Additional limitations include potential researcher bias due to the facilitator also being the primary researcher. While this provided deep insight into workshop dynamics, it may have influenced both the facilitation approach and data interpretation. We attempted to mitigate this through reflexive journalling, intercoder reliability, and member

checking. Additionally, whether this approach can be used in other subject areas or cultural contexts requires further research, given the focus on senior physics and a New Zealand setting. Further research might explore how this approach transfers to other subject areas and whether the effectiveness persists in longitudinal studies that track sustained changes in teaching practices.

ESERA 2025 Copenhagen

Development Of Teacher Training Model That Transforms The Science Teacher Competencies

Hideki Hokari[1,2] and Ichiro Wada[3]
[1] The United Graduate School of Education, Tokyo Gakugei University, Japan
[2] Nakane Elementary School, Japan
[3] Yokohama National University, Japan

This study aims to develop a professional learning model based on lesson study as a form of on-the-job training (OJT). It responds to the current situation in Japan, where teachers have difficulty participating in professional development outside of working hours. Teacher competencies were conceptualized as Competency in Mind (CM), which appears in teachers' conscious awareness, and Competency in Action (CA), which appears in their behaviors during lesson study. The study examined the process through which these competencies transform, based on the relationship between CM and CA. As a theoretical framework, Naumescu's (2008) GPC (Good Practices related on Competencies) and Kiper & Mischke's (2009) Structural Theory of Instruction were adopted. The GPC items were reclassified into three categories—TTC (Teacher–Teacher), TSC (Teacher–Student), and TCC (Teacher–Context)—and used for analysis.

A qualitative study was conducted with one science teacher (Mitsuzane), using a combination of the GPC questionnaire (for CM) and utterance analysis during lesson study (for CA). Prior to the lesson study, the teacher received feedback on his CM profile to enhance awareness of his competency tendencies. The researchers then examined changes in CA during the lesson study. Afterward, interviews were conducted to explore the gaps between CM and CA. Results showed that the teacher made conscious efforts to improve GPC items that had been rated low in his CM. Actual improvement in CA—particularly within the TCC domain—was also confirmed. Notably, GPC items related to classroom management and the analysis of students' responses were prominently manifested in CA. These items had been rated low in CM. The teacher also stated that the prior presentation of CM influenced his actions during lesson study. This suggests that CM awareness may foster intrinsic motivation for learning and may lead to behavioral transformation.

Analyses with three additional teachers indicated that researchers' recommendations contributed to changes in CA. This further supports the influence of targeted guidance. The significance of this study lies in showing that incorporating a CM-awareness process into lesson study can establish an effective learning model. This model enables teachers to enhance their competencies autonomously.

Keywords: Teacher Competencies, Lesson Study, Professional Learning

Introduction

According to TALIS 2018, Japanese elementary and lower secondary teachers spent the least amount of time on professional development among all participating countries. This limited participation was attributed to factors such as scheduling conflicts and responsibilities at home.

In Tokyo, professional development is described as comprising three modalities: on-the-job training (OJT), off-the-job training (Off-JT), and self-directed learning. OJT refers to professional learning that takes place within the school, grounded in concrete situations and teacher actions. Off-JT includes group or online training organized by boards of education and dispatch programs to professional graduate schools of teaching. Self-directed learning refers to voluntary professional learning such as reading books and attending seminars. In other words, the TALIS

2018 results suggest that Japanese teachers face difficulties allocating time for Off-JT or self-directed learning. The same survey also found that many Japanese teachers viewed professional learning in instructional methods and content knowledge more positively when others observed their lessons and provided feedback.

Given this context, professional development that is feasible for Japanese teachers is that which can be conducted during working hours as OJT. To enhance competencies related to instructional methods and content knowledge, it is necessary to create a professional learning environment in which teachers' classroom instruction is observed by others and feedback is provided.

In Japan, lesson study has long been practiced as one form of professional development. According to Isozaki (2015), lesson study consists of the following:

> Lesson study aims to improve teachers' instructional expertise and build collegiality through collaborative engagement among teachers. It is divided into three stages: the planning stage, the implementation stage, and the reflection stage.
>
> In the planning stage, teachers collaboratively identify issues of concern and decide on the research theme, learning goals, and lesson plan. They also determine the lesson content, instructional focus, materials, and assessments. These planned activities serve as concrete indicators that clarify the value of lesson study for both the teacher conducting the lesson and the observers.
>
> During the implementation stage, observers evaluate the lesson using the lesson plan as a guide. They collect data related to learning goals and focal activities, record observations, and attend carefully to the utterances of teachers and students to interpret their understanding of the content. In science classes involving hands-on activities such as experiments, observers may also examine motor-skill aspects or move around the classroom to capture the learning status of specific students. Japanese lessons often follow an inquiry-based learning process consisting of problem setting, information gathering, analysis, and synthesis. Lessons may also be recorded for later analysis.
>
> During the reflection stage, immediately after the lesson, teachers, observers, and invited experts review the lesson based on the collected data. The results of these discussions—both strengths and challenges—are accumulated and often compiled into a research report at the end of the study period. A research presentation meeting may also be held, showcasing the lesson and its outcomes and featuring a lecture by an invited expert.

However, in recent years, lesson study in Japan has been deteriorating due to the severe worsening of teachers' working conditions. TALIS 2024 also reported that Japan had the lowest ratings worldwide on items such as "All in all, I am satisfied with my job," "If I could decide again, I would still choose to work as a teacher," "I enjoy working at this school," and "I would recommend this school as a good place to work." Therefore, this paper seeks to reconstruct lesson study as a method of professional development. This study develops a professional learning model through lesson study to enhance science teachers' competencies and to cultivate teachers who are deeply aware of the noble mission of their profession, who continuously engage in inquiry and self-cultivation, and who strive to faithfully fulfil their professional responsibilities.

Theoretical Framework

This section summarizes prior studies that form the theoretical background of the present paper. Before explaining the theoretical background, Table 1 summarizes the key concepts and abbreviations used in this paper.

Table 1. Key Concepts and Abbreviations

Abbreviation	Full Term	Definition / Explanation
CM	Competency in Mind	Competencies consciously recognized by teachers, measured through the GPC questionnaire.
CA	Competency in Action	Competencies manifested in teachers' behaviors during lesson study.
GPC	Good practices related on competencies	Framework by Naumescu (2008) consisting of 28 competency items used for analysis.
TTC	Teacher–Teacher Competencies	GPC items related to teachers' knowledge, epistemological understanding, and interactions with colleagues.
TSC	Teacher–Student Competencies	GPC items related to teaching–learning processes and interactions with students.
TCC	Teacher–Context Competencies	GPC items related to managing instructional contexts, classroom situations, and contextual factors.
LPM	Lesson Planning Map	Framework adapted from Kiper & Mischke (2009) to analyse teacher competencies across planning, implementation, and evaluation stages.

GPC: Good Practices Related On Competencies

In Japan, no competency framework specifically defines the professional competencies required of science teachers. Therefore, we attempted to apply Naumescu's (2008) "Good Practices related on Competencies (GPC)" to Japanese science teachers (Table 2). Conventional competency frameworks generally focus on qualities derived from knowledge of scientific concepts. In contrast, GPC assumes actual classroom situations and therefore includes competencies related to managing instructional contexts—an essential aspect of science teaching. This study investigates how competencies transform through lesson study. Therefore, we focused on Naumescu's 28 GPC items and examined their applicability to Japanese science teachers.

Table 2. Good practices related on competencies (Naumescu, 2008).

Competence in epistemology
- Epistemological competence on models building, on processes of the students' modelisation, and on the functions and limits of each model.
- Competence in the use of technical and scientific apparatus and engineering.
- Competence to define criteria of categorisation (an important process in different scientific domains, as taxonomy, DNA sequences, …)

- Competence on the history and limits of validity of each scientific concept, and on the social dimension of the science.
- Ability to differentiate a scientific proposition to a non-scientific one.
- Ability to differentiate a scientific discourse to a dogmatic one.

Competence in bibliography

- Competence to use internet, CD-Rom, books library, etc.
- Competence for a critical analysis of documents of science popularisation (journals, magazines, books, radio, TV, etc.)

Competence in Science Education (Didactics of Sciences)

- Analysis of learners' conceptions on a scientific topic, before teaching this topic, and after this teaching to evaluate the eventual conceptual changes.
- Use the learners' errors not to judge them but as conceptions to be analysed and then changed.
- Identification of epistemological (and didactical) obstacles, to define new strategies of teaching focused on these obstacles
- Building of didactical situations adapted to learning. For instance, problem based situations, or projects (to realise individually or by little groups).
- In particular, sequences to learn scientific concepts, and / or scientific processes (laboratories).
- Competence to define the didactical contract and the situation to the learners, and to present them to learners as a space of active autonomy for them.

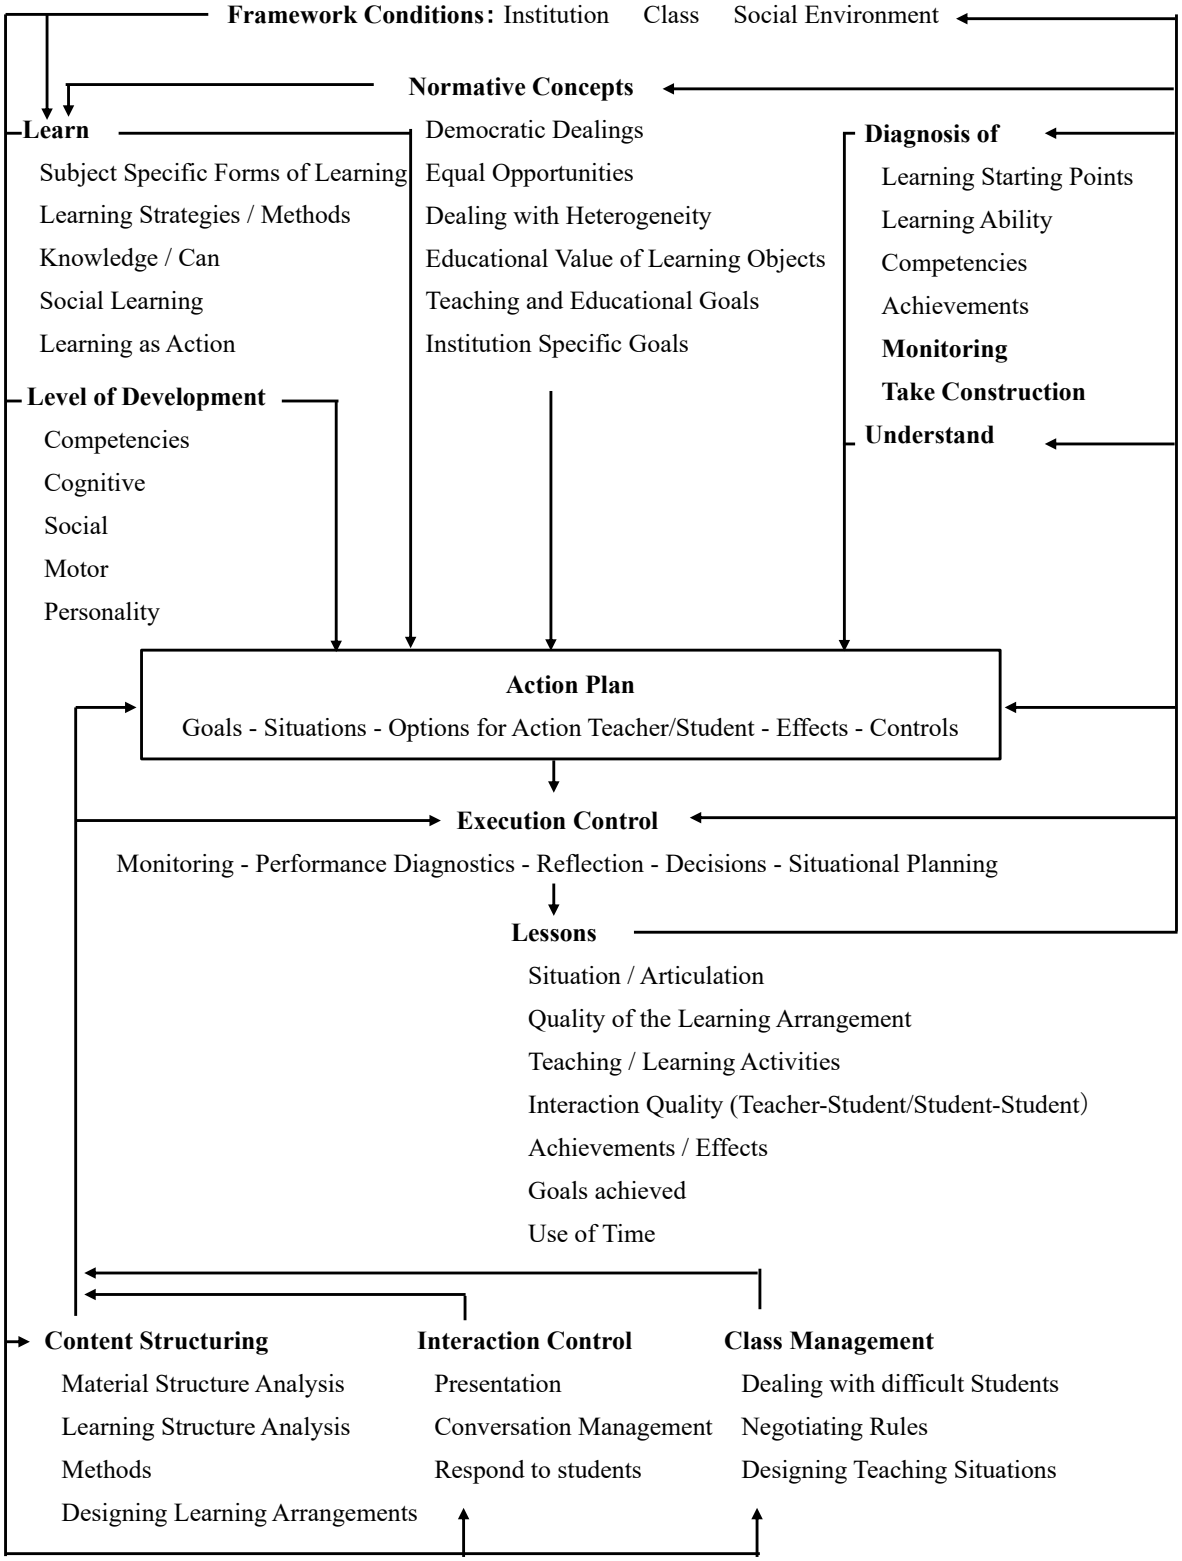
Competence in Didactics of Sciences and in Pedagogy

- Competence to induce the devolution of this situation by the learners: they must be motivated to be active in this situation. They have to be implied in the choice of their topics and activities.
- Competence to manage the situation, to improve debates and socio-cognitive conflicts.
- Competence to hear the pupils and students, and to take into account their questions.
- Competence to manage problems of violence, disorder and other difficulties in the classroom.
- Competence to analyse his or her own reactions (psychology) and the students' ones.
- Competence of the teachers to analyse their own reactions in these situations; to manage students' practical, theoretical or speculative works.

- Competence to analyse the scientific background of each student activity and to help them to find these theoretical pre-required.

Competence in didactical transposition and use of language
- Adaptation of the scientific language in a language adapted to children; idem for the images (didactic transposition for each scholar level). - For each scientific notion, proposition of a progression of teaching – learning sequences, in respect with different students' ways and speed of learning. - Use of good metaphor, examples and other pedagogical strategies. - Competence to motivate and help students to write reports on their activities.
Competence in Evaluation
- Competence to imagine processes of analysis and validation of the students works, of their hypotheses and conjectures. - Competence to do evaluation of the students activities at different steps of their work, to help them in their learning and to prepare them for the final evaluation. - Competence for a final evaluation on known criteria, if possible avoiding the "by heart learning", and corresponding to acquisitions of the taught competencies.

In this study, teachers' utterances during lesson study were analysed to identify competencies. Specifically, each utterance was examined to determine which GPC item it corresponded to. The "interaction target" was categorized as Teacher, Student, or Context (Naumescu, 2008). Based on these interaction types and the nature of the competency, the 28 GPC items were reclassified into three categories, namely TTC (Teacher–Teacher Competencies), TSC (Teacher–Student Competencies), and TCC (Teacher–Context Competencies).



A questionnaire survey using the GPC framework was administered to 135 elementary and lower secondary science teachers in Tokyo. Using a seven-point Likert scale, teachers rated the degree to which they believed each item should be considered an essential science teacher competency. Results showed positive evaluations across all 28 items, indicating that GPC was accepted by Tokyo's science teachers as a valid competency framework.

Further analysis examined correlations among the three GPC categories. Pearson's correlation coefficients revealed strong positive relationships between TSC and TTC ($r = .75$) and between TSC and TCC ($r = .86$). This suggests that Tokyo teachers primarily conceptualize competencies with a focus on interactions with students—namely, TSC.

LPM: Lesson Planning Map

Japan lacks a theoretical model for analysing lesson study. Therefore, we drew on Kiper & Mischke's (2009) Structural Theory of Instruction (Figure 1). In this theory, instructional practice is conceptualized as a cyclical route map consisting of a planning stage, an implementation stage, and an evaluation stage—an idea consistent with Japanese lesson study. We adapted this theory into a lesson-study framework and named it the Lesson Planning Map (LPM).

Figure 1. Structural Theory of Instruction (Kiper & Mischke, 2009).

In this model, teacher utterances from the planning, implementation, and evaluation stages are recorded. In the planning and evaluation stages, interactions occur mainly with colleagues and facilitators; in the implementation stage, interactions occur with students. Recorded utterances are transcribed, and multiple researchers determined whether each sentence corresponds to a GPC item. Then, each utterance is mapped onto the appropriate LPM element according to the stage of lesson study in which it occurred. GPC items, categorized into TTC, TSC, and TCC, are tallied, and these counts are summarized in a table along with GPC questionnaire results.

CM: Competency In Mind And CA: Competency In Action

When comparing a teacher's TTC, TSC, and TCC scores, one may notice distinctive patterns in mean values and frequencies of utterances. These patterns represent the teacher's competency tendencies. Moreover, comparing GPC results from questionnaire data and lesson-study utterances reveals discrepancies (gaps) between mean scores and actual utterance frequencies. These gaps indicate differences between competencies recognized consciously and competencies manifested in practice.

Hokari & Wada (2025a) defined CM (Competency in Mind) as the competencies reflected in a teacher's conscious awareness, as revealed through questionnaire responses, and CA (Competency in Action) as the competencies expressed through actions during lesson study. A gap between CM and CA may indicate competencies that teachers believe they possess but do not exhibit during lesson study, or conversely, competencies that teachers do not consciously recognize but nevertheless demonstrate in practice.

Research Questions

The theoretical framework discussed above has been clarified in Hokari & Wada (2024) and Hokari & Wada (2025b). To further advance this line of inquiry, the present study addresses the following research questions:

RQ1: When teachers are explicitly informed of their CM prior to lesson study, do they attempt to autonomously transform their competencies through the lesson study process?

RQ2: Does teachers' intention to transform their competencies influence their CA?

Methods

This study adopts a qualitative research approach based on questionnaire data and interviews. Using the GPC questionnaire results, the researcher first presented the teacher's CM tendencies to promote self-awareness. In this study, "utterances" refer to all verbal statements produced by teachers during the planning, implementation, and reflection stages of lesson study. Each utterance was treated as a unit of analysis and coded according to the corresponding GPC item. If a teacher expressed multiple ideas in a single turn, these were segmented into separate utterances. The teacher's utterances during lesson study were then analysed to capture changes in CA. After comparing CM and CA, the researcher provided feedback and conducted an interview to explore the observed gaps.

The participant in this study was one teacher, referred to as Mitsuzane (a pseudonym). He holds a bachelor's degree in science education and has worked as a public elementary school teacher for more than 20 years. He has participated in over 26 science lesson studies. At the time of the study, he was teaching a fifth-grade class. The participant had a prior professional relationship with the researchers, which was disclosed to the institution and managed appropriately.

The lesson study analysed in this research was conducted within a district-level research group of science teachers from 29 public elementary schools under the same municipality. The group conducts two to three lesson studies annually, and one of these was selected for analysis. In Japan, the fifth-grade science curriculum includes learning about the flow of rivers—specifically, that flowing water erodes land, transports and deposits stones and soil, that the size and shape of riverbed stones differ between upstream and downstream regions, and that rainfall affects the speed and volume of flow and can cause significant changes to landforms. The present study focused on a lesson within this unit on flowing water. This unit was selected because novice

teachers often report difficulty in conducting science lessons on this topic, making it a meaningful context for examining how teacher competencies transform during lesson study.

Before the lesson study, the researchers identified Mitsuzane's CM tendencies and provided suggestions for improving his GPC in relation to the target unit. After the lesson study, the teacher's utterances were analysed by two researchers to determine which GPC items appeared and at which elements of the LPM these utterances were produced. Based on these analytical results, an interview was conducted to explore the gap between CM and CA. All utterances during the lesson study were recorded using a tablet device. Written consent was obtained from all participating teachers and students after explaining the research purpose and procedure.

Results

The results of the GPC questionnaire for the participating teacher showed mean scores of 5.5 for TTC, 5.3 for TSC, and 4.8 for TCC (Table 3). This indicates that the teacher's CM reflected relatively lower awareness of GPC items related to interactions with the context.

Table 3. Mitsuzane's GPC Profile.

	TTC	TSC	TCC

Lessons	8	9	12
Diagnosis	8	5	10
Understand	3	1	1

Prior to the lesson study, the researcher provided concrete suggestions to the teacher about how GPC related to interactions with the context could be transformed in the unit on flowing water.

> **Researcher:** Among the TCC competencies, one that did not appear strongly in your CM was "Competence to manage problems of violence, disorder and other difficulties in the

classroom." Perhaps you have had few experiences teaching in challenging class environments?

Mitsuzane: No, I think I do have experience. I have often been in charge of classes that were considered difficult to manage.

Researcher: I see. In that case, although you have experience, it appears that you do not regard this as an essential competency for science teachers. In other words, you may be perceiving that classroom management is not necessary for effective science instruction.

Mitsuzane: That's not the case. But I agree there may be a discrepancy between the numerical results and my self-perception of my teaching practices. So I'm curious to see what my CA will look like.

Researcher: Another GPC within TCC that appeared weak in your CM was "Competence to analyse his or her own reactions (psychology) and the students' ones." This suggests that you may not be frequently anticipating students' reactions before lessons, nor analysing them afterward.

Mitsuzane: That's certainly true. I don't do that very often.

Researcher: For example, during the post-lesson discussion, if you are able to say things like, "I intended to do this in the lesson, but since the students responded in this way, I adjusted my approach," such exchanges could help transform this GPC through CA.

Next, the analytical results of the lesson study (CA) were fed back to the teacher, and interviews were conducted to determine whether changes in GPC were related to the teacher's awareness of CM prior to the lesson study.

Researcher: Analysis of the GPC that appeared during lesson study revealed 32 instances of TTC, 30 of TSC, and 31 of TCC. Unlike your CM, your CA did not indicate a weak awareness of TCC. To be more specific, the TCC item "Competence to manage problems of violence, disorder, and other difficulties in the classroom" emerged 12 times during the implementation stage in CA. This occurred despite the item being rated low in CM. For example, before each experiment, you paused all student activity and provided clear instructions. You also verified students' self-designed experimental procedures before allowing them to continue. When a student reprimanded another for talking, you intervened and clarified that classroom discipline is the teacher's responsibility. These behaviors demonstrate clear articulation of class norms and effective classroom management. This was evident in your CA. Similarly, "Competence to analyse his or her own reactions (psychology) and the students' ones" was rated low in CM but was observed 10 times during the evaluation stage in CA. You frequently commented on how you adapted your instruction based on students' responses. Through this analysis of your CA, we were able to gain a clearer understanding of your TCC.

Mitsuzane: Wow, that's surprising. But hearing this analysis, I see your point. I've conducted many lesson studies, and I recognize that I still have weak GPC areas. I now realize that gaps in my own GPC may be connected to areas where I am not fully fostering students' competencies.

Researcher: There were 93 total GPC-related utterances. This is high relative to previous studies that used similar analyses. In other words, the large number of GPC manifestations suggests that the science teacher's competencies you already possess are relatively advanced.

Mitsuzane: Thank you.

Researcher: Do you think receiving information about your CM before the lesson study—and being asked to anticipate how weak areas might emerge in this unit—had any influence on your CA?

Mitsuzane: When I was told that certain GPC scores were low based on the questionnaire, I felt that there must be something lacking in me. So I made a conscious effort to focus on those areas during the lesson study. Although I do not believe that I neglect those competencies in my everyday teaching, having them pointed out numerically made me think that I may be weaker than I had realized. So I reflected on those GPC during my daily lessons as well.

Researcher: Which GPC stayed in your mind most strongly?

Mitsuzane: The TCC item, "Competence to analyse his or her own reactions (psychology) and the students' ones." When it was pointed out, I thought it might indeed be one of my challenges. So yes, discussing my CM before the lesson study definitely shaped my CA.

As Mitsuzane stated, "I made a conscious effort to focus on those areas during the lesson study." This directly answers Research Question 1: When teachers are informed of their CM prior to lesson study, do they attempt to autonomously transform their competencies? Furthermore, Mitsuzane's comment that "discussing my CM before the lesson study definitely shaped my CA" answers Research Question 2: Does a teacher's intention to transform competencies influence CA?

Discussion And Conclusions

The names Furuichi, Wada, and Miyauchi are pseudonyms used to protect the participants' identities. This study demonstrates that providing teachers with their CM prior to lesson study can enhance their awareness of professional competencies and promote autonomous behavioral transformation during lesson study. Moreover, the findings indicate that teachers' intention to improve their competencies plays a significant role in shaping their CA. This intention was evident in the teacher's explicit statements during the interview, in which he reported consciously focusing on areas identified as weak in his CM. These conclusions are supported by the interview results showing that teachers consciously attempted to work on competency areas identified as weak in their CM. The same pattern was confirmed with three additional teachers, suggesting that CM awareness and targeted recommendations may consistently contribute to changes in CA (Table 4).

Furuichi previously worked as a lower secondary science teacher and holds specialized expertise in science. Initially, Furuichi demonstrated limited consideration for TTC. The researcher therefore proposed specific methods for transforming the TTC items "Ability to differentiate a scientific proposition from a non-scientific one" and "Ability to differentiate a scientific discourse from a dogmatic one." As a result, the TTC scores in CA improved, and Furuichi evaluated that the researcher's suggestions contributed to changes in GPC.

Wada's specialty is physical education. In Japanese elementary schools, teachers who are not specialists in science often teach science as well. Through lesson study, Wada's TSC improved in CA, and this was attributed to the researcher's suggestions regarding the GPC item "In particular, sequences to learn scientific concepts, and/or scientific processes (laboratories)."

Diagnosis	5	2	4	3	2	1	4	7	6
Understand	0	0	0	1	0	0	2	1	1

Miyauchi's specialty is Japanese language. In the district research group's lesson study, the high frequency of TSC observed in his CA was attributed to specific recommendations from the researcher concerning the GPC item "Competence to define the didactical contract and the situation to the learners, and to present them to learners as a space of active autonomy for them."

This study has several limitations. First, the primary analysis was conducted with a single science teacher, and the subsequent verification involved only three additional teachers. As a result, the findings should be interpreted with caution, as the sample size and diversity constrain the generalizability of the results. Moreover, all participating teachers had substantial teaching experience, which may have influenced how they interpreted and acted upon their CM. Therefore, future research should examine teachers with different backgrounds, including novice teachers, to further validate and extend the present findings.

ESERA 2025 Copenhagen

Exploring Physics Teachers' Use Of Lab Through Actor-Network Theory

Min-Seong Kim[1] and Nam-Hwa Kang[2]
[1]Jeong-Hyeon High School, South Korea
[2]Korea National University of Education, South Korea

The study explored the application of Actor-Network Theory (ANT) in understanding physics experiment lessons, focusing on the development and implementation of the simplified Michelson Interferometer (MI). Traditional approaches to physics experiments often view tools as passive and prioritize human-centered teaching methods. ANT, however, highlights the active role of non-human actors in shaping networks of interactions. The research investigated two aspects of ANT application to teachers' use of laboratory activity: (a) the process of developing the interferometer and its associated actor networks and (b) teachers' use of new experimental tool and the networks formed during this process. Participants included physics teachers from two groups of teacher learning communities (total 32) and two experienced physics teacher for focus of observations and interviews. Data were collected through observations, surveys, and interviews and analytic framework was based on ANT. Findings revealed that developing the interferometer involved diverse human and non-human actors, creating a dynamic network. In the classroom, the experimental tool demonstrated agency by connecting teachers, students, and other resources, fostering meaningful interactions and emotional engagement. Teachers adapted and reinterpreted the experimental tool based on their goals and contexts, while students engaged with it to achieve experimental objectives, often generating unexpected results and insights. Ultimately, the study highlights the generative role of physics experiment tools in co-creating knowledge alongside students and teachers. Viewing such tools as active participants rather than passive objects offers an alternative perspective on teaching and learning physics, emphasizing the dynamic and collaborative nature of the process.

Keywords: Actor-Network Theory, experimentation, physics

Introduction

Laboratory has been the signature pedagogy in physics education and science education in general. The laboratory serves as more than a supplementary space; it is the signature environment for inquiry and the most distinctive method of both teaching and learning. At its core, physics is an experimental science. While mathematics provides the language, the laboratory experiment remains the most distinctive method of inquiry in science and science education. It is the space where abstract ideas meet reality. As a key pedagogical tool, the laboratory has evolved from the notion of scientific method as static steps to be taken into a dynamic process of observation, measurement, and revision practiced in groups (Hofstein and Lunetta, 2004; National Research Council [NRC], 2012).

The basic premise of using a laboratory as a pedagogical tool in school science education is that meaningful learning occurs when students have opportunities to manipulate equipment and materials to construct their own knowledge. Laboratory experience is essential for helping students move beyond rote memorization toward a deep, conceptual understanding of the physical world. Without the "minds-on, hands-on" interaction with physical phenomena, a student's understanding of concepts such as torque, electromagnetism, or entropy might remain purely symbolic and detached from the material world.

Beyond its pedagogical value, the laboratory serves as a benchmark for science pedagogy because science is fundamentally rooted in the interaction between theory and empirical evidence.

Science—and physics in particular—is defined by empirical **arguments**. Because the goal of scientific knowledge is to understand how things work, human-created explanations must be based on and supported by empirical evidence. Thus, science education aims to help students understand the ways scientists build explanations based on empirical evidence through direct investigative experiences (Berland & Hammer, 2012; Driver et al., 2000; NRC, 2012; Windschitl et al., 2008). The presence and quality of laboratory work act as a standard of authentic instruction; if the lab is missing or reduced to simple cookbook verification, the pedagogy is no longer truly scientific in the professional sense of the word (Lee & Butler, 2003).

The COVID-19 pandemic exposed a significant vulnerability in science education. During this period, students faced a profound lack of opportunity for hands-on physics laboratory experiences, which are traditionally the cornerstone of the discipline. This disruption turned physics into a purely theoretical pursuit for many, stripping away the essential minds-on, hands-on interaction required for meaningful learning. This crisis served as a catalyst for science teachers to be creative in filling the gap (Kang & Seo, 2021). Some teachers in South Korea developed simple and productive physics experimental devices designed for the home environment. The goal was to provide students with opportunities to easily manipulate on their own at home. By shifting the site of inquiry from the school lab to the student's home, experimental physics has been redefined as a flexible, decentralized practice, proving that high-quality inquiry does not always require industrial-grade equipment.

Whereas home-based experiments for classical mechanics are relatively accessible, a significant pedagogical gap persists regarding practical experiments for modern physics concepts. Current physics education lacks accessible, hands-on experimental devices that allow students to manipulate the abstract concepts of modern physics outside of a specialized laboratory. While students can easily drop a ball to study gravity at home, concepts like quantum spin, wave-particle duality, or atomic transitions are often relegated to abstract math or computer animations.

This research is motivated by the need to expand the home-lab revolution into the modern physics realm. By focusing on the development of simple and productive physics experimental devices specifically designed to teach modern physics concepts, we aim to provide students with the same empirical grounding in 20th-century physics that they currently enjoy in classical mechanics. This approach ensures that even the most abstract concepts in the curriculum are supported by a tangible, experimental foundation.

The purpose of this study is to understand how a newly developed simple laboratory setup is adopted by teachers. In particular, this study seeks to move beyond traditional human-centric analyses of education by exploring physics laboratory instruction through the lens of Actor-Network Theory (ANT). By adopting this symmetrical approach, the study aims to reveal the often-invisible influence of non-human actors—such as lab equipment, digital interfaces, and curriculum—on instructional designs of teachers. Ultimately, the study investigates the laboratory instruction as a complex network of interrelated entities, identifying which specific actors serve to catalyze or constrain productive instructional flows.

Theoretical Framework

This research is grounded in the emphasis on the role of experiments within the context of so-called the practice turn in the philosophy of science that refers to a broad shift away from analysing science primarily as a system of theories, propositions, and logical relations, and toward understanding science as a set of situated practices: what scientists *actually do* in laboratories, field sites, and research communities (Gooding, 2012; Schatzki et al., 2001).

Hacking famously argued in *his book (1983)*, "Experimentation has a life of its own" (p. 150), meaning that experiments can lead to discoveries even without a guiding theory. This claim has been supported by several historical reconstructions of detailed experimentation. In an analysis of three episodes in the history of modern science, Galison (1987) demonstrates that experimental traditions have their own continuity and logic that is distinct from the rise and fall of theoretical paradigms. Drawing on his background as an experimental physicist, Franklin (1989) reconstructs detailed experimental sequences from twentieth-century physics—including both successful discoveries and notable non-discoveries—to show how experimental knowledge is generated, stabilized, and sometimes revised. His inclusion of failed or inconclusive experiments is especially significant, as it highlights the contingent, iterative nature of experimental work.

Given the perspective that experiments are not merely servants of theory but are independent, practice-based sources of scientific knowledge experimental practice is seen as an epistemic activity. Experiments are structured sequences involving instrumentation, calibration, and error control that can produce reliable knowledge. This process is shaped by material, instrumental, and procedural constraints. Thus, experiments are open-ended, performative process (Pickering, 1993). Conducting experiments is not only about justification, but also about coping, adjustment, and emergence. Using Galison's historical account of particle physics experimentations in the 1950s and 1960s, Pickering demonstrates that scientific activity unfolds through a continuous struggle between human intentions and material resistance, which Pickering calls the mangling process (1993).

Scientists' struggles during experimentation are best understood through the interplay between human and material agency—the core premise of Actor-Network Theory (ANT) (Pickering, 1993). By rejecting a human-centred perspective, ANT highlights how human and non-human elements interweave to produce collaborative outcomes (Fenwick & Edwards, 2010; Latour, 2007; Law, 2009). As a post humanist framework, ANT is particularly effective for analysing scientific work, where the constant interaction between researchers, instruments, and experimental materials is foundational to constructing knowledge (Latour & Woolgar, 1986).

In his account of how human and material agencies interact, Pickering (1993) utilize the history of the bubble chamber—an instrument that uses superheated transparent liquid to detect electrically charged particles. Invented by Donald Glaser, who received the 1960 Nobel Prize for this achievement, the bubble chamber serves as a prime example of what Pickering called the mangle of practice - a dialectic between material and human agencies. Pickering demonstrates that repeated failures to meet experimental goals, such as increasing detection rates, forced an iterative process of modifying both the equipment and the goals themselves. These failures represent material agency or resistance. Because this resistance is unpredictable, material agency is emergent, requiring the human actor to respond and adapt in real time. Consequently, both human and material agencies are seen as temporally emergent—evolving together through the experimental process.

From the ANT perspective, learning is an effect generated by an assemblage of diverse elements. For example, a physics lesson can be viewed as an "assemblage" where the teacher (human), the student (human), and the lab apparatus (non-human) interact. The knowledge produced is an emergent property of this specific network. We draw on the idea that non-human elements, such as lab apparatus and digital tools are not passive tools but are actants that shape what can be learned. In this framework, the laboratory is viewed as a site of productive intervention. When a student manipulates a device, they are not just verifying an idea; they are engaging in a material practice that has its own internal logic. By analysing how the experimental device (non-human)

and the teacher and students (human) come together, we can understand how abstract concepts become tangible and real.

Methods

The authors devised a low-cost, student-operable Michelson interferometer intended for qualitative use in high school physics classrooms. To address the limitations of commercial interferometers—namely, high cost, complex alignment, and the need for precise optical components—the authors redesigned the apparatus using every day, easily obtainable materials, including convex mirrors commonly used as automobile auxiliary mirrors, slide glass as a beam splitter, and a low-power laser pointer. A key design choice was the replacement of plane mirrors and lenses with convex mirrors, which naturally expand the laser beam into a spherical wave. This eliminates the need for additional optical components such as lenses while making optical-axis alignment significantly easier for students. The expanded beam allows interference fringes to be projected directly onto a wall or sheet of paper, further simplifying the setup and reducing cost and fragility. Details of the lab setup is reported elsewhere (Kim & Kang, 2023). We introduced the interferometer to teachers in a local physics teacher workshop and examined how it was adopted—or not adopted—in their physics classrooms.

As an analytic framework we utilized the concept of translation in ANT to map the sociotechnical evolution of the physics experiment. Callon (1984) adopt the concept of translation to explain how scientific knowledge and social order are co-produced through networks of human and nonhuman actors. Translation is defined as the process through which actors construct, negotiate, and stabilize networks by defining roles, aligning interests, and enrolling both human and nonhuman entities so that collective action becomes possible. In a case study of marine science research, Callon identified four elements of translation: problematization, Interessement, enrolment, and mobilization. Problematization refers to the moment when the focal actor defines a problem and frames other actors' identities and roles in resolving the problem. Interessement refers to the efforts to lock actors into the roles defined in the problematization by using strategies, devices, or arguments that align their interests.

Enrolment refers to the successful acceptance and coordination of the proposed roles by actors, resulting in stabilized relationships within the network. Mobilization refers to the process by which a few actors come to represent and speak for many, ensuring that enrolled actors continue to act as expected. Mobilization is the final stage of the translation process. In this study, mobilization happens when the lab setup reaches a steady state when the students stop asking "What do I do next?" and start acting according to the roles the teacher assigned them. At the same time, the equipment stops being a collection of parts and starts being a measurement or observation system that is mobilized to represent physical reality, such as interference patterns.

Data were collected from multiple sources to examine how the interferometer was taken up in teachers' instructional practice. First, surveys were administered to workshop participants to document teachers' initial responses, perceptions, and intentions regarding the use of the interferometer. Second, in-depth interviews were conducted with two focal teachers to explore their decision-making processes, instructional adaptations, and experiences with adopting—or choosing not to adopt—the interferometer in their classrooms. Third, classroom observations of physics lessons were carried out to capture how the interferometer was enacted in practice, including patterns of teacher guidance, student engagement, and classroom interactions. Finally, instructional materials such as textbooks, handouts, and laboratory materials were collected and analysed to examine how the interferometer was integrated into existing curricular resources and instructional sequences.

Analysis begins by identifying how teachers translate the simplified interferometer into their lessons by mobilizing specific human and non-human actors. We track the four elements of translation to see how a stable network is formed. The analysis culminates in exploring the state of black-boxing, identifying the point at which the complex interrelations of the lab setup become a singular, unquestioned unit of experiment.

Results

Cases Of Non-Adoption

In this section, two cases of non-adoption of the experiment are described. As shown in the case descriptions, the teachers' goals for the experiments in both cases were inconsistent with the goals of the original design, which produced resistance in the experimental setup. This resistance was not accommodated by the teachers and therefore prevented the experiment from being adopted for classroom instruction.

Teacher H, a veteran physics teacher with 22 years of teaching experience, places a high value on meaningful laboratory experiences in physics learning. Despite this strong commitment to experimental instruction, Teacher H ultimately did not adopt the interferometer activity in the classroom.

During the workshop, Teacher H initially failed to produce expected interference patterns and spent relatively more time than other teachers to obtain predicted patterns. Although he succeeded in the end, Teacher H decided not to use the lab in his class. As the primary barrier, he indicated a concern about the reliability and interpretability of the experimental results, particularly the appearance of interference patterns that were perceived as ambiguous or unstable.

Teacher H also expressed reservations about the level of manual dexterity required to manipulate the apparatus, noting that fine adjustments might be challenging for students. This concern reflected an expectation for quantitative analysis of interference patterns—an outcome that the original lab design did not intend, but that Teacher H aimed for. In addition, the use of convex mirrors introduced visual noise in the interference patterns, which Teacher H felt could distract students or undermine confidence in the validity of the results.

Together, Teacher H concluded that the effort required of him and his students was not worth the results they could obtain from the experiment. Consequently, these concerns led Teacher H to judge that the activity did not sufficiently meet classroom expectations for clarity and robustness, resulting in a case of non-adoption.

Teacher Y, who has seven years of experience teaching general science, values experiments that are engaging, accessible, and easy for students to carry out when learning physics. Despite this emphasis on enjoyable hands-on activities, Teacher Y ultimately chose not to adopt the interferometer in classroom instruction. During the workshop, Teacher Y easily produced expected interference patterns and spent much time in explaining the patterns.

A primary barrier for his adoption was uncertainty regarding the experimental results, particularly concerns that the interference patterns might not be sufficiently stable or interpretable for instructional purposes. Similar to Teacher H, Teacher Y also noted limitations in supporting quantitative validation, which reduced confidence in using the activity to substantiate physics concepts rigorously. In addition, the visual noise introduced by the use of convex mirrors was perceived as potentially confusing for students. Collectively, these concerns led Teacher Y to conclude that the activity did not adequately align with instructional goals, resulting in a case of non-adoption.

A Case Of Adoption

In this section, one case of adoption of the experiment is described. Because the teacher applied the experiment in his teaching, the analysis focuses on how the experiment was utilized in the classroom, i.e., the translation process, resulting in the formation of an actor–network.

Teacher J, a physics teacher with six years of teaching experience and an alternative certification background in physics, brought prior experience with a failed Michelson interferometer experiment to the workshop. This experience shaped a strong instructional focus on laboratory activities that are both meaningful and reliably successful for students. As a result, Teacher J approached the interferometer with heightened sensitivity to issues of experimental robustness and classroom feasibility, prioritizing activities that could consistently produce interpretable results within typical instructional constraints.

Problematization

Teacher J framed the instructional problem in terms of both curricular alignment and classroom feasibility. As he explained, “Mere observation of interference patterns is not enough for the time and effort involved… I am trying to connect this to the wave interference conditions in the curriculum, such as path difference and interference conditions. Another concern is helping all students reliably produce stable interference patterns” (workshop interview). Through this framing, Teacher Y positioned successful and reproducible interference patterns as essential to the experiment’s instructional value, defining both conceptual coherence and experimental reliability as necessary conditions for adoption.

Mobilization

Teacher J designed and enacted the lesson by mobilizing a network of key human and nonhuman actors around the goal of understanding and quantifying interference. The instructional sequence began with lectures on the principles of superposition and wave interference, with particular emphasis on interference arising from path differences in the double-slit experiment. These conceptual resources were then extended through a dedicated lecture on the Michelson interferometer, which positioned the apparatus as a legitimate and meaningful tool for exploring interference phenomena.

Building on this conceptual foundation, Teacher J organized student-led experimental exploration using the simplified convex-mirror interferometer, incorporating performance evaluation to encourage active engagement and accountability. Through this sequence, students, curricular concepts, experimental apparatus, and assessment practices were aligned to sustain the instructional network, allowing the interferometer to function as a central actor in classroom practice.

In the process of Teacher J’s translation and actor–network formation, non-human actors—such as simulations, a thermal expansion apparatus, and a micrometre—exercised agency by affording, allowing, encouraging, suggesting, influencing, and rendering particular actions and understandings possible. In addition to the original lab setup, Teacher J created a digital video demonstrating how to set up the experiment so that students could watch it repeatedly as needed, and he added a thermal expansion bar for fine-tuning and a micrometre for measuring interference patterns.

As part of the translation process, the teacher problematized producing quantifiable results and additional laboratory materials were incorporated into the actor–network. In particular, a copper rod was introduced to enable fine-tuning of the interferometer through controlled thermal expansion. This material actor played a key role in stabilizing interference patterns and supporting

quantitative exploration, thereby strengthening the functional alignment of the network and reinforcing the instructional goal of understanding and quantifying interference.

At this point, the translation process is completed, and the actor–network becomes capable of producing instructional outcomes. Diverse actors—including the teacher, students, curricular concepts, experimental apparatus, and assessment practices—are successfully linked and coordinated to form a stable and functional actor–network. Through this alignment, each actor is effectively enrolled to contribute to a shared instructional goal, enabling the experiment to operate as intended within classroom practice.

Student reflections indicated that the experiment supported conceptual understanding of interference by making abstract wave concepts more tangible. As one student noted, "This experiment allows us to understand how the path difference changes as the laser displacement in the Michelson experiment is finely adjusted, resulting in different interference patterns. It provides a valuable introduction to the various properties of waves, which might otherwise remain abstract." This response suggests that the experimental activity helped students connect physical manipulation of the apparatus with underlying theoretical concepts, reinforcing the coherence of the actor–network in supporting learning outcomes as Teach J intended.

Discussion

This study examined how physics teachers adopt—or choose not to adopt—a newly designed laboratory device through the lens of Actor–Network Theory (ANT). The findings highlight the importance of conceptualizing physics laboratory instruction as a socio-material network rather than as a series of isolated instructional events. When the laboratory device became black-boxed, functioning as a stable and reliable agent within the network, it could be mobilized to support extended learning objectives beyond initial demonstration. Across cases, the teacher's emotional openness to uncertainty and adaptability in responding to resistance played a crucial role in the translation process, shaping whether the actor–network stabilized or unravelled.

This perspective encourages a shift away from teacher-centred explanations that attribute ineffective experiments to individual shortcomings and instead directs attention to the broader network of human and non-human actors that shape classroom dynamics. From this viewpoint, teacher professional development should be reconceptualized to address the multilayered actor–networks surrounding experimental tools, while the design of laboratory devices should intentionally support connections to existing curricular, material, and pedagogical networks. Such an approach foregrounds relational alignment over individual blame and highlights the distributed nature of instructional success.

Future research should investigate methods to foster diverse and creative translation processes when teachers engage with new pedagogical materials or instructional tools. In particular, studies are needed to examine how teachers adapt, reconfigure, or extend innovations as they interact with local classroom conditions and existing actor–networks. Furthermore, additional research should investigate how teachers' professional competence, encompassing their knowledge, attitudes, and values, interacts with non-human actors, such as instructional tools, representations, and materials, in the design of innovative lessons. Such work would deepen understanding of how pedagogical innovation emerges through socio-material interactions rather than through the transmission of fixed instructional models.

ESERA 2025 Copenhagen

Addressing Misconceptions Through Questioning: The Application Of Teacher Knowledge In A Primary Science Lesson

Paula García-Viso[1], Soonhye Park[2], M. Ángeles de las Heras[1] and Nuria Climent[1]
[1]University of Huelva, Spain
[2]North Carolina State University, USA

This study explores the role of the knowledge deployed by an expert primary teacher during a lesson on the organs of the human body. The research attempts to uncover which elements of subject knowledge and pedagogical content knowledge underpin her classroom practice and how they interrelate. Employing an intrinsic case study design with a qualitative focus, the study analyses teaching episodes from video-recordings of four lessons with pupils aged 7 to 8 years. From the analysis of the knowledge revealed in her practice, three elements stand out: her knowledge of students' common misconceptions about the topic, her knowledge of questioning as a teaching strategy and her knowledge of facts. The teacher uses purposefully generated questions to elicit the pupils' knowledge about the position of the lungs, and the relationship between the size of the lungs and the heart. Through this approach, the teacher uncovers misconceptions about the topic, such as the idea that there are not two lungs and uncertainty about the heart's location. The findings highlight how the teacher's knowledge of common misconceptions shapes her questioning, enabling her not only to identify these misconceptions but also to promote pupils' knowledge construction by guiding them in re-evaluating their ideas. Furthermore, her science subject matter expertise allows her to identify and address the misconceptions effectively. The study underscores the interplay between subject matter knowledge and pedagogical content knowledge, demonstrating how these knowledge bases underlie the primary teacher's instructional practices.

Keywords: Primary science instruction; Teaching intervention; Case studies

Introduction

It is widely assumed that teachers' knowledge indicates instructional quality (e.g. Barendsen & Henze, 2017) and that teaching requires subject matter knowledge (SMK) and pedagogical content knowledge (PCK) (Shulman, 1986). Science teachers' PCK has been studied extensively, with various conceptualisations (e.g., Gess-Newsome, 2015; Park & Oliver, 2008), often considering SMK as a prerequisite. Moreover, studies on PCK have focused more on secondary than primary school teachers (Chan & Hume, 2019). This study examines the SMK and PCK of a primary teacher, focusing on interconnections between PCK elements and between PCK and SMK. These connections are of particular interest, as both the depth of the teacher's knowledge and its connection demonstrate the strength of her understanding and its transfer to the classroom (following Barendsen and Henze (2017), and Park & Chen (2012), referring to PCK). Previous studies highlight differences in how science teachers' knowledge impacts student performance, though combining SMK and PCK is crucial for addressing misconceptions (Sadler et al., 2013). Further research is needed on how high SMK and PCK teachers engage students (Chen et al., 2020) and how SMK influences PCK (Sen et al., 2018).

The topic of this study, human body, is complex. Research reveals that students aged 7 to 8 can locate two or more internal organs but often struggle to link them (Dempster & Stears, 2014). For students to develop their understanding of the organs, teachers must help students transition from

abstract ideas to detailed understanding, emphasising the characteristics and differences of each organ (Andersson et al., 2019). This requires teachers to be knowledgeable about how students learn, and to have a range of teaching strategies at their disposal.

The study was intended to address the following research question, what are the main elements of SMK and PCK that underpin a primary school teacher's practice in teaching the organs of the human body and how do they interrelate with each other? Our contribution to the research literature on science teacher knowledge is threefold: a) Studying an expert teacher, which is expected to provide access to high SMK and PCK; b) Integrating the study of SMK, less explored in science, with PCK, as well as their interconnections; c) Focusing on a primary school teacher, who has received less attention in studies on science teacher knowledge than secondary school teachers.

Methodology

This research was designed as a case study design (Yin, 2018). We selected an experienced teacher (26 years as primary teacher, with a degree in Primary Education and a doctoral thesis in science education) working in a state school in southern Portugal. Four consecutive lessons, each lasting approximately 1 hour, on the organs of the human body were videorecorded, over the course of a week with second-year pupils aged between 7 and 8.

The data collected was analysed with the PCK categorisation of Park & Oliver (2008), considering Knowledge of Instructional Strategies and Representations for teaching science (KISR), Knowledge of Students' Understanding in science (KSU) and Knowledge of the Science Curriculum (KSC). For categories pertaining to SMK, due to the absence of specific categorisations with respect to science teachers, we drew on the doctoral thesis of Luís (2021), focusing on (biological) subject matter knowledge, encompassing knowledge of: observation procedures and techniques; concepts and associated examples; laws, principles and theories; models associated with the content; and of biological facts and phenomena.

Results

In order to answer the research question, we present two situations in which we can see how the teacher uses different types of knowledge to support her students' learning about organs.

What stands out most is her knowledge of students' possible misconceptions about the organs of the human body (KSU). When approaching, the teacher mainly shows knowledge of questioning as a teaching strategy (KISR). Through questioning, the teacher encouraged her pupils to articulate their existing ideas and to reflect on these. An example occurs during an activity based on a worksheet depicting two bodies, male and female. The pupils call out various ideas about the organs of the body, including the four (heart, lungs, stomach and kidneys) targeted by the teacher. At this point she says:

> Teacher: *Can you all draw these organs here in the outline of the women – or the girl – and the man.* [Focusing the activity on eliciting prior knowledge about the location of the organs].

In doing so, she reveals her knowledge of possible student misconceptions regarding the position of the organs. She tries to elicit her pupils' intuitions through questions such as the following, in which she asks the pupils to say organs they feel most confident of locating:

> Teacher: *And you, Maria, which organ are you confident about? Where is it?* [...] *Are the lungs in the middle* [pointing]*?*

Two misconceptions arise during this episode. First, inaccurate information about the number of lungs:

> Teacher: *How many lungs are there?*
>
> [The teacher repeats various students' answers: two, one]
>
> Teacher: *Is it just one big lung at the front? But I'm talking about lungs* [stressing the plural 's']. *Is that because it's one big one? Is its name in the plural?*

The teacher is aware of the misconception that some students may have regarding the number of lungs, and for this reason draws out these ideas with her questions, and supplies the right answer, thus demonstrating her knowledge of the facts of the subject (there are two lungs) (SMK).

Second, there arises a misconception about the position of the organs, this time the heart. The teacher continues in the same way, using the questioning strategy, but this time she also uses questions to find out how the students perceive their hearts:

> Teacher: *You're saying you feel it here, like Mel?* [Touching her neck] [...] *I'm puzzled. So, the heart is on the left, Mel feels her heart in her neck. Can you feel your heart in your foot?* [...] *Where do you think we can feel our heart, in our knee? Or here?* [She touches her neck] O*r in our foot? Does it make a noise?*

Finally, we infer that the teacher has SMK regarding the slight displacement of the heart to the left, which allows her to be aware of misconceptions about the position of the heart. Likewise, she also knows the fact of the connection between the heart and the size of the left-hand lung. While questioning the pupils about this curious difference in size between the two lungs the following exchange occurs:

> Student: *Because one must have good oxygen, and the other mustn't have oxygen.*
>
> Teacher: *No, that's not why. Ah, look what's in the middle here, come on, what's in the middle?* [...] *That's the heart in the middle. So, to make room for the heart, the other organs have to fit in. And the heart is a little more to the left here, it's not quite in the middle, it's a little more to the left.*

While addressing these misconceptions, in the second situation she goes on to demonstrate awareness of similar misconceptions about whether these organs differ between men and women:

> Teacher: *The worksheet about the body that I gave you, there is a man and a woman on it. Are these organs the same in men and women?*

In response to various doubtful answers, the teacher draws one her knowledge that the lungs and heart are essentially the same in men and women, albeit noting the knowledge of the fact of the relativity of the size for everyone.

> Teacher: *Men and women have the same lungs and the same heart, but a very big person has a bigger heart.*

In summary, the teacher not only uses her KISR, with the use of questioning as the main strategy, to elicit misconceptions from the pupils (supported by KSU), but also uses the questions and answers that emerge during the exchanges to construct basic knowledge of the subject. Throughout the dialogical teaching process, the teacher gives evidence of SMK, namely about the facts underpinning the above-mentioned PCK and especially her knowledge of misconceptions.

Discussion

This study has shown how a primary education teacher's SMK and PCK interact at the point when she adopts a questioning strategy to address misconceptions about the organs and guide the pupils to construct their knowledge. We concur with Akman and Öztekin (2023) regarding the connection between in-depth SMK and knowledge of pupils' misconceptions. We have identified the questions used by the teacher to elicit the pupils' existing notions about the number and position of the lungs, and the position of the heart, along with the fact that these organs are identical in men and women. Her questions are staged so as to guide the pupils away from misconceptions towards the correct subject matter knowledge (Chin, 2007). The use of questioning not only enables misconceptions to be identified, but also facilitates the construction of knowledge, by making the pupils rethink their original ideas and reformulate them where necessary (Benedict-Chambers et al., 2021). The SMK that seems to underpin mainly her knowledge of misconceptions refers to factual knowledge. This may be conditioned by the content of the lessons observed and requires further study. We believe that this study can contribute to how an expert teacher's knowledge supports her approach to teaching particularly complex topics in relation to students' misconceptions.

Section: Evaluating The Impact Of In-service Teacher Training

ESERA 2025 Copenhagen

Exploring The Impact Of A Multidisciplinary Sustainability Course For Teachers: Analysis Through GreenComp

Camilla Fiorello
Università di Trento, Italia

This paper presents the results of the second cycle of a training course on sustainability for in-service teachers, designed according to a Design-Based Research approach. The course was designed to be multidisciplinary, based on the European GreenComp framework. Analysis of the lesson plans developed by teachers and feedback questionnaires shows how the training supported the design of activities that integrate different dimensions of sustainability and are strongly anchored in everyday life contexts. The results also highlight the central role of collaborative work and co-design in supporting sustainability-oriented teaching practices.

Keywords: Sustainability, Teachers, Multidisciplinary

Introduction

Educating for sustainability means dealing with complex issues that not only concern the environment but also involve social, economic and cultural aspects (UNESCO, 2017). For this reason, teacher training cannot be limited to individual disciplines but must offer interdisciplinary and participatory workspaces where it is possible to reflect on teaching practices and design activities that help students develop critical thinking, awareness and the ability to act (Blonder et al., 2014; Fensham-Smith, 2019; Monroe et al., 2019).

The work presented in this contribution is part of a broader research project developed according to a Design-Based Research (DBR) approach (Guisasola et al., 2017). The project began with the design of a Teaching–Learning Sequence on the greenhouse effect, designed to address students' mental models and support teachers in introducing the physical principles underlying the phenomenon (Toffaletti et. al., 2022). However, it became clear that a perspective focused exclusively on physics was not sufficient to adequately address the issue of sustainability. Based on this awareness, a multidisciplinary training course on sustainability was designed for teachers in service, with the involvement of university professors from different departments.

This paper presents the results of the second cycle of the course, which was redesigned on the basis of previous experiences and gave greater space to collaborative work, interdisciplinary integration and shared planning.

Theoretical Framework

The theoretical framework that guided this research is GreenComp (Bianchi et al., 2022), the European framework for sustainability skills. It interprets sustainability as an integrated set of knowledge, skills and attitudes that guide the way people think, make decisions and act. The framework provides a structure that can be adapted to different educational contexts and used as a guide for instructional design.

The framework is organised into four interconnected areas of competence. The first concerns sustainability values and includes reflection on personal and collective values, attention to equity and intergenerational justice, and recognition of the value of nature. The second area focuses on understanding complexity through skills such as systemic thinking, critical thinking and the ability to define sustainability issues in relation to context. The third area is dedicated to the future perspective, promoting the imagination of sustainable scenarios and the ability to deal with

uncertainty and change. Finally, the fourth area concerns action for sustainability, including individual initiative, collective action and participation in decision-making processes.

Together, these four areas offer a coherent framework for supporting educational design that can integrate the value-based, cognitive and operational dimensions of sustainability, providing a useful method for analysing teaching practices and designing them.

Methods

The second cycle of the teacher training program was conceived and implemented within a DBR framework. The course was designed as an iterative intervention aimed at supporting teachers' professional development and informing the refinement of subsequent design cycles. The course took place over two intensive days. This decision was made based on the results obtained in the first cycle (Fiorello et al., 2024) with the aim of improving accessibility while preserving the multidisciplinary structure of the intervention.

On the first day of the course, the conceptual and methodological aspects of sustainability and sustainability education were presented, which then served as resources for the teachers' project work the following day. The day was divided into four thematic sessions. The course began with an introduction to the European framework of sustainability competences (GreenComp). This was followed by three sessions dedicated to environmental, social and economic sustainability. These sessions combined disciplinary perspectives with explicit attention to sustainability as a multidimensional construct, supporting participants in connecting scientific content with broader social, economic, and cultural dimensions. In these sessions, the aim was not only to provide disciplinary perspectives on the topic, but also to highlight how scientific content is linked to other aspects of sustainability. The structure and main topics of the first day are summarized in Table 1.

Table 1. Structure and main topics of the first day of the course.

Session	**Main contents**
Introduction to GreenComp	Presentation of the European framework for sustainability competences (GreenComp): its four competence areas. Discussion on how GreenComp can guide educational practices and lifelong learning for sustainability.
Environmental sustainability	Scientific context relating to climate change and decarbonisation. Analysis of climate data on a global and Alpine scale (temperature, precipitation, snow cover) and the physical basis of greenhouse gas effects. Discussion on energy production and consumption, renewable sources and decarbonisation.
Social sustainability	Reflections on the social and cultural dimensions of sustainability. Legal and anthropological perspectives on community-based governance and the concept of 'territories of life' in mountain areas. Exploration of human-environment relationships, rights and responsibilities, and the role of collective domains in ensuring dignity, justice and long-term coexistence.
Economic sustainability	Introduction to economic indicators for sustainability and the multidimensional nature of sustainable development. Analysis of the ecological footprint and Earth Overshoot Day. Discussion on consumption patterns, global inequality and strategies to reduce humanity's environmental impact.

The second day, on the other hand, was designed as a collaborative and project-based workshop. Participants worked in mixed groups (3 groups), composed in such a way as to ensure diversity in terms of disciplinary background and educational level. Teachers were asked to design educational activities inspired by the GreenComp framework using the Trialogical Learning Approach (CIT.).

Data collection was based on two main sources. At the end of the course, a satisfaction questionnaire was administered. The questionnaire was identical to the one used in the previous cycle, allowing for comparability between iterations, and was designed to gather teachers' perceptions of the organization, content and perceived relevance of the training program. The second resource for analysis concerns the lesson plans developed by the working groups. These constituted a central source of qualitative data, providing information on how teachers interpreted and implemented sustainability skills within their teaching projects.

The teaching plans were analysed qualitatively based on identifying how the different dimensions of sustainability – environmental, social and economic – were developed and integrated into the proposed activities. Attention was paid to the use of elements related to the GreenComp framework and the conceptual structures used by teachers to frame sustainability issues. The aim of this analysis was to evaluate the current intervention and refine the course design for future iterations. At the same time, the qualitative analysis of the feedback questionnaires aimed to capture the suggestions and critical reflections expressed by the teachers. Attention was paid to teachers' perceptions of collaborative work and co-design opportunities, as these were critical issues that emerged from the first training cycle and which we wanted to see improved in this cycle.

Results And Discussion

To give an overview of the teachers' proposals, Table 2 outlines the three lesson plans developed, highlighting the topics addressed, the activity structure, and the resulting artefacts.

Table 2. Summary of the lesson plans developed by participating teachers.

Lesson Plan	**Main contents and artefact**
Group 1: Food waste (lower/upper secondary)	Brainstorming on food waste; identification of local contexts to investigate (markets, restaurants, canteens, households); design of questionnaires and interviews; field data collection; selection and analysis of results; creation of a short documentary to communicate findings to the community. Artefact: documentary on food waste.
Group 2: Everyday energy saving (primary/lower secondary)	Analysis of students' everyday behaviours related to energy use; class discussion of possible improvements; collaborative construction of a "good practices" list to promote energy saving at school and at home; dissemination of the final document within the school community. Artefact: digital energy-saving decalogue.
Group 3: Fast fashion and textile supply chain (lower secondary)	Data collection on students' wardrobes (number of items, frequency of use); graphical representation of the data; reflection on environmental and social impacts of the textile industry; activities aimed at raising awareness of personal consumption habits; creation of a traffic-light tool to guide more responsible clothing purchases. Artefact: traffic-light decision tool.

Analysis of the teaching programmes developed by the teachers shows that each group interpreted the theoretical framework presented during the course (the multidimensional nature of sustainability and GreenComp skills) in a different way. In fact, the proposals vary in terms of pedagogical approaches and teaching choices.

The first project, focusing on food waste in the local area, is characterized by a strongly collective and community-oriented approach. The social dimension of sustainability is a key aspect of the planned activities. The project involves guiding students in exploring the phenomenon through research-based activities, including interviews and data collection. This approach helps students feel actively involved in the issue and develop a sense of shared responsibility towards something they perceive as real and close to their everyday lives. From GreenComp's perspective, the project activates skills mainly in Areas 1, 2 and 4. In Area 1, students develop an awareness of the value of food and its social role (1.1 Valuing sustainability) and reflect on issues of equity and justice in the distribution of resources (1.2 Supporting fairness) in Area 2, investigative activities promote systemic thinking (2.1), which is essential for understanding the relationships between food production, distribution, consumption and waste, and critical thinking (2.2), through the evaluation and reinterpretation of the information gathered in the documentary. Through brainstorming and peer discussion of research questions, it is possible to frame the problem (2.4). Finally, the production of the documentary constitutes a form of collective action (4.2) and an expression of political agency (4.1), as students communicate their findings to the wider community and position themselves as agents of change. Overall, the project coherently integrates the environmental, social, economic and cultural dimensions of sustainability through inquiry-based activities rooted in real-world contexts.

The second project focuses on energy saving in everyday behaviour and represents an intermediate approach between the first lesson plan, where activities are more focused on collective attitudes, and the third lesson plan, which is purely individual. In fact, teachers have designed activities that encourage students to reflect on their energy consumption habits and gradually develop a series of good practices to share with the school. From the point of view of the multidimensionality of sustainability, the project mainly addresses the environmental dimension, linked to the reduction of energy waste, but also involves the social dimension, as the final document seeks to influence shared practices and promote new behavioural norms. The greencomp competences activated are mainly related to Areas 1 and 4. In Area 1, the project supports the value of sustainability (1.1) by encouraging an understanding of energy as a shared and limited resource. Area 4 emerges in two aspects: students reflect on their personal responsibilities through individual initiatives (4.3) and the development of a collective "ten-point charter" promotes collective action (4.2) aimed at influencing the behaviour of the entire school community.

The third project, which addresses the issue of fast fashion and the textile supply chain, takes a more individual approach and is closely linked to the students' everyday experiences. The activity starts with an analysis of the students' personal wardrobes, how often they wear their clothes and why they buy them. This makes the topic concrete and relevant to their experience, helping them to reflect on their own consumption habits. From a sustainability perspective, the project addresses both environmental aspects, linked to the impact of the production chain, and social aspects, such as working conditions and workers' rights, inviting students to reflect explicitly on the ethics of consumption. The GreenComp skills activated in this project cover all four areas. In Area 1, reflection on personal consumption is linked to the importance of promoting sustainability (1.1) and focusing on fairness and rights within the production chain (1.2). Area 2 is activated through systemic thinking (2.1), necessary to grasp the complexity of the textile supply chain, critical thinking (2.3), necessary to analyse personal habits and assess their impact, and problem

definition (2.4), supported by meetings with experts and analyses conducted during the visit. Area 3 is involved through the invitation to plan future purchasing decisions (3.1), linking present actions to possible future scenarios. Finally, Area 4 is supported by the use of the decision-making "traffic light" system for individual use (4.3) and by opportunities to share results with the wider community (4.2).

The analysis of the questionnaires administered at the end of the course provides a very positive overall picture. Participants expressed a high level of satisfaction with both the organisation and the overall quality of the course. Almost all teachers perceived the programme as well-structured and carefully planned, with clear objectives and well-prepared materials. These results suggest that the more compact and practice-oriented format adopted in the second cycle was perceived as coherent and effective. The course content was also highly appreciated. All participants described the training as interesting and motivating, and around 70% said they had learned "many" new concepts. The trainers received very positive evaluations: most teachers found them clear and engaging, with no negative comments. Almost all participants acknowledged that the course content was directly applicable to their teaching practice, and all indicated that what they had learned could be used in their professional context. Furthermore, the fact that most teachers have already applied some ideas in their practice, or intend to do so shortly, clearly indicates the perceived relevance of the course. Another significant result concerns collaboration between teachers. While this emerged as a critical issue in the first cycle, the second cycle saw a marked improvement: around 85% of participants reported an increased ability to work in teams and collaborate with colleagues. The open responses highlighted above all the value of the second day, which was mainly devoted to workshops and shared design activities, where some participants suggested dedicating more time to design.

Conclusions

Analysis of the teaching plans and questionnaires from the second cycle indicates a development in the way teachers interpret and translate sustainability into teaching planning. The questionnaire data show a very positive overall assessment. Teachers particularly appreciated the opportunity to plan collaboratively, confirming co-design as a central and effective element of the programme.

The teaching plans reveal a tendency to frame sustainability through concrete issues closely related to students' everyday experiences, such as food waste, energy use and consumption practices. This suggests that sustainability is increasingly being addressed not only as a set of concepts to be taught, but as a dimension that is part of everyday life.

GreenComp has emerged as a reference point for educational design, providing a framework that has guided the integration of sustainability-related skills into the proposed activities. Overall, the results show a strengthening of sustainability-oriented educational planning, combining scientific content, participatory approaches and a focus on everyday practices.

ESERA 2025 Copenhagen

Enhancing Teachers' Beliefs, Self-Efficacy And Professional Knowledge Through In-Service Teacher Professional Development Programs On The Use Of (Interactive) Experimental Videos

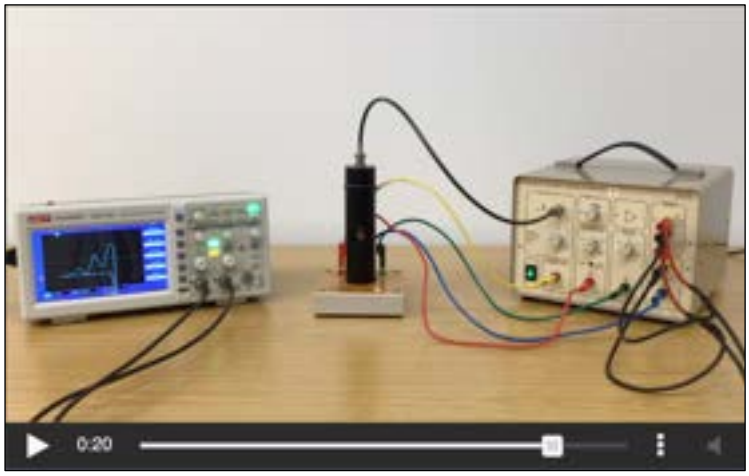
Mathias Ziegler and Lisa Stinken-Rösner
Bielefeld University, Germany

In the context of digital progress, the implementation of Information and Communication Technologies (ICT) in schools is becoming increasingly frequent. Innovative learning media, such as (interactive) experimental videos, are emerging as a significant component in physics education. These technologies are characterized by high interactivity, which facilitates a constructivist approach to domain-specific learning. Despite the increasing availability of such ICT for physics education, its utilization remains limited. This phenomenon can be attributed to a combination of factors, including teachers' beliefs, self-efficacy, technology commitment, and professional knowledge. Specifically, weak beliefs and a lack of professional knowledge regarding the integration of (interactive) experimental videos, coupled with the subjective perception of being unable to meet the digital requirements, can lead to reduced utilization in physics lessons. The implementation of professional development (PD) programs can be a key element in minimizing these effects. For example, the presented study shows that the integration of (interactive) experimental videos within a PD program has a positive effect on professional knowledge and ICT reaction beliefs.

Keywords: beliefs, in-service teacher programs, (interactive) experimental videos

Introduction

Information and communication technology (ICT) is becoming an increasingly relevant part of teaching practice (KMK, 2016). In classrooms, ICT offers innovative approaches to foster students' learning. However, it also creates new demands on teachers' professional development (Caena & Redecker, 2019). Teachers need digitalization-related skills to effectively integrate ICT in their teaching practice (Fernández-Batanero et al., 2020). This is particularly important for domain-specific ICT, since its meaningful implementation depends on the connection between general digitalization-related skills and domain-specific didactic knowledge, as highlighted in current frameworks (DigCompEdu; Redecker, 2017).



Although the frequency of ICT utilization has increased in recent years (Drossel et al., 2024), this mainly relates to established and cross-disciplinary ICT. More innovative and domain-specific ICT, such as (interactive) experimental videos, is still rarely used in classrooms (Drossel et al., 2024; Vogelsang et al., 2019). This can be attributed to teachers' ICT beliefs, their self-efficacy as well as their professional knowledge. Rudimentary digitalization-related skills (Huber et al., 2020) and weak beliefs coupled with the perceived inability to meet digital demands can lead to low utilization of ICT in classrooms.

Despite the availability of in-service teacher professional development (PD) programs, teachers only participate to a limited extent, partly due to a lack of adequate and contextually appropriate offerings (Eickelmann, 2019). Therefore, further tailored domain-specific PD programs are necessary to promote teachers' beliefs, their self-efficacy and their professional knowledge regarding the implementation of domain-specific ICT in lessons (Eickelmann, 2019).

Theoretical Background

(Interactive) Experimental Videos

Figure 1. Experimental Video of the 'Franck-Hertz experiment'. The students' task is to observe the typical curve displayed on the oscilloscope.

One such example is the presented PD on (interactive) experimental videos. Experimental videos are defined as the combination of the classic demonstration experiment and the digital tool of videography (Stinken-Rösner & Meier, 2023). So, initially, these are videotaped demonstration experiments, showing the individual steps of the experiment in linear sequence (see Figure 1). While watching the video, the students observe the outcome of the experiment and may record measurements. In this case, students act as 'passive' viewers in an observing role (ICAP-model; Chi & Wylie, 2014), as is also the case when a demonstration experiment is carried out in reality. To increase cognitive activation, interactive H5P elements can be integrated into experimental videos. These videos, then referred to as interactive experimental videos, are characterised by the fact that students can actively interact with the medium, thereby achieving a deeper understanding of the domain-specific content (Meier et al., 2022a).

In the literature on domain-specific education, (interactive) experimental videos are particularly present in practice-oriented articles (e.g. Meier et al., 2022a; Pfafferodt et al., 2023), highlighting their potential for inclusive teaching and learning (Stinken-Rösner et al., 2023). However, empirical studies dealing with the implementation of experimental videos in physics lessons, as well as teachers' attitudes towards the use of experimental videos, are still rare. A first survey revealed that science teachers generally have a positive attitude towards (interactive) experimental videos (Meier et al., 2022b). At the same time, it became clear that a group of sceptics attributed greater importance to real-world experiments. They worry that interactive experimental videos could replace real-world experiences in physics lessons (Meier et al., 2022b). This concern can be explained by the fact that these teachers do not regard the (interactive) experimental videos as a supplement to real-world experiments, but as a substitute with no added functional value for the experimental process (SAMR-model according to Puentedura, 2006).

Professional Knowledge

Successful integration of ICT into teaching practice largely depends on teachers possessing ICT-related professional knowledge. The TPACK framework proposed by Mishra and Koehler (2006) combines three main components of teachers' knowledge: pedagogical, content and technological knowledge. Pedagogical knowledge (PK) encompasses knowledge of teaching methods and learning strategies. Content knowledge (CK) refers to domain-specific knowledge about the

content to be taught in lessons. Finally, technological knowledge (TK) describes the use of digital tools and software like tablets and presentation programs.

These dimensions are not considered separately but form four important intersections (Mishra & Koehler, 2006). Pedagogical content knowledge (PCK) is equivalent to domain-specific didactic knowledge and focuses on how a particular domain-specific content can be taught effectively. Technological pedagogical knowledge (TPK) deals with how ICT can be used in a didactically meaningful way in the classroom. Technological Content Knowledge (TCK) describes how ICT can be used in the subject. Finally, the central component is Technological Pedagogical Content Knowledge (TPACK). It describes the knowledge required to convey domain-specific content in a meaningful way using ICT in the classroom.

Current research on professional knowledge suggests that targeted interventions can effectively promote STEM teachers' TPACK. Specialized courses within teacher education have resulted in significant improvements in pre-service STEM teachers' TPACK (e.g. Stinken-Rösner et al., 2023; Chai et al., 2010). Furthermore, it has been found that specific in-service teacher PD programs can also contribute to an increase in their TPACK (Lehiste, 2015).

Teachers' ICT Beliefs

In order to implement ICT in a pedagogically meaningful way, teachers need to purposefully apply their professional knowledge in the classroom. (Stinken-Rösner et al., 2023). However, the actual utilization of ICT in teaching practice is not only a matter of teachers' professionalization but also closely related to their subjective beliefs. Schmidt and Reintjes (2020) investigated the ICT beliefs of pre-service teachers and identified three central forms. First, so called reaction beliefs that conceptualize ICT primarily as an instrumental tool to support existing teaching practices. Second, design beliefs that emphasize the pedagogically meaningful integration of ICT in classrooms. Third, identity beliefs that relate to teachers' self-concept in the context of digitalized teaching.

Self-Efficacy

Self-efficacy in general 'refers to beliefs in one's capabilities to organize and execute the courses of action required to produce given attainments' (Bandura, 1997, p. 3). A domain-specific form of this construct is described by the computer-related self-efficacy, which refers to one's confidence in one's ability to successfully perform computer-related tasks (Spannagel & Bescherer, 2009). In the context of utilization of ICT in lessons, computer-related self-efficacy is of central importance as it substantially determines whether certain behaviours (such as integration of ICT in the classroom) are initiated at all (Bandura, 1977). Teachers with a high level of self-efficacy exhibit strong confidence in their ability to use ICT in teaching and are more persistent when encountering problems. Consequently, self-efficacy is a key predictor of successful ICT implementation in teaching practice.

A recent meta-analysis examining the effects of PD programmes on teachers' self-efficacy revealed statistically significant medium effect sizes (Zhou et al., 2023). These findings were confirmed by further studies (e.g. Yang, 2020).

Technology Commitment

Technology commitment consists of three components: Technology acceptance, technology competence beliefs and technology control beliefs. According to Neyer et al. (2012) technology acceptance refers to the subjective assessment of technical advances. Technology competence beliefs describe the subjective evaluation of one's own competencies in utilizing established ICT

and adapting innovative ICT for teaching practice. Technology control beliefs are defined as the degree to which a person perceives having influence or control over technological processes.

Studies on technology acceptance indicate that ICT-related beliefs influence one's intention to use ICT, which in turn is considered a central predictor for actual ICT utilization (Venkatesh et al., 2003). Therefore, PD programs are required to systematically foster teachers' digitalization-related skills and, consequently, strengthen their technology commitment. Current studies on pre-service teachers indicate a higher level of success in the use of ICT when technology acceptance is strongly developed (Köstler & Wolff, 2025). These findings suggest that, for in-service teachers, higher technology acceptance may result in increased implementation of ICT in physics lessons.

PD Program Concept

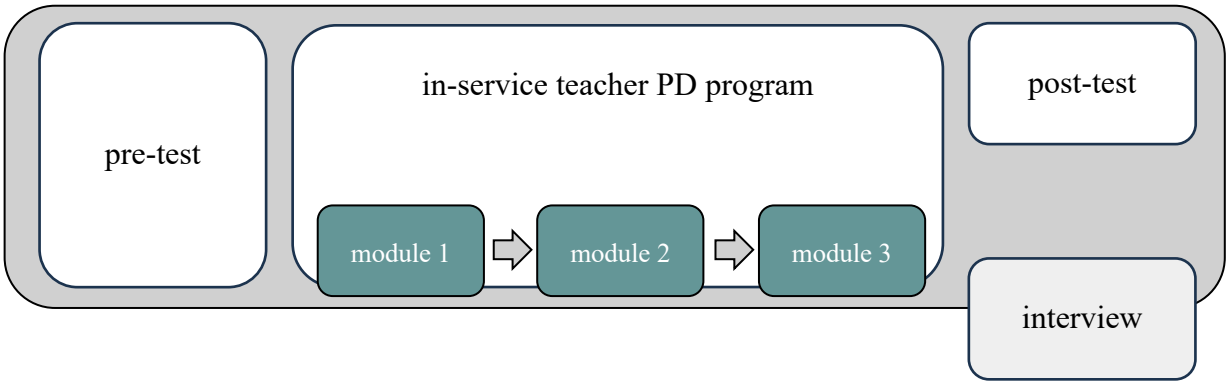
As explained above, teachers' beliefs and their high level of professional knowledge are considered essential prerequisites for the successful use of ICT in the classroom. However, these characteristics do not develop automatically but require targeted support. In-service teacher PD programs could play a key role here, as they offer structured learning opportunities. Against this background, the concept of the designed pd program (see also Ziegler and Stinken-Rösner, 2024) is presented below (Table 1).

Table 1. Description of the designed PD program.

Module 1 (7 hours)	
Actions	Aims
At the beginning, the participating teachers are introduced to the use of videos in physics lessons, along with a definition of experimental videos. This is followed by an input on design principles for demonstration experiments and multimedia applications, as well as on different scenarios for using experimental videos in teaching practice. Subsequently, the participating teachers independently produce experimental videos based on the introduced design principles. For this purpose, they use prepared experiments or alternatively experiments of their own choice. The produced experimental videos are then exchanged with the task of adding a voice-over that describes the experimental procedures (video dubbing). Finally, the participating teachers receive peer feedback from other participants for their experimental videos.	The participating teachers should be able to… … distinguish between different types of videos. … identify design principles in experimental videos. … independently produce an experimental video of a demonstration experiment, considering design principles for demonstration experiments. … add a voice-over to an experimental video.
Module 2 (4 hours)	
The pedagogical usefulness of interactive elements in digital media is discussed, with reference to the ICAP model as a theoretical framework. This is followed by an introduction to the 'Lumi' software and, more specifically, the various interactive H5P tools it provides. Subsequently, the participating teachers integrate the interactive H5P tools into their experimental videos produced in the first module. Finally, teachers receive peer feedback on their interactive experimental videos from other participants.	The participating teachers should be able to… … describe the pedagogical usefulness of interactive elements in digital media in physics lessons. … produce interactive experimental videos.
Module 3 (4 hours)	
Participating teachers visit the student lab with a class from their school. There, the students work with experimental videos either as an independent learning medium or in combination with a real-world experiment. The experimental videos used for this purpose are produced in advance by academic staff. During the implementation in the student lab, the teachers observe the students' learning processes and interactions.	The participating teachers should be able to… …assess the pedagogical usefulness of (interactive) experimental videos across different scenarios.

Research Question

Previous research shows that the utilization of (interactive) experimental videos by teachers has not yet been sufficiently researched. An initial study shows that the majority of teachers have a positive attitude towards experimental videos, but there are also concerns about their use (Meier et al., 2022b). However, the extent to which in-service teacher PD programs affect teachers' professional knowledge, their beliefs towards, as well as the resulting implementation of (interactive) experimental videos in practice was not considered. Therefore, the present study investigates the following research question:



To what extent does participating in a PD program on the use of (interactive) experimental videos influence in-service physics teachers' technology commitment, their ICT beliefs, their self-efficacy and their professional knowledge regarding the use of ICT?

Methods

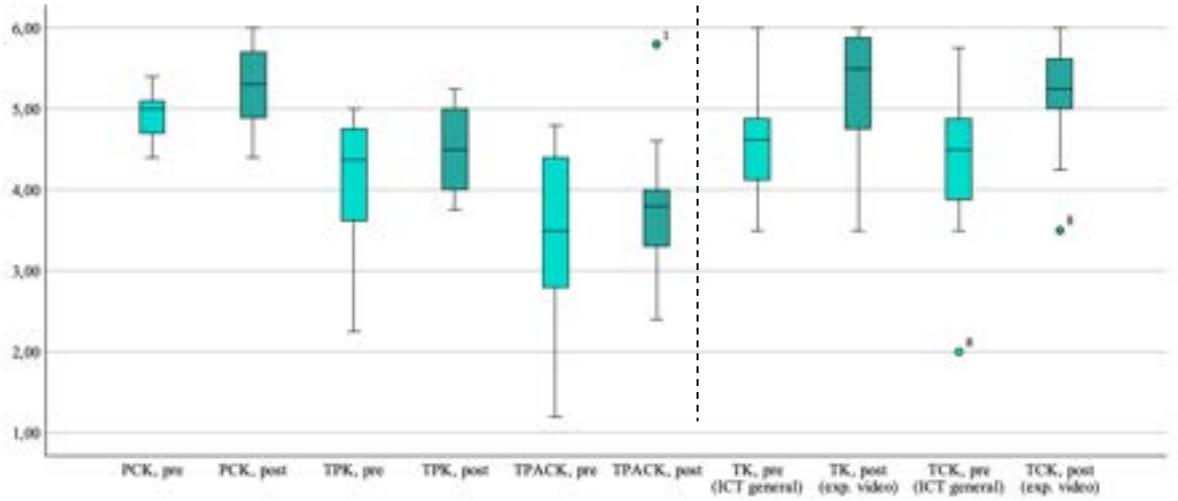
Study design

The data is collected using a mixed-methods approach (see Figure 2). In a pre-post design, the quantitative data were collected using a standardized questionnaire, which includes, among others, well-established scales on technology commitment (TC; Neyer et al., 2012), ICT reaction beliefs (ICT RB; Schmidt & Reintjes, 2020), self-efficacy (SE; Beierlein et al., 2012) and professional knowledge (Stinken-Rösner, 2021). All items are recorded on a six-point Likert scale (1 = strongly disagree, 6 = strongly agree). Regarding professional knowledge, a specific methodological consideration applies. As (interactive) experimental videos are not yet widely used in teaching practice, it can be assumed that the participating teachers had no prior experience with this medium. Consequently, the TK and TCK scales were operationalised with reference to digital media in general at the pre-test measurement and with reference to (interactive) experimental videos at the post-test measurement. As a result, changes over time cannot be directly assessed for these scales. However, there are comparisons between pre- and post-measurements possible. In addition, qualitative semi-structured group interviews were conducted with the participating teachers following the completion of the PD program to explore the conditions for success and the barriers to the implementation of ICT integration.

Figure 2. Visualization of the study design.

Sample

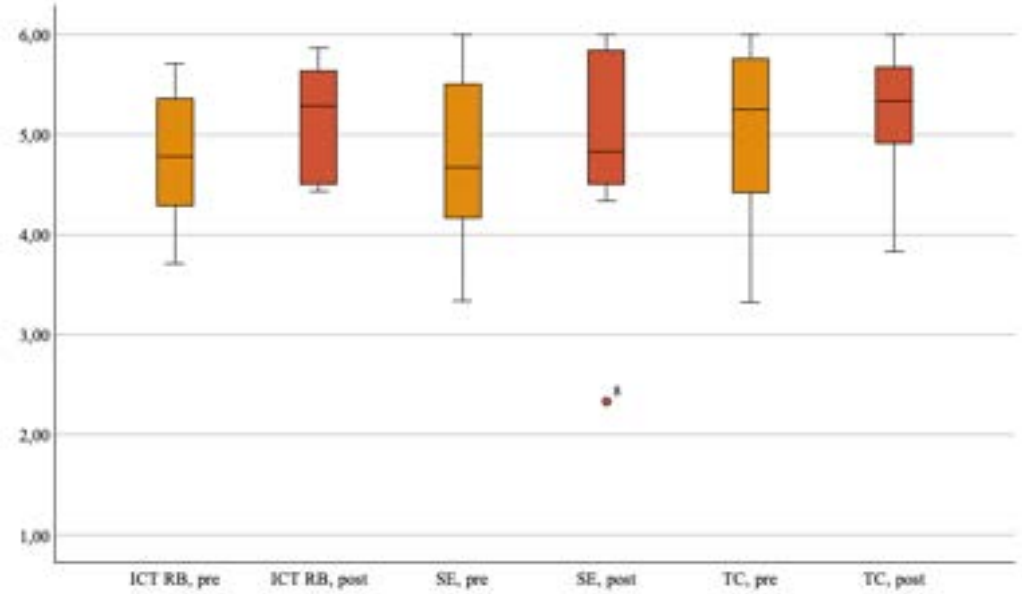
The PD program was offered three times. Three teachers took part in the first round, while five teachers each took part in the second and third rounds. In total, 12 physics teachers took part in the accompanying study (50 % male, 50 % female) and completed both pre- and post-test.



Participation was voluntary and anonymous. The average age of the participants was 39.6 years (SD = 5.9 years), with an average of 13.4 years of professional experience (SD = 16.6 years).

Results

Professional Knowledge



The following Figure 3 presents the results of the study for all TPACK dimensions.

Figure 3. Boxplots for TPACK dimensions, pre-test data (left) and post-test data (right).

A comparison of the pre-test and post-test values suggests a slight upward trend in most TPACK dimensions. PCK, TPK and TPACK show a slight improvement. The post-test values (relating to experimental videos) for TK and TCK are higher than the corresponding pre-test values (relating to ICT in general). Overall, the variance of the post-test scores is slightly lower compared to the pre-test scores.

Figure 4. Boxplots for ICT reaction beliefs (ICT RB), self-efficacy (SE) and technology commitment (TC), pre-test data (left) and post-test data (right).

The results shown in Figure 4 indicate that participation in the PD program led to a slight increase in participants' ICT reaction beliefs and self-efficacy, while the technology commitment remained largely at the same level. It can also be observed that the variance of the post-test data tends to be lower than that of the pre-test data.

The results of the comparison of the mean values between pre- and post-test confirm most findings (see Table 2). The small increase in the mean self-efficacy score could be attributed to the presence of an outliner in the data (see Figure 4).

Table 2. Overview of the pre- and post-test mean values of all constructs.

Construct	Mean Value, Pre	Mean Value, Post
Pck	4.90 (Sd = 0.31)	5.28 (Sd = 0.51)
Tpk	4.08 (Sd = 0.92)	4.50 (Sd = 0.54)
Tpack	3.47 (Sd = 1.09)	3.80 (Sd = 0.86)
Tk	4.60 (SD = 0.76), ICT General	5.23 (SD = 0.79), Exp. Video
Tck	4.31 (SD = 0.95), ICT General	5.15 (SD = 0.71), Exp. Video
Ict Rb	4.79 (Sd = 0.67)	5.14 (Sd = 0.57)
Se	4.78 (Sd = 0.87)	4.94 (Sd = 1.05)
Tc	5.07 (Sd = 0.87)	5.21 (Sd = 0.69)

The analysis of the qualitative data has not yet been completed.

Discussion

The present study aimed to investigate the impact of an in-service teacher PD program addressing learning with (interactive) experimental videos on teachers' professional knowledge as well as on their ICT-related beliefs. Comparing pre- and post-test data, slightly positive tendencies were observed in selected TPACK dimensions, for ICT reaction beliefs and for self-efficacy. In contrast, no increase was identified for technology commitment. For this construct, the post-test score remained approximately at the same level as before participating in the PD program.

The designed PD program aimed to enhance teachers' competencies in using domain-specific ICT, specifically (interactive) experimental videos. During the PD program, participating teachers engaged intensively with this domain-specific ICT and acquired fundamental skills for the independent production of such media. As a result, teachers rated their TK and TCK regarding the specific medium '(interactive) experimental video' higher after participating in the PD program than they had prior to participation regarding digital media in general. Moreover, positive tendencies were observed for PCK, TPK and TPACK. These findings are consistent with further studies reporting positive effects of targeted interventions on professional knowledge (within the TPACK framework), both for pre-service teachers (Stinken-Rösner et al., 2023) and in-service teachers (Lehiste, 2015). In particular, the results demonstrate that practice-oriented PD programs can make a substantial contribution to teacher professionalization.

One key element of the PD program is the implementation of (interactive) experimental videos in the student lab, where participating teachers gain experience in using these videos with their own class. During this implementation phase, teachers were able to observe students' interactions with the (interactive) experimental videos and thereby identify their potential for effectively conveying domain-specific content as well as domain-specific language (through adding a voice-over to an experimental video). We hypothesized that an embedded implementation phase would be an opportunity to positively affect teachers' beliefs about the use of digital media. Positive tendencies for ICT reaction beliefs and self-efficacy were found, with the increase in self-efficacy being marginal. Furthermore, no change in technology commitment could be observed (see

Figure 4). This finding is not entirely consistent with previous research reporting a medium effect of general PD programs on STEM teachers' self-efficacy (e.g., Zhou et al., 2023). This discrepancy may be related to the PD program itself. It was both domain- and media-specific, whereas teachers' self-efficacy was assessed in the questionnaire with respect to the utilization of digital media in general. Consequently, the small increase in general self-efficacy suggests that the domain-specific focus of the program was not reflected in overall self-efficacy beliefs. However, this does not preclude the possibility that teachers' domain- and media-specific self-efficacy increased more strongly because of the program.

Furthermore, observing students working effectively with (interactive) experimental videos may explain the increase in ICT reaction beliefs. Thus, teachers perceived (interactive) experimental videos as effective and meaningful digital tools for physics lessons. However, this would also suggest an increase in technology commitment, which is not indicated by the data. One possible explanation may lie in the independent production of (interactive) experimental videos, which several participants perceived as time-intensive during the program. This may represent a potential implementation barrier. Also, these outcomes suggest that technology commitment can be regarded as a relatively stable construct. So, the targeted promotion may require long-term interventions, as stated by Lipowsky and Rzejak (2021). In this context, no generally valid appropriate time frame can be specified, as the assessment of appropriateness depends on a wide range of factors, such as individual prerequisites of the participating teachers or specific focus of the PD program (Lipowsky & Rzejak, 2021). In addition, one can identify that the scales used to assess the teachers' beliefs were utilized to a high degree (see Figure 4), meaning that the presence of potential ceiling effects cannot be ruled out.

Limitations

When interpreting the results, several limitations need to be considered. Firstly, the present study concerns a small sample size with only 12 physics teachers. Therefore, the generalizability of the results is limited. Consequently, future research with larger samples is needed to examine the reported effects. Secondly, the study relies on self-assessed measures of professional knowledge, which may not accurately reflect teachers' actual levels of competence. As self-assessed competencies do not fully correspond to objectively measured professional knowledge (Stinken-Rösner et al., 2023), future research should incorporate performance-based measures to more comprehensively assess teachers' professional knowledge. Finally, the transferability of the results to school practice needs to be critically assessed. In this context, instructional actions were conducted under conditions that differ from regular school practice, in the learning environment, the availability of technical resources, and the instructional role. This role was assumed by a scientific staff member rather than the classroom teacher. Consequently, actual belief-related constructs may be lower than indicated in the post-test, as participating teachers may experience uncertainties when implementing (interactive) experimental videos in their own teaching practice. Therefore, future studies should include follow-up assessments to examine the development of teachers' self-efficacy in authentic school settings.

Conclusion

This study investigated the impact of an in-service teacher PD program focusing on learning with (interactive) experimental videos on physics teachers' professional knowledge (TPACK) and ICT-related beliefs. The findings indicate that the designed PD program slightly positively influences selected dimensions of teachers' professional knowledge, their ICT reaction beliefs, as well as their self-efficacy. However, no changes were observed in teachers' underlying technology commitment. Two main conclusions emerge from the findings. First, digitalization-

related, domain-specific PD programs have the potential to foster teacher professionalization. Second, an implementation phase in which the domain-specific medium is tested may represent a condition to successfully initiate changes in teachers' beliefs. In this context, it is assumed that the time-intensive production of (interactive) experimental videos may constitute a potential barrier. To further investigate these assumptions, the data obtained from the interviews regarding conditions for success and barriers to the implementation of ICT, particularly (interactive) experimental videos, will be analysed in future work.

ESERA 2025 Copenhagen

Navigating Digital STEM Professional Development: Insights From Out-Of-School Labs

Mientje Lüsse[1], Ronja Sowinski[2], Simone Abels[2] and Maja Brückmann[1]
[1]University of Oldenburg, Germany
[2]Leuphana University Lueneburg, Germany

The demand for high-quality teacher professional development (PD) is significant, especially in the context of a digitalised world. Effective PD fosters collaborative work, self-efficacy and student-centred approaches. In this context, PD programmes that take place in out-of-school labs or are closely linked to them in various ways offer great potential that has not yet been realised. The ministry-funded research project "LFB-Labs-digital" investigates this potential in Germany by taking eight STEM out-of-school labs as venues for PD in teachers' information and communication technology (ICT) skills. An accompanying interdisciplinary quality management captures, among other things, the expectations and perceptions of the participating teachers regarding the PD programmes. The study explores these aspects as well as teachers' perceived relevance, cognitive activation, and the sustainability of the implementation of PD content. Data was collected from 83 teachers in pre-surveys and 48 teachers in post-surveys across eight out-of-school labs. Pre-survey results indicate that teachers primarily demand subject-specific digital media use, the application of specialized software, and guidance on designing digital learning environments. Teachers consider the PD programmes relevant when it offers feasible implementation, manageable workload, and curriculum relevance. Post-survey results show positive perceptions of PD programmes' perceived relevance, cognitive activation, and sustainability regarding digital teaching. The data shows promising potential for the approach of out-of-school lab-based teacher PD across multiple STEM subjects.

Keywords: digital learning, teacher education, professional development

Introduction

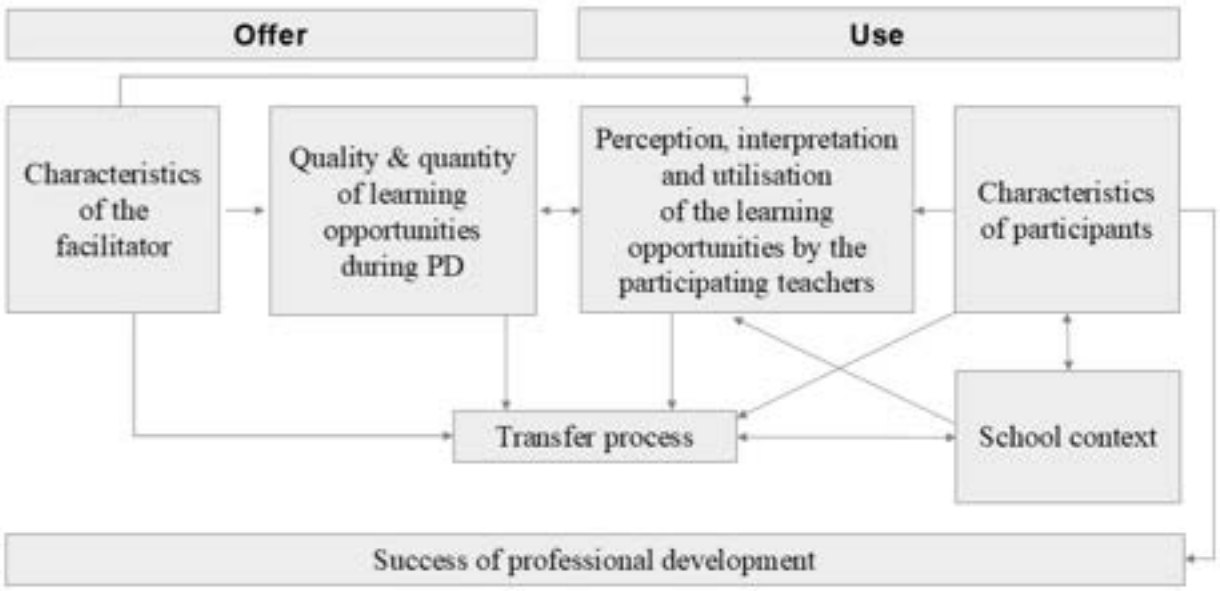
Due to ongoing digitalisation worldwide, the development of digital competencies is more important than ever in society and is therefore a core topic of the European Union's Digital Education Action Plan (European Commission, 2023). As the development of students' digital competencies largely depends on teachers' instructional practices, there is a particular need for professional development (PD) targeting teachers' information and communication technology (ICT) skills (OECD, 2019). Teachers must not only possess digital competencies themselves but also give their students possibilities to improve these skills. Added to this is subject-specific knowledge required in the classroom, so that teachers are faced with multifaceted requirements: the integration of technological, pedagogical and content knowledge (TPACK) (Mishra & Koehler, 2006). The continuous development of relevant competencies must be a cornerstone of teacher education and PD (Eickelmann et al., 2019).

While offering ICT-related PD for teachers is highly relevant due to deficits with regard to ICT training among teachers (Eickelmann et al., 2019; Fernandes et al., 2020; Fernández-Batanero et al., 2022), implementation and evaluation is challenging in many countries (Popova et al., 2022). Despite high demand, comparatively low participation rates in PD are observed (Popova et al., 2022). Another problem is that many PD programmes are conducted as so-called one-shot events (Fernandes et al., 2020), although research indicates longer-term programmes being more sustainable regarding positive effects on students (Lipowsky & Rzejak, 2015). These challenges are also evident in Germany (Mußmann et al., 2021), even though the national Conference of Ministers of Education and Cultural Affairs strongly emphasises the importance of digital media (Kultusministerkonferenz, 2017).

In recent years, out-of-school labs and other non-formal learning environments have established themselves as innovative extracurricular learning opportunities for students (Kirchhoff et al., 2022). They provide a unique setting where students can gain authentic practical experience and apply scientific concepts, potentially increasing interest and motivation in STEM subjects (Itzek-Greulich & Vollmer, 2017; Mohr-Schroeder et al., 2014; Roberts et al., 2018). These characteristics present promising potential to use these out-of-school learning environments as venues for PD related to digitalisation. This potential has been empirically examined by Reher et al. (2025), who found positive effects of digitalisation-related PD in out-of-school labs on teachers' self-assessed professional knowledge, while belief-related dimensions such as self-efficacy and technology commitment remained largely stable.

Within the same project, complementary analyses have focused on success factors and implementation barriers of these PD programmes (Lüsse et al., 2025). This research identifies factors such as technical support, curricular alignment, hands-on orientations, and structured reflection as potential success conditions, alongside persistent organisational and technical challenges. However, this research has primarily focused on the perspectives of PD facilitators or on external observations of programme implementation. The perspectives of teachers as the users of these PD programmes, particularly with regard to how they perceive and evaluate digitalisation-related PD in out-of-school lab settings, remain underexplored.

Addressing this research gap, the present study focuses explicitly on teachers' perspectives on digitalisation-related PD programmes conducted in out-of-school labs. The study examines teachers' needs and expectations prior to participation and investigates how participating teachers perceive the relevance, cognitive activation, and sustainability of the PD programmes with respect to digitalisation-related aspects. By adopting the users' perspective, the study aims to contribute to a more differentiated understanding of the potential and limitations of out-of-school labs as venues for effective and sustainable teacher PD.



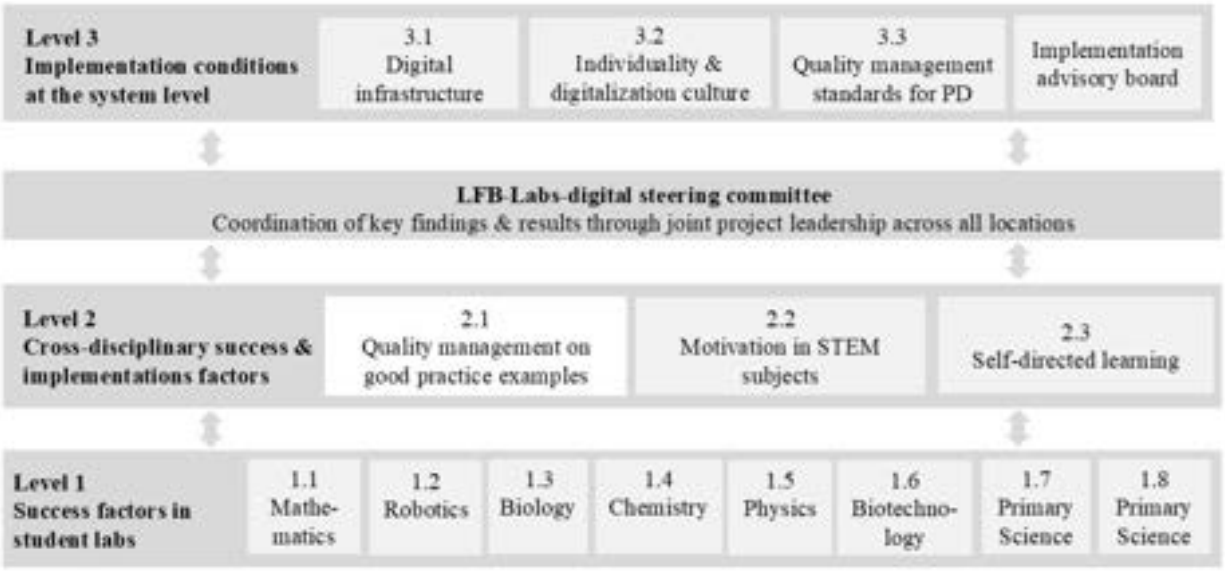
Theory And State Of Research

Key Features Of Effective Professional Development

To illustrate the multifactorial transfer processes and influencing factors in PD, an adapted offer-and-use model by Lipowsky and Rzejak (2015) can be applied (Figure 1). The model conceptualises PD as an interaction between the offer side, referring to the design and implementation of PD programmes, and the use side, representing participating teachers with their individual prerequisites and school contexts.

On the offer side, relevant aspects include the professional expertise of facilitators as well as the quality, structure, and coherence of the learning opportunities provided. Empirical research has consistently shown that effective PD for STEM teachers is characterised by a strong focus on subject-specific content, pedagogical approaches, and the integration of technology into teaching and learning processes (Joseph & Uzondu, 2024). Lipowsky and Rzejak (2015) also identify essential characteristics of effective PD, including the integration of input, trial, and application phases, as well as creating situations where teachers experience self-efficacy and focus on student learning within professional learning communities. These principles, including inquiry-based and collaborative learning, also apply to ICT-related PD programmes (Fernandes et al., 2020).

Figure 1: Offer-and-use model for research on teacher PD (adapted from Lipowsky & Rzejak, 2015, p. 30).



Beyond these general features, recent empirical studies have begun to specify conditions for effective PD in non-formal learning environments such as out-of-school labs. Focusing on digitalisation-related PD in such contexts, Lüsse et al. (2025) identified technical support, curricular alignment, flexible formats, hands-on orientations, peer exchange, and structured reflection opportunities as potential key success factors for PD in out-of-school labs. These features support teachers in critically reflecting on and adapting digital tools and strategies for their own teaching practice. At the same time, the study highlights persistent technical and organisational challenges as well as heterogeneous digital competencies among teachers as implementation barriers. Together, these findings underline the importance of designing PD programmes that combine coherence and adaptability in order to address diverse teacher needs.

Context Of The Study

Against this theoretical and empirical background, the collaborative, ministry-funded project *LFB-Labs-digital* was initiated (Figure 2; Kirchhoff et al., 2024). The primary objective of this project is to establish out-of-school labs as innovative learning environments for digitally supported PD programmes. To achieve this, eight STEM-focused out-of-school labs in the state of North Rhine-Westphalia, Germany, are being adapted and expanded to serve as PD venues. These labs cover a range of disciplines, including Mathematics, Biology (two labs), Chemistry, Physics, Biotechnology, and Primary Science Education (two labs).

As part of the project, an interdisciplinary quality management approach accompanies the ongoing PD programmes. This involves systematic observation, continuous exchange with PD facilitators, and the identification and discussion of good practice examples across sites. Previous analyses conducted within the project context have examined PD programmes from the perspectives of facilitators and external observers, focusing on implementation conditions and barriers (Lüsse et al., 2025). However, the perspectives of teachers as the users of these PD programmes have not yet been systematically investigated.

Figure 2: Project structure of LFB-Labs-digital (adapted from Kirchhoff et al., 2024, p. 136).

Addressing this research gap, the present study focuses explicitly on the teachers' perspectives. The central research question is how teachers perceive the PD programmes. Initially, the needs and expectations of teachers regarding digitalisation-related out-of-school labs PD programmes will be assessed. Furthermore, it will be examined how participating teachers evaluate the relevance, cognitive activation, and sustainability of the PD programmes concerning aspects related to digitalisation.

Method

The study combines qualitative feedback and quantitative surveys and was conducted via LimeSurvey. Participation in both the pre- and post-survey was voluntary. In the pre-survey, teachers were asked about their expectations and perception of relevance regarding the out-of-school lab PD programme using self-developed two open-ended items:

1. "In the PD programme, I would like to learn more about ... / I expect insights into ... from the programme."
2. "For me, a PD programme is relevant to my teaching if it…"

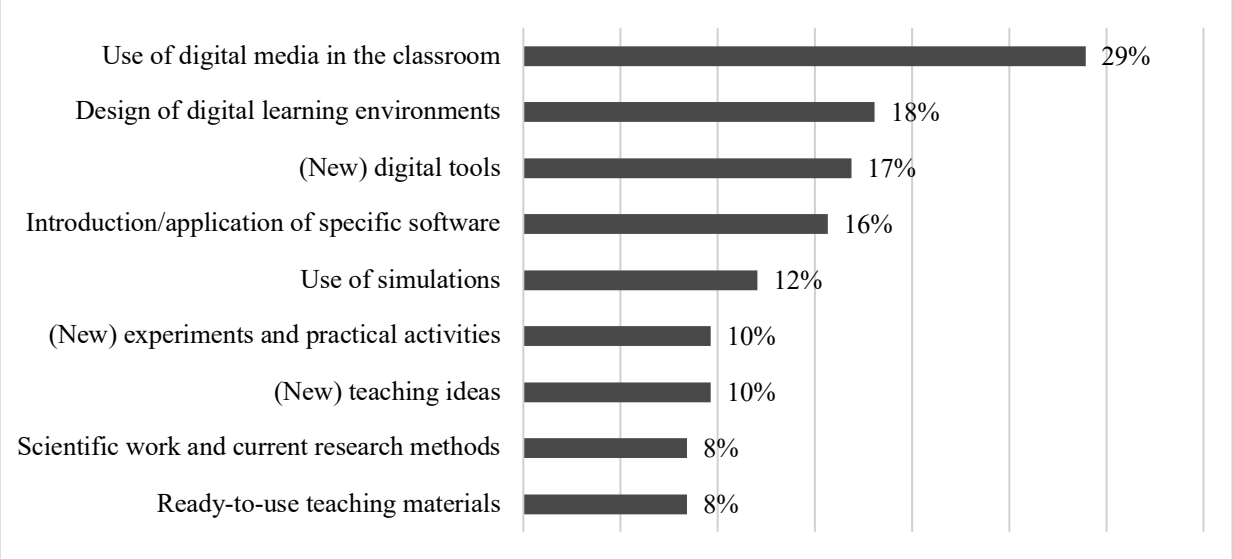
Table 1: Post-survey instrument.

	Relevance	Cognitive Activation	Sustainability
	3 Items α = .900	6 Items α = .910	6 Items α = .896
Example item	RelAd1: "In the PD programme, we talked about why the topic is important for digital teaching."	KogA2: "In the PD programme, we reflected on our professional practice regarding digital teaching."	Nach4: "In the programme, we discussed how the PD content on digital teaching can be implemented at our schools."
Measurement	Post-Survey: 6-point Likert scale from 1 = strongly disagree to 6 = strongly agree		

In the post-survey, validated six-point Likert scales developed by Rzejak et al. (2023) were shortened and adapted to the context of digital learning. These scales assessed teachers'

perceptions of relevance, cognitive activation, and sustainability after participating in the PD programme (Table 1). The post-survey was administered immediately after the PD programme.

The open-ended responses were analysed using content analysis (Kuckartz, 2018). An inductive category system was developed and subsequently discussed, revised, and refined in collaboration with two additional research associates. The resulting category system was then validated using the AI Assist tool in MAXQDA Analytics Pro (24.0.0), but no further modifications were deemed necessary.



To analyse the quantitative data of the post-survey, descriptive statistics were applied. Additionally, potential changes in participants' evaluations across different PD programme iterations were examined in the context of the design-based research approach. Here, comparisons between the first and second iteration were conducted for PD programmes that were implemented more than once, as not all programmes were offered in multiple iterations. Given the ordinal scale level and small sample sizes, Mann-Whitney U tests were applied.

Results

Pre-Survey

Data was collected from 107 teachers (83 teachers in pre-surveys and 48 teachers in post-surveys) across all eight PD programmes. The results of the pre-survey indicate that teachers most frequently expected the aspects shown in Figure 3 from digitalisation-related PD programmes in out-of-school labs. In some cases, individual teachers' responses were assigned to multiple categories.

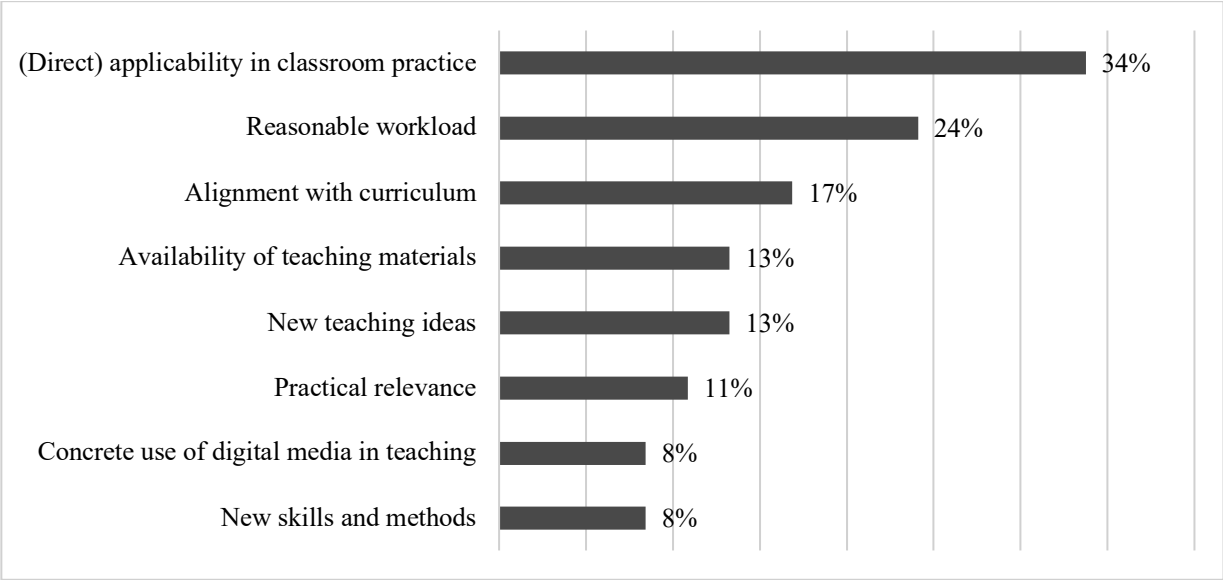


Figure 3: Most frequently expected aspects from digitalisation-related PD programmes in out-of-school labs mentioned by participating teachers (*n* = 83).

Among the most frequently mentioned expectations, many responses were related to digitalisation, e.g.: information on using digital media in the classroom (29%), designing digital learning environments (18%), and discovering new digital tools (17%). However, participants also expressed expectations that were not directly related to ICT, such as engaging in practical activities and (new) experiments (10%), exploring new teaching ideas (10%), engaging with scientific methods and current research practices (8%), and receiving ready-to-use teaching materials (8%).

In response to the question on relevance, the surveyed teachers stated that they consider a PD programme relevant to their teaching if it addresses the aspects shown in Figure 4.

Figure 4: Aspects that make a PD programme relevant to teachers (*n* = 83).

Across all topics, the most frequently mentioned criterion for relevance was that the PD content should be directly applicable to classroom practice (34%), and that it should involve a reasonable amount of time and effort (24%). Teachers also emphasized that content should be aligned with the curriculum (17%) and offer real-world or practical relevance for students (11%). Additional aspects mentioned included the desire for new teaching ideas (13%) and opportunities to learn new skills and methods (8%). As already seen in the expectations, teachers considered a PD programme to be relevant if it provided ready-to-use teaching materials (13%) and gave practical guidance on how to implement digital media in the classroom (8%). A few teachers also mentioned aspects such as strategies for differentiated instruction (4%) and opportunities for collegial collaboration (2%).

Post-Survey

In the Post survey, 48 teachers rated the relevance of programme regarding digital teaching with a mean value of $M = 4.78$ ($SD = 1.19$, $\alpha = .900$) on a scale range from 1 for negative perception to 6 for positive perception. Cognitive activation regarding digital teaching was scored with a mean value of $M = 4.02$ ($SD = 1.26$, $\alpha = .910$) and sustainability regarding digital teaching with a mean value of $M = 4.62$ ($SD = 1.13$, $\alpha = .896$) on the same scale range.

The PD programmes in the subjects of Mathematics, Chemistry, Physics, and Biotechnology were each conducted more than once. Table 2 presents the descriptive post-survey results for the three evaluated scales for the first and second iteration of these PD programmes.

Table 2: Post-survey results of the PD programmes with more than one iteration: Mathematics, Chemistry, Physics, and Biotechnology.

	First Iteration (n = 19)		Second Iteration (n = 33)	
	M	*SD*	*M*	*SD*
Relevance	4.67	1.26	4.96	1.02
Cognitive Activation	3.68	1.23	4.33	1.22
Sustainability	4.64	0.93	4.86	0.98

To examine whether these observed differences between the two PD iterations were statistically significant, Mann-Whitney U tests were conducted for each of the three scales. The comparison revealed no statistically significant difference in perceived relevance between the first and second

iteration (U = 282.00, Z = -0.606, p = .545). Similarly, ratings regarding sustainability did not differ significantly between the two iterations (U = 273.00, Z = -0.772, p = .440). For cognitive activation, the difference did not reach statistical significance but showed a trend toward higher ratings in the second iteration (U = 212.50, Z = -1.923, p = .054).

Discussion

Initial insights of the pre-survey demonstrate that effective PD for teachers must balance theoretical knowledge with practical applicability, which is consistent with findings of other studies (Darling-Hammond et al., 2017; Rzejak et al., 2023). Additionally, teachers demand subject-specific digital tools, digital learning environments, and use of specific software. From a theoretical perspective, the pre-survey results contribute to existing research on PD by highlighting the importance of subject-specific digital competence training (Mishra & Koehler, 2006). The findings further underscore the need for continuous professional learning in digital environments that are closely connected to authentic, practice-oriented learning settings. These findings support the growing body of literature on TPACK and its role in effective teaching in the digital age (Fernandes et al., 2020; Thoms et al., 2022). Additionally, the results provide insights into the user side of PD, capturing aspects such as the perception, interpretation, and utilisation of the offered learning opportunities (Lipowsky & Rzejak, 2015). In this regard, the findings underline the relevance of teachers' subjective relevance judgements for understanding PD effectiveness, as design features alone may not determine how learning opportunities are perceived and taken up.

The scales used in the post-test, adapted from Rzejak et al. (2023), have shown to be a suitable instrument for evaluating the perceived relevance, cognitive activation, and sustainability of out-of-school labs related PD regarding digital aspects. The positive trend in the results provides initial indications that the expectations of teachers on the offer side could be addressed. In particular, the descriptively higher ratings observed in the second iteration, especially with regard to cognitive activation, may point towards iterative improvements within the design-based research process, although these differences did not reach statistical significance.

However, the findings need to be interpreted with caution. First, the results are based on teachers' self-reports and rely on relatively small sample sizes, which limits the generalisability of the findings. Second, the use of open-ended items in the pre-survey constitutes a further limitation. Teachers were likely to articulate only one or two aspects they perceived as most important, while other potentially relevant dimensions remained unmentioned. As a result, aspects such as collegial collaboration appear only marginally in the resulting category system, although they are well established in the literature as important features of effective PD (Lipowsky & Rzejak, 2015; 2021). This should therefore not be interpreted as a lack of relevance, but rather as an effect of prioritisation processes in teachers' spontaneous responses.

Conclusion And Outlook

In conclusion, this study provides insights into teachers' perceptions of digitalisation-related PD programmes conducted in out-of-school labs. The findings show that participating teachers particularly value PD formats that combine subject-specific digital tools with practical applicability and curricular relevance. Overall, the participating teachers reported positive perceptions of the PD programmes with regard to relevance, sustainability, and cognitive activation. However, cognitive activation was rated comparatively lower, indicating a potential area for further development.

By explicitly focusing on the teachers' perspective, this study extends previous research on PD in out-of-school labs, which has predominantly addressed design features and facilitator

perspectives (Lüsse et al., 2025). The results underline the importance of teachers' subjective relevance judgements in understanding PD effectiveness, thereby supporting the offer-and-use model of PD. Moreover, the descriptively higher ratings observed in the second implementation cycle suggest that iterative refinements within a design-based research approach may contribute to perceived improvements in PD quality. Due to the limited number of participants, this assumption needs further research.

Taken together, the findings highlight the potential of out-of-school labs as innovative learning environments for digitally supported teacher PD, particularly when PD offers are closely aligned with teachers' professional needs and classroom realities.

Looking ahead, several areas warrant further investigation. Future research should examine the longer-term impact of such PD programmes, particularly regarding the transfer of acquired digital competencies into classroom practice. Furthermore, as highlighted by Lipowsky and Rzejak (2015), the role of PD facilitators deserves closer attention. Investigating facilitators' perspectives, professional backgrounds, and attitudes towards digitalisation may provide valuable insights into factors influencing PD effectiveness.

ESERA 2025 Copenhagen

Assessing The Impact Of Lesson Study-Based Professional Development On Spatial Skills Of Primary Students

Ergi Bufasi, Ildze Cakane, Karlis Greitans, Inese Dudareva and Dace Namsone
University of Latvia, Latvia

This study evaluates a structured professional development (PD) program aimed at enhancing primary students' spatial ability by equipping teachers with targeted instructional strategies. As the final cycle of a design-based research (DBR) framework, it assesses student outcomes to determine PD effectiveness. The PD program, implemented through lesson study, guided 24 teachers in integrating spatial reasoning into STEM instruction using hands-on activities, visualization tasks, and spatial problem-solving exercises. Pre- and post-tests administered to 345 students in grades 1–3 showed significant gains, particularly in spatial visualization, followed by mental transformation and spatial orientation. Findings highlight the effectiveness of PD in fostering spatial ability and underscore the need for structured spatial ability instruction in early STEM education.

Keywords: Spatial ability, professional development, primary education

Introduction

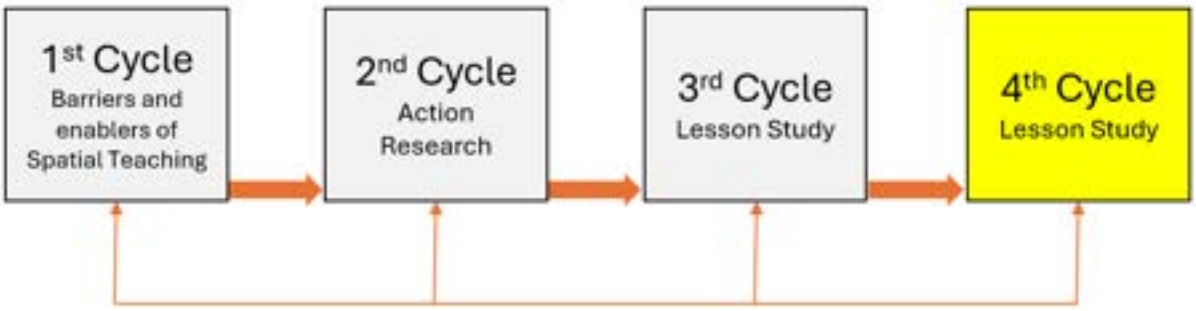
This study examines the impact of a structured professional development (PD) program on enhancing primary school students' spatial ability by supporting teachers in integrating spatial ability into instruction. As the final cycle of a design-based research framework, it evaluates student outcomes as a measure of PD effectiveness. Spatial ability—the capacity to visualize, manipulate, and reason about objects in space—is a critical cognitive skill linked to success in STEM education (Uttal et al., 2013). Despite its importance, it remains underrepresented in primary curricula (Cheng & Mix, 2014). Research shows that PD programs focusing on spatial reasoning equip teachers with effective instructional techniques, such as hands-on activities, visualization tasks, and spatial problem-solving exercises (NRC, 2006). This study provides empirical evidence on how teacher PD improves student performance in spatial tasks, including mental transformation, spatial orientation, and spatial visualization, demonstrating the broader impact of targeted teacher training on STEM-related cognitive skills (Wai et al., 2009).

Theoretical Framework

This study explores the impact of PD on student learning and the role of spatial ability in STEM education. Using lesson study (LS) (Lewis et al., 2009) within a design-based research (DBR) framework, teachers collaborated to refine spatial reasoning lessons. The study applies the IMTP framework (Sims et al., 2023) to assess PD effectiveness through insights, motivation, techniques, and embedding practices. Results show that teachers deepened their understanding, improved instructional strategies, and enhanced student gains in mental rotation and spatial orientation. By linking teacher learning to student outcomes, this research highlights the value of structured, collaborative PD in fostering STEM-related skills.

Aim Of The Study

This study evaluates the impact of a structured teacher PD program on student spatial performance in primary STEM education. As the fourth cycle of a DBR project, it examines how improved instructional practices from LS translate into student gains, identifying which spatial components show the most and least improvement. Findings offer insights into the effectiveness of PD in fostering spatial ability in young learners by addressing the following research questions:



1.To what extent did students' spatial performance improve after teachers implemented the PD-based instructional strategies, as measured by pre- and post-test results?

2.Which spatial ability components (spatial visualization, mental transformation, spatial orientation) showed the most significant improvements, and which demonstrated the least change after the PD intervention?

Method

This study is part of a broader DBR project aimed at developing and refining a PD model to enhance spatial ability instruction in primary STEM education. Specifically, this paper reports on the fourth cycle of DBR, which focuses on evaluating the impact of the PD program on student spatial performance (see Figure 1). The study was conducted in two primary schools, involving 24 female teachers from grades 1–3 (with teaching experience ranging from 4 to 47 years) and their 345 students—104 first-grade students, 115 second-grade students, and 126 third-grade students. The PD program was designed to equip teachers with strategies for integrating spatial reasoning into STEM subjects, ensuring that the enhanced pedagogical practices translate into measurable student learning outcomes. The PD intervention followed a structured four-phase workshop model: (1) Reflection, where teachers analysed their current teaching practices; (2) Input and Modeling, where they explored core spatial ability components—spatial visualization, mental transformation, and spatial orientation—through expert-led activities; (3) Discussion, where collaborative engagement facilitated deeper pedagogical insights; and (4) Outcome Formulation, where teachers co-developed lesson plans incorporating spatial reasoning tasks. To embed these strategies into real classroom practice, the PD utilized a LS framework (Lewis et al., 2009), in which teachers worked in triads or groups of five to collaboratively design, implement, observe, and refine spatially enriched lessons for mathematics, science, and technology. This iterative process ensured systematic role rotation, promoting shared learning and continuous instructional improvement. To measure the impact of the PD program on student spatial performance, pre- and post-tests assessing key spatial ability tasks (e.g., mental transformation, spatial visualization, spatial orientation) were administered to the students of participating teachers. These tests provided quantitative evidence of changes in student performance, while teacher reflections and lesson study observations offered qualitative insights into how improved instructional practices influenced student learning. By systematically evaluating both student performance outcomes and teacher pedagogical growth, this study assesses the effectiveness of the designed PD model in enhancing spatial ability development in primary STEM education.

Figure 1. The Design-Based Research (DBR) process and the focus of the fourth cycle.

Findings

Findings For Research Question 1

A dependent t-test (paired t-test) was conducted for each grade level to compare students' pre- and post-test spatial performance scores. The results indicate a statistically significant improvement in spatial ability across all three grade levels. Below is a summary of the findings:

Table 1. Summary of Pre- and Post-Test Spatial Performance Scores Across Grade Levels,

Grade Level	Mean (Pre)	SD (Pre)	Mean (Post)	SD (Post)	t (df)	p-value	Significance
1st Grade	18.67	2.76	20.88	2.4	5.88	< .00001	Significant
2nd Grade	17.76	3.30	20.32	2.47	6.99	< .00001	Significant
3rd Grade	11.63	3.79	14.94	4.80	7.56	< .00001	Significant

*p < 0.05. SD: Standard deviation

All p-values are below the significance threshold ($p < .05$), indicating that the observed improvements in spatial ability are unlikely to be due to chance.

- First Grade: Students showed a significant improvement in spatial test performance after their teachers implemented PD-based instructional strategies ($M_{pre} = 18.67$, $SD = 2.76$; $M_{post} = 20.88$, $SD = 2.40$). The paired t-test yielded $t(104) = 5.88$, $p < .00001$, confirming a statistically significant increase.
- Second Grade: A notable improvement was also observed among second-grade students ($M_{pre} = 17.76$, $SD = 3.30$; $M_{post} = 20.32$, $SD = 2.47$). The dependent t-test result of $t(115) = 6.99$, $p < .00001$ supports the effectiveness of the instructional intervention.
- Third Grade: Students in third grade exhibited the most substantial improvement relative to their baseline scores ($M_{pre} = 11.63$, $SD = 3.79$; $M_{post} = 14.94$, $SD = 4.80$). The paired t-test analysis ($t(126) = 7.56$, $p < .00001$) confirms a significant positive shift in their spatial ability.

Findings For Research Question 2

This study also aimed to determine which spatial ability components (spatial visualization, mental transformation, spatial orientation) showed the most significant improvements after teachers implemented instructional strategies from the PD program. Since Grades 1 and 2 used the same test, the analysis was conducted for these two groups, while Grade 3 was excluded due to a different test format. To evaluate improvements, a dependent t-test (paired t-test) was conducted for each spatial ability component within Grades 1 and 2. The results indicate that all three spatial ability components demonstrated statistically significant improvements ($p < .05$) following the intervention. However, the degree of improvement varied across components as illustrated in table 2.

Table 2. Summary of Pre- and Post-Test Results for Spatial Ability Components in Grades 1 and 2.

Grade	Spatial Ability Component	Mean (Pre)	SD (Pre)	Mead (Post)	SD (Post)	t (df)	p-value	Significance
1st Grade	Spatial Visualization	6.21	1.21	7.13	1.05	5.73	<.00001	Significant
	Mental Transformation	6.43	1.25	7.11	0.96	4.74	<.00001	Significant
	Spatial Orientation	6.00	1.34	6.70	1.15	4.25	<.00001	Significant
2nd Grade	Spatial Visualization	5.95	1.28	6.73	1.12	6.10	<.00001	Significant
	Mental Transformation	6.14	1.43	6.90	1.08	5.79	<.00001	Significant
	Spatial Orientation	5.67	1.59	6.71	1.17	7.31	<.00001	Significant

Spatial visualization showed the greatest improvement across both grades, with first graders increasing from $M = 6.21$ to $M = 7.13$ ($t = 5.73$, $p < .00001$) and second graders from $M = 5.95$ to $M = 6.73$ ($t = 6.10$, $p < .00001$), indicating the strongest effect of PD-based strategies on spatial visualization. Mental transformation also showed substantial gains, with first graders improving from $M = 6.43$ to $M = 7.11$ ($t = 4.74$, $p < .00001$) and second graders from $M = 6.14$ to $M = 6.90$ ($t = 5.79$, $p < .00001$), though effect sizes were slightly lower than for spatial visualization. Spatial orientation showed the least improvement but remained significant, with first graders increasing from $M = 6.00$ to $M = 6.70$ ($t = 4.25$, $p = .00005$) and second graders from $M = 5.67$ to $M = 6.71$ ($t = 7.31$, $p < .00001$), suggesting a relatively stronger initial ability in this area, leading to smaller gains compared to the other two components.

Discussion

The significant gains in pre- to post-test scores highlight the effectiveness of structured PD interventions in enhancing students' spatial reasoning, a key skill for STEM learning and problem-solving (Newcombe, 2010). RQ1 findings indicate that students in Grades 1–3 showed

significant improvements in overall spatial ability after PD-based instructional strategies were implemented, supporting research on the benefits of early and sustained spatial training (Wai, Lubinski, & Benbow, 2009). The success of these strategies is likely due to their emphasis on hands-on, visualization-based, and problem-solving approaches, which strengthen spatial cognition (Lowrie, Logan, & Ramful, 2017). RQ2 analysis of spatial ability components in Grades 1 and 2 revealed that spatial visualization showed the greatest improvement, followed by mental transformation, while spatial orientation exhibited the least change. The strong gains in spatial visualization align with studies on the cognitive benefits of explicit training in mental imagery (Taylor & Hutton, 2013), while improvements in mental transformation support evidence on the malleability of spatial skills in classroom instruction (Levine et al., 2012). The smaller gains in spatial orientation suggest either a higher initial proficiency or a focus on static rather than dynamic spatial tasks (Verdine et al., 2014).

ESERA 2025 Copenhagen

Shifting Teachers' Knowledge And Confidence For Engaging Students In Science Practices From A Program Designed By Scientists And Pedagogical Experts

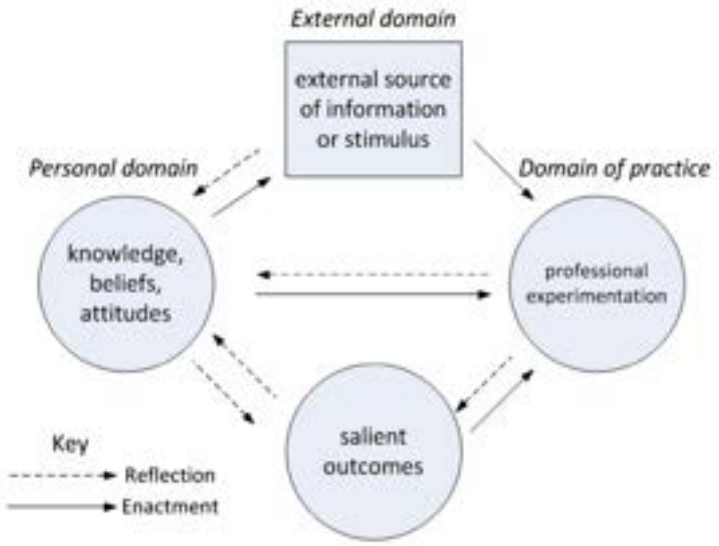
Kathleen M Hill[1], Amber Cesare[1], Tiffany Lewis[1], Jennifer Gruber[2], and Lisa Shannon[2]
[1]The Pennsylvania State University, United States
[2]Magnolia Consulting, United States

The Next Generation Science Standards (NGSS) in the United States call for engaging students in authentic science through the practices of scientists (NRC, 2013). One challenge to translating the NGSS into the classroom is the lack of resources and programs that model and feature the scientific practices. This study describes a 10-day teacher professional development (PD) designed by both science researchers and education experts. As part of the PD, teachers developed and implemented a classroom research project (CLRP) curriculum plan centered on authentic scientific practices in molecular biology and the unique contexts of their schools. Following implementation, teachers delivered a presentation of their curriculums and the impact of implementing the curriculum on their instructional practices. In this mixed-methods study, we sought to answer two research questions: 1) To what extent do teachers who implement CLRPs increase their knowledge about how to align their teaching practices to the NGSS? and 2) To what extent do teachers who implement CLRPs increase their skills to engage students in scientific practices in their classroom? The findings indicate that teachers can increase their knowledge and confidence for aligning their teaching practices to NGSS. In addition, teachers also increased their skills and confidence for engaging students in science practices, particularly developing and using models. This study highlights the potential of teacher PD programs to enhance teachers' understanding and incorporation of science practices into their instruction, thereby promoting more authentic science learning experiences for students.

Keywords: Science practices, professional development, teacher education

Introduction

The Next Generation Science Standards (NGSS) in the United States call for engaging students in authentic science through the practices of scientists (NRC, 2013). Authentic science in the classroom involves engaging students in investigations that seek to answer scientific questions in ways that closely approximate those of scientists (Crawford, 2012, p.113). Traditional teacher education programs do not require preservice teachers to engage in scientific research (Burgin, 2020). This puts secondary science teachers at a disadvantage as most teachers lack expertise in the day-to-day practices of scientists such that they effectively integrate these practices into their science curriculum (Davidson et al., 2022). In particular, teachers' lack of understanding about scientific models and modelling limits their ability to engage students in developing and using models in the classroom (Gilber & Justi, 2016).



Successful implementation of high-quality instructional materials requires ongoing and sustained professional learning for teachers (Bybee & Chopyak, 2017). Biology curricular and instructional materials are loaded with visual representations and can be presented in a variety of ways (Dries et al., 2017). Yet, students are not explicitly taught how to interpret these representations and move between them as they are commonly used for exposure (Dries et al., 2017).

One strategy to increase teachers' knowledge of science practices and support the development and implementation of practices-based curriculum is to engage teachers in professional development (PD) involving both science education faculty and science research faculty.

Theoretical Framework

Clarke and Hollingsworth's (2002) teacher professional growth model served as the conceptual framework for designing the PD program and conducting this study (Figure 1), as it describes key elements for examining individuals or groups of teachers in the context of a particular PD program.

Figure 1. Clarke and Hollingsworth's (2002, p. 951) interconnected model of teacher professional growth.

Specific Aim And Research Questions

The program included a multi-disciplinary team with expertise from education, biochemistry, and medicine. The PD program was designed to engage high school biology and biochemistry teachers in molecular modelling science techniques and pedagogical strategies for classroom instruction.

The specific aim of the project was to create biomolecular science curriculum centred on authentic science practices. As part of a 10-day PD, teachers developed and implemented a classroom research project (CLRP) curriculum plan centred on authentic scientific practices in molecular biology and the unique contexts of their schools. Following classroom implementation, teachers delivered a presentation of their curriculum plans and the impact of implementing the curriculum on their instructional practices.

With this aim, we sought to answer two research questions:

1) To what extent do teachers who implement CLRPs increase their knowledge about how to align their teaching practices to NGSS?
2) To what extent do teachers who implement CLRPs increase their skills and confidence to engage students in scientific practices in their classrooms, with an emphasis on developing and using molecular models?

Methods

This mixed-methods study was designed to characterize teachers' understanding of science practices and how implementing their CLRPs increased their skills and confidence for engaging students in more authentic science practices.

Professional Development Program

The two-week summer PD program was designed to increase teachers' knowledge of the scientific practices, specifically *developing and using models*, *analysing and interpreting data*, and *communicating information*, involved in molecular biology research. The summer workshop was divided into three parts 1) content knowledge development, 2) research and design, and 3) curriculum development. During the content knowledge development portion of the workshop, teachers learned the fundamentals of protein folding, the technique of x-ray crystallography, and explored an example molecular story of insulin and diabetes. Teachers engaged in *modelling of* by using classroom molecular modelling kits. These kits were used to help build teachers' content knowledge, to map between a real molecule (insulin) and the representation being used, and to prepare teachers to engage in modelling for later in the workshop. Teachers engaged in *modelling for* through learning how the structures of proteins are determined using x-ray crystallography and how scientists make decisions based on data to generate a 3D model of a protein. Models generated from x-ray crystallography are published in a freely accessible public database, the Protein Data Bank (PDB). Using various PDB insulin files, teachers used JUDE, a molecular visualization program, to examine the active form of insulin, the monomer. Then, teachers looked at the dimer, and finally how insulin was stored as a hexamer. The workshop culminated with an open JUDE investigation looking at different designer insulins. Teachers worked in small groups to answer structure-function questions about how insulin was altered to control blood sugar in diabetes. Then, teachers transitioned to working with Penn State researchers to explore and develop a molecular story based on the work of Penn State research lab. The teachers developed a project poster and presented their findings at the workshop. Finally, in the curriculum development portion of the workshop, teachers collaborated with molecular biology researchers, science education faculty, and other participants in the cohort to develop a CLRP for their high school students around a protein of their choice.

Teacher Participants

Twenty-four teachers were recruited to participate in the program over three different cohorts. Teaching experience varied, with 42% of teachers reporting they had been teaching for 11 to 20 years. Teachers also indicated that they taught a range of subjects, the most common being biology (67%). Of the 24, 13 provided data pertaining to the implementation of their CLRPs.

Data Collection And Analysis

Multiple sources of data were collected for this mixed-methods study, including:

- Teacher surveys (CLRP survey)
- Teacher artifacts (CLRP documents and presentations slides)

Quantitative analyses of data collected from closed-ended survey items were conducted, including descriptive statistics and paired samples t-tests to determine whether the mean differences between participants' ratings from before to after implementation of the CLRP were statistically significant.

Qualitative analysis of teacher artifacts included a priori coding and comparative analysis. A priori coding involved applying predefined codes of the science practices to identify the presence of specific practices in their CLRPs (Creswell & Creswell, 2018) and implementation presentations. Open coding was conducted to identify shifts related to skills and confidence for engaging students in authentic science. Themes were identified using a thematic analysis approach (Clarke et al., 2015). The project team triangulated the findings from the various data sources.

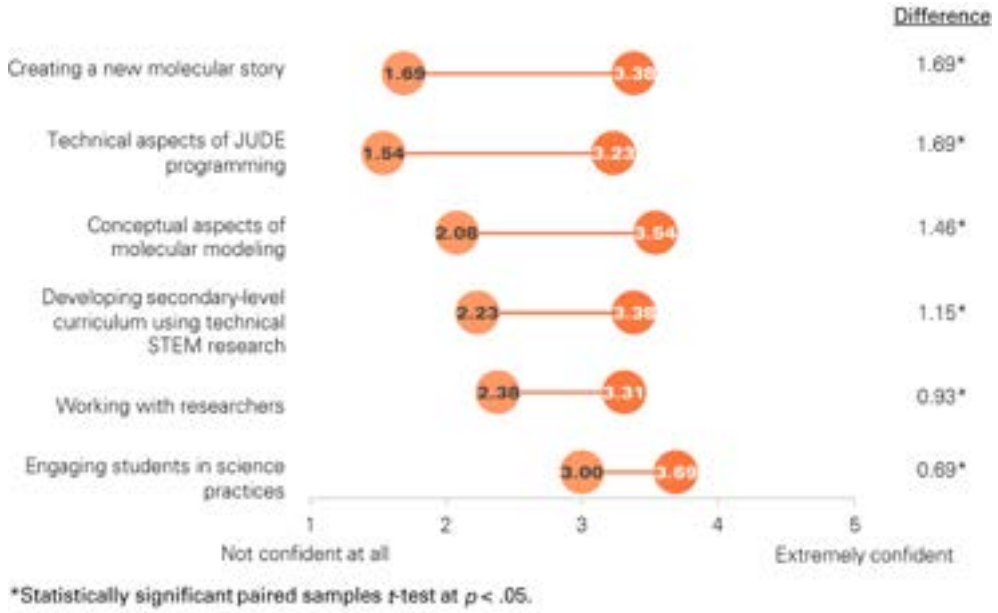
Limitations

Several limitations exist in the study. Participating teachers self-selected to take part in the program, so the sample is skewed to teachers that are apt to participate in PD they chose, which limits generalizability to larger groups of teachers that do not select to participate in PD. In addition, we were only able to collect teacher-reported data, not the observations of implementation in the classroom.

Findings

Research Question 1

The teachers demonstrated knowledge of designing instructional plans for engaging students in science practices. In the CLRP documents, all teachers described how students would engage in molecular modelling practices to investigate a particular molecule (e.g., proteins, nucleic acid) of interest. Most teachers (67%) selected molecules for their CLRP that differed from those investigated during the workshop to attend to their students' interests and teaching context. This choice to explore other molecules indicates teachers' increased confidence in supporting students to use modelling practices to investigate molecules novel to teachers and students. Teachers also integrated the CLRP activities into their existing curriculum to provide scaffolding, align with state-level education standards, and incorporate molecular biology practices used by researchers.



Teachers reported increased knowledge in the three target NGSS science practices after implementing their CLRPs relative to before implementation (Figure 2). Their self-rated knowledge about all three practices increased from before to after the CLRP implementation, particularly regarding developing and using models. The mean differences between their pre- and post- ratings were all statistically significant based upon the results of the paired sample t-tests.

Figure 2. Teachers' self-rated knowledge in target NGSS science practices before and after implementing the CLRPs in Years 2, 3, and 4 (n=13).

Teachers also reported increased confidence in various techniques and teaching practices after implementing their CLRPs (Figure 3). Their self-rated confidence in all areas increased from before to after their CLRP implementation, particularly in their confidence in creating a new molecular story and the technical aspects of JUDE programming. The mean differences between their pre- and post-ratings were all statistically significant based on the results of paired samples t-tests.

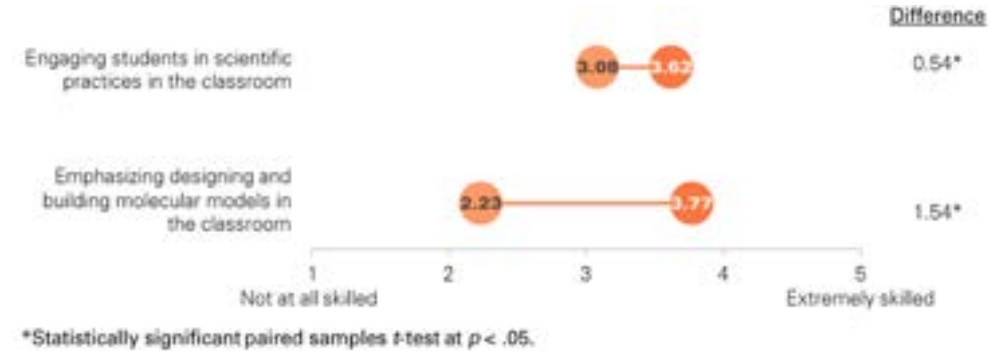


Figure 3. Teachers' self-rated confidence before and after implementing the CLRPs in Years 2, 3, and 4 (n=13).

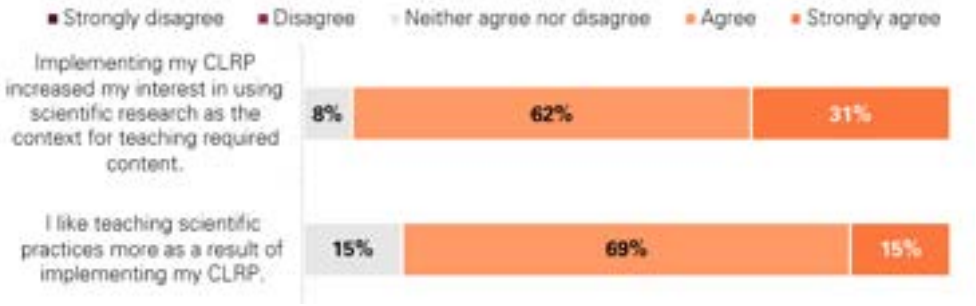
Research Question 2



Teachers reported increased skills to engage students in scientific practices and molecular modeling after participating in the CLRPs relative to before (Figure 4). After implementing their CLRPs, teachers rated their skills in engaging students in scientific practices and molecular modeling before and after implementation. Their self-rated skills increased from before to after the CLRP implementation, particularly their skills in emphasizing designing and building molecular models in the classroom. The mean differences between their pre- and post-ratings were all statistically significant based on the result of paired sample t-tests.

Figure 4. Teachers' self-rated skills in engaging students in scientific practices and molecular modeling before and after implementing the CLRPs in Years 2, 3, and 4 (n=13).

After implementing their CLRPs, teachers rated the extent to which implementing their CLRPs increased their interest in and enjoyment of using scientific research and practices in their teaching (Figure 5). Most teachers agreed (62%-69%) or strongly agreed (15%-31%) with these statements, indicating that implementing the CLRPS not only increased teachers' skill in engaging students in scientific practices and molecular modelling, but also impacted teachers' interest in and enjoyment of using these practices in their teaching.

Figure 5. Teachers' ratings of the impact of implementing their CLRPs on their interest in and enjoyment of using scientific research and practices in Years 2, 3, and 4 (n=13).

In the post-implementation presentation slides, teachers identified specific NGSS science practices that students engaged in during the CLRP. All of the teachers described engaging students in developing and using models along with other science practices (e.g., asking questions, obtaining, evaluating, and communicating information). However, the practice of analysing and interpreting data was not mentioned. Multiple teachers described the challenges of scaffolding the learning of reading and understanding research papers and programming in JUDE to create 3-D visualizations of molecules.

Discussion And Implications

One of the key insights from this study is that sustained professional development can increase teachers' knowledge of and confidence for aligning their teaching practices with NGSS standards. With PD designed to engage teachers in current science practices and support their development of practices-based curriculum appropriate for their teaching context, teachers successfully incorporated science practices into their existing curriculum plans and identified molecules of interest relevant to their specific teaching situations. This alignment between NGSS standards and classroom implementation is particularly evident in teachers' adoption of the scientific practices—a central component of the three-dimensional learning framework outlined in NGSS. Consistent with Capps and Crawford (2013), sustained PD can help teachers to better understand these scientific practices and translate standards into meaningful classroom experiences.

The study revealed that teachers increased their skills and confidence for engaging students in science practices, particularly in developing and using models. This finding is unsurprising given that modeling was the central practice explored throughout the workshop. The depth of teachers' self-reported implementation and the transfer to their unique teaching contexts demonstrates meaningful learning. Our study supports the findings of Justi and Gilbert (2002) in that teachers identified the substantial scaffolding required for students to engage authentically in the developing and using models practice in molecular biology. We also found that teachers reported a high degree of interest and enjoyment in using scientific research and practices in their teaching. This positive affective response aligns with findings from Kreifels et al. (2021), who found that teachers participating in a 12-month inquiry-based learning professional development program developed increased confidence, possessed positive attitudes toward implementation, and felt that barriers could be controlled. Such affective outcomes are particularly important, as teacher confidence and interest often predict sustained implementation of new instructional approaches (Desimone, 2009).

The study also revealed teachers increased their skills and confidence for engaging students in science practices (Davidson et al., 2022), particularly *developing and using models* (Gilber & Justi, 2016). While teachers identified the challenges of scaffolding required for students to engage in these practices, the teachers reported a high degree of interest and enjoyment for using scientific research and practices in their teaching.

Several directions for future research emerge from this work. First, longitudinal studies are needed to examine whether teachers' increased confidence and skills in implementing science practices persist over time and become embedded in their regular instructional routines. Second, future research should investigate student learning outcomes associated with teachers' implementation of practices-based instruction following this type of PD. While teacher knowledge and confidence are important intermediate outcomes, the ultimate goal is enhanced student understanding of both disciplinary core ideas and the nature of scientific inquiry. Third, research is needed to identify the specific components of the PD model that were most effective in promoting teacher learning and implementation. Understanding which elements, whether the authentic research context, sustained duration, collaborative curriculum development, or other factors, most strongly influence outcomes would allow for more efficient and targeted PD design. Finally, exploring how this model might be adapted for teachers in different contexts (e.g., varying levels of resource availability, diverse student populations, different grade levels) would support broader dissemination and impact.

In conclusion, this study highlights the potential of carefully designed teacher PD programs to enhance teachers' understanding and incorporation of science practices into their instruction, thereby promoting more authentic science learning experiences for students. The findings suggest that when teachers engage directly in scientific practices within their own subject-matter contexts and receive sustained support for curriculum development, they can successfully align their instruction with NGSS standards and develop the confidence to implement challenging pedagogical approaches. Continued collaboration between science researchers and pedagogical experts is essential to bring such authentic science learning experiences to secondary classrooms at scale.

Science Teacher Educators In Professional Learning Communities: Exploring The Possibilities Of Creating New Organizational Routines

Karina Kiær[1,2] and Thomas R.S. Albrechtsen[2]
[1]University of Southern Denmark (SDU)
[2]University College Southern Denmark (UCSYD), Denmark

One of the ways to support the professional development of science teachers in schools is through the establishment of professional learning communities (PLCs). But what about the professional learning of science teacher educators? The aim of this paper is to analyse and discuss the following two research question: How is it possible to organise professional learning communities for science teacher educators? How do science teacher educators experience their participation in such professional learning communities? We explore these questions building on an ethnographic study of a national program in science teacher education (NAFA) involving all science teacher educators in Denmark. We use a practice theoretical and Routine Dynamics perspective to understand how the new PLC-routines are created in the program. We identify some of the strengths and weaknesses of working together in this type of routines and discuss possible implications for the further development of professional learning communities for science teacher educators.

Keywords: Science Teacher Educators, Professional Learning Communities, Organizational Routines

Introduction

The purpose of this paper is to analyse and discuss how science teacher educators participate in professional learning communities. In the recent 30 years professional learning communities (PLCs) have become a certain way of organising professional collaboration in educational institutions worldwide (Albrechtsen et al., 2022; Lee et al., 2022; Moosa et al., 2024; Nguyen et al., 2024; Olsson, 2019; Sai & Siraj, 2015; Stoll et al., 2006). Beginning in North America in the 1990's and building on theories of the learning organization and organizational learning, the research primarily focused on school-based teacher collaboration. Since, the practice of and research on PLCs has expanded to also include other participants, like the whole school, the whole school district, research-practice partnerships and collaboration across educational organizations (Admiraal et al., 2021; Mundry & Stiles, 2009; Stoll & Louis, 2007). The interorganizational collaboration is also conceptualised as 'professional learning networks' (PLN) (Carpenter et al., 2022; Poortman et al., 2022; Prenger et al., 2021). Some research focusses on the more subject-specific parts of PLCs such as how they play a role in the professional development of science teachers (Blonder & Vescio, 2022; Dogan et al., 2016; Eylon et al., 2020; Jones et al., 2013; Vossen et al., 2020), but it is still limited how much we know about their significance for the professional development of science teacher educators. Science teacher educators are expected to develop different forms of knowledge (Mork et al., 2021) and strengthen their 'pedagogical content knowledge' (Hume et al., 2019), but how they share it with colleagues and how they build a 'pedagogy of teacher education' together (Loughran, 2006) is not something we know much about. We want to contribute with knowledge on how this is made possible in local PLCs and across organizational boundaries such as PLNs. These questions concerning the professional development of science teacher educators lie behind this paper presentation, but it can also be seen in the light of a more general and current interest in research on the professional learning of

teacher educators as our empirical data stem from the Danish teacher education system (Kelchtermans et al., 2018; Klink et al., 2017; Ping et al., 2018; Vanderlinde et al., 2021).

The empirical background is a 4-year longitudinal study (2022-2025) of an emerging interorganizational network of PLCs in the field of science teacher education in Denmark called *Naturfagsakademiet* (NAFA) (English translation: *Danish Academy of Science Education* - For a short English introduction see the homepage: About NAFA - NAFA). NAFA is a national program supported by Novo Nordisk Fonden and VILLUM FONDEN with more than 25 million Euros in the period from 1st August 2021 to summer 2028. The main objective of NAFA is to enhance knowledge sharing and knowledge creation among science teaching professionals at different educational levels, both teacher education and primary and lower secondary schools. A central part of this is the organising of local and national PLCs at all the six university colleges in Denmark. In NAFA, a PLC is defined *as a committed and systematic inquiring community between a group of educators, who share experiences and knowledge from practice through inquiry and reflective dialogues focused on students' learning.* We will use NAFA as a case to analyse and discuss the following two research questions:

How is it possible to organize professional learning communities for science teacher educators?

How do science teacher educators experience their participation in such professional learning communities?

Method

Theoretically we build on a practice theoretical approach and a Routine Dynamics lens (Feldman, 2021; Kiær & Albrechtsen, 2024) to understand, how the science teacher educators in NAFA enact the new organizational routines in the form of 'PLC-routines' (Spillane et al., 2016). PLC-routines have a function as 'coupling mechanisms' (Spillane et al., 2011) in and between university colleges and are routines meant to support the professional learning of the science teacher educators (Horn & Little, 2010)

We explore how the idea and the actual performance of the PLC-routines constitute each other, and how different artifacts play a role in this creation of routines, using the analytic framework of Feldman & Pentland (2003). The empirical material in this paper stems from an ongoing ethnographic study that began in 2023 where we follow and observe the enactment of the PLC-routines at both online and physical meetings among the science teacher educators. Currently we have collected 61 hours audio- and video-recordings, and we have 2318 pages of transcribed data, including fieldnotes. We have also interviewed some of the science teacher educators (N=7) asking them about their experiences of participating in the PLCs of NAFA. In our paper presentation we will analyse and discuss these observations and interviews to understand how the PLCs – as defined in NAFA – are enacted in practice as new organizational routines.

Preliminary Findings

Our preliminary findings show how there is an ongoing process of building the new PLC-routines where there are examples of science teacher educators trying to find balance between the ostensive and performative aspects of the PLC-routines. The Routine Dynamics perspective enables us to describe and understand these processes in depth. We see a potential in using this approach for further investigation of the organization of professional learning opportunities for science teacher educators (see also Wolthuis et al., 2022). Our analysis of the empirical material from our observations and interviews also show how different artifacts are used to organise the PLCs and establish the new routines such as the use of a Teams platform with different folders, inspirational materials, collaboration agreements, theme reports, meeting agendas etc. The

interviewed science teacher educators explain how they work together, when and how often they meet, facilitate the meetings, invite experts to the meetings, include pre-service and in-service students in their activities, plan instruction, make decisions and communicate with science teacher educators from other university colleges. The PLC meetings we have observed are quite different in how they are enacted although they all work with the same overall theme (such as technological literacy) and we also see how the part of doing inquiries together seems limited. In the paper presentation we will discuss the possible implications of the findings for the further development of PLC-routines for science teacher educators.

Fostering STEM Teacher Identity Development In Primary And Secondary Science Education

Emily Michailidi, Chara Bitsaki, Eleni Botzaki and Athanasia Kokolaki
University of Crete, Greece

Integrated STEM (Science, Technology, Engineering, and Mathematics) education is promoted as an approach that equips students to address complex real-world challenges. Its implementation, however, requires teachers to move beyond single-subject instruction and adopt interdisciplinary roles and practices. This study examines the development of STEM teacher identity among primary and secondary science teachers participating in a 7-month professional development programme. Guided by the Dynamic Systems Model of Role Identity (DSMRI), the research explores shifts in teachers' self-perceptions, beliefs, goals, and perceived action possibilities. Twenty-four in-service teachers engaged in collaborative curriculum design, reflective activities, and classroom implementation of STEM modules, supported by mentors within learning communities. Data were collected through questionnaires, reflective journals, and recordings of community meetings. Findings revealed differentiated trajectories of professional identity development. Many teachers, particularly at the secondary level, underwent transformational change, marked by expanded perceived action possibilities, more integrated epistemic understandings of STEM, and greater use of design-oriented, inquiry-driven practices. Others followed a more elaborative trajectory, extending existing practices with interdisciplinary elements while retaining aspects of prior disciplinary orientations. Across both groups, self-perceptions remained comparatively stable, suggesting that changes in professional self-understanding may require more sustained identity-focused support.

Keywords: STEM education, Teacher education

Introduction

Contemporary global challenges are increasingly understood as complex, wicked problems characterized by the interaction of environmental, technological, and social factors. Addressing such challenges in educational settings requires interdisciplinary teaching approaches that highlight the critical links between distinct disciplines and provide opportunities for students to apply knowledge and relevant skills to complex problem situations in ways that mirror the interconnected nature of scientific, technological, and societal decision-making (Schpakow & Zambak, 2025).

The integrated STEM (Science, Technology, Engineering, and Mathematics) approach operationalizes this interdisciplinarity in classroom practice. Integrated STEM denotes instructional designs that deliberately interconnect disciplinary and interdisciplinary knowledge and practices around authentic, real-world problems (Kelley & Knowles, 2016). Despite variation across frameworks, descriptions of integrated STEM tend to converge on a set of core pedagogical principles, emphasizing learning through inquiry and problem-based processes, engaging students in authentic STEM practices, and positioning engineering design as a central organizing structure for instruction (Johnson & Czerniak, 2023; Roehrig et al., 2021). When coherently enacted, integrated STEM enables students to apply interdisciplinary knowledge across contexts and supports competencies necessary for addressing complex challenges such as systems thinking, problem framing, and evidence-informed decision making.

Implementing integrated STEM requires teachers to move beyond subject-matter knowledge. This, in turn, calls for targeted professional development that supports pedagogical design, collaboration, and work with open-ended problems. In this study we position teacher identity as

the principal analytic lens for understanding professional development (Avraamidou, 2014). Compared with purely knowledge-centred or competence frameworks, an identity lens is more inclusive; it encompasses teachers' beliefs, self-perceptions, and motivations, thereby acknowledging the personal and professional meanings teachers attach to instructional change (Russ, et al., 2016). Although there is no universally accepted definition of what teaching identity consists of, the literature consistently portrays it as encompassing the ways teachers understand and position themselves in relation to teaching, learning, and subject matter, while also being shaped by how they are recognized by others within their professional contexts (Avraamidou, 2014). Rather than a fixed personal attribute, teaching identity is understood as a dynamic and evolving construct that develops over time through experience. It comprises multiple, interacting sub-identities formed through engagement with diverse social, institutional, and disciplinary contexts, and it plays a significant role in shaping teachers' instructional choices (Beauchamp & Thomas, 2011; Capps, Crawford, & Constas, 2012).

From the perspective of identity, in order for teachers to effectively implement the integrated STEM teaching approach they must develop a strong STEM teacher identity; that is, a professional stance that goes beyond teaching subjects in isolation and instead embraces the integration of knowledge, practices, and purposes across disciplinary boundaries (El Nagdi et al., 2018). A teacher with a strong integrated-STEM identity is characterized by a coherent professional self-image as an educator who works across STEM disciplines and is recognized as such within their professional community. This identity is further reflected in strong self-efficacy for designing and implementing inquiry-driven STEM learning experiences, as well as in a redefinition of their role from content delivery toward the facilitation of student-centred problem solving. Moreover, teachers who enact such an identity demonstrate a willingness to experiment, tolerate ambiguity in their instructional practice, and engage in sustained collaboration with colleagues across grades and disciplinary boundaries, practices that are essential in interdisciplinary and design-oriented learning environments (El Nagdi et al., 2018, Galanti & Holincheck, 2022).

A tool that in this study helped us operationalize this complex identity construct is the Dynamic Systems Model of Role Identity (DSMRI; Garner & Kaplan, 2019). The model starts from a socio-cultural view of learning emphasizing the importance of the particular social and educational context in shaping teachers' identity. DSMRI conceptualizes identity as a dynamic system composed of five interacting components: (i) teachers' ontological and epistemological beliefs - in other words, assumptions about knowledge and learning; (ii) purposes and goals teachers set for their instruction; (iii) self-perceptions and role definitions - including perceived competence and self-image; (iv) perceived action possibilities - the behaviours and strategies teachers consider feasible in their context and (v) action which represents the enactment of identity in practice. In this context, STEM education professional development will manifest itself in the enrichment of STEM teacher identity components with new elements, as teachers encounter new practices, expectations, and forms of collaboration. Depending on the number and strength of these changes, shifts in identity are characterized as transformation, elaboration or stagnation (Gunersel et al., 2016).

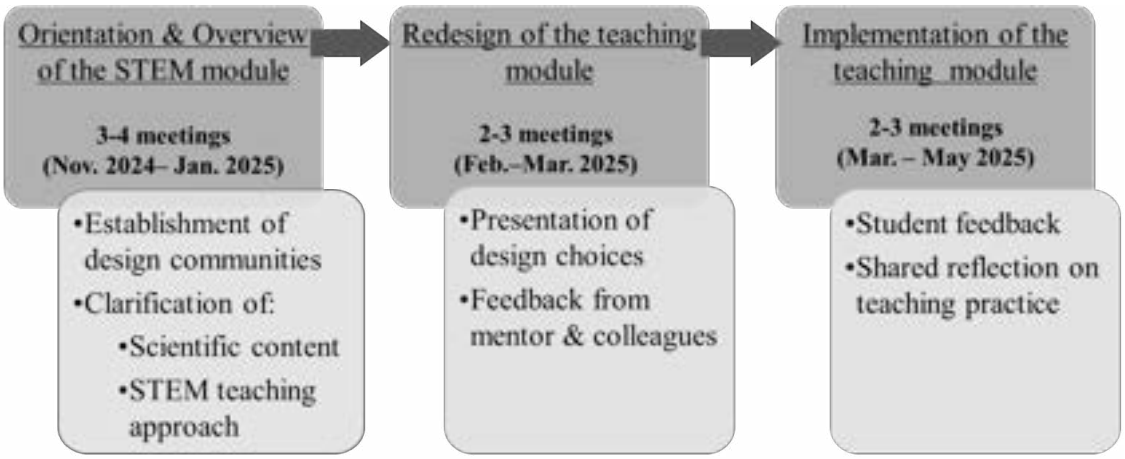
Building on the conceptualization of teacher identity as a dynamic construct, this study aims to explore how primary and secondary science teachers develop a STEM teacher identity while participating in a professional development program focused on climate-change education. In particular, we examine how this development is reflected across the components of the DSMRI model and how identity tensions emerge, are negotiated, and potentially mediate or constrain these processes of change.

To address this aim, the study is guided by the following central research question:

What shifts occur in the ways teachers manifest aspects of STEM teacher identity during the aforementioned professional development program?

Methodology

Research Context And Design



This study was conducted within the STEM-id project (https://stem-id.edc.uoc.gr/en/) aimed at supporting teachers in integrating STEM approaches with climate-change content into coherent classroom lessons across educational levels. The project was structured in two interrelated phases that combined material development with teacher professional learning.

In Phase A, eight mentor teachers engaged in a community of practice with STEM education and climate science researchers. Within this collaborative setting, they were introduced to key principles of integrated STEM and climate change education and jointly developed an integrated STEM teaching module on climate change. The teaching module was deliberately designed as a flexible, educative resource. Its modular structure allowed teachers to select, reorder, combine, or omit activities according to their classroom context. It also included prompts for adaptation, optional extensions, and differentiation strategies across grade levels.

Building on this groundwork, Phase B — which constituted the context of this study — engaged twenty-four teachers (twelve primary and twelve secondary) in a structured professional development program focused on STEM teacher identity. The program was centred on the module developed in Phase A and supported by the mentors within design communities. Participating teachers varied in teaching experience (between 3 and 18 years) and none had prior formal training in climate education or integrated STEM approach.

The professional development program lasted approximately seven months and was organized around a series of synchronous community meetings complemented by asynchronous design and reflection activities. Training occurred within designing communities, where the teachers worked collaboratively and received ongoing support from the eight mentors. An overview of this sequence of collaborative activities - from initial orientation, through redesign of teaching materials, to classroom implementation and reflection - is presented in Figure 1.

Figure 1. Phased structure of the professional development programme.

More specifically, the program began with group meetings aimed at clarifying key scientific concepts, introducing the integrated STEM approach, and familiarizing teachers with the module. Teachers then selected activities, designed and synthesized their own lesson plans, received

feedback from mentors and peers, and subsequently implemented those plans in their classrooms, allowing them to iteratively connect design decisions with classroom realities.

Data Collection

To capture teachers' perspectives and evolving understandings throughout this process, multiple qualitative data sources were collected. Primary data included teachers' open-ended initial questionnaires and the reflective journals they kept throughout the professional development process. The initial questionnaires elicited teachers' prior experiences, beliefs, and expectations regarding STEM and climate-change teaching, thereby providing a baseline for identity-related analysis. The reflective journals captured teachers' ongoing sense-making, challenges, and evolving perceptions of their role during the design and implementation phases. In addition, learning community meetings were audio-recorded, capturing discussions and feedback among mentors and teachers, as well as moments of negotiation, uncertainty, and emerging shared understandings.

All participants provided informed consent for their participation and for the recording of meetings, and all data were anonymized prior to analysis.

Data Analysis

Table 1. Coding scheme identifying manifestations of DSMRI identity components.

DSMRI Components	Subcategories
Ontological & Epistemological beliefs	Statements expressing knowledge & beliefs about: - Scientific content of Climate change - S-T-E-M disciplines connections - STEM teaching approach - Students
Self-perceptions	Statements on: - Teaching role (facilitator/mentor) - Self-efficacy for STEM teaching
Purpose & Goals	Statements expressing teaching objectives: - Learning scientific content - Solving real-world problems - Applying knowledge - Environmental awareness - Sustainability values
Perceived action possibilities	Statements expressing: - implementation of experimental activities - engineering design activities - use of ICT

For data analysis we used qualitative content analysis methods with an abductive coding strategy, combining theory-driven and data-driven codes to iteratively refine categories (Bryman, 2016). For coding we used DSMRI components and related subcategories. These categories captured

teachers' oral or written statements about ontological and epistemological beliefs, self-perceptions, purposes and goals, and perceived action possibilities, as summarized in Table 1.

To examine identity development over time, we characterized the level of change in each DSMRI component as radical, moderate, or no change, following an adaptation from Gunersel et al. (2016). Radical change denotes a component that was initially limited or absent and later became extensively developed; moderate change denotes an initially developed component that became more elaborated; no change denotes no meaningful difference across time, based on comparisons between early and later data sources for each teacher.

Combining these component-level judgments produced an overall profile for each teacher that reflects the pattern and intensity of change across DSMRI components. These profiles, summarized in Table 2, enabled cross-case comparison while preserving attention to individual developmental trajectories.

Table 2. Criteria used to characterise the overall pattern of identity change.

Identity change	Description
Transformation	At least 4 radical change occurs in a DSMRI component
Elaboration	At least 4 moderate changes occur in DSMRI components
Stagnation	No change or fewer than 4 moderate changes occur in DSMRI components

Results

Changes in STEM Teacher Identity Components

Table 3. Distribution of primary and secondary teachers by level of change across DSMRI identity components.

Identity components	Radical change		Moderate change		No Change	
	Prim	Sec	Prim	Sec	Pri	Sec
Ontological & Epistemological beliefs	5	2	6	4	4	3
	Total: **7**		*Total:* **10**		*Total:* **7**	
Purpose & goals	2	4	8	6	2	2
	Total: **6**		*Total:* **14**		*Total:* **4**	
Perceived action possibilities	4	8	5	2	3	2
	Total: ***12***		*Total: 7*		*Total:* **5**	
Self-perceptions	2	2	5	3	5	7
	Total: **4**		*Total:* **8**		*Total:* **12**	

This section presents the findings concerning changes in teachers' STEM teacher identity as they participated in the professional development program. Guided by the DSMRI framework, the analysis focuses on how different components of role identity were manifested and reconfigured over time.

Table 3 presents the distribution of teachers who manifested shifts in STEM teacher identity across the DSMRI components. Each component shows a different degree of change, reflecting both teachers' initial identity configurations and the extent of reorientation required to engage with the integrated STEM approach.

Examination of these distributions reveals three notable patterns. First, the largest number of radical changes occurred in perceived action possibilities - twelve teachers in total - and these radical shifts were concentrated among secondary teachers (eight of twelve). This pattern suggests that many secondary teachers reconsidered what forms of classroom activity they viewed as feasible, moving toward more complex and design-oriented STEM practices. For example, a secondary teacher moved from a constrained, low-effort plan (just to show a video) to a concrete classroom enactment involving student data collection and iterative testing. In the initial questionnaire she stated:

> As I teach in a high school and class time is very limited, I have not taught anything related [to climate change] before. I would probably show a video to give them some food for thought.

In contrast, during the redesign phase she wrote in her reflection journal:

> For the climate change solutions, students will build a system to measure real-time CO_2 emissions so they can test the effectiveness of their constructions.

In DSMRI terms, this illustrates an expansion of perceived action possibilities, as the teacher envisioned and intended hands-on, authentic STEM tasks that students can carry out within class time, rather than only passive exposure. At the same time, this shift in lesson planning implies a redefinition of her instructional role, from content deliverer toward facilitator of student-centred inquiry, a transition that aligns closely with the identity of an integrated-STEM teacher.

A second pattern concerns shifts in ontological and epistemological beliefs, observed in seven teachers, the majority of whom were primary educators, suggesting a reorientation in how they conceive what STEM teaching is for and how knowledge is produced in those lessons. For example, one teacher initially defined STEM as "all about the educational robotics competitions the kids take part in". After collaborative design meetings he reframed STEM as:

> It's not enough to know Math, Physics, etc; you must support students in their constructions within the engineering design cycle so they can apply what they know.

This contrast points to a shift from associating STEM primarily with discrete activities toward viewing it as a learning process that involves guided design and the application of knowledge.

In addition to these more pronounced transformations, numerous teachers exhibited moderate shifts in their instructional purposes and related beliefs. These changes often took the form of extending existing goals - such as content understanding - to include broader aims related to problem solving, real-world relevance, or environmental awareness, while still retaining elements of their prior instructional orientation.

By contrast, self-perceptions emerged as the most stable DSMRI component, with twelve cases showing no change, and secondary teachers particularly reporting stable, high STEM teaching self-efficacy. This relative stability may reflect the resilience of self-evaluative beliefs, which are

often less susceptible to short-term change, or a tendency toward optimistic self-assessment in self-reported data.

Patterns Of STEM Teacher Identity Change

When considering the aggregated patterns of identity change across DSMRI components, most identity shifts were classified as Transformation, with secondary teachers comprising the larger share of those transformations - consistent with the concentration of radical changes we saw in action possibilities and epistemic framing.

Table 4. Overall patterns of STEM teacher identity change among participating teachers.

Types of identity change	Primary	Secondary	Total
Transformation	5	8	13
Elaboration	6	3	9
Stagnation	1	1	2

Primary teachers more often followed an Elaboration trajectory, which may be associated with their prior use of cross-domain and project-based practices that could be extended rather than fundamentally replaced. In contrast, secondary teachers - often working within more rigid disciplinary structures and curriculum constraints - appeared to undergo more visible reconfigurations of their instructional repertoires, resulting in Transformation profiles.

Finally, two teachers showed no detectable change across components. These cases point to the importance of examining contextual constraints, such as workload or school-level support, as well as strongly held prior beliefs that may limit engagement with identity-related change processes.

Discussion

The findings of this study point to two distinct trajectories of teacher identity development within the professional development context. In the *Transformation* profile, teachers deepened their science knowledge, gained confidence with engineering, and adopted interdisciplinary STEM conceptions. Moreover, they reframed their instructional goals from knowledge acquisition toward skills development such as systems thinking and problem solving (Eilam, 2022), and introduced experiential and engineering, design-based activities for climate problems - a move consistent with calls to foreground engineering design as a central organizing practice in integrated STEM (Stohlmann et al., 2012). These shifts suggest a reconfiguration not only of classroom practices but also of the underlying purposes and epistemic orientations that frame teaching and can enable more coherent forms of integrated practice (Ennes et al., 2021).

By contrast, teachers classified under the *Elaboration* profile demonstrated more incremental forms of change, where mostly moderate and a few radical changes were concentrated in teachers' perceived action possibilities and in purposes and goals, while beliefs often retained disciplinary anchors that were enriched with interdisciplinary elements. In these cases, teachers expanded their instructional goals toward application and problem solving yet frequently continued to rely on established knowledge-centred routines. Such a pattern aligns with research describing additive pathways to integrated STEM, in which teachers integrate new practices into existing professional identities rather than fundamentally replacing them (Guzey et al., 2016). From an

identity perspective, this trajectory may reflect a process of negotiation, where elements of integrated STEM are accommodated within pre-existing frameworks of meaning and practice.

Across both profiles, self-perceptions appeared comparatively stable, as only a few teachers revised how they saw their role as STEM educators. The relative persistence of this component is consistent with literature suggesting that shifts in self-perception often require more explicit and sustained identity work than changes in practices or goals alone (Rushton et al., 2023).

Conclusions

Overall, this study contributes to a growing body of research that conceptualizes teacher change in integrated STEM education not merely as the adoption of new practices, but as a dynamic process of identity development shaped by the interaction between beliefs, goals, perceived possibilities for action, and professional self-perception.

In conclusion, the findings of this study suggest three interrelated implications for teacher practice and the design of professional development in integrated STEM education. First, when teachers reconceptualize STEM learning from a focus on disciplinary content toward processes and transferable skills, corresponding shifts tend to occur in classroom practice, including greater use of engineering design tasks and iterative forms of inquiry. The enactment of such practices, particularly when they were experienced as feasible and pedagogically valuable, appears to reinforce and further reshape teachers' epistemic beliefs and instructional goals, suggesting a mutually reinforcing relationship between changes in practice and teachers' developing professional identities.

Second, shifts in teachers' self-perceptions as STEM educators seem to require more targeted and explicit forms of support, such as structured reflective activities, opportunities for social recognition within professional communities, and sustained mentoring relationships.

Finally, the identification of multiple identity development trajectories highlights the need for professional development models that combine short-term support for instructional redesign with longer-term processes of identity work. Such models should be responsive to teachers' starting points, acknowledging that primary and secondary teachers may differ in their prior experiences with interdisciplinary practice, curricular flexibility, and disciplinary identification.

Ultimately, supporting teachers in adopting integrated STEM approaches requires recognizing professional learning as an ongoing process of identity development, in which changes in practice, beliefs, and self-perceptions evolve in mutually reinforcing ways over time. Future research may further illuminate how these identity trajectories are sustained across longer time scales and varied educational contexts.

ESERA 2025 Copenhagen

Didactic Dimension Of The Professional Identity Of Tunisian Physics And Chemistry Teachers

Chiraz Kilani[1] and Patrice Venturini[2]
[1]SILAB, Higher Institute of Documentation, University of Manouba, Tunisia
[2]University of Toulouse, France

This research explores determinants of teachers' action and the didactic dimension of professional identity in physics and chemistry teaching. Drawing on the Joint Action Theory in Didactics (Sensevy & Mercier, 2007; Sensevy, 2011), we analyse in situ classroom practices to characterise this didactic dimension. Our analytical approach combines a pragmatic analysis of teaching activity with a didactic perspective on knowledge construction. The study is based on six qualitative case studies involving Tunisian secondary school teachers, combining classroom video recordings, interviews, and curriculum analysis, with students aged 15 to 19. Results reveal recurrent instructional configurations across cases: teacher-controlled knowledge progression structured by Initiation–Response–Evaluation interactions, student activity mainly oriented towards participation, strong reliance on curricular resources, and an empirico-inductive practical epistemology.

These shared configurations are interpreted both as determinants of instructional action and as indicators of the didactic dimension of professional identity. This dimension is characterised through recurrent ways of organising knowledge, student activity, and instructional progression. The study suggests that this didactic dimension is not only constructed through classroom practices, but also contributes to orienting teachers' instructional choices, in relation with practical epistemology and joint didactic action.

Keywords: Professional identity; Joint Action Theory; Science teaching

Introduction

Research in science education has consistently shown that students' attitudes towards science—particularly physics—tend to decline during secondary schooling, affecting motivation, engagement, and learning outcomes (Osborne et al., 2003; Adesoji, 2008). These attitudes are considered a central component of scientific literacy and are closely related to students' beliefs about science and their perceived competence (OECD, 2007). Among the factors influencing these attitudes, teaching practices play a decisive role (Gauthier et al., 2005; Blazar & Kraft, 2017). Understanding how teachers organise classroom activity and introduce disciplinary knowledge therefore constitutes a major research issue.

In parallel, research on teachers' professional identity has highlighted its dynamic and situated character, constructed through practice and shaped within institutional frameworks (Dubar, 1994; Cattonar, 2001; Lasky, 2005). Professional identity both guides classroom action and is reshaped by it. In science education, several studies have underlined the influence of disciplinary epistemologies on teaching practices, particularly in physics and chemistry (Robert & Robine, 1989; Boilevin, 2013). However, relatively little attention has been paid to the didactic dimension of professional identity—that is, the way teachers relate to disciplinary knowledge and organise its transmission in classroom interactions.

The present study addresses this gap by focusing on Tunisian secondary school physics and chemistry teachers. We adopt the Joint Action Theory in Didactics (JATD; Sensevy, 2012) as an analytical framework to examine classroom practices as joint actions between teachers and students organised around knowledge. This perspective allows us to move beyond descriptive accounts of teaching activity and to infer macroscopic determinants of teacher action from

recurrent instructional configurations, including practical epistemologies and institutional framing through curricula and textbooks.

Our research is based on six qualitative case studies combining classroom video recordings, interviews, and curriculum analysis. Rather than concentrating on individual teaching styles, we identify recurrent features of practice across cases in order to characterise shared determinants of instructional action and to examine how the didactic dimension of professional identity both emerges from teaching activity and contributes to structuring it.

The study addresses the following research questions:

1. How do common characteristics of classroom practices allow us to infer determinants of teacher action in physics and chemistry teaching?
2. How do these determinants contribute to the didactic dimension of teachers' professional identity, and in what ways does this dimension act as a structuring principle of instructional action?

By articulating classroom practices with professional identity through a didactic lens, this study aims to clarify how stabilised ways of relating to knowledge and student activity organise teaching in physics and chemistry classrooms.

Theoretical Framework

Professional Teaching Identity And Its Didactic Dimension

Over the past two decades, professional identity has emerged as a major focus in educational research, conceptualised as a dynamic and situated process shaped through practice and social interactions (Knowles, 1992; Connelly & Clandinin, 1999; Dubar, 1994). Professional identity enables teachers to recognise themselves as members of a profession while being recognised as such by others (Cattonar, 2001). It encompasses shared professional norms as well as individual trajectories, negotiated within institutional and contextual constraints.

From this perspective, identity is not understood as a fixed attribute but as continuously constructed through teaching activity. It both guides classroom action and is reshaped by it (Lasky, 2005). Previous studies in subject-specific didactics have shown that disciplinary knowledge plays a central role in this construction, influencing how teachers interpret curricular prescriptions and organise learning situations (Robert & Robine, 1989; Boilevin, 2013).

In this study, we focus on the *didactic dimension* of professional identity, defined as the way teachers conceive disciplinary knowledge and organise its transmission in classroom interactions. This dimension includes teachers' epistemological orientations, their positioning in relation to knowledge, and the instructional strategies through which scientific content is made accessible to students. Rather than approaching identity through declared beliefs, we examine it through recurrent classroom practices, considering these practices as observable manifestations of underlying professional dispositions.

Joint Action Theory In Didactics

To analyse classroom practices, we adopt the Joint Action Theory in Didactics (JATD; Sensevy & Mercier, 2007; Sensevy, 2011), which conceptualises teaching and learning as a joint action between teachers and students organised around knowledge. Within this framework, didactic activity is understood as the functioning of a system composed of three interdependent components: teacher, students, and knowledge.

JATD provides conceptual tools for analysing how knowledge emerges and evolves during classroom interactions. Central among these are the notions of didactic contract and didactic

milieu (Brousseau, 1980). The didactic contract refers to the implicit expectations governing teacher–student interactions, while the milieu designates the set of material and symbolic resources that support learning activity. Changes in one necessarily imply adjustments in the other.

Didactic action is further characterised through the processes of mesogenesis (construction of knowledge objects), chronogenesis (temporal organisation of learning), and topogenesis (distribution of epistemic responsibility between teacher and students) (Sensevy, 2012). These concepts allow us to analyse how teachers structure classroom activity and position students with respect to knowledge.

In JATD, classroom activity can be modelled as a succession of learning games, during which teachers and students jointly engage with specific knowledge stakes. Learning is understood as the progressive acquisition of epistemic capacities through participation in these games.

Methodology

This study adopts a qualitative multiple case study design focusing on six secondary school physics and chemistry teachers in Tunisia. The teachers were selected to reflect variability in teaching experience, grade levels, and school contexts. Their classes involved students aged between 15 and 19 years.

Data Collection

Data were collected through a combination of classroom video recordings, teacher interviews, and document analysis. For each case, full teaching sessions were filmed, covering both theoretical lessons and practical activities. These recordings constituted the primary empirical corpus.

In addition, pre- and post-lesson interviews were conducted with each teacher in order to clarify instructional intentions and refine the interpretation of classroom interactions. Official curriculum documents and textbooks were also analysed to account for institutional framing of teaching practices.

Analytical Approach

Following a clinical approach of ordinary classrooms, the analysis aimed to identify recurrent features of practice rather than individual teaching styles. Video data were fully transcribed and organised using Transana software, allowing segmentation of classroom interactions into instructional sequences and interaction patterns.

The analytical process proceeded in four stages. First, each lesson was examined to characterise dominant modes of interaction and task structures. Second, practices were compared across cases to identify recurring patterns. Third, these patterns were interpreted in terms of didactic strategies and practical epistemologies. Finally, we inferred macroscopic determinants of teacher action—such as epistemological orientations and institutional constraints—and examined how these determinants contribute to the didactic dimension of professional identity.

In line with the Joint Action Theory in Didactics, particular attention was paid to the distribution of epistemic responsibility between teachers and students, the nature of tasks proposed, and the ways scientific knowledge was introduced and stabilised during classroom activity.

Rather than relying on teachers' declared beliefs alone, this methodology prioritises observable classroom practices as empirical indicators of professional dispositions. By triangulating video data, interviews, and curriculum materials, the study seeks to establish robust links between recurrent instructional practices and shared components of professional identity.

Results

Analysis of the six classroom case studies reveals recurrent patterns of instructional practice across physics and chemistry lessons. These patterns concern classroom discourse, the nature of student tasks, and the way scientific knowledge is constructed. Rather than isolated teaching styles, they point to shared modes of organising teaching and learning.

Teacher-Controlled Knowledge Progression: Dominance Of The IRE Pattern

Across all six cases, classroom interactions predominantly followed an Initiation–Response–Evaluation (IRE) structure (Sinclair & Coulthard, 1992). Teachers initiated exchanges through closed questions, students provided brief responses, and teachers evaluated or reformulated these answers before moving on.

In this dialogic lecture format, the progression of knowledge remained largely under teacher control. Students' contributions were mainly limited to completing expected statements or recalling previously introduced information. For example, during a chemistry lesson on acid–base titration, the teacher guided students step by step towards the expected formula, leaving little space for alternative reasoning or conceptual elaboration.

Excerpt 1 (P6, titration lesson). The interaction follows an IRE pattern in which knowledge progression is tightly controlled by the teacher

T: We performed a titration… for example… you titrated an acid with a base. What exactly are we determining when we titrate the acid? (1:32:51)

Class: …

T: At equivalence, what do we have? (1:32:55)

Class: …

T: What relation do we have? (1:33:00)

S: The number of moles. (1:33:04)

T: Yes… yes, yes. What do we have then? (1:33:10)

Class: …

T: Earlier… what did we say? (1:33:17)

Class: …

T: At equivalence, we have… as a relation… if it's a monobasic acid and a monobasic base. (1:33:24)

Class: …

T: So we say CAVA equals… (1:33:27)

Class: CbVb

T: CAVA equals CbVb. Then, from this relation, what are we going to determine? (1:33:35)

S: The number of moles of acid.

This interactional pattern ensured curriculum coverage but restricted opportunities for students to engage in deeper conceptual discussions. In this configuration, epistemic responsibility remained largely on the teacher's side, with students positioned primarily as respondents rather than as contributors to knowledge construction.

Low Epistemic Demand Of Student Tasks

A second recurrent feature concerns the nature of tasks proposed to students. In both physics and chemistry lessons, activities mainly involved reproducing experimental protocols already designed by the teacher or described in textbooks. Students carried out basic measurements

(volume, mass), mixed reagents, or observed predefined phenomena, but rarely participated in designing experiments or formulating investigative questions.

Although students were kept active through frequent questioning and hands-on manipulation, their engagement remained largely procedural. Tasks required execution rather than interpretation, and conceptual demands were limited. As a result, student activity was equated with participation, without necessarily involving knowledge construction. This procedural orientation is illustrated in Excerpt 2.

Excerpt 2 (P1, practical work). Student action is largely constrained to reproducing a protocol already prepared by the teacher

T: This is [T points with finger] sodium bicarbonate.

Scheima: Should I put it all?

T: Just a small amount.

T: Bilel, add a few drops of the sulfuric acid solution. [Bilel picks a test tube at random, the teacher intervenes] No, no, a flask [an Erlenmeyer]. You need to read the labels.

Classroom observations showed that students followed step-by-step instructions with little opportunity to modify procedures or explore alternative explanations. This organisation supported technical familiarity with laboratory practices but offered few occasions to engage with scientific inquiry as a process of hypothesis generation and testing. Overall, student engagement was high in terms of participation, yet its epistemic value remained low: being active does not necessarily mean building knowledge.

Empirico-Inductive Construction Of School Science

Across cases, scientific knowledge was systematically introduced through observation-based situations drawn from experiments, textbook activities, or videos. Lessons typically began with concrete phenomena, such as chemical reactions (e.g., zinc and copper sulfate), stoichiometric transformations illustrated by indicator colour change, inertia observed through space-probe videos, wave propagation via elastic-string vibration, concentration through tasting sugar solutions, or acids–bases through everyday examples (heartburn and antacids).

These activities were followed by teacher-led generalisations, during which scientific relations or definitions were formalised. Students were expected to move from observation to accepted conclusions, without being invited to formulate hypotheses, explore alternative explanations, or engage in theoretical modelling. Across the six classrooms, opportunities for questioning results, comparing interpretations, or examining underlying assumptions remained limited. As a consequence, scientific knowledge was presented primarily as a set of established facts derived from empirical observation rather than as a process involving uncertainty, argumentation, and conceptual construction.

Taken together, these recurrent instructional configurations point to an empirico-inductive epistemology in which knowledge appears to emerge directly from observable phenomena and experimentation. Within this framework, science is framed as stable and authoritative, constraining students' engagement with scientific reasoning as a dynamic and dialogical practice.

Recurrent Classroom Practices

Taken together, the six case studies reveal four recurrent features of classroom practice:

- a dialogic lecture format structured by IRE interactions;

- teacher-driven progression of knowledge;
- student tasks characterised by low epistemic demand;
- inductive construction of school science based on experiments or textbook examples.

These shared patterns suggest common ways of organising teaching and learning in physics and chemistry classrooms, beyond individual differences between teachers.

Taken together, these recurrent classroom practices point to shared ways of organising knowledge, student activity, and instructional progression. In line with our analytical framework, we now move from the description of these practices to the identification of macroscopic determinants of teacher action, in order to examine how they contribute to the didactic dimension of professional identity.

Discussion

The results make it possible to move beyond the description of classroom practices to infer shared determinants of teacher action across the six cases. These determinants concern teachers' relationship to knowledge, their conception of student activity, the institutional framing of teaching through official curricula and textbooks, and their practical epistemology. Together, they constitute central components of the didactic dimension of professional identity.

First, teachers position themselves primarily as holders and transmitters of knowledge. This is evidenced by the dominance of IRE interactions and teacher-controlled progression of scientific content. Within the Joint Action Theory in Didactics, this configuration corresponds to a topogenesis in which epistemic responsibility remains largely on the teacher's side. Students are invited to respond but rarely to initiate or transform the knowledge at stake. Teaching is thus organised around ensuring that prescribed content is introduced and formalised, reinforcing a transmission-oriented model of instruction.

Second, student activity is consistently valued, but mainly in the sense of participation rather than inquiry. Classroom practices show that being "active" is equated with answering questions, manipulating materials, or following procedures. However, this activity carries limited epistemic weight, as tasks rarely require hypothesis formulation, interpretation, or argumentation. Student engagement therefore functions primarily as an indicator of participation rather than as a driver of knowledge construction.

Third, instructional practices are strongly structured by official curricula and textbooks. Teachers closely follow prescribed sequences and experiments, which contributes to the stabilisation of classroom routines across cases. From a didactic perspective, this institutional framing shapes both the didactic milieu and the didactic contract, orienting the organisation of tasks and the progression of knowledge.

Finally, teaching practices are underpinned by an empirico-inductive practical epistemology. Scientific knowledge is introduced through observation and experimentation and presented as a set of established relations derived from empirical evidence. Students are rarely invited to engage with theoretical modelling, alternative explanations, or the tentative character of scientific knowledge. This epistemological orientation positions science as something to be revealed through experience rather than constructed through inquiry, debate, and abstraction.

Taken together, these four determinants—teacher-centred knowledge transmission, student activity conceived primarily as participation, institutional framing through curricula and textbooks, and empirico-inductive practical epistemology—form a coherent system organising classroom action. These determinants are not interpreted here as individual teacher preferences,

but as shared professional dispositions enacted in ordinary teaching situations. Moreover, they do not only emerge from classroom practices; they also orient teachers' instructional action by stabilising recurring ways of organising knowledge and student activity. The didactic dimension of professional identity—understood as teachers' relationship to knowledge, student activity, and instructional organisation—functions as a structuring principle of teaching. It orients teachers' choices, stabilises recurring instructional configurations, and guides the way scientific content is introduced and formalised

In this sense, professional identity appears not as a set of declared beliefs, but as a stabilised configuration of practices and orientations produced and reproduced through everyday didactic activity. The didactic dimension of professional identity emerges through recurrent ways of organising knowledge, positioning students, and responding to curricular constraints. These findings support the view that professional identity both guides instructional action and is continuously shaped by it.

Conclusion And Implications

This study examined the didactic dimension of professional identity among Tunisian secondary school physics and chemistry teachers through the analysis of classroom practices using the Joint Action Theory in Didactics. By focusing on recurrent features of teaching activity across six case studies, we identified four shared determinants of instructional action: teacher-centred knowledge transmission, student activity conceived primarily as participation, institutional framing through curricula and textbooks, and an empirico-inductive practical epistemology.

These determinants are inferred from recurrent instructional configurations and constitute shared components of the didactic dimension of professional identity. They structure classroom interactions and stabilise particular ways of engaging with scientific knowledge beyond individual teaching styles. Professional identity thus appears as a stabilised configuration of didactic practices enacted in ordinary teaching activity and continuously reproduced through recurrent ways of introducing knowledge, distributing epistemic responsibility, and positioning students with respect to scientific inquiry. Importantly, the didactic dimension of professional identity does not merely emerge from teaching activity; it also acts as a determinant of instructional action. Through shared orientations towards knowledge, student participation, and epistemic responsibility, teachers mobilise stabilised professional dispositions that organise classroom activity and shape the progression of scientific content. From a theoretical perspective, this study contributes to research on teacher professional identity by grounding it in observable didactic practices and by showing how macroscopic determinants of action can be inferred from classroom interactions. The JATD framework proved useful in linking instructional organisation with practical epistemologies, offering a situated account of identity construction in science teaching. The findings also have important implications for teacher education and professional development. Making these determinants explicit may support teachers in reflecting on their epistemological orientations and instructional routines. Professional learning initiatives could build on such reflexive work to foster alternative ways of engaging students in knowledge construction, particularly by strengthening inquiry-based approaches and promoting greater epistemic diversity in classroom discourse. In this perspective, teacher–researcher cooperation within design-based approaches, such as cooperative didactic engineering (Sensevy & Bloor, 2019), offers promising avenues for supporting professional evolution while remaining coherent with curricular requirements.

Several limitations must be acknowledged. The study is based on a limited number of cases within a single national context, restricting generalisability. Future research could extend this approach to comparative studies across educational systems to examine how different institutional

configurations shape the didactic dimension of professional identity. Longitudinal and intervention-based designs would also help clarify how these determinants evolve over time and how targeted professional development might support more inquiry-oriented science teaching practices. By articulating recurrent classroom practices with practical epistemologies and institutional framing, this study contributes to a didactic understanding of how professional identity is constructed—and how it structures teaching activity—in physics and chemistry classrooms.

Framing Early Science Learning

This chapter in the eProceedings, related to the *Science Education in Primary and Pre-Primary Learning Contexts* strand, brings into focus a formative phase in learners' engagement with science, where foundational dispositions, identities, and ways of knowing begin to take shape. Across this strand, science education is understood not simply as the acquisition of early concepts, but as a situated and relational process through which young learners come to make sense of their natural and designed world. Contemporary research increasingly positions early experiences of science education as an active and socially mediated endeavour, where children engage through questioning, observing, exploring, and refining ideas across diverse contexts.

Learning Through Participation, Design And Experience

Across the contributions in this chapter, science learning is consistently framed as participation in scientific practices rather than the passive reception of knowledge. Inquiry, experimentation, engineering design, computational thinking, and multimodal meaning-making are positioned as central approaches through which children construct understanding. Evidence continues to highlight the importance of engaging learners in meaningful science experiences from the early years, with well-designed interventions contributing to sustained learning outcomes. Importantly, these practices extend beyond the classroom. Several papers emphasise the pedagogical potential of outdoor and place-based environments, including schoolyards and green spaces, where learners engage with biodiversity, ecosystems, and environmental processes through embodied and sensory experience.

A key insight emerging across the chapter is that access to engaging or resource-rich environments does not, in itself, guarantee meaningful learning. Whether in outdoor or digital contexts, high levels of activity and participation do not necessarily lead to conceptual understanding, which highlights why the design of pedagogical environments is critical. Across the contributions, inquiry-based materials, learning–teaching sequences, and digital tools are shown to require careful structuring to support a progression from exploration to explanation. This includes balancing structure and openness to ensure that learners are supported in moving beyond interaction towards reasoning and meaning making. Within this, the role of the teacher remains central as a mediator of learning, guiding reflection and supporting conceptual development.

Agency, Coherence, And Contemporary Challenges

Young learners are consistently positioned across these contributions as capable, creative, and active participants in science learning. Creativity is framed as integral to scientific thinking, particularly within contexts such as engineering design and computational activity, while collaboration, negotiation, and even resistance, are understood as productive elements of learning. At the same time, several contributions highlight issues of equity, access, and inclusion,

drawing attention to how socioeconomic factors, access to digital resources, and the design of learning environments shape opportunities for meaningful participation.

Alongside this emphasis on participation, the strand also engages with questions of conceptual coherence and disciplinary integrity. Several papers highlight the importance of structuring learning around key scientific ideas and supporting progression towards more sophisticated understandings. This includes the design of learning–teaching sequences and the introduction of complex scientific perspectives, such as elements of contemporary physics, within primary education. Such work reflects a broader commitment to aligning early science education with the epistemological foundations of the discipline, while remaining responsive to learners' developmental trajectories.

Finally, the contributions connect strongly to broader societal priorities, particularly sustainability and digital transformation. Science education is positioned as a means of fostering awareness of human–nature interdependence and supporting engagement with environmental challenges, often grounded in local and place-based contexts. At the same time, the increasing presence of digital technologies in children's lives raises important questions about the quality and depth of learning in digital environments. While these tools offer new opportunities for engagement, their value depends on thoughtful pedagogical design and alignment with principles of effective learning.

Taken together, the papers in this chapter reflect a dynamic and evolving field that is attentive to the complexities of early science learning. They highlight the importance of designing learning environments that are pedagogically intentional, conceptually coherent, and socially responsive, while recognising young learners as capable, creative, and engaged participants in science. In doing so, the strand contributes to ongoing conversations about how primary and pre-primary science education can support more meaningful, inclusive, and future-oriented educational practices.

Beyond The Slide: Rethinking Playgrounds As Learning Spaces

Sara Fernández-López del Moral, Ester Mateo González, María José Sáez-Bondía and Jorge Martín-García
Instituto Universitario de Investigación en Ciencias Ambientales de Aragón (IUCA), Departamento de Didácticas Específicas, Universidad de Zaragoza, Spain

Outdoor spaces have been shown to function as powerful pedagogical environments, enriching children's understanding of and connection with the world around them. Yet, some schoolyards remain little more than concrete jungles, devoid of natural elements and thus silencing nature's invitation to discover.

This preliminary study explores the potential of a Spanish preschool playground as a context for scientific learning. By analysing both teachers' perceptions of the playground and children's use of it, a proposal for change was developed and implemented. The findings reveal that even small modifications to the physical environment can foster changes in children's behaviour, increasing their engagement in scientific activities. Following these changes, children engaged more explicitly with scientific concepts and skills, what created opportunities to extend their interests within the classroom. These findings also highlight the central role of teachers in such spaces. Fostering meaningful science learning in free-play outdoor environments requires more than just physical transformations; it also demands that educators rethink their roles and actively support children's scientific exploration.

Keywords: Early-childhood Education, science learning, outdoor play

Introduction

Children engage with the world as if in constant dialogue with it. Driven by an innate curiosity, "they question, observe, investigate, experiment, and question again" (Raven & Wenner, 2023, p. 485). Unaware of their own scientific potential, children participate in cycles of action and reflection that help them navigate their environment and lay the foundations for their interactions with it (Pedreira & Márquez, 2019).

It is through play that this dialogue unfolds. In its spontaneous and creative nature, play provides a particularly rich context for children to explore and reflect on everyday scientific phenomena (Gomes & Fleer, 2020). This potential is especially evident in outdoor environments, where diverse sensory stimuli invite multiple forms of exploration (Speldewinde, 2024), from the crunch of leaves underfoot to the scent of flowers in bloom.

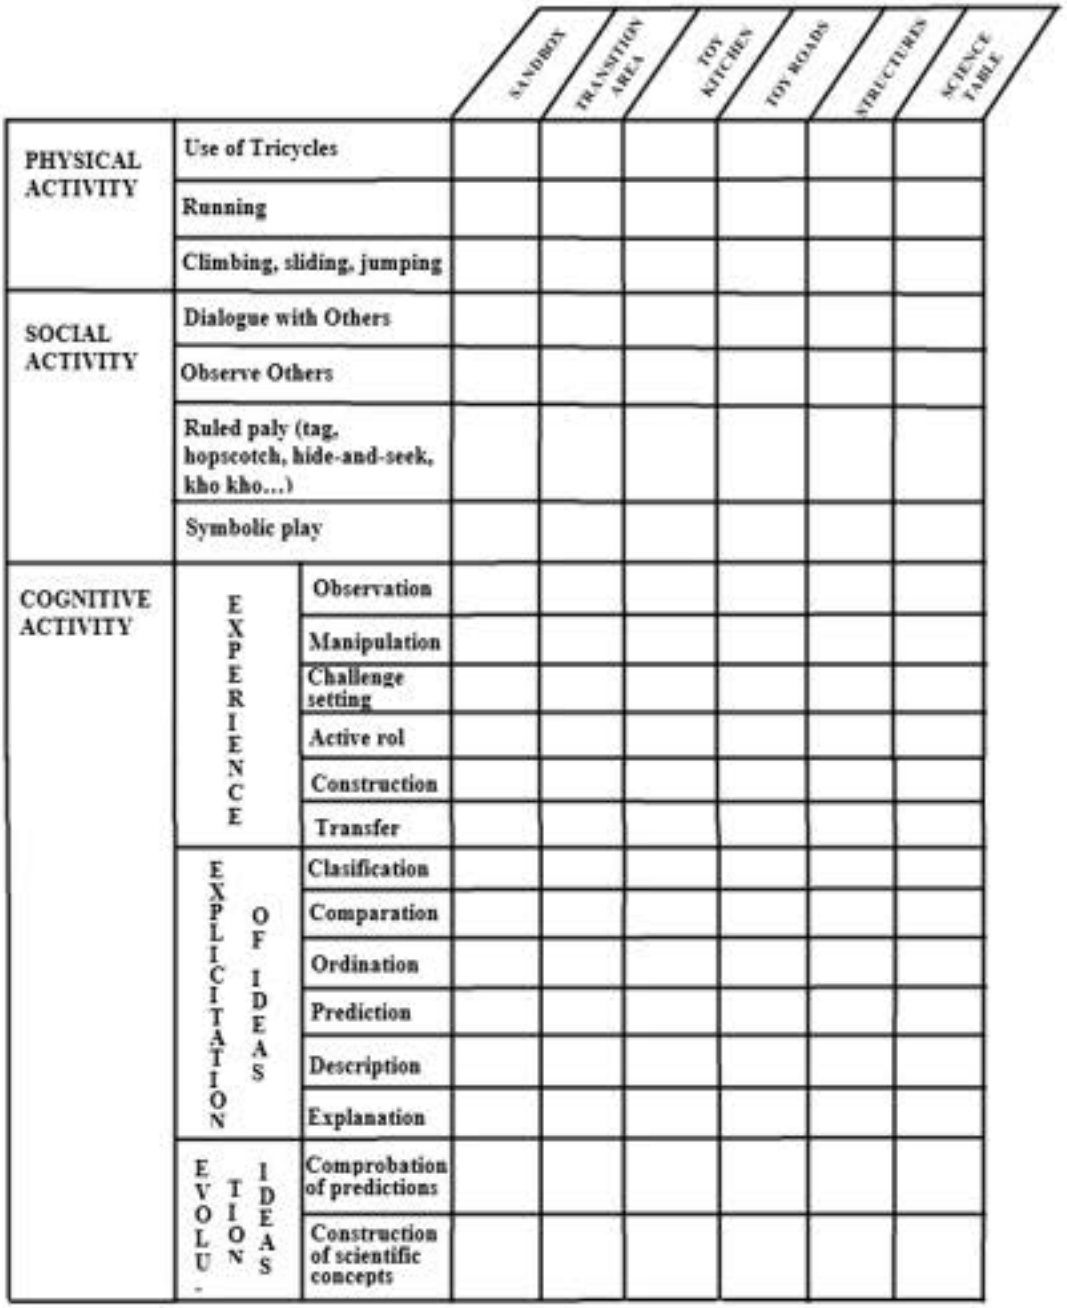
Such dynamic environments can inspire open-ended play, physical activity, risk-taking, emotional engagement, exploration, and interaction with both peers, and the environment (Speldewinde, 2024). In doing so, they become powerful allies in nurturing scientific learning. Outdoor spaces encourage children to actively engage with their surroundings, creating opportunities for meaningful, hands-on encounters with scientific ideas (Lee & Ensel Bailie, 2020). Nevertheless, despite research suggesting that it is possible to go beyond the strictly ludic in these contexts, linking playing and learning in a meaningful way (Sanz et al., 2021), the potential of play to foster scientific learning remains underexplored (Gomes & Fleer, 2020). Play is frequently positioned as separate from learning, a dichotomy that becomes even more pronounced in outdoor settings (Lee & Ensel Bailie, 2020). As a result, outdoor playtime is frequently treated as a break from formal learning rather than as a pedagogical opportunity.

In recent years, however, this trend seems to be reversing. Schoolyards are increasingly being revalued as educational spaces in which children can engage with their surroundings and learn

from them (Sanz et al., 2021). Despite this growing recognition, many schoolyards remain barren and lack natural elements (Mateo et al., 2021). Motivated by this reality, we immersed ourselves in the daily life of a Spanish preschool, analysing its schoolyard, teachers' perceptions of its educational potential and how children use it. Based on this analysis, we introduced physical modifications to the schoolyard aiming to explore how these changes influence children's physical, social, and cognitive activities, with a particular emphasis on children's scientific activities.

Study Design

The study was designed as a preliminary case study (Yin, 2014) conducted in a Spanish preschool that had initiated a process of schoolyard naturalization. The aim was to understand this preschool's needs and use these insights to design and implement playground modifications that could support children's scientific learning. To achieve this, we engaged in an in-depth immersion in the daily life of this preschool, where the first author was completing a student-teacher placement at the time.



To explore the school's needs, we conducted semi-structured interviews with nine teachers. The interviews focused on teachers' perceptions of the schoolyard, including its strengths, limitations, and educational potential. Teachers were asked about their views on the space, how science learning was currently supported (or could be supported), and how the playground was used in their daily practice.

Following the interviews, we analysed how children and teachers actually used the playground. We began by identifying the different areas within it, considering the materials available and the activities that typically took place in each area to differentiate them. The areas included in the analysis are shown in the top row of Figure 1. Over a three-week period, we observed children's and teachers' behaviour during recess, the only time the playground was used. Each 30-minute recess involved approximately 170 children aged 3 to 5 years, who played freely in the playground. Given the large number of children and the size of the space, direct observation posed significant challenges. To address these, we focused on identifying recurring behavioural patterns and recorded only actions that were consistently observed across multiple days.

Data were collected through field notes and photographs. Observed activities were categorized as physical, social, or cognitive, following the example of Peinado Alamillo et al. (2022). Cognitive activities were further divided into three subcategories: experience with reality, explicitation of ideas, and evolution of ideas. These subcategories align with the three stages of the scientific activity defined by Pedreira and Márquez (2019). The observation instrument used for data collection is presented in Figure 1.

Data from all sources were triangulated to identify needs and potentialities. These findings informed the design and implementation of physical modifications to the playground. The same observation instrument was subsequently used to analyse changes in children's activities after the intervention, enabling direct comparison. The limitations of this approach are acknowledged, in line with the preliminary nature of the study.

Figure 1. Analysis template used to identify changes in children's scientific actions adapted from Pedreira and Márquez (2019) and Peinado Alamillo et al. (2022).

Findings

The interviews revealed that teachers perceive spaces as active educational agents that shape children's actions. Consequently, they emphasized ongoing collaborative efforts to transform school spaces into welcoming environments that promote learning. This perspective also extended to outdoor areas, which teachers recognized as contexts in which children learn both in and from their surroundings.

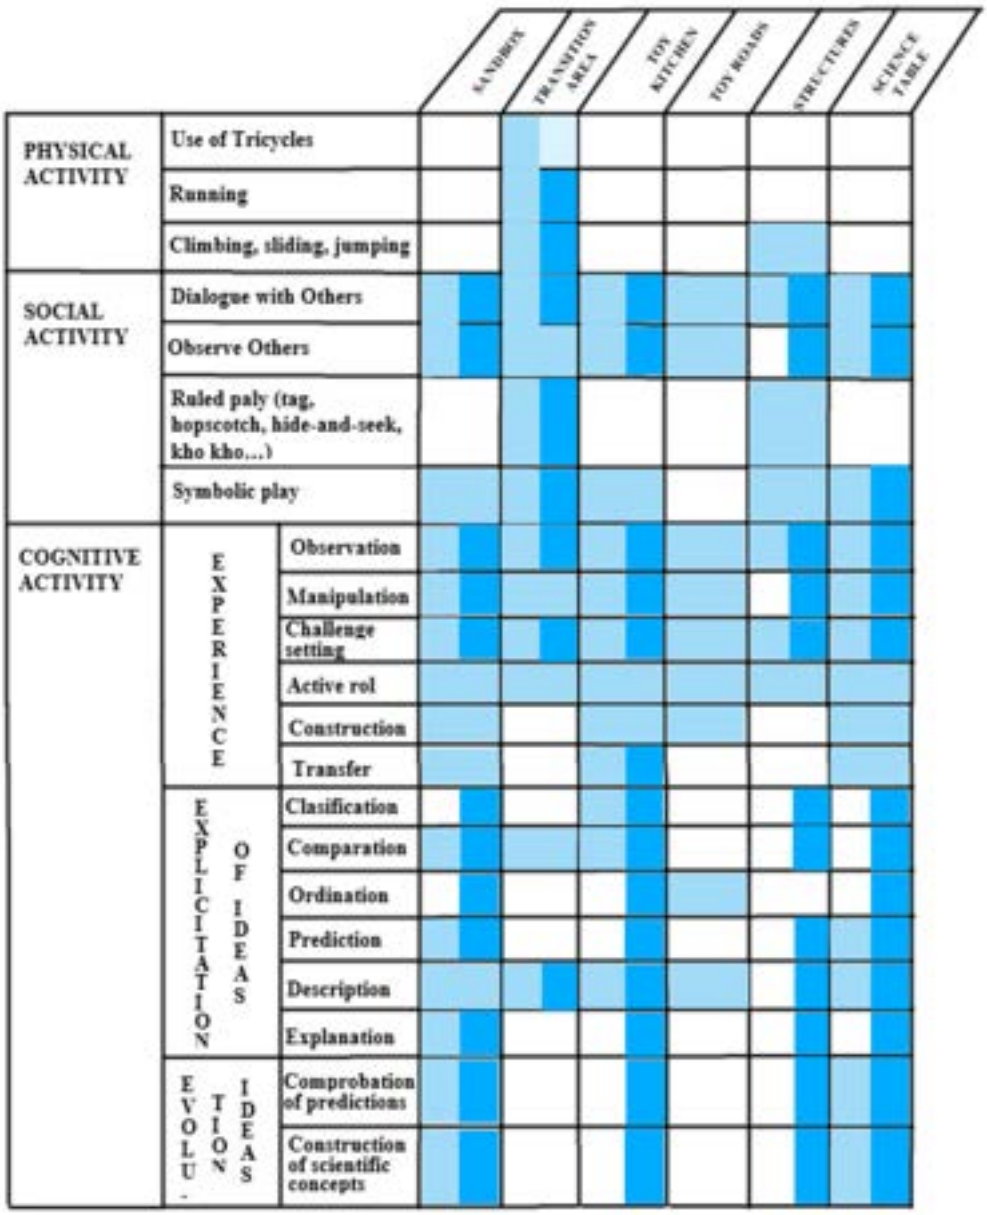
Most teachers valued recent renovations to the playground, particularly the addition of materials such as tricycles, strainers, and building blocks, which they associated with scientific learning (e.g., "*Children learn science outdoors when playing with tricycles and strainers*."). However, they also acknowledged that some areas remained underused or lacked a clear educational purpose. On this behalf, teachers expressed appreciation for our intervention in helping them reflect on the playground's potential, noting the importance of collective reflection (e.g., *"It is necessary not to have just one mind thinking, but several minds discussing."*).

When asked about their own use of the schoolyard, only one teacher reported using it outside recess. Most described adopting a non-interventionist role during break time, allowing children to interact freely with the environment. Only one teacher explicitly questioned this approach, suggesting that educators' roles in outdoor play may need to be reconsidered if the aim is to foster scientific learning.

Observational data showed that children's activities varied notably depending on the area and materials available. Overall, social, physical, and cognitively driven activities, particularly those involving direct interactions with their surroundings, were the most common (Figure 2, next page). Following the modifications, overall activity increased, with a particularly noticeable rise in cognitive engagement among children (Figure 2).

In Figure 2, blue shading indicates the activities observed in each playground area. Each cell is divided into two sections: the left side represents activities observed before the modifications, and the right side those observed afterward. The intensity of the blue tone is proportional to the number of activities observed, so that a darker tone indicates a greater number of activities. Consequently, a cell with a lighter tone on the left and a darker tone on the right shows an increase in the number of activities carried out after the modification of the playground. It is important to note that the frequency of each type of activity was not considered. An activity was considered as long as at least one child engaged in it. Post-intervention changes were analysed by comparing each activity with its occurrence prior to the modifications, without cross-area or frequency comparisons.

Activities involving the explicit articulation and evolution of ideas were the least frequently observed during recess. Although frequency was not quantitatively analysed, these interactions occurred far less often than physical activities, which were more prominent in practice despite their limited representation in the table.



Discussion

The results of this preliminary study suggest that, although playground modifications increased overall activity and facilitated children's engagement with various scientific phenomena, physical changes alone are insufficient to ensure learning. While the modifications appeared to support children's experience with reality, activities involving explicitation and, especially, the evolution of ideas remained scarce. These latter stages are cognitively more demanding, as they require children to reflect on their experiences, make connections, and progressively transform their initial ideas. The limited presence of such activities during recess suggests that, in free-play outdoor contexts, advancing beyond direct experience towards conceptual development is unlikely to occur without intentional pedagogical support. This finding reinforces the importance of teacher scaffolding as a key element in fostering deeper forms of scientific learning, particularly when the aim is not only to provide rich experiences, but also to support meaning-making processes. In this sense, it is necessary to go beyond the design of high-quality spaces that offer meaningful experiences and accompany these experiences with pedagogical support that helps children connect evidence with scientific ideas (Gomes & Fleer, 2020; Peinado Alamillo et al., 2022).

As noted by Sanz et al. (2021), there is a tendency to over-rely on rich and stimulating environments to promote learning. In line with this observation, and echoing the reflections of one of the interviewed teachers, our findings suggest that rethinking outdoor spaces as learning environments must also involve reconsidering teachers' roles within them. The schoolyard is undoubtedly an educational space, rich in opportunities for discovery (Speldewinde, 2024).

However, recognizing its pedagogical value must go hand in hand with teaching approaches that align with this understanding.

Figure 2. Activities taking place in the different areas of the playground before (left) and after (right) the modifications.

The findings also point to the need to rethink what it means to teach and learn science in early childhood education. While some interviewed teachers emphasized the importance of strategies such as questioning or encouraging hypothesis formation, their descriptions of scientific learning in the schoolyard were often limited to references to specific activities or materials. This suggests a predominantly activity-oriented view of science learning, rather than one that considers concept formation. Such a perspective may help explain the limited teacher intervention observed during outdoor play. If scientific learning is understood simply as "*playing with specific materials,*" then further involvement may seem unnecessary. Similar patterns were identified by Gomes and Fleer (2020), who distinguish between activity-oriented and conceptually-oriented "sciencing attitude". Further research could explore teachers' attitudes towards science learning and how these perspectives shape their practices in outdoor spaces.

Figure 3. Activities taking place before and after the modifications.

In this sense, moving beyond the slide implies rethinking playgrounds not merely as spaces for physical activity or unstructured play, but as learning environments with genuine educational potential. While the design and naturalisation of outdoor spaces are important starting points, they are insufficient on their own. Fully realising the educational value of playgrounds requires teachers to adopt an active and reflective role, recognising when and how to intervene to support children's progression through the different stages of scientific activity. Only by combining thoughtfully designed environments with intentional pedagogical accompaniment can playgrounds become spaces where play and scientific learning meaningfully converge, thus enabling us to truly move beyond the slide.

Measuring Motivation And Socioeconomic Status In Primary Science Learning

Bianka Carrier and Lisa Stinken-Rösner
Bielefeld University, Germany

Educational inequalities related to family income emerge early in primary school and affect children's performance and motivation in science, as well as their digital skills ('digital habitus'). To investigate the impact of digital gamification on the motivation and learning outcomes of children with different backgrounds, two child-appropriate instruments were developed and piloted: a motivation questionnaire based on the CAIMI scale (Gottfried, 1985) and a socioeconomic status (SES) questionnaire that relies solely on child-reported information. The adapted motivation scale demonstrated high reliability in the pilot study (α = .89). Although the reliability of the SES instrument is questionable (α = .55), it reflects the correct correlations with the occupational status of the parents and the social index of the respective school (a value used in Germany to describe a school's social composition).

Keywords: Inclusive Education, Socio-Economic Status, Primary Science Education

Framing Project

Within the framing project 'Level up! Digital Gamification in Primary Science Education. How Digital Gamification Affects Motivation and Learning Outcomes – Especially in Children from Families with a Lower Socio-Economic Status' (Wartig & Stinken-Rösner, 2023), we developed two questionnaires. One measures children's motivation for science, and another tries to determine children's socioeconomic status (SES) solely based on the information given by the children. Both instruments and their development are described in this article.

Context And Relevance To Science Education

In Germany, educational performance and success are significantly affected by family income (Wößmann et al., 2024). Furthermore, children from families with a lower income do not attend grammar school as often as their peers from higher-income families. Also, children from lower-income families often get lower grades even if the children's performance is the same as that of more well-to-do children (Maaz et al., 2011).

In addition, children from lower-income families have to deal with inferior motivation (Maaz et al., 2011) and often a lack of (non-)material resources to promote their interests, talents, or personal strengths (Solga & Dombrowski, 2009). As a result, by the end of primary school, less affluent children are up to two years behind their peers in STEM subjects (Schwippert et al., 2020, 2024). Such clear differences in STEM education cannot be ignored. Developing scientific literacy is essential for trusting scientific facts (Stekelenburg, 2026) and resisting misinformation (Osborne & Allchin, 2025). Therefore, it is a fundamental goal of the German school system (KMK, 2004) that is already relevant in primary education, forming the basis for further education (GDSU, 2013). In addition to the described issues, there are also disparities in the 'digital habitus' between children from lower- and higher-income families. While children from more privileged social backgrounds also use tablets or other digital devices for educational purposes, children from lower socioeconomic backgrounds mostly consume leisure content (Rudolph, 2019). This discrepancy in the utilization of digital media can lead to a further increase in inequality (Kutscher, 2019). Van Dijk (2017) describes these differences and their consequences as 'second-

level divide'. These problems contrast with the German Ministry of Education's goal of building a school where digital competencies are conveyed to everyone (KMK, 2015).

Aim And Methods

The framing project aims to determine what impact digital gamification has on the motivation and learning of students from socio-economically various backgrounds. Gamification hereby describes the introduction of gaming elements into non-gaming contexts (Kapp, 2012). Even though digital gamification shows a positive impact on intrinsic motivation (Xi & Hamari, 2019), it is barely used in primary science education in Germany (acatech & Joachim Herz Stiftung, 2023). The effects of digital gamification on lower-income children have not yet been explored.

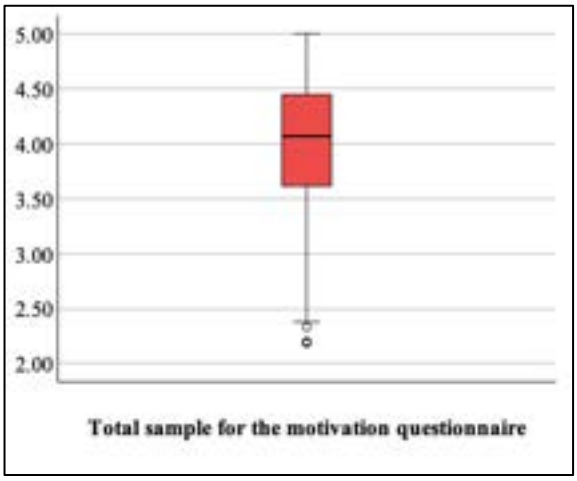
This status quo serves as the foundation for our research question: What is the effect of digital gamification on the motivation and knowledge of students from a variety of social backgrounds in primary science education?

To address the research question, we are conducting an intervention study that includes an intervention group receiving a digital gamification treatment and a control group with approximately the same number of participants, drawn from different schools in North Rhine-Westphalia, a federal state of Germany.

A digital learning environment was designed for the intervention group, comprising several gamification components and accompanying hands-on activities for discovering different types of forces (Wartig & Stinken-Rösner, 2025). Gamification elements we used are collecting points, storytelling (Fischer & Reichmuth, 2020), and (direct) feedback (Kapp, 2012) given by a pedagogical agent (Clarebout & Heidig, 2012) or by visualizations (e.g. a wrong answer turns red, a right one turns green). We chose the direct feedback because it is a highly effective form of feedback (Kopp & Mandl, 2014). The control group explores the same types of forces with worksheets and hands-on activities, but without any kind of digital gamification.

To measure intrinsic motivation and the students' knowledge about forces in the pre- and post-test, as well as the children's SES, we needed instruments designed specifically for our target group. Intensive research showed that none of the existing instruments fit our requirements completely.

Construction Of The Motivational Instrument



To measure the children's motivation, we developed a test based on the 'Children Academic Intrinsic Inventory' (CAIMI) by Adele Gottfried (1985). The CAIMI investigates the motivation of children between the ages of 8 and 13 in different school subjects and general academic motivation. We concentrated on the 24-items science scale, whose items are answered on a five-point Likert scale. Because the CAIMI is in English, we had to translate the science scale into German; we loosely followed the TRAPD approach (Harkness, 2003). In a first step, six different persons translated the CAIMI science scale into German. The translators stayed as close as possible to the original items. In a second step, we discussed which of the translated items best fit the original one. Hereby, language-specific terms were discussed, as it is recommended in the TRAPD approach. For example, one of the relevant issues was how to translate the word 'science'. The literal German translation (Naturwissenschaften) does not match to the name of the corresponding subject (Sachunterricht) in German primary school curricula. To prevent misunderstandings, we decided to use the term 'Sachunterricht'.

The original questionnaire includes a few negatively formulated statements (like 'I am not curious about learning things in science.'). We reformulated these into positive statements ('I am curious about learning things in science.') to reduce the impact of negative items on the answering

behaviour to a minimum (Stinken-Rösner & Laumann, 2023). Furthermore, especially younger children have problems with answering inverted questions (Woods, 2006). Since several items addressed the same thing (e.g., curiosity), but one was phrased positively and the other negatively, we ended up with duplicate items. Consequently, we deleted the duplicates. By doing so, we could reduce the questionnaire to 17 items. As provided in the TRAPD approach, we tested the modified instrument before using it in our main study (Harkness, 2003). The translated and adapted questionnaire achieved a Cronbach's $\alpha = .89$ (N = 119 fourth graders).

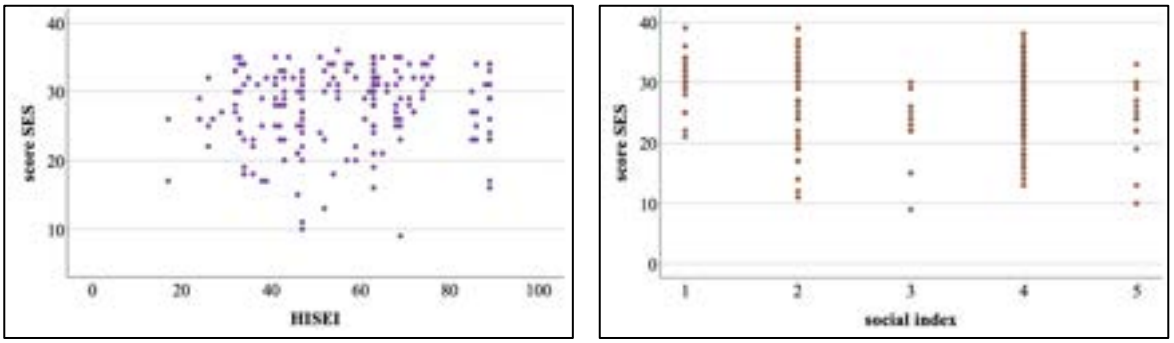
This result is similar to those from the original science scale, which were .69; .90; and .91 (Gottfried, 1985). Additionally, we interviewed fourth graders who did not participate in the pilot study about the questionnaire. The conversation revealed an item that the children did not understand; respectively, the children believed the item was a further duplicate. Removing the item did not affect the instrument's reliability ($\alpha = .89$, N = 119). As a result, we obtained a final questionnaire with 16 items. Furthermore, the children requested an 'I don't know' option and the option to tell the researchers their favourite primary science topic and activity. Figure 2 visualizes the results on motivation from the pilot study as a box plot.

Figure 2. The box plot illustrates the mean scores on a scale from 1 to 5, with higher values indicating a stronger level of motivation. The line within the box symbolizes the median.

Construction Of The SES Instrument

Normally, the SES of children is determined by the education, income, and occupation of the children's parents or legal guardians (Ditton & Maaz, 2011). However, this method poses the risk of a drastically reduced sample, as experience has shown that not all guardians take part in this kind of survey. The resulting challenge was to develop an instrument for the children's SES by asking only the children. For this purpose, we first analysed existing studies (for example: Andresen et al., 2020; Fishbein et al., 2024; Lenz et al., 2021; Mang et al., 2021) searching for items that give information about the SES of the participants. We categorized the items according to Bourdieu's concept of capital into the groups 'economic capital,' 'social capital,' and 'cultural capital' (Bourdieu, 1986). We identified the most frequently used items and established criteria to minimize our item pool. For example, we decided not to ask about smartphones owned by the children, because in Germany, children of primary school age often do not own a smartphone of their own for reasons other than lack of money (LFK, 2023). Additional items were developed based on recent survey results, like membership in a sports club. This question is promising because in Germany, only 40% of children from low-income families are members of a sports club, while 71% of the children from better-off backgrounds participate in sports clubs (Tempelmann et al., 2022). Furthermore, we also chose items that appear more contemporary.

All in all, we ended up with ten items. Although we know that children are not always aware of their parents' occupations (Currie et al., 1997), we included a question about it in the pilot survey. Answers were coded according to the '(Highest) International Socio-Economic Index of Occupational Status' (HISEI). The HISEI assigns numeric values to occupations based on income and educational level (Ganzeboom & Treiman, 1996; Ganzeboom, 2010) and is also used in studies like PISA (Lewalter et al., 2023).



In addition, we recorded the social index of the participating schools. The social index is a value between 1 (fewer social challenges) and 9 (heavy social challenges) in North-Rhine-Westfalia (Germany) to describe the social composition of a school. The social index is based on different indicators, e.g., how many minors in the vicinity of the school receive social welfare. It can therefore be used as a rough measure of the SES of the student body, but not of individual students. Both measurements, parents' occupations and the social index of the school, are used as references to evaluate the quality of our scale.

To validate our instrument, we tested the following hypotheses:

1) The children's answers correlate positively with the parents' occupation (respectively, the corresponding HISEI).
2) The children's answers correlate negatively with the school's social index.

Piloting took place in the 'teutolab physik,' an extracurricular learning venue at Bielefeld University. After excluding one item that children constantly misunderstood, we ended up with nine final items and a questionable Cronbach's α of .55 (N = 201) for the SES-scale. However, there is a low (not significant) correlation between the SES-scale and the parents' HISEI (r = .133, p = .056; N = 207) (Figure 3, left) and a low significant negative correlation between the SES-scale and the social index of the respective schools (r = -.126, p = .032; N = 289) (Figure 3, right). For the final set of items, see Table 1 (next page).

Figure 3. Relationships Between Socioeconomic Status Indicators. *Left*: Correlation between HISEI scores and results of our SES questionnaire. *Right*: Correlation between the social index and the results of our SES questionnaire.

Discussion

The pilot study of the motivation scale shows that our questionnaire's psychometric properties are quite similar to the source questionnaire's. This indicates that our instrument can quantify the motivation of children in primary science education in Germany.

Measuring SES solely based on children's answers remains challenging. With a questionable Cronbach's α of .55, our scale does not stand out from existing instruments (cf. versions of the FAS: Corell et al., 2021; Kehoe & O'Hare, 2010). The theoretically predicted correlations between SES, parents' occupation and social index are low and only significant in the case of the social index and the SES. Even though reliability and validity are comparable to existing scales,

the strength of our questionnaire is that our items are more contemporary and much closer to the children's living environment.

Table 1. Translation of the SES items. Please note that only the German version was piloted. Items 1 and 2 are answered on a four-point Likert scale from every day to never while items 3 to 9 are yes / no questions. The last question is about the parents' / legal guardians' occupation. Moreover, all items have a 'I don't know' option.

	German original item	English translation	source / reasoning
1	Wie oft liest du in deiner Freizeit Bücher oder Comics?	How often do you read books or comics in your leisure time?	Lenz et al., 2021
2	Wie oft trinkst du Limonade?	How often do you drink lemonade?	Lower-income families do not eat as much healthily as wealthier families do (Fakete et al., 2016).
3	Hast du ein Zimmer für dich allein?	Do you have a room on your own?	Bos et al., 2016; Lenz et al., 2021; Mang et al., 2021; Wagner et al., 2009
4	Gibt es bei dir zu Hause Musikinstrumente?	Do you have any musical instruments at home?	Mang et al., 2021
5	Hat deine Familie einen Rasenmäher oder einen Rasenmähroboter?	Does your family have a lawn mower or a robotic lawn mower?	Beese et al., 2022; Schaufelberger et al., 2024
6	Gehst du in einen Sportverein?	Do you belong to a sports club?	Beese et al., 2022
7	Gehst du mit deiner Familie ins Theater, Kino oder ins Museum?	Do you go to the theater, cinema, or museum with your family?	Beese et al., 2022; Holz, 2006
8	Warst du letztes Jahr mindestens eine Woche im Urlaub?	Did you go on vacation for at least one week last year?	Andresen et al., 2020; Beese et al., 2022
9	Lesen deine Eltern Bücher?	Do your parents read books?	Solga & Heisig, 2015.
10	Welche Berufe haben deine Eltern?	What do your parents do for a living?	Mang et al., 2021

Furthermore, based on our data, we see the necessity to critically discuss the use of measures like the social index. Both the social index and parents' occupation are commonly used as predictors for the children's SES in Germany. Because of the opposite polarity in their definition, it is assumed that the HISEI and the social index correlate negatively. However, our results differ from this expectation ($r_{\text{occupation and social index}} = .006$; $p = .940$; $N = 160$), as no correlation could be proven. This contrasting outcome should be investigated further, as it may indicate that a school's social index reflects its actual student body only to a limited extent, even when the school is viewed as a whole. One possible explanation for this conflict is that although the social index uses data on the proportion of children in the local area who receive social benefits, it does not consider the proportion of benefit recipients who attend the school (Schräpler & Jeworutzki, 2021).

Outlook

Data collection of the main study is currently being completed. The final number of participants is satisfactory, but we encountered the problem that mainly schools with an average social index

participated in our study. In the final step, we will compare the effect of digital gamification on content knowledge gain and motivation for groups with varying SES.

Learning Science Through Multimodal Representations

Deepa Chand[1], Rebecca Harrop[1], Parmeshwar Mohan[2] and Michelle Parks[3]
[1]Victoria University of Wellington, New Zealand,
[2]St Patrick's College, New Zealand,
[3] University of Tasmania, Australia.

There is growing agreement that guided inquiry and multimodal representations support students' meaning making in science. Grounded in Lemke's social-semiotic perspective and sociocultural views on collective sense-making, this study employs a case study approach across three year 5 classes in a Fijian primary school. Data was collected through learning space observations and Talanoa, a culturally appropriate qualitative data collection approach and methodology in Pacific contexts. Data was thematically analysed with findings showing that multimodal representations enhanced students' cognitive engagement by contextualising their learning of scientific concepts. Data highlighted improved affective engagement through the use of culturally relevant representations. Furthermore, Talanoa showed that sharing stories and reflecting collaboratively with peers deepened students' understanding of science concepts. The findings also revealed the key role that teachers play in scaffolding the meaning making process. These findings provide valuable insights for science educators into leveraging multimodal and culturally relevant strategies to enhance students' meaning making in scientific activities.

Keywords: Multimodal representations, Science, Engagement, Talanoa

Introduction

There is growing research interest in the meaning making process of science activities and concepts and the use of multimodal representations that support learners. Multimodal is defined as "the practice in science discourse of coordinating different modes to represent complex claims and evidence, where textual, mathematical and visual modes are integrated to explain and justify findings" (Waldrip & Prain, 2013, p. 15). In this study, the term 'multimodal' will be used to refer to a combination of more than one mode in representing scientific concepts. There is now evidence that encouraging all learners of science to generate their own representations to demonstrate their knowledge and understandings, construct a logical scientific argument and show the reasoning that they have used to arrive at a particular conclusion (Chand, 2019; Greeno & Hall, 1997; Waldrip & Prain, 2011).

The study is guided by a social semiotic perspective of multimodal representation to enhance meaning making (diSessa, 2004; Lemke, 2003) and socio-cultural theory (Vygotsky, 1978). Researchers are in consensus that learning outcomes of science learners improve with the integration of multimodal representations (Andersen & Munksby, 2018; Tytler et al., 2013).

The authors highlight the importance of multimodal and culturally responsive pedagogies in science to better support all learners, recognising that much of the current scholarly literature on the use of multimodal representations, have been pursued mainly in developed, western settings. The need to establish culturally appropriate practices when exploring student and teachers' knowledge and understandings of science concepts is critical. This study is informed by the Talanoa methodology (Vaioleti, 2006) to seek answers to the questions:

The paper examines the use of multimodality in the meaning making process in science by answering the questions:

1. How does the use of multimodal teaching strategies influence student engagement?

2. What role do the teachers play in creating and making sense of multimodal representations?

Methodology

This study is based within a qualitative research paradigm, using a case study approach to examine the impact of multimodal representations had on the students in year 5 at a primary school in Fiji. Qualitative methods were employed for this research to capture the use of multi-modal representation in the participants' setting (Punch, 2013). Data was collected through learning space observation and Talanoa.

Talanoa is rooted in oral communication and recognised in many Pacific Island countries such as Samoa, Tonga and Fiji (Nabobo-Baba, 2006; Otunuku, 2011; Prescott, 2008). Talanoa is also considered a way to engage in dialogue or tell stories (Halapua, 2008). In this study, Talanoa was conducted with intentional openness to listen to participants' experiences (Farrelly & Nabobo-Baba, 2014) which enabled the researcher to become part of the family to listen and find solutions to the phenomena being studied.

The study involved three year 5 teachers at a Fijian urban primary school. All teachers had over 10 years of experience. The class teachers from the case study class were invited for Talanoa after the learning space observation. Chosen class represented students from diverse cultural backgrounds. From each of the three classes, 10 students ages 9-10 participated in the research.

This study did not involve intervention. The teachers of the chosen classes planned and devised an instructional context in which students' conceptual understanding and reasoning were to be challenged. During the sequence of lessons, the researcher's role was mostly that of a participatory observer. Before the study began, the first researcher acted as an observer in the class for a few lessons to familiarise herself with the operation of the class and build respect and gain the acceptance and trust of students and the teacher (Farrelly & Nabobo-Baba, 2014).

The learning activities required the students to consider possible reasons for increased flooding in Fiji in recent years. The design of the activity assimilated concepts and skills from other areas of the curriculum, notably Society and Economic Development classes (Ministry of Education Heritage and Arts, 2013), to allow students to investigate the events in relation to their own people, culture, resources and environment. As part of the instruction, the class teachers introduced a picture of flooding from a daily newspaper and facilitated the students' focus on the picture to develop a question relating to the flooding phenomena which they would like to explore. Students were asked to interpret the phenomena collaboratively and represent their understandings multimodally through using drawings with written and verbal explanations.

Ten participating students, representing each of the two collaborative groups, were invited to engage in a 30-minute Talanoa session to expand and reflect on the learning experience from the student perspective. These students were selected based on the consent provided. A further three class teachers who had previously taught the lessons observed were invited to participate in a 40–60 minute Talanoa session focusing on pedagogical decision-making and the instructional strategies employed throughout the teaching experience.

The analytic process of Talanoa transcripts and field notes from the learning space observation drew on inductive thematic analysis as outlined by Braun and Clarke (2006). This involved multiple close readings of transcripts, the creation of preliminary codes, and the iterative refinement of patterns across the dataset. Particular attention was paid to culturally embedded language and the contextual meanings conveyed during Talanoa and subsequent verification

discussions, supporting accurate interpretation of culturally specific expressions and concepts (Vaioleti, 2006).

Trustworthiness of the data was enhanced through collaborative analysis by Researchers One and Three, both of whom identify as Pacific People and possess contextual and cultural knowledge relevant to the study. This shared positionality supported culturally informed interpretation and enabled systematic cross-checking of themes and insights. Such collaborative sense-making helped to minimise the influence of individual subjectivity and strengthened the credibility of the findings. Throughout the analysis, the focus remained firmly aligned with the research questions by exploring the ways teachers articulated cultural knowledge as: (1) How does the use of multimodal teaching strategies influence student engagement? and (2) What role do the teachers play in creating and making sense of multimodal representations?

Findings

The study identified that teachers' planning was prescribed by the curriculum with little emphasis on the use of varied representational modes in their learning spaces. However, actual teaching provided intentional opportunities for students to display their conceptual understanding through multiple modes.

The findings of this study indicate that the use of multimodal teaching strategies positively influenced students' engagement in science learning, while teachers played a central role in designing, modelling, and scaffolding multimodal representations to support meaning-making. When students were provided with space and opportunities to represent their understanding through multiple modes such as drawings, diagrams, charts, written text, and Talanoa demonstrated increased engagement.

Teachers reported that multimodal approaches generated excitement and enthusiasm among students, particularly when culturally familiar modes were incorporated into science learning. There was a high level of affective engagement. Students expressed enjoyment and a sense of pride when constructing drawings and charts, and when sharing their ideas through Talanoa. One student stated, "I always feel good when we are asked to draw and share our stories (S10) while another commented, "we prepare charts and do drawings, it's fun" (S6). Teachers similarly observed that students were highly motivated during multimodal activities, noting that students wanted to create their best work and were more willing to participate when drawing and discussion were included (T1).

In addition to affective engagement, multimodal teaching strategies support deeper cognitive engagement. Teachers shared that students were better able to reason, critique their learning, and explain scientific concepts when they used different modes of representation to learn and present their understanding. The construction of representations allowed students to break down complex phenomena into more manageable components, which supported analysis and synthesis of information. Teachers facilitated this process by guiding students to represent scientific ideas through structured approaches "using separate diagrams to illustrate causes, effects, and solutions related to phenomena like flooding" (T3). This approach supported students in organising their thinking and developing clearer explanations. Student evidence further demonstrated increased conceptual understanding and scientific language use, with students sharing that they had "learnt new scientific terms and could now explain the concept of flooding and its impacts on their people" (S7). The emotional story associated with flooding was also shared during Talanoa with both participating students and teachers.

Engagement was also enhanced through multimodal strategies, particularly through the use of Talanoa as a communicative practice. Teachers reported that students were more engaged and confident when sharing their learning through Talanoa (T1), as it created a safe and familiar space for discussion (T2). Through these interactions, students collaboratively shared personal stories, listened to their peers, and made connections between lived experiences and scientific concepts. As evidenced from the findings, students enjoyed engaging collaboratively in learning and sharing their understanding, "I like creating drawings with others" (S8) and having Talanoa in our science class" (S5). The findings showed that Talanoa supported deeper discussions, allowing students to collaboratively construct understanding and relate scientific ideas to other phenomena and contexts.

Teachers played a crucial role in enabling students to engage meaningfully with multimodal representations. Although teachers indicated that lesson planning was often driven by curriculum requirements with a stronger focus on content coverage than on representational modes, they made intentional decisions during instructions to integrate multimodal representations. Teachers described selecting representational modes responsively based on the learning context, "the phenomenon being explored, and the students present in the classroom" (T1). Some teachers deliberately aligned task outcomes with particular representations and considered cultural appropriateness when choosing modes, noting that "drawing, Talanoa, and storytelling were especially effective for engaging students" (T2).

Teachers also acted as expert models by demonstrating how different representations could be constructed and explaining why specific modes were appropriate for sharing meaning. It was evident that modelling the use of diagrams, labels, gestures and written texts was beneficial to the students. Teachers helped students understand how representations functioned as tools for scientific communication (T3). Alongside modelling, teachers scaffolded students' representational skill through explicit instruction, questioning, and gradual release of responsibility as students engaged in representation contraction. Teachers shared that "students were initially provided with clear guidance on which representations to use" (T1), and as they developed confidence, they were encouraged to explore additional modes independently.

Culturally responsive practices were a prominent feature of teachers' approaches to multimodal teaching. Teachers recognised drawing and Talanoa as culturally embedded practices and intentionally incorporated them into science lessons. One teacher described "drawing and design-making as cultural skills" (T4), while Talanoa was identified as a "practice grounded in cultural values and commonly used to share experiences and ideas" (T3). By allowing the use of these practices within science learning, teachers supported students to engage more confidently and meaningfully with scientific concepts while maintaining strong connections to their cultural identities.

Overall, the findings demonstrate that multimodal teaching strategies enhance student engagement by fostering enjoyment, supporting deeper thinking, and encouraging collaborative learning. Teachers played a key role in shaping these outcomes through their responsive planning, modelling of expert representations, scaffolding of students' meaning making, and integration of culturally meaningful modes of communication. These practices collectively supported students to use multimodal representations as effective tools for understanding and communicating scientific ideas.

Discussion And Implications

The findings of this study demonstrate that multimodal teaching strategies enhance student engagement and support meaningful science learning when they are used appropriately in science

learning. Although teachers' planning was largely prescribed by curriculum requirements, pedagogical decisions and reasoning created opportunities for students to express understanding through drawings, diagrams, charts, written texts, verbal explanations and Talanoa. This aligns with research which positions science learning as inherently multimodal, where meaning is constructed through the coordination of visual representations such as drawings, verbal, and gestural representations (Chand, 2019; Jewitt et al., 2016; Ainsworth, 2006). Providing multimodal representations enabled students to engage effectively, as evidenced by enjoyment, enthusiasm, and work completion, a factor strongly associated with sustained engagement in learning (Fredricks et al., 2004).

The findings also indicate that multimodal practices supported deeper cognitive engagement. Students' construction of drawings and diagrams allowed them to break down complex phenomena, organise relationships between elements of the task, and articulate explanations more clearly. Such reasoning processes are central to scientific meaning-making and are strengthened when students actively construct and refine representations rather than simply receiving information (Tytler et al., 2013; Cirkony et al., 2022). Decisions regarding what to include, how to organise components, and how relationships are shown represent important sites of conceptual development.

The findings extend our understanding of the use of multimodal representations and integration of Talanoa as a culturally responsive mode. The use of Talanoa as an informal conversation through which students shared their stories and relating it to their context was effective. It enabled students to unlock the richness of experience and knowledge embedded in a socio-cultural environment (Halapua, 2008). On the one hand, Talanoa gave insight of students' understanding and reasoning of science concepts, while on the other hand, it captured the emotions associated with the phenomenon being studied. We suggest that scientific terms be introduced slowly while engaging in Talanoa to link scientific concepts to real life situations.

The findings indicate that affective and cognitive engagement of students improved with the use of multimodal and culturally relevant representations. Findings indicated that students showed an increased level of interest in exploring the given phenomenon. Drawing and Talanoa were the most common representations used, indicating the cultural connection these modes have with the context of the study. The construction of appropriate and logical diagrams, the inclusion and placement of components, showed the students' ability to convey their mental representations on each drawing. This aligns with Tytler et al. (2013) who asserted that reasoning happens when students make representational selections and decide appropriate size or how to put different components together, hence improving the meaning making process.

A key implication of these findings is the central role of teacher expertise in designing, modelling, and scaffolding multimodal representations. Teachers functioned as expert guides, modelling how representations operate as scientific tools and supporting the meaning making process for students. This highlights the importance of teacher professional learning that moves beyond content coverage to include representational pedagogy. Supporting teachers to intentionally plan for multimodality as well as choosing culturally appropriate representations can strengthen student engagement and conceptual understanding.

Conclusion

This study identifies and analyses the processes through which primary school students strengthen their conceptual understanding and scientific reasoning. It is evident that multimodal representations, including those with cultural connectedness, have a positive impact on students' cognitive and affective engagement. While the authors acknowledge the small sample size of

students involved in the learning space observations limits the generalisability of the findings, this research highlights the broader question of the need to consider culturally sensitive forms of expression as part of the overall conception of a learning environment designed to elicit student thinking. Valuing diverse modes of knowledge representation in science can enhance Indigenous learners' engagement, understanding, and cultural affirmation (Chand, 2019).

ESERA 2025 Copenhagen

Designing Video-Tutorials As A Supporting Tool In The Experimentation Process

Svenja Reuter and Lisa Stinken-Rösner
Bielefeld University, Germany

Interactive video-tutorials represent a promising tool for enhancing science education by supporting learners in acquiring procedural competences critical for scientific literacy. Unlike traditional explanatory videos, interactive video-tutorials are action-guiding in nature, providing step-by-step instructions to help students replicate actions and engage in hands-on scientific practices. This study focuses on identifying design criteria for effective interactive video-tutorials that support learners in the proper use of measuring devices, such as thermometers, scales, stopwatches, and rulers, during experimental processes.
Using Kulgemeyer's (2020) framework for effective explanatory videos as a foundation, this research adapts and extends the criteria to meet the specific demands of interactive video-tutorials. To achieve this, the criteria were critically reviewed for their applicability to action-guiding content and adjustments were made to address the unique challenges of designing interactive video-tutorials for primary learners. These include emphasising clarity, coherence, age-appropriate content, and accessible language, while maintaining the authenticity of the experimentation process.
The results demonstrate how interactive video-tutorials should be designed to integrate digital media into hands-on learning, enabling learners to actively engage in measuring processes in experimental contexts and develop critical skills. These tools offer a means of bridging the gap between digital resources and authentic scientific practices in primary education. Future research will explore the effectiveness of interactive video-tutorials that follow the identified design criteria across educational contexts and their potential to foster independence in experimental tasks, contributing to the development of innovative strategies for science education.

Keywords: Digital Learning, Instructional Design, Primary Science Education

Introduction

The acquisition of scientific competences is central to fostering scientific literacy, a key goal of science education. Scientific literacy not only forms the foundation for individual personal development but also equips learners with the knowledge necessary to participate actively in society. To foster scientific literacy, it is essential to identify the competences learners must develop and to explore how these can be effectively enhanced within school contexts. The OECD's definition of scientific literacy**,** as outlined in the PISA (2018) framework, further underscores this by categorising it into content knowledge, procedural knowledge, and epistemic knowledge. While content knowledge focuses on factual and conceptual understanding, and epistemic knowledge on the processes behind acquiring scientific knowledge, procedural knowledge encompasses the practices of science (*PISA for Development Assessment and Analytical Framework*, 2018). To foster these competences, students must engage in authentic learning environments and participate actively in scientific practices, such as conducting experiments. This highlights the critical role of experiments in science education (Osborne, 2014).
However, despite their critical role, experimental activities can pose considerable barriers for learners, including methodological, communicative, and cognitive demands (Stinken-Rösner et al., 2023). The integration of digital tools has the potential to overcome barriers and to support these experimental practices in learning settings, provided they maintain the authenticity of the

experimentation process.
As digital media become increasingly integral to educational contexts, explanatory videos have gained prominence as tools to support learning (Kulgemeyer & Wittwer, 2023). While explanatory videos are commonly used in schools to support the acquisition of content knowledge, they are primarily designed for passive viewing (Wolf, 2015), making them less suited to fostering procedural competences that require active engagement. In contrast, video-tutorials, with their action-guiding character (Wolf, 2015), offer step-by-step instructions that could encourage learners to imitate demonstrated actions. This unique characteristic positions video-tutorials as a promising digital tool for supporting the development of procedural skills, such as handling measurement devices, recording data, and conducting experiments independently. Building on this approach, interactive video-tutorials extend traditional formats by integrating learner-controlled decision points that actively involve the viewers during the experimentation process. Rather than following a fixed linear sequence, learners can interact with interactive video-tutorials to access support that is relevant to their current task. These forms of interactivity are assumed to support active and self-regulated engagement, which is considered essential for the acquisition of procedural knowledge in experimental contexts (Chi & Wiley, 2014). By bridging the gap between digital resources and hands-on learning, interactive video-tutorials can provide an innovative way to engage students in scientific practices and enhance their experimental competences.
The importance of investigating the use of interactive video-tutorials is twofold. First, the increasing integration of digital media into classrooms requires a deeper understanding of how to design and implement these tools effectively. Second, at primary school level, where the foundation for scientific literacy is established, fostering the acquisition of scientific competences, especially procedural ones, through innovative methods is paramount. Despite the potential of interactive video-tutorials to support experimentation, their application in primary education remains unexplored. This research aims to address this gap, focusing on the systematic identification of design criteria for interactive video-tutorials to promote scientific competences at the primary level. These design criteria are theoretically derived and defined based on established frameworks for instructional design, multimedia learning, and research on experimental and measuring competences.

Theoretical Framework

The use of digital media, especially media such as explanatory videos, plays a central role both in everyday lives of students and in school contexts. With regard to teaching contexts, there are numerous possible applications, such as in flipped classroom settings or the production of videos by students as a presentation tool. It can be assumed that the relevance of explanatory videos for science lessons will increase in the future (Kulgemeyer, 2020).
Explanatory videos are typically defined as self-produced short films designed to explain complex concepts. However, in contrast to these classic explanatory videos, (interactive) video-tutorials are instructional in nature. Their defining characteristic is their action-guiding purpose, offering step-by-step instructions that encourage viewers to replicate the demonstrated actions (Wolf, 2015). While explanatory videos have been extensively researched, the potential of (interactive) video-tutorials as a medium to support hands-on-activities in science education remains unexplored. Interactive video-tutorials are particularly well-suited to contexts that require hands-on-activities, such as scientific experimentation, as they allow learners to access procedural guidance in close temporal and functional proximity to their own actions. Experiments are a cornerstone of science education and involve numerous practical steps, requiring students to develop various experimental competences (Tesch & Duit, 2004). Experimental processes can be categorised into three overarching phases: planning, performing, and evaluating experiments,

each of them requiring specific competences (Schreiber et al., 2009). Supporting the acquisition of these competences requires instructional formats that can be flexibly aligned with different phases of the experimentation process and with learners' situational needs. Interactive video-tutorials on the use of measuring devices appear to be particularly suitable, as they address competences that are independent of the individual experiment. Also, learners at the primary school level are faced with the challenge of not only familiarising themselves with relevant measuring devices and the respective quantities and units, but also having to apply them for the first time in experimental settings to differentiate subjective sensory impressions from objectively measured physical quantities (GDSU, 2013).

In the context of experimental learning, instructional support needs to be closely aligned with the procedural structure of the measuring process. Learners are required to make decisions and perform actions at the different stages of measurements to foster sub-competences. Accordingly, instructional approaches aimed at experimental competences should allow learners to access guidance that corresponds to their current phase within this process. However, the effectiveness of interactive video-tutorials, just like that of explanatory videos, depends heavily on their design. To ensure they support learning effectively, they must adhere to key instructional design principles (Kulgemeyer & Wittwer, 2023) and integrate seamlessly into the broader learning process.

Aims And Research Questions

The research presented focuses on identifying design criteria for interactive video-tutorials that effectively support learners in using measuring devices during experimental processes. The overarching aim is to explore how these interactive video-tutorials can best facilitate the development of experimentation competences, with a particular emphasis on guiding students through the proper choosing and handling of measuring devices as well as accurate data acquisition. We address the following research question:

What design criteria are essential for creating interactive video-tutorials that support the handling of measurement devices in experimental contexts?

Methods And Relevant Research Literature

The study employed a deductive research approach, drawing on established research literature on instructional video design as well as on models of experimental and measuring competences. On this basis, both relevant measuring-related sub-competences and design criteria for interactive video-tutorials were systematically derived and defined. The focus was placed on relating the structural characteristics of measuring processes in experimental contexts to suitable instructional design criteria for interactive video-tutorials.

Research literature on experimental competences was analysed in order to conceptualise experiments as a structured scientific practice comprising the phases of planning, performing, and evaluating experiments (Nawrath et al., 2011; Schreiber et al., 2009). These models provide a process-oriented framework that describes the sequence and structure of experimental processes in science education as well as certain experimental competences within each phase. Building on these models, measuring processes were conceptualised as a central scientific practice that occurs within all three phases of the experimentation process (Murer et al., 2025). This analysis informed the alignment of the interactive video-tutorials with relevant decision points and actions that learners need to successfully select measuring devices, read and record measured values, and represent data correctly.

Kulgemeyer's (2020) framework for effective explanatory videos informed the identification of design criteria, particularly in relation to structuring and tailoring interactive video-tutorials to

support the named measuring competences throughout the three overarching phases of the experimentation process. It is grounded in principles derived from empirical research on instructional explanations and findings about multimedia learning. The concluding framework outlines 14 key criteria to guide the production of explanatory videos that are both scientifically accurate and pedagogically effective. These criteria fall into seven main categories: structure, adaption, tools for adaption, minimal explanation, highlighting relevancy, follow-up learning tasks and new, complex principles (Kulgemeyer, 2020). All criteria were critically analysed with regard to a possible implementation for interactive video-tutorials that support the handling of measuring devices in experimental contexts. Particular attention must be paid to the extent to which the criteria can be adapted to learner-controlled, non-linear digital learning formats such as interactive video-tutorials that allow for situational access to instructional support.
Bringing together both perspectives, measuring related competences and instructional design criteria were systematically related to each other in order to inform the design of interactive video-tutorials that are aligned with the measuring process and tailored to the demands of measuring activities in primary science education.

Results

Table 1 specifies measuring related sub-competences within the model of experimentation in primary school settings.

Table 1. Measuring Sub-Competences in the experimentation process in primary school settings.

Measuring Sub-Competences	Planning	Performing	Evaluating
SC1: Learners know measuring devices and can name them.	✓	×	×
SC2: Learners indicate which measuring device to use to measure different quantities.	✓	×	x
SC3: Leaners know corresponding units for quantities and can name them.	✓	×	✓
SC4: Learners select suitable measuring devices in specific experimental situations.	✓	✓	×
SC5: Learners select suitable measuring devices with regard to the measuring range.	✓	✓	×
SC6: Learners correctly read measured values from different measuring devices for the same quantity.	×	✓	×
SC7: Learners correctly read measured values while taking a parallax error into account.	×	✓	×
SC8: Learners document the measured values taken.	×	✓	×
SC9: Learners correctly transfer measured/documented values into a table.	×	×	✓

In the phase of planning, learners must decide which measuring device is suitable for the

measuring process based on their knowledge about measuring devices, quantities and units. While performing the experiment, learners must correctly use each measuring device as well as correctly read and document measured values. For transparency and traceability, the documented values must then be visualised in a table during the evaluation phase (Reuter & Stinken-Rösner, submitted).

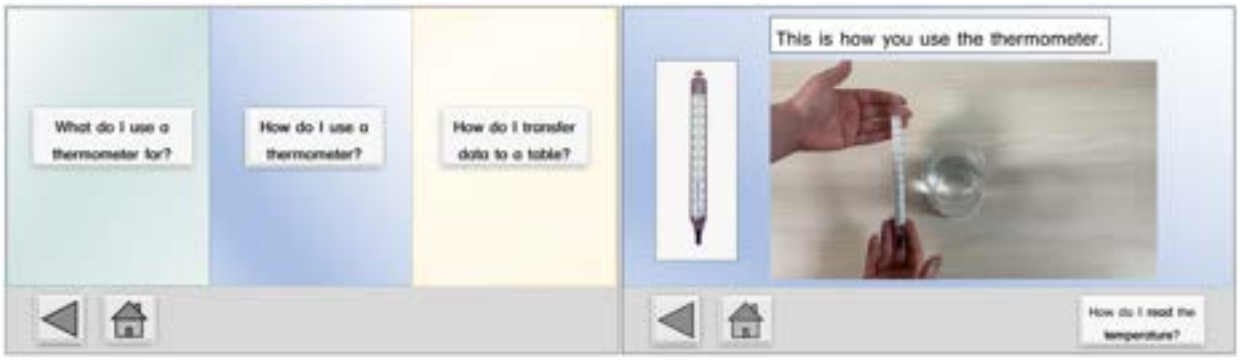

Table 2 shows the extent to which the criteria for effective explanatory videos (Kulgemeyer, 2020) can be applied to the creation of interactive video-tutorials to fit their action-guided purpose as well as our target group (primary school children).

Table 2. Implications for the design of the interactive video-tutorials based on video criteria (Kulgemeyer, 2020).

Factors	Feature	Implications for interactive video-tutorials
Structure	Rule-example/example-rule	Interactive video-tutorials follow the example-rule structure by first demonstrating its use on a selected measuring device and then deriving general rules.
	Summarising	Interactive video-tutorials are divided into individual sections for clarity, making a summary about the whole process redundant.
Adaption	Adaption to prior knowledge, misconceptions and interest	Interactive video-tutorials focus on familiar devices and quantities (mass, time, length, temperature) and address typical handling errors.
Tools for adaption	Examples	Interactive video-tutorials show standard devices (e.g., digital and analogue scales) for each measurement type.
	Analogies and models	Not necessary with regard to interactive video-tutorials.
	Representation forms and demonstration	Interactive video-tutorials demonstrate exact procedures for using each device.
	Level of language	Interactive video-tutorials use simple, familiar professional language, avoiding unnecessary terms.
	Level of mathematisation	Interactive video-tutorials focus is on familiar units (e.g., kg, °C) and numbers ranges for clarity.
Minimal explanation	Avoiding digressions	Interactive video-tutorials focus strictly on core tasks (e.g., handling of specific measuring devices).
	High coherence	Interactive video-tutorials for each measurement device follow the same structure.
Highlighting relevancy	Highlighting relevancy	Viewing is optional; learners decide which interactive video-tutorials they need and are therefore relevant.
	Direct addressing	Interactive video-tutorials use the second person singular.
Follow-up learning tasks	Follow-up learning tasks	Hands-on activities are the motivation for using interactive video-tutorials, eliminating the need for separate follow-up tasks.
New, complex principles	New, complex principle	Interactive video-tutorials introduce new measurement actions rather than new principles.

In interactive video-tutorials, the example-rule structure comes naturally, as they demonstrate individual steps of the measurement process. Similarly, demonstrations and direct addressing are inherent to the tutorial format.
Certain criteria, like summarising and follow-up learning tasks, are unnecessary. The interactive video-tutorials are divided into clear steps, according to relevant actions in the measuring process, making summaries redundant, and hands-on activities are the actual starting point for utilisation. Other criteria require specification. Tools for adaption focus on familiar devices, accessible language, and appropriate mathematisation to match learners' prior knowledge. Coherence is ensured by following an idealised measuring process as well as using the same structure for multiple tutorials. Rather than introducing new principles, the interactive video-tutorials teach new actions in order to foster measuring competences.
The resulting criteria were used to design an interactive video-tutorial for relevant measurement devices at primary school level to measure length, time, mass, and temperature. Exemplary screenshots for the use of thermometers in the measurement process are shown in Figure 1.

Figure 1. Exemplary screenshots from the interactive video-tutorials.

When starting the measuring process, viewers must first decide which is the suitable measuring device for the quantity to be measured. For example, a thermometer should be selected for temperature measurements. In the shown example (see Figure 1, left), viewers can choose between three options: To obtain information on what a thermometer can be used for (planning), information on how to use a thermometer (performing) or how to transfer collected data to a table (evaluating). This directly aligns with the three overarching phases of the measuring process. Within these sections, further decisions aligned to the sub-competences can be made. In the planning phase (option "What do I use a thermometer for?"), learners are presented with different types of thermometers to support their decision on which instrument is suitable for a specific measuring situation and measuring range. Once a suitable thermometer has been selected, the interactive video-tutorial continues with thermometer-specific guidance. Learners can watch a short video sequence on the use of a thermometer in an exemplary measuring situation and then continue on how to correctly read the temperature (see Figure 1, right).

Outlook

The interactive video-tutorials developed in this project constitute a first step towards supporting measuring-related competences in primary science education. The next phase of research focuses on embedding the interactive video-tutorials into an experimental learning environment on sensory illusions. These provide authentic and motivating experimental situations in which learners are required to measure physical quantities in order to contrast subjective sensory impressions with objective, measured data. Within this setting, the interactive video-tutorials are integrated as a situational support that learners access during the phases of the measuring process. To investigate the effectiveness of the interactive video-tutorials, a pre-post study design is employed using a competency test targeting the named measuring sub-competences (Reuter &

Stinken-Rösner, submitted). This design allows for the systematic analysis of learners' competence development and provides insights into how interactive video-tutorials can contribute to fostering procedural competences in primary science education. The first empirical studies are planned for 2026.

Conclusions

This study highlights the potential of interactive video-tutorials as a valuable tool for enhancing science education, particularly at the primary school level. Unlike traditional explanatory videos, interactive video-tutorials are action-guiding in nature, providing step-by-step instructions that enable learners to replicate actions and acquire essential procedural skills. Given the importance of experiments in fostering scientific literacy, the integration of well-designed interactive video-tutorials could support learners in developing measuring competences while leveraging digital media to promote authentic scientific learning. By adhering to well-defined design criteria, these tools have the potential to enhance student engagement and foster the acquisition of vital experimental skills.

Using Kulgemeyer's (2020) framework for effective explanatory videos as a foundation, this study adapted and extended the criteria to address the specific challenges of designing action-guiding tutorials. Additionally, the interactive video-tutorials focus on age-appropriate measuring devices and accessible language to ensure clarity and usability and to adapt to prior knowledge. The application of these criteria was demonstrated through the development of an interactive video-tutorial for common measuring devices such as thermometers, scales, stopwatches, and rulers. By addressing specific steps in the measuring process, such as selecting, operating, and documenting with these devices, the interactive video-tutorial provides targeted support for learners, helping them to acquire procedural knowledge and improve their measuring competences.

Future research will focus on evaluating the effectiveness of interactive video-tutorials in diverse educational contexts, particularly their impact on learners' procedural competences and their ability to foster independence in experimental tasks.

Creativity and Programming Essentials as Skills for a Transitioning Digital World

Marisa Alena Holzapfel[1], Nadine Dittert[2] and Cornelia Susanne Große[3]
[1]University of Greifswald, Germany
[2]University of Koblenz, Germany
[3]Johannes Kepler University Linz, Austria

In a fast-paced technological world, children need to be equipped with skills that allow them to keep that pace and to act accordingly. Therefore, a basic understanding in technology as well as creativity might be helpful. This enables children to find their way in a digital world that is developing at a very fast pace and also to draw on their own expertise and creative solutions to problems. It is advisable to address these skills in elementary school and lay the necessary basics here.

This study therefore examines the question of how creative and algorithmic thinking are connected. In addition, an attempt was made to develop a creative learning unit to train basic programming skills. As a basis for addressing this topic, a suitable test instrument was designed and evaluated to assess the creativity of elementary school children in the context of a learning unit on programming.

The results show that the test instrument for creativity was successfully evaluated. The results revealed that the elementary school children surveyed had almost no prior knowledge with respect to programming skills, but these skills improved significantly with the learning unit proposed in the present study.

Keywords: Computational Thinking; Early Science Education; Play and Science Learning

Introduction

In a fast-developing, increasingly digital world, a fundamental understanding of digitality and the associated processes are essential. This includes a basic understanding of the fundamental functionality of programming and the ability to think creatively and develop innovative approaches and problem-solving strategies. Creativity is described as a 21st-century skill for good reason, especially in the context of unpredictable new challenges. At this point, the question rightly arises as to where and how such skills can be examined and developed. Following the results of the latest PISA study from 2022, the consortium is also calling for creativity to be promoted in schools (Diedrich et al., 2024). Particularly in natural science and social science education in elementary school, there is seen to be special potential for creative educational processes (Holzapfel et al., 2022; Rau-Patschke et al., 2024). Further the results of the International Computer and Information Literacy Study (ICILS) from 2023 show a lack of both – computer and information literacy skills at higher proficiency levels, including operationalizing solutions (Fraillon, 2024). Digital learning environments open up a wide range of opportunities to challenge and support children technologically and in developing IT skills, as well as in the ability to think creatively and generate innovative ideas.

Agreeing with the Informatics for All Coalition that computer science education should start in elementary school (Caspersen et al., 2018), we designed a learning setting that combines creativity and computational thinking skills in elementary school.

Theoretical Framework

In the study presented here, both aspects are combined in an intervention for creative programming for elementary school children that is tested and evaluated. Now that an initial small feasibility study has been carried out and the project has been confirmed (Holzapfel et al., 2024), the focus will be on the relations between the two constructs of programming experience and creativity. Therefore, both aspects will be discussed theoretically below.

Computer Science As An Essential Skill For An Innovative World

Computer science and creativity are closely linked. Modeling activities, for example, require and simultaneously promote the application of creativity (Schubert & Schwill, 2011). Through computer science ways of thinking, working and acting, one's own ideas become functional programs, games or entire interactive systems that take on a perceptible form. The promotion of creativity in computer science lessons is therefore an important goal which can also be transferred to the technical perspective of science education in elementary school (Hubwieser, 2007). Learning environments therefore open up a wide range of opportunities to challenge and encourage children both technologically and creatively. Robot-assisted settings in particular combine creative, reflective, and technical requirements, allowing creative thinking to be immediately visible in action.

Robotic learning environments promote technical, creative, and social learning in combination (Bers, 2008). They follow the principle of technological fluency—that is the ability to use technologies creatively and purposefully, like a language. Programming skills expand children's expressive possibilities: sensors, movement patterns, and audiovisual elements can be embedded in self-selected themes and narratives. Tactile systems such as BlueBots enable intuitive, action-oriented access in the sense of “hands-on” pedagogy (Bers, 2008, p. 48). Digital storytelling with robots for example combines technology, language, and individual design. Children program robots, assign them roles, and stage stories—an expression of digital creativity (Bers, 2008; Sawyer & Henriksen, 2024).

Creatively Facing New Challenges

In order to be able to make statements about children's creativity, a suitable test instrument is needed. In line with current research, creativity was operationalized as first step for this project (Holzapfel et al., 2022). The current discourse is clear: creativity is often operationalized as construct that is composed of divergent and convergent thinking and requires both equally (Runco & Jaeger, 2012). Divergent thinking - that is, the flexible, imaginative variation of approaches to solutions - is considered central to this (Cropley, 2006). Guilford (1967) also emphasizes the importance of convergent thinking, which structures selection, evaluation, and decision-making processes. In other words, those who think creatively think innovative and different, but also solution-oriented and goal-oriented (Sternberg & Lubart, 1998).

Creativity research often refers to four sub-areas of creativity: the creative person, the creative process, the creative product and the creative environment (Rhodes, 1961). These sub-areas are all relevant for teaching and learning. The creative person can therefore be a teacher or student, the creative product a learning outcome, the creative environment an appropriately designed classroom and the creative process can be a learning process (Bliersbach & Reiners, 2017).

The project presented here considers all four areas, with the focus being on the creative person, i.e., the creative students.

Purpose Of The Study

Since creativity and the basics of computer science are considered important skills in a modern, fast-paced world, the question arises as to the status quo of these two skills among children of elementary school age. Furthermore, it seems important to examine the interaction between these skills and to develop ways of teaching them. This study therefore investigated the following research questions.

As can be deduced from the theory, creativity is a very complex construct that can be roughly described by specific abilities in both divergent and convergent thinking. In order to make a statement about the creativity of elementary school students, it must be possible to operationalize and measure it. The first research question is therefore:

> RQ 1: How can creativity of elementary school students be measured?

The operationalizability of the construct of creativity should be considered specifically in the context of the basic computer science education of elementary school students. In addition, the question arises as to what prior knowledge in basic programming skills the children have and whether it is possible to develop a successful intervention to promote basic programming skills. This leads to the following question:

> RQ 2: Is the intervention effective for promoting basic programming skills? Are there gender differences or differences between the grades?

In a next step, the question occurs as to the connections between creativity and basic programming skills. The corresponding research question is:

> RQ 3: Is there a relation between creativity (i.e., divergent/convergent thinking) and algorithmic thinking?

Methods

To answer these questions, a half day intervention for the floor-robot BlueBot was developed, and data on basic programming skills (adapted from Zapata et al., 2021), creative thinking (adapted from Landmann et al., 2014 and Torrance, 1966) and demographic information and control variables (joy of learning, use of digital media, interest in technology, age, gender) were collected in a paper-pencil questionnaire in a pre-post design. In addition to this quantitative data, qualitative data (photos, videos and observation sheets) was also collected, but will not be discussed in detail here. In the creative learning intervention, the children were asked to work in tandems to invent a story on a topic of their choice, and to program the robot so that it acts according to the story. To gain initial experience in this process and to express this, the children were given the task of creating a field for the BlueBot on which it would follow a programmed, predetermined path. The tandems were able to design the field individually from wooden puzzle tiles. Each tandem received the following tiles: a start and finish tile, 5 tiles prepared with blackboard varnish, which the children could paint as they wished, and 13 blank tiles on which the BlueBot was allowed to move.

Sample

A total of $N = 405$ pupils from grades two to four from elementary schools in Germany (Ø 8.29 years; 202 girls and 193 boys, 3 non-binary/other genders, 7 missing values) were surveyed. Participation was voluntary and school management, and all parents gave their consent.

Results

With regard to *research question one*, it can be stated that the scaling of creativity was successfully calculated using SPSS. Two parameters, divergent and convergent thinking, were determined using collected data. Divergent thinking was measured via three scales, two figural and one verbal scale, based on Torrance (1966). As with Torrance (1966), a value for Originality, Fluency and Flexibility was determined for each scale. Originality stands for the uniqueness or rarity of the idea, fluency for the number of ideas of a person, and flexibility for the number of different ideas of a person. The values determined for all three scales were converted into an overall value for divergent thinking and then were z-standardized. For convergent thinking, a scale of eight items based on the Compound Remote Associates Test (Landmann et al., 2014) was used and a sum score was calculated. For uniformity, this sum score was also converted into a z-standardization and forms the value for convergent thinking. Based on these two values, four subgroups were formed using a median split. The median split was calculated once for the value of the divergent thinking and again for the value of the convergent thinking. The sample showed a relatively equal split into four groups: low convergent and divergent thinking (n= 104), low convergent and high divergent thinking (n= 94), high convergent and low divergent thinking (n= 98), and high scores in convergent and divergent thinking (n= 109). The group with high values in divergent and convergent thinking can be described as creative based on the literature (Holzapfel et al., 2024).

Regarding to the *second research question*, it can be stated that the children learned significantly overall ($t(399) = -11.24$, $p < .001$, Cohen's $d = -.562$). The prior knowledge was very low ($M = 1.94$, $SD = 2.16$, maximum achievable score 8) and the value of the post-test does not show a very high level of knowledge either ($M = 2.96$, $SD = 2.61$). Even though prior knowledge was very low, there was a clear increase in learning. However, there would have been further potential for improvement.

Table 1: Algorithmic thinking scores separated by grade.

Grade	alg. *(Pretest)*	alg. *(Posttest)*	alg. (*learning gain)*
2	1.38 (1.71)	2.23 (2.44)	.81 (1.73)
3	1.92 (2.29)	2.73 (2.58)	.80 (1.65)
4	2.95 (2.36)	4.63 (2.24)	1.73 (2.04)

alg. = algorithmic thinking

Descriptively, there are gender differences in the basic programming skills pretest scores (f: $M = 1.61$, $SD = 2.06$; m: $M = 2.29$, $SD = 2.23$), as well as in the posttest scores (f: $M = 2.55$, $SD = 2.55$ and m: $M = 3.39$, $SD = 2.61$), which revealed to be significant for both the pretest and the posttest (pretest: $F(1, 393) = 9.67$, $p = .002$, $\eta_p^2 = .024$, and posttest: $F(1, 391) = 10.24$, $p = .001$, $\eta_p^2 = .026$, respectively). With respect to learning gain, both for girls and boys significant results were observed (f: $t(200) = -8.14$, $p < .001$, Cohen's $d = -.574$; m: $t(191) = -7.74$, $p < .001$, Cohen's $d = -.559$), thus, both girls and boys had significant learning gain. A further analysis however did not reveal significant gender differences with respect to learning gain ($F(1, 391) = 1.174$, $p = .279$, $\eta_p^2 = .003$), indicating that girls and boys learned to the same extent.

In addition, some differences between the grades can be reported. There were significant differences between the pretest scores ($F(2, 399) = 16.68$, $p < .001$, $\eta_p^2 = .077$), as well as significant differences between the post-test scores ($F(2, 400) = 29.74$, $p < .001$, $\eta_p^2 = .129$), with higher scores in higher grades (see Table 1). Learning gain also differed significantly between grades ($F(2, 397) = 9.81$, $p < .001$, $\eta_p^2 = .047$), with the highest learning gain in grade four (see Table 1).

A comparison between children with low and high levels of creativity revealed significant differences with respect to pretest and post-test scores for algorithmic thinking (pretest: main effect "convergent thinking": $F(1, 398) = 17.85$, $p < .001$, $\eta_p^2 = .043$; main effect "divergent thinking": $F(1, 398) = 0.093$, $p = .760$, $\eta_p^2 < .001$; interaction effect: $F(1, 398) = 0.002$, $p = .963$, $\eta_p^2 < .001$; post-test: main effect "convergent thinking": $F(1, 399) = 3.53$, $p = .061$, $\eta_p^2 = .009$; main effect "divergent thinking": $F(1, 399) = 0.49$, $p = .485$, $\eta_p^2 = .001$; interaction effect: $F(1, 399) = 0.43$, $p = .514$, $\eta_p^2 = .001$). This would also address the question regarding the connection from *research question three*.

Discussion And Implications

A practicable operationalization of the creativity of elementary school students in the context of an intervention to introduce programming was demonstrated. The elementary school students surveyed had almost no prior knowledge of programming. Against the background of existing but very limited prior knowledge, it seems necessary to teach the basics, especially in view of the rapid technological development. The evaluation presented here shows that the learning unit is suitable for providing initial insights into the basics of computer science. It should be noted that there are differences between boys and girls. The boys achieved significantly higher scores in both the pretest and post-test, but there was no significant difference between boys and girls in terms of learning gains. Although this suggests that the intervention is equally suitable for boys and girls, it also shows that it did not succeed in raising girls' algorithmic thinking skills to the level of boys. In addition, there was a significant difference in algorithmic thinking between the grades. Overall, algorithmic thinking skills increase continuously from grade two to grade four with fourth graders achieving almost twice as high scores as children in grades two and three in terms of both pre- and post-test results and learning gains. It therefore appears that the intervention is most suitable for children in grade four with respect to algorithmic thinking skills. However, other constructs like for example developing interest and self-concept regarding Computer Science were not in the focus of the present study and should therefore be examined in the future.

A concrete implication for practice based on the data collected is that the synergy between creativity and programming skills is not only successful but also extremely useful and both can benefit from each other. This applies especially to convergent thinking. If we succeed in promoting this, it could probably have an impact on the algorithmic thinking. The results of this study already indicate this, but further analyses should be carried out in order to be able to make a more precise statement here.

On this assumption, further research should be conducted to repeat or extend the intervention with other learning robots in order to achieve a possibly even higher effect and also to determine whether the results of this study can be replicated or even improved upon with other robots. It would also be very informative and exciting to look at how the tandems interact with each other on the basis of the data already collected or additional studies. In this context, it would be interesting to see what influence the creativity of both children and their programming skills have on the creation and design of the stories and the coding. Further, it would also be interesting to take a closer look at the differences between the grades or genders. The results of the study

presented suggest that second and third graders may have even more difficulties with algorithmic thinking, whereas fourth graders demonstrate much better skills. Therefore, further studies should clarify whether this is only a phenomenon of the present intervention or measurement, or how and when algorithmic thinking skills need to be addressed. Further, gender differences need to be addressed more explicitly.

ESERA 2025 Copenhagen

Not Produced "For The Wastebasket" – Materials In The Fops Project

Sandra Puddu[1], Christian Nosko[2, 3] and Anja Lembens[2]
[1]University College of Teacher Education Vienna, Austria
[2]University of Vienna, Austria
[3]Private University College of Teacher Education of Christian Churches, Austria

The new primary schools curriculum in Austria (BMBWF, 2023) places greater emphasis on inquiry-based learning in science studies. To support teachers, the FoPs project is developing teaching materials based on four pillars. In addition to inquiry-based learning, these pillars are scientific ways of thinking and working, using concrete matter (German: die Sache) as a starting point, and the scaffolding of language. Based on a common research question, all materials enable internal differentiation in lessons. Therefore, materials based on the same research question are provided for structured inquiry (Level 1) and guided inquiry (Level 2) of inquiry-based learning. A teachers' guide is also provided. The materials were used by teachers in general studies (German: Sachunterricht) in an initial evaluation phase. To ensure the materials are used beyond the project period, a questionnaire was developed and conducted with primary school pre-service teachers on Bachelor Level. The aim was to find out what is necessary for pre-service teachers to integrate these materials into their lessons in the long term and what improvements they would like to see.

Keywords: Primary Science Instruction, Science Practices, Learning Environments,

Introduction

Basic scientific literacy should be introduced in science teaching at primary level (AAAS, 2012). In Austria there is a main subject called Sachunterricht (general studies) which includes social studies and natural sciences. The aim of this subject is to offer learning opportunities to convey concepts, promote scientific ways of thinking and working, and address nature of science. This is where FoPs ("Forschendes Lernen in der Primarstufe" that means inquiry-based learning in primary education) comes in. Three institutions are cooperating in this research and development project to promote inquiry-based learning at primary school (Nosko et al., 2025; Puddu et al., 2024). In doing so, different learning opportunities are developed based on a specific matter to promote scientific ways of thinking and working. "The soup" is one of these learning opportunities, for which teaching materials and a teachers' guide have been created. Soup powder is a quick way to make soup, and it is probably found in almost every household. Most students are familiar with it, and many learning opportunities related to chemistry, physics, social sciences or economics can be developed based on the scientific phenomenon of solubility.

Conception Of The Materials

The materials in the FoPs project are based on four pillars that are anchored in the primary school curriculum (BMBWF, 2023): a) starting with the matter at hand, b) scientific ways of thinking and working, c) the use of inquiry-based learning with varying degrees of openness and d) language support.

The Four Pillars

When Köhnlein (2022, p. 39f) writes about the "matter of general studies" (Sache), he is referring to everything that gives rise to a discussion or investigation. He is not only referring to real objects, but rather to "objects of our thinking and speaking". Matter always exists in a certain factual context. This implies that subject lessons must never focus on just one aspect of the topic.

It is important to also consider the social, environmental, technical or historical aspects of a matter.

Scientific ways of thinking and working can be seen as diverse methods of encountering new knowledge. This gives pupils in science lessons the opportunity to engage intensively with matters and explore them in depth. According to Nerdel (2017), these ways of thinking and working have a dual function: on the one hand, the understanding of important technical aspects should be ensured, and on the other hand, methodological skills should be acquired. When choosing specific scientific ways of thinking and working for the project, we are guided by Steffensky's description (Steffensky, 2018): Asking questions, hypothesising, measuring, planning and conducting investigations, observing, comparing, ordering, classifying, analysing and interpreting data, drawing conclusions, generalising, arguing, using models, and documenting.

To understand scientific ways of thinking and working, it is helpful to adopt an inquiry-based learning approach. Many aspects of research correspond to the aforementioned scientific ways of thinking and working, which are brought together in an inquiry-based learning process, actively experienced by the pupils.

Through inquiry-based learning, it is possible to develop skills that are required under the keyword 21st Century Skills (National Research Council, 2012) in the primary school curriculum. These skills include asking a question, investigating this question creatively and collaboratively using suitable methods, observing, experimenting, collecting data and drawing conclusions in order to answer the question posed at the beginning. All of these skills are part of inquiry-based learning but can also be practiced individually under certain circumstances (NGSS Lead States, 2013). Depending on the question, different scientific ways of thinking and working can be used and promoted.

If inquiry-based learning is implemented in the classroom, this can take place with varying degrees of openness (levels 0 to 3, see table 1) (Blanchard et al., 2010). The FoPs project materials were developed at levels 0, 1 and 2, enabling work to be carried out at different levels based on the same research question.

Table 1: Levels of inquiry (Blanchard et al., 2010, p. 581).

	Source of the Question	Data collection Methods	Interpretation of Results
Level 0: Verification	Given by teacher	Given by teacher	Given by teacher
Level 1: Structured	Given by teacher	Given by teacher	**Open to student**
Level 2: Guided	Given by teacher	**Open to student**	**Open to student**
Level 3: Open	**Open to student**	**Open to student**	**Open to student**

When implementing scientific ways of thinking and working, spoken and/or written language is essential. Children need to be able to put their thoughts, questions and arguments into words to be able to successfully discuss them with others. Many learners find this difficult. Appropriate scaffolding is therefore important to promote the transition to academic language and terminology in subject lessons through language-sensitive subject teaching (Gabler et al., 2020; Leisen, 2013; Lembens & Krebs, 2025; Quehl & Trapp, 2015) and also to enable participation with regard to highly diverse school classes.

The Materials In The Project

“The soup”, “The snow” or “My classroom” are some of the learning opportunities designed as part of the FoPs project. The subject is always a concrete matter that is physically available in the pupils' immediate environment. Dealing with it provides many opportunities to familiarise with and apply scientific ways of thinking and working in the classroom. When creating the learning opportunities, care was taken to ensure that a multi-perspective approach is possible, as required by the curriculum for general studies (BMBWF, 2023, p. 1). This makes it possible to link the areas of competence (social science, natural science, geography, technology, history and economics) in a structured, meaningful and appropriate way when dealing with the content.

Extensive materials for teachers and students are available for each topic. Meaningful symbols have been used in the text for better orientation and easier readability. In order to provide teachers with the best possible support for their lesson planning, the teachers’ guide contains the following elements: a brief description of the respective matter, a detailed presentation of the individual investigation sheets with a description of the scientific thinking and working methods to be practiced, the levels of inquiry-based learning and the required materials for the investigations, a list of possible links to all areas of competence in science teaching, and ideas for the solution of the students’ investigation sheets. The explanation of the content is provided at different levels of difficulty, one for teachers and one for pupils.

The investigation sheets for pupils are differentiated and named as follows: A) Sheet for all researchers (the basic exploration of the matter using all senses); B) Sheet for beginning researchers is based on level 1 of inquiry-based learning (Both research questions and concrete suggestions for carrying out scientific investigations are provided on the sheet and are worked on by pupils.); C) Sheet for advanced researchers is based on level 2 of inquiry-based learning (Research questions are formulated, the planning and execution of the scientific investigations as well as the interpretation of the observations or collected data are the responsibility of the pupils.).

Research Design

In addition to a classic evaluation design which we used to further develop the materials, we wanted to think ahead. We were interested in learning what features concerning learning materials teachers and pre-service teachers expect so they use materials repeatedly even after the project period ended. Therefore, the research questions of the study presented here are: What is necessary for teachers to integrate our materials into their lessons in the long term? What are their wishes for the provided materials? To what extent do the materials meet their requirements?

To answer these questions, a questionnaire consisting of five sequences was conducted (Baur & Blasius, 2019). A four-level Likert-scale was used, ranging from “very important” to “not important at all”. The first part is about the importance of different aspects of the subject “scientific studies” like perceived importance of inquiry-based learning or nature of science. The second part addresses the preparation of lessons. Sample items are “The time required for preparation is minimal.”, “There is easy access to the materials.” or “The additional consumables (glasses, pens, …) for the investigations are easily available.” The third part shifts the focus to the pupils with statements like “The pupils have fun with the materials.”, “Accessibility for all pupils (screen reader, colors, design) is given.” or “Linguistic differentiation is possible with the materials.” The focus of the fourth part is on the teachers’ guide with the following items: “The desired competencies of the pupils are specified.”, “Lesson plans are available.” or “Suggestions for possible solutions are given.” The final section deals with the alignment of the pre-service teachers' ideas with the materials from the FoPs project.

40 pre-service teachers on the Bachelor's degree program in Primary Education (7 male, 33 female, 0 diverse) completed the questionnaire. The participants' progress in their studies varied greatly. 21 were in the 3rd semester, 12 were in the 7th semester. The remaining seven pre-service teachers were in their 5th to 9th semester. 17 of the 40 pre-service teachers are currently teaching part-time in a primary school, two even full-time.

Findings

This section presents the answers of the pre-service teachers, beginning with an evaluation of the importance of different aspects of the subject "general studies" (see figure 1). The most important aspect is the importance of natural sciences in everyday life, followed by inquiry-based learning and that the students conduct experiments. In general, the pre-service teachers consider most of the aspects to be important. Only the aspect of "talking about how natural scientists work", which is one of the aspects of nature of science, is considered less important. In Austria, it seems that this topic is still not given the attention it deserves.

Figure 1. How important are the following aspects of the subject?

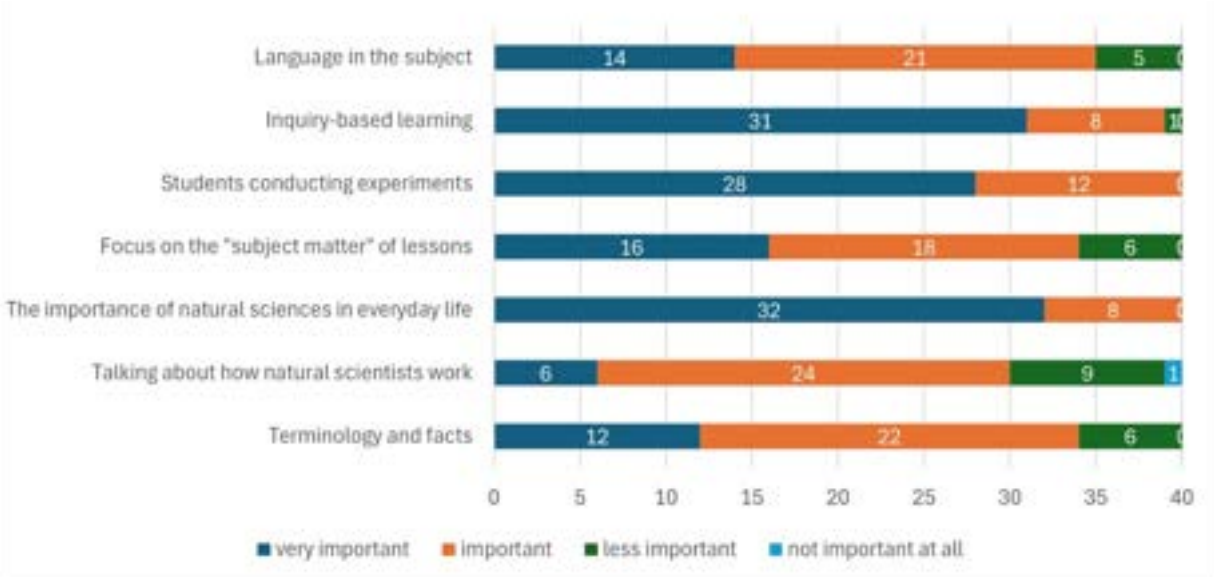

Figure 2 shows relevant criteria concerning pupils with interesting results. While hands-on and minds-on parts are quite important, the item with the highest priority for the pre-service teachers is that the pupils have fun (all 40 pre-service teachers consider it to be either very important or important). Another important criterion is the possibility of internal differentiation in terms of content. 24 pre-service teachers say that it is very important and 15 say that it is important.

The importance of aspects of language was evaluated using two items. Linguistic differentiation is only slightly important (very important: 18), the easy understanding of texts is much more important (very important: 26).

For the pre-service teachers it is important that the pupils can work independently (very important: 23) and that there is a clear and easy-to-understand structure (very important: 26).

Another part of the questionnaire is about the teachers' preparation for the lessons. Figure 3 shows the priorities of the pre-service teachers. The items ranked as "very important" according to the response options are that the materials are easily adoptable and accessible, followed by a digital availability. Interestingly, 26 pre-service teachers stated, that it is "less" or "not important" if additional work like cutting out or crafting is necessary. Only 10 out of the 40 pre-service teachers said that a minimal preparation time is "very important".

Figure 2. How important are the following criteria concerning students?

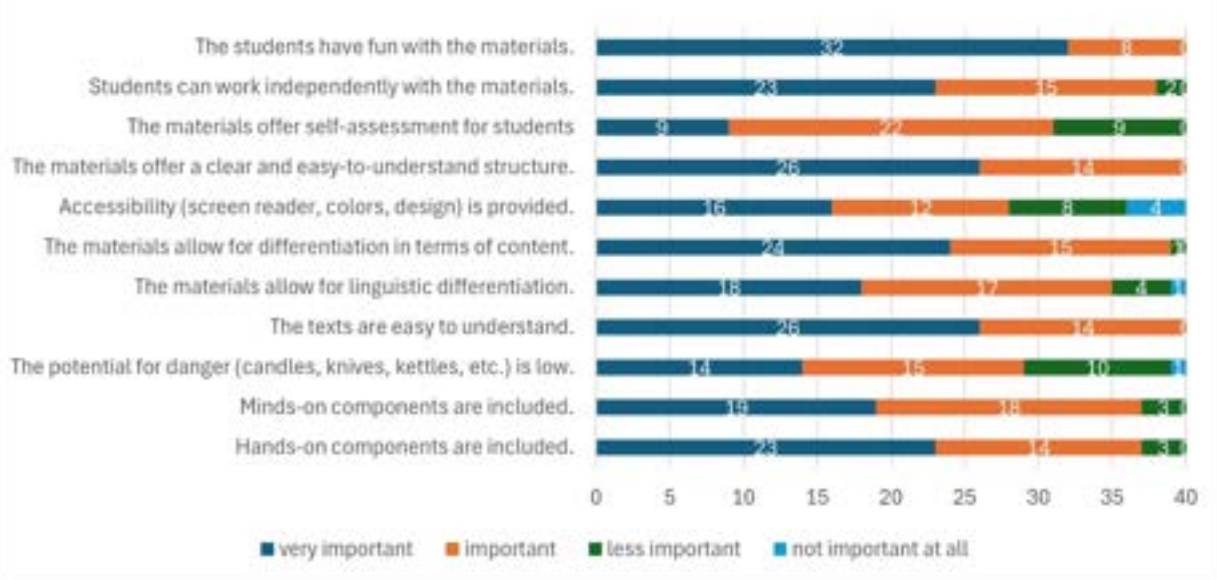

Figure 3. Preparation of lessons

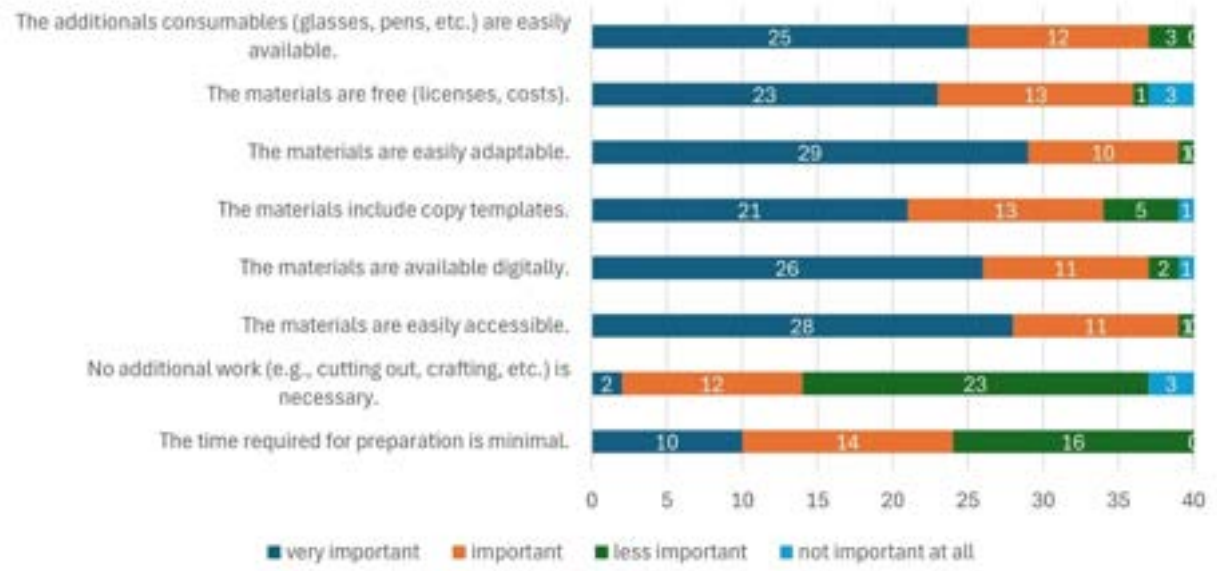

Figure 4 illustrates the fit between the pre-service teachers' expectations and the project materials. It seems that the expectations have been well met. The lowest level of acceptance was shown concerning the preparation.

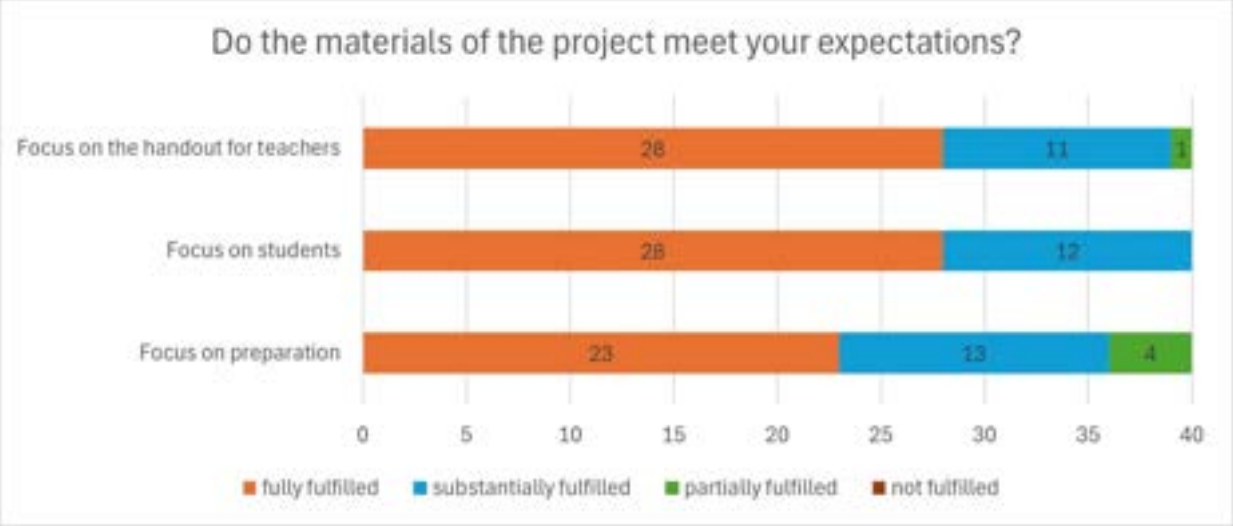
At the end of the questionnaire, the teachers' students had the option to write a comment. There, comments like "Cool idea, I'd definitely try that out in class!" but also "The presentation seems a bit monotonous/boring." could be found. The comments were varied, but not helpful in terms of further development.



Discussion

In this paper, we presented the findings from a questionnaire completed by pre-service teachers.

The aim of our project was to create materials that are used even after the project is finished. To learn more about the features the materials need to have, a questionnaire was conducted.

The pre-service teachers have very different expectations. It is impossible to meet them all at the same time. Therefore, some compromises must be made between the following three juxtapositions.

Figure 4. Do the materials of the project meet your expectations?

Short information vs. exact description: One point that was raised in the open section of the questionnaire was the amount of text in the teachers' guide that had to be read. The desire for shortening and simplification is understandable. However, the problem with this is that something always gets lost when things are shortened. This contradicts the goal of carrying out the teaching as intended.

Easy adaptability vs. intended structure: It is great that pre-service teachers are willing to invest time for adaptation to the respective learning groups. To enable them to meet the needs of their pupils, it would be desirable to provide an easily modifiable format. However, the worksheets are based on findings from the literature and have been evaluated before dissemination. Therefore, revising the worksheets is not always desirable from the authors' perspective.

Student-oriented vs. scientific-oriented: The questionnaire revealed that pre-service teachers tend to prioritise simplification and children's enjoyment. They focus mainly on the children and their experiences when planning lessons and teaching. Content and scientific concepts play a minor role. This approach disadvantages children from educationally disadvantaged backgrounds (Fölling-Albers, 2022). The project materials are intended to support the currently required addition of a science orientation to the curriculum.

However, there are some questions open. It is still unclear what motivates (pre-service) teachers to engage more intensively or in greater detail with the materials. How long do teachers need to decide for or against this? In any case, the successful combination of professional development courses with the distribution of materials can be relied upon (Lipowsky & Rzejak, 2021).

ESERA 2025 Copenhagen

Exploring Science Through Screens: An Analysis Of Mobile Apps For Preschoolers

Melek Merve Yilmaz
Çukurova University, Turkey

Mobile applications are becoming an increasingly common part of the everyday experience of preschool children, including their encounters with science-related content. However, the pedagogical structure of these digital environments has not yet been adequately examined. This study explores how scientific content is presented in mobile apps designed for early childhood education. A qualitative content analysis was conducted on 14 science-themed apps, which were selected through a systematic search of the Apple App Store and Google Play Store between December 2024 and January 2025. The analysis focused on five dimensions: Scientific content; pedagogical appropriateness; motivation; inclusivity; and science communication. The findings suggest that life science themes (e.g. plants, animals and life cycles) are more prevalent than physical or earth science topics. Applications commonly include visually rich, reward-based interaction patterns that may help to sustain engagement. However, explicit conceptual explanations, scaffolded guidance and opportunities for dialogic or inquiry-based interaction are limited within the apps themselves. Feedback structures generally focus on task completion rather than reasoning processes. Inclusive representations are present in some cases, but not systematically. Overall, the apps appear to provide exposure to scientific phenomena, while features associated with deeper conceptual support are less visible. This study provides a descriptive overview of current design trends and could inform future research and development efforts aimed at enhancing the pedagogical quality of digital science experiences in early childhood.

Keywords: Early Childhood Science; Educational Apps; Mobile Learning; Science Communication; Preschool STEM

Introduction

Young children are inherently curious, driven by an intrinsic desire to explore and make sense of the world around them (Jirout & Klahr, 2012). Research characterizes preschoolers as little scientists who actively seek to understand biological and physical phenomena through observation and explanation (Gopnik, 2012; Zimmerman, 2007). From early childhood, children display sustained interest in how nature works, positioning science as a particularly meaningful domain within early education (French, 2004). Engagement with scientific content can further stimulate this curiosity. Studies indicate that exposure to science topics increases children's motivation to learn and supports the development of scientific vocabulary and discourse (Oppermann et al., 2018; Peterson & French, 2008). With digital technologies becoming an integral part of life today, mobile applications offered on smartphones and tablets are among the primary environments where children can interact with science.

In contemporary childhood, digital technologies—particularly mobile applications on tablets and smartphones—have become prominent environments where children encounter scientific ideas. The National Association for the Education of Young Children emphasizes that technology and interactive media can be valuable learning tools when used intentionally and in developmentally appropriate ways (NAEYC & Fred Rogers Center, 2012). Empirical studies support this position, showing that well-designed digital experiences can positively influence learning outcomes in early childhood (Bullock et al., 2017; Xie et al., 2018). Touchscreen educational apps, for instance, have produced meaningful gains in early literacy and mathematics (Griffith et al., 2020; Outhwaite et al., 2022). Within science education specifically, research demonstrates that

preschoolers can learn new factual information through interactive apps as effectively as through direct instruction (Kwok et al., 2016) and that mobile game contexts can support understanding of physical science concepts such as projectile motion (Herodotou, 2018). These findings suggest that thoughtfully designed science apps have the potential to enhance conceptual learning and scientific understanding during early childhood.

Contemporary evidence suggests that pre-school children spend around 2–3 hours a day on screen-based activities (Chang et al., 2018; McNeill et al., 2019), devoting almost an hour of this time to using mobile apps (Rideout & Robb, 2020). This level of exposure highlights the important role that app design plays in shaping early learning environments. When used in supportive contexts, educational technology can meaningfully contribute to early childhood development and learning (Clements et al., 2024). Consequently, the pedagogical quality of mobile applications, particularly those accessed via tablets and smartphones, becomes a central concern in early education research. Despite this extensive engagement, there is limited systematic knowledge about the scientific content that children encounter in mobile apps. In Turkey, there is a notable absence of comprehensive analyses examining the science-related content of children's mobile applications. A recent study evaluating STEM-oriented mobile apps (Konca et al., 2024) found that most of the apps were in English and that evaluations focused primarily on general app features rather than the scientific content, conceptual accuracy or science communication practices. Consequently, our understanding of how science is represented, structured and communicated in digital environments frequently accessed by young children is inadequate. A comprehensive examination of the scientific content embedded in preschool mobile apps is therefore necessary. Such analyses could shed light on the current state of digital science learning environments and provide a foundation of evidence to guide parents, educators, and developers in creating developmentally meaningful and pedagogically sound early science experiences.

Method

This study employed qualitative content analysis to examine mobile applications designed for preschool children (aged 3–6) that contain science-related content. A systematic search of the Apple App Store (iOS) and Google Play Store (Android) was conducted between December 2024 and January 2025. Search terms included science, ages 3–6, preschool, early childhood, and popular. Additional scans were conducted within the Education and Kids categories, and the most downloaded and highest-rated children's applications were examined. The search and selection procedures were documented to ensure transparency and reproducibility of the sampling process.

Applications were included if they explicitly contained scientific content (e.g. topics related to life sciences, physics, or earth sciences) and targeted an early childhood audience. Applications that focused solely on general early learning without science-related components were excluded. Based on these criteria, 20 applications met the initial inclusion threshold. The sample included both free and paid applications that were widely used by children in Turkey, ensuring that the analysed content resembled real-life usage contexts. Although 20 applications met the initial search criteria, a secondary eligibility screening was conducted during the coding phase to ensure that apps contained accessible science content relevant to preschool learners. Applications in which science-related sections were locked behind paywalls, lacked substantive science content despite categorical labeling, or targeted broader age ranges without developmentally appropriate science activities were excluded from full analysis. Following this refinement, 14 applications constituted the final analytical sample. This step enhanced the ecological validity of the content analysis by ensuring that findings reflected children's actual exposure to science-related

experiences within apps. Table 1 presents the final set of applications included in the analysis, along with their primary science domain classifications.

Table 1. Primary dcience domains represented in the analysed preschool science apps.

App Name	Primary Science Domain
MarcoPolo Weather	Earth Science (weather, seasons, atmosphere)
TRT Çocuk Anaokulum	Mixed (plants, animals, environment)
Sevimli Dostlar	Life Science (animals, plant growth, health themes)
What's in the Ocean	Life Science (marine life, ecosystems, food chains)
Caillou	Life Science (living–nonliving, plant/animal care)
TRT Çocuk Oyun Dünyası	Mixed (plant growth activities)
Farm Games for Kids	Life Science (farming, animals, food sources)
Animal Farm for Kids	Life Science (farm animals, habitats)
Minikler için Eğitici Oyunlar	Life Science (animals, plants)
Playo	Mixed (nature, weather, environmental elements)
Maşa ile Koca Ayı	Life Science (farming, animals, plant growth)
Eşle ve Öğren	Life Science (animals, plants)
TRT Kare	Mixed (day–night, hot–cold)
Science Games	Mixed (life cycles, states of matter, space themes)

The coding framework followed a conventional qualitative content analysis approach as described by Hsieh and Shannon (2005). Rather than applying a predefined coding scheme, codes emerged through repeated interaction with the apps, enabling patterns specific to preschool science applications to be identified. At the same time, existing academic work in early childhood education and digital learning provided theoretical guidance without constraining interpretation (e.g. Bruner & Kúcelová, 2024; Callaghan & Reich, 2018; Clements et al., 2024). This approach ensured that the analysis remained data-driven while aligned with existing research on educational media and early science learning. The coding framework consisted of five categories: Scientific Content, Pedagogical Suitability, Motivation, Inclusivity, and Science Communication. Subcodes addressed conceptual accuracy, misconceptions, scaffolding, reward structures, diverse representation, accessibility, and communication models.

The analysis was conducted by two coders. The primary coder engaged with each application for approximately 15–20 minutes, systematically documenting interface structure, task flow, and science-related content. Code definitions were subsequently refined. The second coder was trained on the framework, and both coders jointly coded five pilot applications to calibrate code application. The second coder then independently coded 30% of the sample. Disagreements were discussed and resolved, resulting in a final coding scheme with explicit definitions. Inter-coder reliability was high (Cohen's $\kappa = .94$). Analytical notes were used to identify cross-case patterns.

This study involved analysing publicly accessible digital applications and did not include human participants, personal data or identifiable user information. Accordingly, formal ethical approval and informed consent procedures were not required in accordance with institutional research ethics guidelines.

Results

The results are organized according to the five analytical dimensions guiding the coding framework: Scientific Content, Pedagogical Appropriateness, Motivation, Inclusivity, and Science Communication.

Scientific Content

The analysed applications were dominated by life sciences content. Most of the applications focused on biological and nature-related themes, such as plants, animals and health. Gardening simulations were popular, involving children planting seeds and watering the soil, before observing fruits or vegetables appear almost instantly, sometimes after just one interaction. Despite these accelerated representations, some applications presented scientifically accurate concepts. For instance, the app depicted in Figure 1 accurately positioned roots and shoots to depict plant growth, correctly representing both underground and above-ground structures. Animal themes were also prevalent, ranging from farm animals to insects. Many applications included repetitive sequences, such as life cycles or the stages of vegetable cultivation. Figure 2 illustrates the human life cycle, and the same application presents the life cycles of butterflies and frogs, visually highlighting the differences between species. While these topics were consistent with children's familiarity with nature and living organisms, the limited diversity of disciplines was evident. Content related to physics and earth sciences was scarce, suggesting that the applications primarily focused on life sciences.

Figure 1.

Accurately positioned vegetables

Figure 2.

Human life cycle

Although the apps generally aimed to present accurate information, various forms of scientific inaccuracy were observed. A common pattern was the oversimplification of processes. In particular, instantaneous depictions of plant growth misrepresented the temporal dimension of biological development. Anthropomorphic representations were also frequent. For example, in one app a *queen bee* character appeared dressed in human clothing and behaved as a royal figure. Figure 3 shows a crowned cartoon bee character illustrating this type of representation.

Figure 3.

Anthropomorphic Bee Character

Figure 4.

Sunlight and Microorganism

Furthermore, some scientifically grounded phenomena were presented in a way that could lead to misunderstandings. In one app, for example, children were asked to hang out the washing and position it so that it would receive sunlight. The drying process was shown gradually. However, the underlying mechanism of heat transfer was not explicitly represented. In the same section, when the children zoomed in on the clothes, visual depictions of microorganisms appeared and then disappeared when the sunlight icons were shown (see Figure 4). Scientific literature indicates that sunlight can reduce the survival of pathogens and the risk of infection (Hobday & Dancer, 2013). In this section, relevant concepts were linked to observable outcomes, but cause-and-effect relationships were not explicitly defined. Consequently, the representations operated through surface-level causal framing rather than mechanistic explanation. Using sunlight icons as visual representations may evoke the idea of sunlight as tangible particles, which could lead to conceptual misunderstandings.

Pedagogical Appropriateness

Each app's design was examined in terms of its alignment with developmentally appropriate practices for preschoolers. The majority of apps maintained simple interfaces and instructions, minimizing text and relying primarily on visual elements, icons, and audio cues. These design features align with the early literacy levels typical of preschool children. However, the depth of learning observed across apps was generally limited. Built-in progression mechanisms that extend learning beyond basic task completion were scarce. Gradual increases in difficulty and the introduction of more complex concepts in later stages were rarely observed.

In most apps, the cognitive demand of tasks remained relatively constant, while different life science concepts were introduced across successive sections. The sequence of concepts appeared to move from topics likely to be more familiar to children (e.g., plant cultivation) toward less familiar domains (such as fishing, beekeeping, and sheep shearing). Later stages included more specific contextual concepts. For instance, one app presented a task requiring drainage of water accumulated around a cherry tree following rainfall. In this section, children were required to complete the action correctly before progressing. However, the concept of *drainage* was not explicitly named in text or speech; the process was presented solely as a task-based interaction. In such cases, concepts were embedded within activities but were not accompanied by explicit conceptual labelling or integrated explanation.

Another dimension of pedagogical design concerns how apps guide children during learning. Educational applications for preschoolers are typically expected to provide scaffolding through hints, modelling, or feedback that supports learning from mistakes. Most apps in the sample adopted a trial-and-error approach. Children could interact freely, correct actions were reinforced through positive feedback, whereas incorrect actions were typically addressed through brief auditory cues or simple redirection. Instances of explanatory feedback were not observed. This pattern indicates that opportunities for explicit conceptual clarification were limited within the apps' feedback structures.

Motivation

Consistent motivational design features were observed in all applications. One such feature was the widespread use of instant feedback systems. Almost all applications reinforced children's actions with lively sounds, animations and celebratory visual elements. Upon completing a task, stars, music or enthusiastic character reactions were often displayed on the screen to provide immediate reinforcement (see Figure 5). These feedback events occurred rapidly and at frequent intervals throughout interactions. Reward structures extended beyond symbolic indicators. Many apps incorporated progression-based systems that unlocked new content or virtual collectibles upon completing a level. Gamification elements such as points, badges and level advancement made progress visible within the app environment. Stars were particularly common as a performance marker, serving as a visual representation of achievement (see Figure 6).

The narrative framework and character design further supported interaction. Various activity formats and animated characters were widely used. Some apps featured well-known characters that children would recognise from YouTube, cartoons or books. This placed learning activities within familiar narrative contexts. In such cases, these characters served as guides or participants in science-related activities. Several applications featured adaptive pacing, where the transition speed or task flow changed based on the child's interaction speed. Although not common, these design models were present in multiple applications. Elements supporting autonomy were also present, allowing children to select activity centres within the application and choose between different characters or task paths.

Figure 5.

Instant celebratory feedback

Figure 6.

Star-based reward

Inclusivity

The inclusivity analysis addressed both on-screen representation and accessibility for diverse users. In terms of representation, the diversity of characters and contexts was limited across most of the apps. Many featured animal protagonists or generic cartoon children without clearly identifiable racial or cultural backgrounds. When human characters were present, some degree of gender diversity was evident. However, only one app in the sample displayed more explicit inclusive representation. In this underwater exploration-themed app, the diver characters were portrayed as a girl and a boy. One character was depicted as a light-skinned boy and the other as a dark-skinned girl. The characters worked together and had equal roles in scientific exploration. In this example, both gender and ethnic diversity were visually represented. However, none of the apps addressed cultural dimensions of science, such as scientists from different parts of the world or references to traditional knowledge systems. Notably, there were no characters with visible disabilities. There were no depictions of mobility aids or assistive devices, nor any scenarios reflecting differently abled individuals. Overall, these preschool science apps appeared to depict a relatively homogeneous landscape, largely reflecting able-bodied and Western-oriented contexts.

Science Communication

The apps were examined to see how scientific information was presented, and whether children were encouraged to engage in scientific reasoning or dialogue. Overall, the apps were found to follow a one-way 'show-and-tell' approach, which is consistent with a deficit model of science communication. Information or outcomes were usually presented for the child to absorb, rather than encouraging active thinking or inquiry. For instance, in one app, when a child waters a virtual plant, the narration says, 'Let's water it so it can grow', accompanied by a watering icon. However, the child is not asked to consider how or why this process occurs. Although the communication format was embedded within interactive gameplay, it was largely scripted and instructional in nature. No dialogic communication model, in which children are asked open-ended questions or encouraged to express their ideas, was observed. Interactive elements such as reasoning-based multiple-choice prompts (e.g. 'Why do you think this happens?') were not present. A participatory communication model, in which children record observations, make predictions or freely explore and draw conclusions, only appeared in limited forms. Some apps included sandbox-style exploration areas where children could mix materials and observe the results. However, even in these cases, the apps did not provide scientific explanations for the phenomena observed.

Scientific content was predominantly conveyed through visual and animated representations. Processes such as seed germination were demonstrated through animation. However, these representations did not incorporate explanatory dialogue or conceptual justification. In summary, science communication in preschool science apps was characterised primarily by one-directional information delivery. While the apps focused on demonstrating phenomena, there were limited opportunities for interaction requiring questioning, explanation or verbalisation of ideas.

Discussion

The analysis of 14 preschool-oriented science applications indicates the presence of highly engaging yet pedagogically under-supported digital learning environments. The findings suggest that while these applications increase children’s access to scientific content, they remain limited in meeting core principles of early childhood science learning. One of the major strengths of the apps is accessibility. Consistent with research demonstrating that children can acquire scientific knowledge through interactive media (Kwok et al., 2016), the apps provide exposure to scientific concepts that children might not encounter before formal schooling. The predominance of life science themes reflects developers’ tendency to capitalize on young children’s natural interest in animals and plants. However, the limited representation of physical and earth sciences points to a narrow interdisciplinary scope. Early childhood science education aims for a balanced distribution of domains, including physical science concepts such as forces and materials (French, 2004). The current distribution may reinforce, for preschool children who spend extensive time with apps, the perception that science is primarily equivalent to nature.

The anthropomorphic representations and depictions of instantaneous biological processes observed in the apps raise pedagogical concerns regarding potential misconceptions. Anthropomorphic narratives can enhance engagement and may even foster positive attitudes toward animals (Reider & LoBue, 2024). However, Bonus and Mares (2019) demonstrated that preschool children’s ability to evaluate the reality status of information presented in educational videos is associated with learning and transfer, suggesting that distinguishing real from fictional elements may not be straightforward for young learners. In most of the apps analysed, this distinction was not explicitly clarified. This finding aligns with early childhood teachers’

concerns that anthropomorphism may contribute to cognitive confusion (Kallery & Psillos, 2004). Given that misconceptions acquired in early childhood can persist over time, clearer separation between anthropomorphic elements and scientific explanations becomes essential.

Motivational design features constitute one of the strongest aspects of these applications. Frequent rewards, gamified progression, and celebratory feedback mechanisms help sustain children's engagement. Positive emotional experiences with science in early childhood are known to support later motivation for science learning (Jirout & Klahr, 2012). Nevertheless, the intensive use of extrinsic rewards raises questions regarding depth of learning. In edutainment designs where game elements are appended as external rewards to learning elements (e.g., *the chocolate-covered broccoli* approach), attention and flow may shift from educational goals to game goals. Indeed, lower levels of learning-task engagement have been reported under extrinsic design conditions. In contrast, the intrinsic integration approach, in which learning content and game mechanics are structurally unified, enables motivation and cognitive engagement to align toward the same objectives, resulting in a more balanced learning experience (Habgood & Ainsworth, 2011).

Another critical limitation concerns feedback structures. While apps celebrate correct responses, they rarely explain why incorrect responses are wrong. Encouraging children to explain phenomena is known to strengthen conceptual understanding (Zimmerman, 2007). Transforming errors into explanatory learning opportunities could more effectively connect motivation with learning processes. Regarding inclusivity, the findings parallel broader trends in children's digital media. Although gender representation appeared relatively balanced, ethnic diversity and representations of disability were largely absent, aligning with research indicating limited diversity in preschool applications (Bruner & Kucirkova, 2024). The analysis also showed that characters were predominantly animals or humans. This may be coded as a potentially inclusive feature, as animal characters can serve as culturally neutral figures that transcend specific social identities (Williams, 2014).

The most prominent pedagogical gap emerged in the domain of science communication. The apps predominantly adopted one-directional information delivery. Phenomena were visually presented, yet opportunities for questioning, explanation, and dialogic interaction were limited. Early science education literature emphasizes that guided inquiry and conversational exchanges are critical for conceptual development (Peterson & French, 2008). The absence of such dialogic processes may result in these apps functioning more as visual information sources than as interactive learning tools.

Limitations and Implications

This study is based on a qualitative content analysis examining the pedagogical structure of science-focused mobile applications designed for the preschool age group, and therefore carries several limitations. First, the sample was limited to 14 applications selected through a systematic search conducted between December 2024 and January 2025 on the Apple App Store and Google Play Store. Given the dynamic nature of app ecosystems, rankings, visibility, and availability of applications may change over time. Accordingly, the findings represent a snapshot of popular content within a specific time frame. Second, the study did not include direct measurement of children's learning outcomes. Evaluations were grounded in expert interpretation of app content features, pedagogical design elements, and the early childhood science education literature. Therefore, the results offer inferences about the potential learning affordances of the applications but do not experimentally verify actual learning gains. Third, the analysis focused on the design characteristics of the applications, without examining how children and caregivers experience these apps in naturalistic use contexts. App engagement is shaped by multiple factors, including

adult guidance, duration of use, contextual support, and individual child characteristics. As such, discrepancies may exist between the pedagogical potential identified in the design and the learning experiences that occur in real-life usage.

Despite these limitations, the study provides important implications regarding current pedagogical tendencies in preschool science applications. The findings indicate that while digital designs are strong in motivational engagement, they remain underdeveloped in conceptual structuring, dialogic learning opportunities, and inclusive representation. This suggests a need for digital learning experiences to align more closely with established principles of effective early childhood science education.

Finally, collaborations among researchers, app developers, and educators may enable research findings to more directly inform design processes. Such interdisciplinary approaches are critical for enhancing the pedagogical quality of digital science environments developed for early childhood learners.

Creative Sparks And Constructive Tensions: How Resistance Shapes Young Children's Collaborative Engineering Design

Alison K. Mercier and Mia Kim Williams
University of Wyoming, United States

This study examines how young children demonstrate creativity during collaborative engineering design tasks in early childhood education. Using a basic qualitative approach, researchers observed 17 children (ages 4-7.5 years) engaged in engineering projects at a Montessori summer program. Analysis of conversations during a shelter design task revealed both conventional aspects of creativity (novelty, risk-taking, variety) and an unexpected element: resistance. Rather than impeding progress, instances of resistance—where children challenged each other's ideas—served as catalysts for creative development and solution refinement. Children's resistance fostered deeper engagement with design constraints and facilitated collaborative problem-solving. For example, when children resisted certain design choices, it led to more sophisticated considerations of material properties and physical concepts like light and shadow. These findings suggest that constructive resistance should be recognized as an integral component of creative development in early childhood engineering education, with implications for both research and practice in STEM education

Keywords: Early childhood education, engineering education, critical thinking

Introduction

Engineering education in early childhood has been increasingly recognized as a valuable component of young children's development, yet it remains relatively underexplored in both research and practice (Cunningham & Kelly, 2017). While much attention has been given to literacy and numeracy, the integration of engineering concepts in early education provides unique opportunities for fostering creativity and problem-solving skills among young learners. Early childhood engineering activities, such as building structures, designing simple machines, or experimenting with materials, allow children to explore the world around them in innovative ways, thus laying a foundation for later STEM learning (Moore et al., 2019). Despite this potential, the creative processes children engage in during these activities are often disregarded as valuable (Bolden et al., 2020). In this study resistance appears as an unanticipated analytic finding, emerging as a productive form of participation through which children challenged ideas, negotiated design decisions, and advanced creative engineering thinking.

Framework And Relevant Literature

Creativity is foundational to human development, extensively studied and valued in educational contexts (Rhodes, 1961). Contemporary research underscores it's vital role in fostering critical thinking, problem-solving, and innovation—abilities essential for navigating future complexities (Beghetto & Kaufman, 2017). Defined by divergent thinking, originality, flexibility, and the ability to generate novel solutions, creativity engages multiple brain networks and can be cultivated through intentional educational interventions (Runco, 2014). Notably, resistance, characterized as constructive challenges to ideas, enhances creativity by fostering reflection, idea refinement, and collaborative problem-solving. Pedagogical strategies promoting autonomy, exploration, risk-taking, and constructive resistance effectively nurture creativity across disciplines and educational levels (Beghetto & Kaufman, 2017).

In early childhood education, creativity holds significance as it aligns with young children's inherent tendencies toward imaginative play and exploration. These formative years of peak neural plasticity, provide an optimal period to cultivate creativity (Mohammed, 2018). Imaginative play and exploration underpin cognitive flexibility, problem-solving skills, and emotional regulation (Stoltz et al., 2015). Resistance, through questioning and rethinking, aligns with young learners' propensity to experiment with ideas, challenge peers, and refine their thinking. Play-based learning environments significantly shape creative development, with STEM education offering unique opportunities to integrate creativity. Activities in engineering design, scientific inquiry, and mathematical problem-solving not only require creative thinking but also foster deeper conceptual understanding, engagement, spatial reasoning, and knowledge retention (Stoltz et al., 2015).

Engineering tasks encourage young children to practice divergent thinking, while building critical and emotional skills necessary for future challenges (Moore et al., 2019). These activities support children's curiosity, adaptability, and resilience by prompting (Mohammed, 2018). Resistance plays a central role as children debate ideas, challenge designs, and refine solutions. For instance, questioning material choices or debating structural elements leads to deeper engagement and innovation. Understanding creativity in early childhood STEM education, including the role of resistance, equips educators to design inclusive, engaging experiences that foster creativity and prepare learners for lifelong innovation (Mohammed, 2018).

Creativity In Early Childhood STEM And Engineering Contexts

Creativity in early childhood is central to engagement in STEM and engineering education. Across the literature, creativity is consistently defined as the capacity to generate ideas that are both original and appropriate to the task at hand (Dow, 2022; Joubert, 2022; Peterson & French, 2021; Sternberg & Lubart, 1999). In STEM contexts, creativity manifests through problem-solving, experimentation, and iterative design processes that encourage young children to explore, question, and make sense of the world around them (Lippard et al., 2017; French, 2018).

Many argue that engineering design is a fertile context for fostering creative thinking in young learners. Studies have shown that when children are engaged in design challenges, they naturally exhibit engineering habits of mind like persistence, systems thinking, and creativity (Peterson, 2019; Lippard et al., 2017). This kind of thinking is nurtured through open-ended materials, child-directed inquiry, and opportunities for iteration (Murcia et al., 2022; Simoncini & Lasen, 2018). Creative markers in children's engineering and design work include novel uses of materials, original approaches to solving problems, and verbal or visual expressions that reflect children's reasoning and imagination (Tippett & Gonzalez, 2022; Kuhn et al., n.d.).

Resistance In Young Children's Engineering

Resistance in young children's collaborative group work and engineering activities can be both a site of tension and a source of generative potential. Resistance is not simply oppositional behaviour, but a legitimate form of agency wherein children assert their autonomy, question authority, and reshape their roles in learning environments (Rainio, 2008). Often emerging in social contexts where children encounter externally imposed structures or expectations, resistance shapes how children respond to such events as a teacher's vision for classroom norms or a group's idea of how a project should unfold. Rather than viewing resistance as defiance to be managed or eliminated, Rainio (2008) suggests that it can be a creative, transformative force. In the playworld studied, for example, a child's initial resistance evolved into meaningful participation once the activity allowed space for narrative flexibility and individual investment (Rainio, 2008). Similarly, Litvinaitė (2022) situates resistance within the broader context of cultural negotiation,

arguing that resistance can be a productive force that disrupts cultural reproduction and fosters hybrid ways of working and knowing. These insights align with sociocultural views that see agency as emergent from interaction, with resistance offering children opportunities to reconfigure the social and intellectual terms of engagement (Stetsenko & Ho, 2018; Vygotsky, 1978).

In the context of collaboration among young children, especially in early childhood engineering education, resistance may manifest as silence, withdrawal, refusal to follow peers' ideas, or challenging the assumptions embedded in others' proposals (Perumal, 2008; Rainio, 2008). The literature highlights how this behaviour is not necessarily unproductive. Instead, it signals that children are negotiating the norms of participation, authority, and identity within a group. Perumal (2008) emphasized that resistance in collaborative learning contexts often emerges as a response to the shift from passive reception to active engagement, particularly when students are asked to share cognitive or social authority. For young children in engineering tasks, this could look like questioning the utility of a peer's design, insisting on using an unconventional material, or rejecting a plan that doesn't align with their sense of how something should work. While these moments may appear disruptive, they can also prompt critical reflection, negotiation, and innovation within the group. Here, resistance is not a barrier to collaboration, it is a mode through which collaboration can be deepened and made more authentic.

Within early childhood engineering, resistance has particular affordances to advance thinking and design processes. Engineering design is inherently iterative, requiring testing, failure, and re-design (Cunningham & Kelly, 2017). When children resist a suggested solution or choose not to go along with a group consensus, they are engaging in critical evaluation and proposing alternative pathways. Litvinaitė (2022) describes how resistance can lead to greater creativity and the reconfiguration of roles and norms, allowing children to move beyond reproduction of adult-expected designs and toward genuine invention. Rainio (2008) and Perumal (2008) both argue that when children are given space to resist, new forms of agency and understanding emerge. In engineering tasks, this might include a child refusing to use an adult-suggested material because it does not meet the demands of their imagined function, or a child insisting that a tower's stability matters more than height. These actions reveal a depth of engagement with engineering concepts and an investment in the process that extends beyond compliance. Resistance serves as a catalyst for learning, identity development, and the cultivation of collaborative engineering mindsets.

Research Aim And Questions

The following question guided the study:

- How do young children demonstrate creativity when engaged in collaborative engineering design tasks?

Methodology And Research Methods

This study was conducted using a basic qualitative research approach, which allowed for close examination of how young children demonstrated creativity while engaging in collaborative engineering design tasks (Merriam, 2009). This methodology was well-suited to our focus on how children expressed themselves and made meaning through their talk, actions, and shared design experiences. Our goal was to better understand the character of children's creative participation during a summer engineering program. To do so, we analysed transcripts of audio recordings, design products, and interviews with participating children to explore their experiences with and expressions of creativity in engineering contexts (Merriam, 2009).

Context And Participants

The study took place over a five-day period during a summer enrichment program hosted by a public Montessori charter school located in a small community in the Mountain West region. This school, guided by Montessori principles such as hands-on learning, mixed-age classrooms, and learner-directed inquiry, offers year-round learning opportunities (Lillard, 2012, 2017). The summer programming retained these values, offering a flexible and supportive setting for continued exploration and play.

Twenty-four children were enrolled in the week-long program, although attendance varied by day. Participants ranged from nearly four years old to seven and a half years old, with the group comprising eight boys and sixteen girls. For engineering activities, students were grouped into teams of three or four by Montessori staff, who used their familiarity with the students' social skills and dynamics to create mixed-age, mixed-gender groupings.

Engineering Programming

The engineering curriculum used in the study was developed and facilitated by the research team rather than the classroom teachers, who remained in observational roles when present. A member of the research team with a strong background in early childhood and elementary teaching led the activities to ensure both developmental suitability and sound pedagogy. Each day began with a full-group session to introduce the engineering challenge, followed by group-based building and problem-solving. The engineering sessions ran for roughly three hours daily over the five-day period, giving children time to iterate on their designs, build social and collaborative skills, and interact with STEM ideas in tangible ways. The week's activities were adapted from the *Engineering is Elementary* (EiE) Kindergarten curriculum from the Museum of Science, Boston (Museum of Science, Boston, n.d.). The EiE curriculum supports young learners in exploring engineering through structured but age-appropriate tasks that emphasize the design cycle (Ask, Imagine, Plan, Create, Improve), real-world connections, and teamwork (Museum of Science, Boston, n.d.). These elements aligned naturally with Montessori educational goals, which value hands-on work, guided autonomy, and collaborative exploration (Cunningham & Lachapelle, 2014; Lillard, 2016). This alignment enabled smooth integration of engineering into an already inquiry-rich learning environment.

Two EiE units were selected and modified to shape the program: *Here's the Scoop: Designing Trash Collectors* (2018) and *Raise the Roof: Designing Shelters* (2018). The former served as an introduction to testing materials and iterative building in a fun, low-stakes activity. Later in the week, students tackled the shelter-building challenge, which was especially relevant due to a concurrent heat wave. This context helped students see how engineering could solve real-life problems and invited engagement with key scientific and design concepts like heat management, material properties, and structural integrity. The engineering curriculum was thoughtfully designed to root children's creativity in personally meaningful and relevant challenges.

Data Collection

Throughout the week, we audio-recorded all engineering sessions, including morning introductions, small-group work, and end-of-day reflections. Altogether, these recordings totaled over 18 hours. For this study, we concentrated our analysis on approximately six hours of audio captured during the small-group sessions of the *Raise the Roof* activity. This portion of the week's work was selected because it featured rich collaborative interactions, prolonged problem-solving efforts, and dynamic engagement with engineering practices. It provided a particularly strong window into children's creative and social participation.

Data Analysis

We focused our analysis on eight transcripts capturing children's dialogue and collaboration during the *Raise the Roof* engineering task, which asked them to design a sun shelter for a stuffed dog. All audio was transcribed verbatim to preserve the details of the children's language (Saldaña, 2016). We began with a deductive coding framework drawn from the OECD creativity rubric (OECD, n.d.) and the creativity domain of the engineering habits of mind framework (Lippard et al., 2019), both of which view creativity as a process. These initial codes are shown in Table 1.

To begin coding, each researcher individually analysed Transcript #1 using these predetermined codes while also engaging in open coding to allow for emergent insights (Strauss & Corbin, 1998). When we compared our initial codes, inconsistencies emerged, prompting a collaborative process of code refinement. Through discussion, we clarified and revised code definitions, resolved overlapping categories, and added new inductive codes (e.g., such as *resistance* and *uncertainty*) that captured additional nuances in the children's collaborative problem-solving (Charmaz, 2014; Patton, 2002; Strauss & Corbin, 1998).

We then recoded the first transcript using this revised codebook and assessed the alignment of our coding through axial coding techniques (Saldaña, 2016; Strauss & Corbin, 1998). This second round produced much greater consistency among team members. When discrepancies remained, we discussed them until consensus was reached. Using this finalized coding scheme, we independently analysed the remaining seven transcripts. Afterward, we met again to compare our coding results and resolve any further disagreements (Miles et al., 2014; Saldaña, 2016).

Following this final round of coding, we reviewed all coded excerpts and annotated them with interpretations about how they contributed to the unfolding creativity of the design process. This interpretive step helped us identify the ways specific moments and decisions advanced the children's learning and innovation (Braun & Clarke, 2006). We then grouped data by code and examined how themes intersected across categories. Through ongoing collaborative discussion, we refined these cross-code patterns to generate consistent, well-supported themes in our final analysis (MacQueen et al., 1998; Saldaña, 2016).

Results

Across our analysis of the children's dialogue during the engineering task, as they designed and constructed a shelter to keep a dog cool in the sun, we observed the presence of creativity aligned with expected markers. Children generated a variety of novel ideas (coded as *variety* and *novel*), often building on or combining others' contributions in flexible and exploratory ways. They demonstrated risk-taking behaviours, particularly when sharing uncertain or unconventional suggestions (coded as *risk*), and frequently introduced radically new ideas that shifted their group's design trajectory entirely (coded as *radical*). In many instances, children's ideas were grounded in scientific disciplinary knowledge (coded as *connected*), such as reasoning about heat absorption, material properties, or the relationship between structure and function. These connections not only enriched their design justifications but also highlighted how disciplinary thinking supported creativity during engineering. Table 1 (next page) gives examples of each of these markers of creativity, how they surfaced in the data, and how they shaped the engineering design.

In addition to the more expected markers of creativity, a new and unexpected theme emerged during our coding and analysis process – *resistance*. While not initially framed as a tenet of creativity in the literature, resistance surfaced as a meaningful form of participation and marker of young children's creativity when engaged in engineering. At times, children pushed back on

each other's suggestions, on design directions, or on the pace of decision-making. Rather than halting progress, this resistance often served to sharpen the group's thinking, slow the rush to consensus, and open space for further elaboration or clarification. In this way, resistance appeared not as a barrier, but as a generative force in the collaborative creative process, shaping how and when new ideas were taken up and how designs evolved.

Table 1. Markers of creativity, examples from the data, and descriptions of how the engineering design was shaped.

Marker of Creativity	Children's Quote from the Data	How the Process was Shaped
Variety	We could put it in the middle and one of us could wrap the tape around to make it stay (Child 14)	Adding on to an existing idea and design choice, pushing the process forward
Novelty	How about we make a circle, a door… (Child 2)	Proposes a new idea to the group, shifting the design ideas and process
Connected	That's, that's, is that skin? (Child 5)	Links knowledge about skin to properties of materials to enable materials choices
Risk	And we, and we might use that (Child 8)	Proses a new material, previously untested and undiscussed, pausing the group to weigh options
Radical	Why the middle? How would it get in the middle? We could just do it on the side and make it cute (Child 1)	Questions the design idea and suggests a change, changing the direction of the original design

We interpreted moments of resistance as instances of critical collaboration, or points in the design process when the children actively contested ideas. These expressions, which were sometimes subtle and occurred less often than other, more prominent themes, reflected important dimensions of creative agency. Rather than simply obstructing progress, children's resistance shaped the course of group decision-making and design development. Children voiced disagreement through short statements (e.g., "No," or "I don't think that will work") to pause the activity, to prompt reconsideration, or questioned material selections, placements, or strategies based. In some cases, doubt was articulated through reasoning tied to prior knowledge or lived experience. The excerpt below illustrates how resistance functioned as a productive and generative part of the engineering process:

Child 5:	Where is the other piece? The other part you wanted to put here?	
Child 6:	I've got a shadow!	*Connected*
Child 5:	No.	*Resistance*
	I don't think that will work	*Resistance*

	this side can't go here	
	it has to be all the way down to the ground	*Novelty*
Child 6:	Careful	*Connected*
	we almost made Penny hot	
Child 4:	To get in there	
Child 6:	We need shadows for Penny	*Connected*
Child 7:	Not yet	*Resistance*
	not there	
Child 6:	[Child 2] what do we do now?	
Child 5:	Okay, sir	*Novelty*
	What about this?	
	Use this?	
Child 6:	AHHHHH!	
	Yes.	
	That would be a good choice	

Resistance was purposeful. This is highlighted by Child 7 saying, "Not yet", implying a thoughtful response that indicated the proposed action did not align with the current stage of their process. Resistance did not derail the project or the design choices, it helped children refine their ideas. Some instances of resistance, like in the excerpt above, prompted shifts in direction of ideas and work, drawing the group's attention toward alternative possibilities. In other cases, work briefly paused as children explored alternative lines of reasoning or tried new possibilities. For example, when Child 6 said "No. Guys, hold on. This right here, do this…" the design process and engineering were paused to entertain a new idea. Only a few times did the resistance move the project seemingly backwards. In these cases, the resistance was purposeful action to undo a decision or take an idea apart. This was illustrated by Child 1 when they said, "Wait, stop, stop. We can't do that. We could take that apart…" Even actions that appeared to reverse progress (e.g., dismantling part of the structure) functioned as intentional moves toward refinement and improvement.

Resistance created tension which, in turn, sometimes sparkled deliberation. Although these moments slowed the immediate flow of activity, they also gave rise to new understandings or revised ideas. These actions did not impeded creativity; instead, they revealed children's active, critical engagement with both the design task and their peers. Rather than just complying with peer suggestions, children actively shaped how the work unfolded. Such forms of resistance and critical collaboration are overlooked in interpretations of young children's design activity. Through these interactions, children positioned themselves as evaluators and decision-makers who actively shaped the direction of the design work. Productive design work, in these cases, involved not only proposing ideas but also weighing alternatives. Design progress depended om moments when children collectively interrogated, reshaped, or set aside prior ideas. This positioned critical creativity as a driving force in the engineering process.

Discussion

When viewed through a sociocultural lens of resistance, the findings from this study position resistance as a meaningful and productive form of participation for young children in collaborative engineering design (Rainio, 2008). Rather than functioning as defiance or disruption, resistance emerged as an interactional resource for children as they questioned their peers' suggestions, delayed decisions, rejected other's proposed solutions, and engaged in practices central to engineering, including evaluating constraints, testing assumptions, and reconsidering how materials and structures function (Cunningham & Kelly, 2017). In this way, resistance became a visible mechanism through which the young children exercised agency within the group, shaping both the social and intellectual trajectory of the process (Litvinaitė, 2022).

Resistance was closely tied to several engineering habits of mind (Lillard et al., 2019), particularly creativity, optimism, and systems thinking. When the children resisted an idea (i.e., saying "not yet", pausing construction, proposing to take something apart) they often did so in response to perceived misalignments between a design choice and the problem at hand. These moments required the children to hold the design goal in mind, anticipate consequences, and advocate for alternatives that were more functional or aesthetically pleasing – practices that align with iterative and evaluative dimensions of engineering thinking (Cunningham & Kelly, 2017; Moore et al., 2018). Rather than completely halting progress, resistance slowed the pace of work in productive ways – creating space for deliberation, justification, and new ideas or thinking (Perumal, 2008). In these cases, resistance functioned as a form of collective sensemaking, enabling children to cooperate on thoughtful and intentional design choices.

Resistance also shaped the social dynamics of collaboration. Moments of pushback redistributed authority within groups, positioning children as both idea generators and as evaluators and co-directors of the design work. This aligns with the literature that conceptualizes resistance as a site for the negotiation of norms and where participation can be redefined (Perumal, 2008; Rainio, 2008). In early childhood engineering contexts, this kind of negotiation can support deeper engagement with both peers and materials. In turn, this allows young children to assert their perspectives, test boundaries, and contribute to shared and co-created solutions (Stetsenko & Ho, 2018).

Conclusion

This study contributes to early childhood engineering education by reframing resistance as an integral component of creative and collaborative design work. By attending closely to young children's talk during an engineering task, we highlighted how resistance can generate productive tension that has the ability to advance reasoning, support engineering habits of mind and ways of thinking, and deepen collective problem-solving and sensemaking. Moments of disagreement, hesitation, or pushback in young children's collaborative work do not always signal disengagement and conflict. Instead, these can be moments of engagement and possibility. Creating learning environments that allow space for children to exercise resistance by questioning ideas, slowing decisions, or revising plans, may support more authentic engineering practices and honour children as capable, thoughtful contributors to shared work. Attending more closely to resistance opens new possibilities for theorizing creativity in early childhood engineering as a socially negotiated process shaped by tension, critique, and collective decision-making.

Learning The 5Rs To Promote Citizen Science In Primary Schools

Diana Prado-Arenas[1], Lucia Stacchiotti[2] and Jorge Torrente Velásquez[3]
[1]Universidad Católica de Santa María, Perú,
[2]IC "Coldigioco-Mestica", Cingoli-Italia,
[3]Fundación SEED, Panamá

This study presents the development and validation of a Waste Manual based on the 5Rs (Reduce, Redistribute, Reuse, Recycle, Recover), designed to promote citizen science in primary education. The Manual integrates community involvement by offering a practical guide for teachers, parents, and guardians to foster environmental awareness and critical thinking in students. Aligned with Montessori principles, it emphasizes autonomy and active learning, encouraging students to develop skills for responsible decision-making. By engaging in structured activities, children learn to understand the environmental, social, and personal impact of waste management practices, fostering both individual responsibility and collective action. The pedagogical approach of the Manual incorporates levels of mastery adapted from Miller's framework, guiding students through progressively complex tasks that build their competence in applying the 5Rs. These activities also align with Bruner's spiral curriculum, ensuring that concepts are revisited and expanded upon to deepen understanding. The Manual encourages critical and creative thinking as central components for developing scientific literacy and fostering a long-term commitment to sustainable behaviours. The validation process involved eight experienced educators, each with advanced degrees and extensive teaching backgrounds, who analysed the Manual using a detailed questionnaire. Early results indicated its effectiveness in enhancing students' grasp of the 5Rs while also supporting their intellectual autonomy. Teachers highlighted the Manual's practical design, relevance, and potential to transform science education by linking theory with real-world environmental challenges. This paper explores the design process, the theoretical underpinnings, and the implications for advancing citizen science and sustainability education in primary schools.

Keywords: Citizen science, urban solid waste, Montessori.

Introduction

Primary education curricula highlight the importance of fostering environmental awareness and critical thinking. Despite differing approaches, they share the goal of equipping children with the skills to understand their environment and reflect on their actions, aligning with the broader aim of cultivating informed and responsible citizens.

This study addresses the integration of environmental education into primary schools through citizen science as a pedagogical framework. Specifically, it examines how the 5Rs (Reduce, Redistribute, Reuse, Recycle, Recover) can develop competencies in sustainable waste management and scientific literacy. The guiding research question is: How can we foster critical and active citizen science in primary school students? To explore this, a Waste Manual was developed to help teachers, parents, and guardians facilitate engaging activities centred on the 5Rs.

The Manual combines critical thinking principles, adapted from Miller's framework, with Montessori pedagogy, emphasizing autonomy and hands-on learning.

It aims to teach students the environmental impacts of waste while empowering them to take informed actions. By integrating theory with practice, the Manual seeks to instill lifelong habits of responsibility and scientific inquiry. This paper outlines the Manual's development, its activities, and validation by expert educators, demonstrating its potential as a transformative educational tool.

The Montessori Methodology For Citizen Science Learning

The Montessori methodology provides a robust framework for fostering critical thinking and active learning, essential for developing scientific literacy and promoting citizen science. This approach emphasizes hands-on experiences and autonomy, encouraging children to explore, experiment, and reflect meaningfully on their actions. Central to this framework is the concept that mistakes are opportunities for growth, fostering self-esteem, confidence, and intellectual autonomy—key for addressing complex environmental challenges.

Citizen science within the 5Rs framework requires students to acquire scientific knowledge and apply it to real-world scenarios. Montessori pedagogy supports this by offering authentic learning experiences that connect students with their immediate environment. Research highlights that grounding education in tangible, local experiences enhance understanding, retention, and a sense of responsibility toward sustainability (Reis, 2021; Kowasch et al., 2021; García, Reis, Vásquez, 2022).

By integrating Montessori principles, the 5Rs Waste Manual empowers students to progressively develop critical thinking skills, aligned with levels of mastery adapted from Miller's framework. Structured activities foster observation, analysis, and reflection, deepening students' understanding of waste management and its societal implications. This holistic approach equips students to act responsibly within their communities and contributes to broader environmental and scientific initiatives.

Mastering The 5Rs In Primary Education

Developing competencies for solid waste management requires a progressive approach, especially in primary education. The 5Rs provide a framework aligned with Miller's levels of mastery (1990), adapted by Albareda et al. (2019). As shown in **Table 1**, students' progress from basic understanding (*knows*) to autonomous action (*does*), fostering critical thinking and practical application.

Table 1. Levels of mastery of competences through the development of critical thinking skills for science education.

LEVELS OF SKILL DOMAINING (Adapted from Miller, 1990)	CRITICAL THINKING (Prado, Junyent and Oliveras, 2022)
Knows	Understanding, Analysis
Knows how	Valuation, Inference
Shows	Explanation, Approach to context
Does	Self-regulation, Intellectual autonomy

Prado, Junyent, and Oliveras (2022) emphasize critical thinking as central to achieving these competencies. Structured around the 5Rs, activities guide students from recognizing waste issues (*knows*), to proposing solutions (*shows*), and implementing actions (*does*). This iterative learning

aligns with Bruner's spiral curriculum (1960), which revisits concepts with increasing complexity.

By mastering the 5Rs, students connect personal actions to societal impacts, gaining scientific literacy, autonomy, and responsibility essential for sustainability and active citizenship.

Developing A Spiral To Learn The 5Rs

The spiral curriculum, proposed by Bruner (1960), introduces concepts at basic levels and revisits them with increasing complexity. This approach is particularly effective for teaching the 5Rs, as illustrated in Figure 1, were iterative learning fosters progressive understanding and application of waste management. Each R addresses a key aspect of waste management:

- Reduce: Avoid unnecessary consumption and minimize waste at the source.
- Redistribute: Sort waste to enable reuse, recycling, or recovery.
- Reuse: Extend product life through repurposing.
- Recycle: Transform materials into resources, reducing raw material use.
- Recover: Extract value from waste, such as nutrients or energy.

As shown in Figure 1, students revisit these Rs at increasing levels of complexity. For example, reducing waste begins with identifying unnecessary items (knows), progresses to evaluating bulk purchasing alternatives (knows how), leads to strategy design (shows), and culminates in real-world implementation (does). This progression mirrors Miller's levels of mastery (Table 1) and integrates critical thinking skills.

This iterative framework evolves with students, embedding critical thinking into activities, as highlighted by Prado, Junyent, and Oliveras (2022). It empowers learners to connect personal actions to societal and environmental impacts, fostering scientific literacy, autonomy, and responsibility.

Figure 1. Adapting Bruner's spiral for learning the 5Rs

Methodology

This study adopts a qualitative methodology to develop a Manual for solid waste management based on the 5Rs. The Manual combines playful and educational activities for each R, fostering engagement and learning. Its primary goal is to support teachers in promoting citizen science through a structured framework for environmental education.

Designed for both classroom and informal use, the Manual enables parents or guardians to participate alongside children, creating opportunities for collaboration and shared learning. This dual approach reinforces community involvement and encourages both children and adults to reflect on their waste management practices, fostering a collective commitment to sustainability.

Development Of A 5R Learning Manual

The 5R Learning Manual provides a structured yet flexible framework for teaching solid waste management to primary school students. It emphasizes practical, hands-on activities aligned with children's cognitive and developmental needs. The Manual includes clear objectives, detailed instructions, expected outcomes, and necessary materials to support effective learning.

Activities follow Miller's levels of mastery (Table 1), progressing from foundational knowledge (knows) to intellectual autonomy (does), fostering critical thinking and practical skills.

For instance, in the Reduce category (Table 2), activities like "Buy fresh and local products to reduce more" help students identify packaging types, consider bulk purchasing, and reflect on zero-waste principles through puzzles and reflections. These activities connect individual health with environmental sustainability.

The Manual supports both autonomous and guided learning, offering contextualized introductions, step-by-step methodologies, and reusable materials to reinforce resource efficiency. Its design ensures practicality for classroom and informal use, enabling parents or guardians to actively participate, fostering collaboration and shared responsibility.

By integrating critical thinking and sustainability principles, as proposed by Prado, Junyent, and Oliveras (2022), the Manual empowers students to connect personal actions to societal and environmental impacts. Following the spiral approach, activities build progressively, cultivating autonomy, reflection, and lifelong responsibility.

Table 2. Excerpt from the general structure of the 5R Manual.

5R	ACTIVITIES	OBJECTIVES AND METHODOLOGY
Reduce	Buy fresh and local products to reduce more	Through the cards and dates provided in the Manual, students learn to recognize different types of food packaging and reflect on how to reduce its use and volume. They are also encouraged to consider bulk purchasing to align with the zero-waste philosophy and complete a food pyramid puzzle to emphasize how individual health connects with sustainability and environmental health.
	Food Pyramid	
	Without packaging, like our grandparents did!	
	Reduce your waste to zero!	

5R Manual Validation Process

The validation of the 5R Learning Manual is a multi-stage process designed to ensure its effectiveness and relevance in fostering environmental education and critical thinking among primary school students. This paper focuses on the first two stages: the development of the Manual and its evaluation by expert educators. Subsequent stages, including practical classroom implementation and focus group analysis, will be addressed in future work.

The initial evaluation involved eight science teachers with extensive professional experience (a minimum of six years) and advanced academic qualifications (two Bachelor's, two Master's, and four Doctorate degrees). The teachers reviewed the Manual and completed a detailed

questionnaire designed to assess its quality and applicability. The questionnaire consisted of 20 items across six key dimensions:

1. Writing: Clarity, readability, and coherence of the Manual's content.
2. Relevance: Alignment of activities with the needs and developmental levels of primary school students.
3. Use of materials: Feasibility and accessibility of the resources required for the activities.
4. Objectives: Coherence between the stated objectives and the proposed activities.
5. Autonomy: Ability of the activities to promote independent learning among students.
6. Critical and creative thinking: Effectiveness in fostering higher-order thinking skills.

Responses were measured using a 5-level Likert scale, ranging from “strongly disagree” to “strongly agree.” Teachers who rated any item a 3 or below were asked to provide detailed feedback for improvement. This additional input ensured a robust and iterative refinement process for the Manual.

Preliminary results from this evaluation indicate that the Manual is well-structured and effective in achieving its intended objectives. Teachers highlighted the clarity of the writing, the relevance of the activities, and the appropriateness of the materials. They also suggested integrating a unifying narrative or theme to further enhance student engagement and motivation, such as a story with challenges that link the activities cohesively. These insights will guide future iterations of the Manual to ensure its continued effectiveness and adaptability in various educational contexts.

Results And Discussion

The validation process of the 5R Manual involved an in-depth evaluation by eight expert teachers, who provided feedback on six critical dimensions of its design and applicability. Key findings are summarized below:

1. Writing: The Manual’s content was praised for its clarity, conciseness, and accessibility for teachers, parents, and guardians. Respondents noted its balance between scientific rigor and accessibility, ensuring relevance across diverse contexts.
2. Relevance: Activities were deemed appropriate for primary students and aligned with their developmental needs. Teachers valued the real-world connections and suggested additional complementary exercises to enhance the Manual’s scope.
3. Use of materials: The resources required for the activities were practical, easily obtainable, and simple to handle. This accessibility was noted as a strength, reducing barriers to implementation.
4. Objectives: The stated objectives were coherent with the activities and effectively guided intended learning outcomes, fostering critical and creative thinking.
5. Autonomy: Activities were effective in promoting independent learning while maintaining a balance between guided and autonomous tasks, allowing students to develop self-regulation and decision-making skills.
6. Critical and creative thinking: The Manual was recognized as a valuable tool for fostering higher-order thinking skills. Teachers suggested adding a unifying narrative or theme to further motivate students and contextualize the activities.

Overall, feedback reinforced the Manual's effectiveness as an educational tool, highlighting its potential to meaningfully engage students in sustainability education. These insights will inform iterative improvements to ensure the Manual continues to meet the needs of educators and students.

ESERA 2025 Copenhagen

"The Living Things In Our Schoolyard": Design Of A Teaching-Learning Sequence For Primary Education

Arantza Rico, Igone Palacios-Agundez and Unai Coronel-Gastiain
Euskal Herriko Unibertsitatea (EHU), Department of Mathematics and Science Education, Faculty of Education and Sport, Spain.

The study of living beings and their classification is part of the curriculum in Primary Education. However, its study is often disconnected from the study of the relationships of interdependence between living beings and their habitats or problems associated with the loss of biodiversity. Therefore, in accordance with most Primary Education curricula, it is important that students acquire a general understanding of the organization of living things and their interaction with its environment, along with knowledge about local ecosystems and the services they provide. In that sense, many proposals and teaching materials to learn about biodiversity in primary education are available, but there is a pressing need to evaluate the potential of the naturalized school grounds to promote a deep understanding of this concept. We present a proposal for the design of a teaching-learning sequence (TLS) about biodiversity using the school's green space and its habitats. This proposal follows a Design-Based Research (DBR) methodology, because it offers an iterative process of design, implementation, evaluation and refinement, in an attempt to get a specific product - in our case a TLS - explicitly based on research results. We present results derived from the design phase using the DBR methodology, which involved the analysis of the school context through qualitative observational data from a pilot implementation in a 4th year primary classroom, definition of learning objectives and learning demands, to sketch a TLS about biodiversity in Primary Education.

Keywords: Teaching Learning Sequences, Biodiversity, Habitat, Primary Education, Ecodependence

Introduction

Biodiversity loss, one of today's most urgent socio-environmental crises, is closely linked to the growing disconnection between people—particularly children—and the natural world, which hinders the development of ecological understanding and the acquisition of knowledge about biodiversity and ecosystems that underpins sustainable lifestyles (Lindemann-Matthies, 2005; Lindemann-Matthies & Hyseni, 2009; Barrutia et al., 2022). Within Primary Education, the scientific model of living beings is a core curricular concept whose effective teaching benefits from the study of familiar animal and plant species in students' everyday environments and from direct, place-based experiences that enhance interest, connection with nature and understanding of environmental complexity (Willard, 2014; Gómez-Galindo et al., 2007). In this context, school green spaces—vegetated areas within school grounds, including school gardens and other outdoor learning environments—constitute authentic educational settings, comparable to classrooms or laboratories, with demonstrated potential to foster meaningful learning, well-being and community health and to contribute to competence-based learning and ecosocial resilience (Williams & Dixon, 2013; Chiumento et al., 2018; Eugenio-Gozalbo et al., 2019; Rammou et al., 2024; Aragón & Erdozain, 2025). There is thus a need for teachers to become familiar with these environments and with pedagogical approaches that leverage their potential, such as guided inquiry, which structures oriented research activities that reproduce essential aspects of scientific practice and position the instructor as mediator of learning rather than transmitter of knowledge (Rivero et al., 2011; Grossman, 2018). The integration of guided inquiry within school gardens enables learners to encounter biodiversity as a living, evolving reality, linking abstract ecological concepts to direct empirical experience and supporting conceptual change and the development

of ecological literacy in real contexts (Eugenio-Gozalbo & Ortega-Cubero, 2024; Ayotte-Beaudet et al., 2025; Doychinova, 2023).

With this in mind, we propose a Teaching-Learning Sequence (TLS) for Primary Education contextualized in the habitats of a school green space, developed within a Design-Based Research (DBR) framework in which TLSs function both as research interventions and curriculum products, refined through iterative cycles of design, implementation, evaluation and redesign to address students' learning difficulties and local contextual characteristics (Méheut & Psillos, 2004; Juuti & Lavonen, 2006; Guisasola et al., 2023). The contribution reported in this paper focuses on the Design phase, in which we analyse the school context, conduct an epistemological analysis of biodiversity and habitats, and define learning goals and associated learning demands—understood as the gap between intended objectives and students' prior ideas—while adding a distinctive element: the contextual analysis is complemented by qualitative evaluation of a draft TLS, including pilot implementation of selected activities in the school green space, to inform the refinement of design tools, teaching strategies and learning trajectories before full implementation (Barab & Squire, 2004; Leach & Scott, 2002).

Method

The Design-Based Research (DBR) methodology for Teaching-Learning Sequences (TLSs) comprises three general phases: i) Design, ii) Teaching experiments, and iii) Retrospective analysis (evaluation and refinement of the TLS) (Guisasola et al., 2023). In this paper, we focus exclusively on the Design phase.

Contextual Analysis Through A Pilot Implementation

The research team designed and organised the TLS around an initial scenario that asks whether students can mention at least five organisms living in the school green space. From this scenario, a set of driving questions was developed to address three key ideas: 1) diversity of living things, 2) living things and their habitats, and 3) eco-dependent humans. A preliminary version of the TLS, adapted from a sequence originally designed in the context of pre-service primary teacher education (Rico et al., 2026), was piloted with a 4th-year primary class, focusing on key ideas 1 and 2, to gather contextual implementation data. This contextual analysis was conducted through external observation by the third author and focused on (a) implementation constraints (clarity of activities, time allocation, pedagogical feasibility) and (b) learning constraints (students' difficulties) (Coronel-Gastiain et al., 2025). Data sources included the observer's notes from each session and notes from post-implementation meetings with the primary school teachers, where practical challenges were discussed. These implementation and learning constraints (educational, material or scientific), which may limit students' learning (Kariotoglou, 2003), were used, together with other DBR tools, to design and tailor the TLS to 4th-year primary students.

Definition of Learning Objectives and identification of Learning Demands

The definition of learning objectives is a central step in TLS design. In our case, three elements were considered: i) analysis of the Primary Education curriculum, ii) a literature review focused on learning difficulties related to biodiversity and ecosystems at this level, and iii) an epistemological analysis of the concept of biodiversity and its relevance. The analysis of the school context determines the conditions under which the TLS will be implemented; beyond curriculum standards, it includes students' feedback and socio-cultural characteristics of the setting, which is essential when comparing results across schools or countries and responds to calls to better specify contextual factors in TLS design and evaluation (Cobb et al., 2003). The TLS is intended for implementation from the 4th year of Primary Education onwards, whenever biodiversity and ecosystems are addressed in the curriculum.

An epistemological analysis of biodiversity—which examines both its historical development and current scientific models and theories (Chu et al., 2021)—allows us to define learning goals (LG) grounded in disciplinary epistemology rather than school tradition. This is crucial both for evaluating students' achievement and for obtaining valid evidence on TLS effectiveness. The second key element is the analysis of the gap between these LG and students' typical learning difficulties, as identified in the literature. These learning demands are understood as the ontological and epistemic distance between students' ideas and the scientific concepts, and they guide the organisation of the TLS by indicating the type and degree of difficulty that students are expected to encounter. Larger learning demands require more specific and sustained instructional support (e.g., more activities, scaffolding), whereas smaller demands can be addressed with fewer or less intensive interventions (Guisasola et al., 2023; Ruiz-González et al, 2025).

The designed TLS, "Our school's biodiversity", proposes an experiential approach to biodiversity through guided inquiry in the school green space. Starting from students' initial models of living beings, students sample the different habitats in a naturalised area of the school to investigate its biodiversity. The design is structured around: i) Driving Questions (DQ) linked to the key ideas about biodiversity, ii) LG associated with each DQ and set of activities, which guide students towards constructing explanations for each key idea (Guisasola et al., 2023), and iii) the scientific procedures to be carried out by students. Learners work in collaborative groups and record their observations and reasoning in a student workbook, which also serves as a data source for subsequent phases of the DBR cycle.

Results And Discussion

Observed Constraints In The Pilot Implementation

A series of selected activities was piloted in a 4th year PE classroom in 2024, where the topic of living things and ecosystems was being taught. These practical activities were directed towards the examination and sampling of different habitats in a park near the school and a visit to the university organic garden at the end of the sequence (Figure 1). The implementation was carried out during the third term, between April and June in parallel with the classroom instruction on ecosystems conducted by the Primary Education teachers. This pilot version comprised a total of seven activities. Figure 1 (next page) presents the overall structure of the proposed sequence.

Based on the data obtained from the qualitative tools, such as the external observer's report and post-implementation meeting notes, we identified several constraints in the pilot, mostly in the material and the scientific domain (Kariotoglou et al., 2003). For example, students could predict some of the living things that could be found in their schoolyard or nearby park, but they could not depict their particular habitat, and this hindered the subsequent sampling activity. These scientific constraints also informed the definition of some learning demands, as we will show in the following section. A clear material constraint was the consideration that going outside was not a cooperative academic task, and 4th year students struggled to understand that field sampling involves a set of particular rules and procedures. A summary of constraints identified in the implementation for two activities and design decisions are shown in Table 1.

Epistemological Analysis And Definition Of Learning Goals

This pilot implementation informed the sketch and design of a TLS specifically targeted to Primary Education children. As stated in methodology, the proposed TLS was designed based on the epistemological analysis of the concept of biodiversity by looking at both its historical development, and current models and theories that allow scientific explanations about biodiversity (Chu et al., 2021).

Figure 1. Sequence of the activities

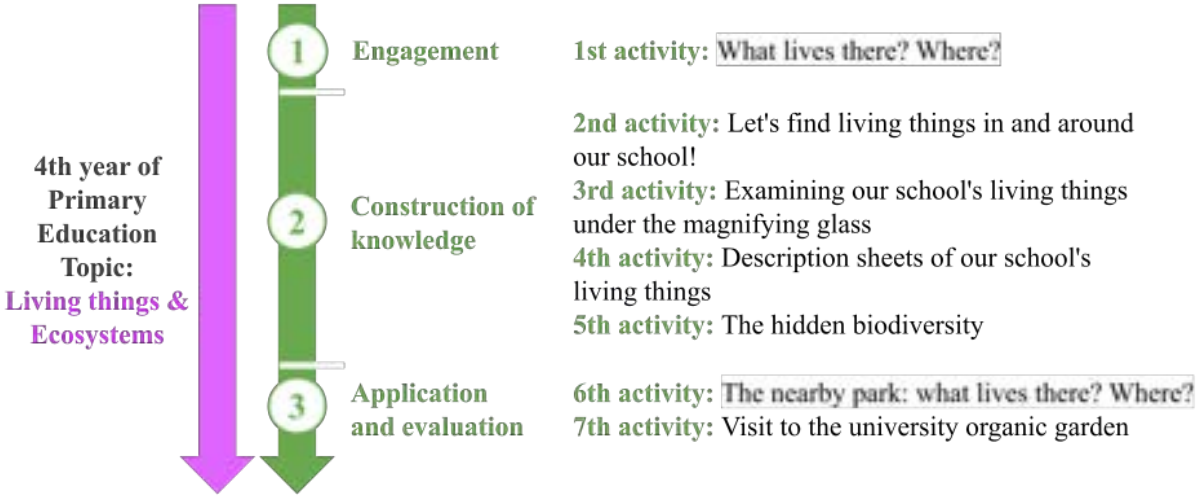

Table 1. Designed decisions based on observed constraints found in two activities of the pilot implementation.

Example of activities	Observed constraints	Design decision
Detecting student's initial ideas What lives there? Where?	Students can enumerate living things, but they have difficulties predicting where each one can be found. Although some examples were given, students were not able to represent the "habitat".	When covering the topic of living things and its classification, the concept of habitat must be explicitly taught.
Guided inquiry activity Let's find living things in and around our school!	Students show plant awareness disparity and do not consider them worth collecting or registering. Rule abiding and collaborative work while collecting data proved to be difficult.	Include a dedicated session to plant identification. Introduce students to the methods of sampling and data collection in a controlled space before exploring wider areas such as parks.

Biodiversity encompasses the variety of living organisms at genetic, species, and ecosystem levels, as defined by the Convention on Biological Diversity (United Nations, 1992), and includes not only species richness but also their relative abundance and functional roles within ecosystems (e.g., producers, consumers, decomposers) that enhance ecosystem resilience (Campbell et al., 2020). For 9-10-year-old children, this epistemology translates into five key learning goals aligned with primary curriculum standards: E1) recognizing millions of different living things with varying similarities; E2) grouping them by shared characteristics; E3) understanding species populations in specific habitats with suitable conditions for survival; E4) appreciating human well-being's dependence on other living beings and environments; and E5) identifying human impacts like habitat destruction, pollution, overexploitation, invasive species, population pressure, and climate change that threaten biodiversity (Campbell et al., 2020; Millennium Ecosystem Assessment, 2005; Willard, 2014). This focused framing grounds TLS design in disciplinary knowledge while addressing children's learning demands, such as scaling from observable school habitats to global concepts and normative conservation values (Navarro-Perez & Tidball, 2012).

The definition of our learning goals (see Table 2) is anchored in this epistemological analysis, instead of relying on textbooks or particular teaching styles (Guisasola et al., 2023). These indicators are measurable and will form the basis of specific open-ended questionnaires and teaching strategies to evaluate students' learning.

Table 2. Learning goals that define the concept of biodiversity and habitats in a TLS for Primary Education.

Elements from the epistemology of biology	Learning goals
E1. There are millions of different living things on Earth, some are very similar to each other, while others are very different.	**LG1.** To understand that there are many kinds of living things
E2. Living things can be classified into different groups based on their shared characteristics and features.	**LG2.** To learn to classify living beings into different groups according to their characteristics. **LG2.1.** To learn to distinguish and classify different types of animals. **LG2.2.** To learn to distinguish and classify different types of plants.
E3. Populations of particular species live in a specific place, which is called a habitat. The physical conditions and resources of the habitat must ensure the survival and reproduction of such a population.	**LG3.** To understand that there are different habitats at different scales according to physical conditions. **LG4.** To understand the connection between living beings and specific habitats and that changes in those habitats affect the organisms living there. **LG4.1.** To know which living things live in the immediate environment.
E4. Our well-being depends on the well-being of other living beings and the environment.	**LG5.** To understand the benefits or contributions that biodiversity (nature) offers to people. **LG6.** To understand that humans depend on nature (eco-dependency)
E5. Human activities have negative consequences on biodiversity due to: i) excessive human population; ii) overexploitation of natural resources; iii) habitat destruction, iv) pollution; v) introduction of invasive species and vi) climate change.	**LG7.** To know the impacts that humans have on nature and understand that we have the ability to influence it both positively and negatively.

Table 3. Alignment of Learning Difficulties with Learning Goals and identification of Learning Demands for a TLS about biodiversity in Primary Education

Learning difficulties	Learning demands	Learning Goal

• Difficulties in distinguishing between living and non-living beings (Driver et al., 1994). • Difficulty of naming taxons, other than mammals (Lindemann-Matthies, 2005). • Plant and native species awareness disparity (Barrutia et al., 2022). • Anthropocentric thinking (domestic, farming, cultivated,..) (Coronel-Gastiain et al., 2025)	Low Medium High Low	LG1
• Difficulties in biological classification skills and use of keys (Lindemann-Matthies, 2005).	High	LG2
• Limited knowledge about habitats makes it difficult to relate a specific living being to a habitat (Marulcu, 2014; Savvaidou-Kambouropoulou & Skoumios, 2012)	Medium	LG3 LG4
• Ignoring that biodiversity provides us with benefits other than material ones (e.g. regulatory services) (Rodriguez-Loinaz et al., 2022). • Lack of understanding of the normative dimension of biodiversity for conservation measures (Lindemann-Matthies et al., 2009).	Medium High	LG5
• Lack of awareness of the importance of biodiversity in the health of the planet and people (Menzel & Bögeholz, 2009).	Medium	LG6
• Lack of criteria to decide on effective measures for improving biodiversity (Rammou et al., 2024). • Lack of perception of the consequences of daily decisions (good or bad) on local biodiversity (Rammou et al., 2024).	High High	O7

Table 3 shows an example on how the definition of learning goals and the identification of learning difficulties allows for the identification of our student's expected learning demands. This is a pre-requisite to design appropriate teaching strategies, activities and evaluation tools. Primary students commonly struggle to distinguish living from non-living beings at an early age (Driver et al., 1994) and show limited recognition of plant and native species beyond familiar mammals, reflecting persistent biodiversity awareness disparities (Lindemann-Matthies, 2005; Barrutia et al., 2022). They often exhibit anthropocentric biases favoring domesticated species, face challenges in biological classification and using identification keys (Lindemann-Matthies, 2005), and struggle to link organisms to specific habitats due to limited ecological knowledge (Marulcu, 2014). Additionally, they overlook non-material ecosystem services, fail to grasp biodiversity's normative conservation dimension (Lindemann-Matthies et al., 2009; Torkar & Krašovec, 2019), and lack awareness of how daily decisions impact local biodiversity or criteria for effective conservation measures (Rammou et al., 2024). Despite these challenges, Primary Education students show high engagement and rapid learning when studying living things and nature through hands-on, inquiry-based activities in familiar contexts like school gardens, where they exhibit greater motivation, curiosity, and science achievement compared to traditional classroom

settings (Dillon et al., 2006; Randler, 2008). Table 3 illustrates how these documented learning difficulties align with our learning goals to determine the corresponding level of learning demands (Leach & Scott, 2002).

Conclusion

We have presented an application of the DBR methodology for designing a TLS about biodiversity contextualized in the school green space for Primary Education, which will form the basis of a broader research program validating evidence-based TLSs in primary science education. A key novelty of this work lies in the contextual analysis conducted through pilot implementation of selected activities transposed and adapted from a TLS originally designed for pre-service primary teachers (Rico et al., 2026). This preliminary testing with 4th-year students provided critical data on implementation constraints (activity clarity, timing, feasibility) and learning obstacles, enabling us to tailor the TLS more precisely to primary learners' needs and school realities before full-scale development. As stated previously, the early DBR phases anchor the TLS robustly by integrating epistemological analysis of biodiversity, curriculum requirements, and documented learning difficulties from the literature. Further work involves defining instructional strategies to foster biodiversity understanding, while subsequent phases will evaluate the sequence's quality and learning outcomes to refine the TLS and generate empirical evidence on primary students' conceptual grasp of biodiversity, its ecological significance, and the impact of school green space interventions.

Bridging Classical And Modern Physics: An Integrated Astronomy Curriculum For Primary Schools

Sara Mattiello
University of Turin, Italy

General Relativity, despite its central role in contemporary science, remains largely absent from school education. At the same time, research in science education shows that traditional instruction often fails to promote deep conceptual restructuring, leading to the persistence of misconceptions, particularly in astronomy. This paper presents an experimental study in physics and astronomy education that investigates whether integrating core principles of General Relativity into an astronomy curriculum can support the development of scientific competences. The intervention, conducted in Italian primary school, included activities focused on spatial reasoning and the use of reference frames, followed by the introduction of the basic ideas of light and gravity from a relativistic perspective. Data analysis is currently ongoing. The study discusses the potential of this approach to contribute to the renewal of science curricula.

Keywords: astronomy education, primary school, Einsteinian physics.

Introduction

In science, models play a central role in shaping how phenomena are interpreted and explained. Since the epistemological transformations of the early twentieth century, science has increasingly been understood not as a linear accumulation of empirical data, but as a coherent theoretical system grounded in conceptual models that guide observation, experimentation, and meaning making (Kuhn, 1962; Geymonat, 1972). From this perspective, empirical evidence cannot be separated from the theoretical framework in which it is embedded, as all observation is inherently theory-laden (Hanson, 1958). The formulation of General Relativity in 1915 represented a major paradigm shift in the understanding of space, time, and gravity, profoundly reshaping the scientific image of the world (Cassirer, 2015). Despite its foundational role in modern physics and cosmology, this theory remains marginal in compulsory schooling. In particular, astronomy education continues to rely mainly on classical models, with limited attention to the epistemological implications of modern physics.

At the same time, research on science learning has long documented the persistence of intuitive conceptions that are resistant to formal instruction, highlighting the limitations of traditional teaching practices in fostering deep conceptual change (Ausubel, 1968; Driver & Easley, 1978; Novak, 1987; Trumper, 2000). In astronomy education, these difficulties are especially pronounced and affect both students and teachers, contributing to low levels of conceptual understanding and to disengagement from the discipline (Atwood & Atwood, 1996). Current theoretical interpretations of these learning challenges are mainly framed within the Knowledge in Pieces Theory (diSessa, 2018) and the Framework Theory (Vosniadou, 2019). However, empirical studies explicitly examining how the adoption of different scientific models influences learning processes and the construction of a view of the universe remain scarce (Plummer et al., 2015).

Considering this context, physics education requires a non-hierarchical integration of epistemological, cognitive, and instructional dimensions (Gagliardi & Giordano, 2018). From this perspective, the present study investigates whether and to what extent the introduction of selected core concepts of General Relativity can support learning and motivation in primary school. Situated at the intersection of physics education research and educational science, the

study designs and implements instructional sequences in fifth-grade classrooms, embedded within a broader astronomy curriculum conceived as an epistemic context for constructing meanings consistent with a modern physical–cosmological perspective. The study is currently ongoing, and data analysis has not yet been completed; therefore, this paper focuses on presenting the research design and the structure of the experimental intervention, which is part of a broader ongoing study.

Research In Astronomy And Physics Education

Research in the field of science education has long demonstrated that the practice of science teaching is frequently characterised by fragmentation and a lack of coherence. The pedagogical approach is typically predicated on linear and cumulative models, which are observed to have difficulty in reflecting the intricacies inherent in the learning process (Adams & Slater, 2000). In response to these limitations, numerous studies have emphasised the necessity to reconsider instructional design, commencing from Big Ideas, which are defined as conceptual macro-structures with the capacity to integrate and interpret a broad array of phenomena, situations and problems, thereby furnishing a unifying explanatory framework for comprehending the natural world (Plummer, 2012). Despite the absence of a unifying definition of a Big Idea in the extant literature, the various classifications proposed do align in acknowledging their role in the organisation of science instruction (Slater & Slater, 2009; Lelliott & Rollnick, 2010).

Big Ideas are closely connected to Learning Progressions, which are theoretical models that describe learning trajectories characterised by increasingly sophisticated levels of understanding. These models are grounded in empirical evidence on students' conceptual development (Rogat et al., 2011). Rather than representing a simple incremental accumulation of knowledge, these models aim to depict qualitative transformations in understanding, accompanied by increasing cognitive and epistemological complexity (ibid.). From this perspective, big ideas and learning progressions can be interpreted as complementary components of the same curricular structure: the former function as core conceptual nodes, while the latter outline the trajectories through which these nodes are progressively reorganised and deepened over time.

Despite the theoretical relevance of this framework, the literature highlights persistent difficulties in translating such models into coherent curricular designs, particularly with regard to the teaching of modern physics and astronomy concepts. In addition to theoretical contributions, a considerable number of instructional interventions focusing on specific physical and astronomical subjects have been developed. However, as Plummer et al. (2015) have noted, a perspective that systematically investigates the connections among these aspects within a coherent, progressive and long-term view of astronomy learning is still lacking. This limitation renders it challenging to ascertain the extent to which the adopted theoretical models influence learning processes and the construction of a coherent scientific view of the universe.

Within this context, the present study builds on two main strands of research. The first concerns the study of the apparent motions of celestial bodies, with particular reference to the experimental work of J. Plummer, who proposed a Learning Progression model in this domain. The secondary strand encompasses studies that are oriented towards the integration of contemporary physics and non-Euclidian geometry within educational settings. Among the most relevant initiatives is the Einstein First project, developed at the University of Western Australia, which has led to a vertical curriculum implemented in approximately sixty schools, from early childhood education to upper secondary school, integrating selected concepts of modern physics (Blair & Kersting, 2021; Popkova et al., 2021; Foppoli et al., 2018; Kaur et al., 2017, 2023; Choudhary et al. 2022). Complementary contributions are provided by the research of Kersting (2019; 2021) in secondary education and by the instructional experiments conducted by Gambini (2021) in primary school,

aimed at introducing Euclidean and non-Euclidean geometry in an integrated and parallel manner from the early years of schooling.

While the extant studies reviewed here provide relevant contributions to the field, there is a need for further methodological refinement and greater attention to the transferability of results across different contexts.

Research Questions

In this framework, there is a necessity to develop studies that combine greater methodological robustness with a more systemic approach to disciplinary content. This would be capable of enhancing the conceptual and curricular integration of the different dimensions of astronomical and physical knowledge. In this study, the objective is to examine the hypothesis that integrating classical and modern paradigms in teaching can facilitate the development of scientific skills. This aspect represents one of the dimensions explored within a broader research project. Specifically, the hypothesis is that the systematic introduction of Einsteinian physics principles within an astronomy curriculum from primary school onwards has the potential to enhance students' scientific competence.

The research therefore aims to answer the following questions: i) In what ways does the learning of astronomy vary in relation to a curriculum that is more or less structured and integrated with Einsteinian physics principles? ii) What are the effects in terms of learning in socio-economically disadvantaged student groups? iii) What exogenous factors influence the achievement of these objectives?

The objectives of the research can thus be stated as follows: i)Analyse the impact of integrating Einsteinian physics into the teaching of astronomy on improving science skills; ii) Investigate the relationship between learning and the ESCS (*Economic, Social and Cultural Status*) indicator; iii) Investigate the impact on teacher training; iv) Contribute to the delineation of Learning Progress in the field of General Relativity.

Method

In view of the theoretical framework that has been presented and the necessity for further in-depth research, it was decided to adopt a quasi-experimental design with quantitative and qualitative data collection. On the one hand, the quantitative approach engenders results that are statistically stable and extends the conclusions to a broader context. Conversely, the integration of qualitative data facilitates the capture of the intricacies, variability and distinctive characteristics of the individual experimental groups and students involved, thereby circumventing an excessive reduction in the richness of information that is characteristic of educational experiences. A qualitative analysis is also necessary given the exploratory nature of research in the field of modern physics teaching in primary schools.

Three public primary schools in the Turin urban area were selected with average, medium-low and low ESCS indicators, based on the reports of the individual schools for the last two school years. The sample was selected on the basis of the research objectives, namely to investigate the relationship between the development of scientific skills and the ESCS indicator; therefore, it is not a random sample, but a reasoned one. The project was presented to three different public schools and was aimed at 4th and 5th grade classes, specifying the number of experimental groups required for each school. Participation in the project was voluntary. Four classes were selected for each school, corresponding to four experimental groups, for a total of 12 experimental groups and N=255 students. In particular, the following groups were established:

• G1: group in which a complete intervention by the researcher was tested in the 5th year primary class during the first term (complete group 1);

• G2: group in which a complete intervention by the researcher was tested starting from the 4th year primary class (complete group 2);

• G3: group in which the 5th grade class followed the teacher's educational programme and the researcher carried out a series of sporadic interventions during the first term (*spot* group);

• G4: control group.

Four experimental groups were created to analyse changes in variables based on different teaching choices. Firstly, a time frame similar to that usually adopted in Italian schools was utilised, i.e. condensing the teaching of astronomy into approximately five months of Year 5 primary school. This choice was linked to the availability of the teachers themselves. Concurrently, it was necessary to understand how learning varies when the teaching intervention is presented before the fifth year of primary school. The findings of research in this area indicate that there is no age below which it is impossible to introduce scientific teaching, on condition that it is calibrated according to the level of complexity that the child can manage (Levrini & Fantini, 2013). Consequently, the G2 group was identified, and the intervention was initiated in Year 4. These activities focused on the development of the necessary prerequisites related to the apparent motions of celestial bodies, as a basis on which to build future learning starting in Year 5 of the following school year.

Lastly, the G3 group was introduced, named “spot” for being a group in which the researcher carried out sporadic interventions in the classroom, in order to compare how learning varied between a complete curriculum, in which elements of classical and modern physics were integrated within the course, and a traditional one, conducted entirely by the teacher, in which the external specialist inserted himself and superimposed some activities specifically related to General Relativity. The choice adopted responds to the need to assess the effectiveness and transferability of short-term teaching interventions carried out by non-school personnel, a typology that is now widespread in the contemporary Italian school context. The division into experimental groups allows a comparative analysis of the outcomes, taking into account the differences between the experimental interventions and the socio-economic (ESCS) and gender characteristics of the participants.

An in-depth study on teacher training was planned to analyse the perceptions of the teachers involved and understand how they attributed meaning to the teaching experience, exploring how the proposal was integrated into professional practice and its contribution to the development of shared skills in the school community.

Knowledge And Skills Involved In The Curriculum

Following the operationalisation of the construct of scientific competence on the basis of international literature, the fundamental conceptual nodes of the curriculum were identified and developed. The experiment employed the Pedagogical Content Knowledge (PCK) model in an attempt to integrate the following criteria: i) content knowledge; ii) curriculum knowledge; iii) knowledge of students' difficulties and misconceptions; iv) knowledge of learning assessment; v) knowledge of teaching strategies (Magnusson et al., 1999). The curriculum was then constructed on the basis of a selection of four Big Ideas from those proposed in the literature:

- *Apparent motions of the Sun, Moon and starry sky.* Based on Vosniadou's studies (Vosniadou, & Brewer, 1994) on the patterns of naïve knowledge possessed by children,

Plummer (2012) points out that apparent motions represent the crucial conceptual node and fundamental prerequisite for any future learning of astronomy.

- *Dimensions and distances*. It is widely acknowledged that the comprehension of cosmic dimensions and scales constitutes a fundamental intellectual concept that is notoriously challenging to master, particularly during primary school education (Lelliot & Rollnick, 2010). Despite its relevance, this aspect receives little attention in school curricula and textbooks, with frequently present distorted representations of the Solar System (Testa et al., 2014). This fosters the development of misconceptions that often persist well into adulthood (ibid.).
- *Dynamic properties of planets*, in which the concept of gravity is directly involved. Several studies have examined the misconceptions held by children and adolescents about this phenomenon (Bar & Zinn, 1998; Baldy, 2007; Bar et al., 2016), particularly emphasizing a geocentric view that frames gravity as a phenomenon limited to the Earth. However, despite these contributions, research on gravity within astronomy education remains scarce, and the topic is still marginal in school curricula, likely because of its abstract character and the challenges associated with making it accessible in educational settings. In addition, the majority of existing studies focus on instruction grounded in the Newtonian framework. From this perspective, General Relativity remains among the least investigated topics in educational research (Blair & Kersting, 2021). Within the Big Ideas approach, gravity can therefore be addressed in schools not only through the Newtonian paradigm, but also by introducing elements of General Relativity. Didactic tools such as the *elastic sheet* model (Kaur et al., 2017), while limited, are particularly useful in making changes in gravitational attraction visible as a function of mass, orbital speed around a central body, and that body's capacity to dominate the surrounding space gravitationally.
- *Stars*, with emphasis on the difference between stars and planets. In this regard, the primary distinguishing factor between stars and planets is light, rather than the nuclear reactions characteristic of stars. The concept of light and its properties is of significant importance and merits particular attention from the earliest stages of education, particularly pre-school (Leone, 2020).

After translating the Big Ideas into specific learning objectives, these were integrated with key conceptual elements of General Relativity, which were also defined in relation to the same objectives. The conceptual elements identified as relevant included: (i) gravity, (ii) reference frames, (iii) light, and (iv) geometry on curved surfaces. These elements were then incorporated within the corresponding Big Ideas.

Research Instruments

The literature proposes several standardised instruments for the detection of conceptual understanding in science, such as concept inventories (Lindell, 2001; Bardar et al., 2006; Sadler et al., 2009). However, such instruments are limited with respect to the assessment of scientific competences, particularly in astronomy, as they are designed for secondary school and are predominantly performance-oriented and do not allow for the systematic investigation of attitudes and processes underlying competence (Allal, 1999). Similarly, large-scale surveys such as PISA and TIMSS (OECD, 2019; Mullis & Martin, 2023) do not consider astronomy as a stand-alone area of assessment.

This framework highlights a structural problem in the detection of scientific competences, understood as the integration of knowledge, processes and attitudes, in line with a view of science as evidence-based model building (Gagliardi & Giordano, 2018). Consequently, it became necessary to design a purpose-built assessment tool. Starting from the conceptual cores and the

specific objectives identified, a semi-structured test was developed for the detection of knowledge and skills, integrated with Guilford's (1967) model of cognitive processes and flanked by qualitative instruments aimed at investigating attitudes, considered to be the foundations of competence in astronomy. Participant observation, the authentic task and an evaluation rubric inspired by Allal's (1999) criteria were used.

The analysis was further deepened through semi-structured interviews aimed at teachers, designed from the logbooks and conducted according to an inductive bottom-up approach (Birks & Mills, 2015), in order to integrate the data collected and bring out the meanings attributed to the teaching experience.

Limitations And Perspectives Of The Research

At present, no definitive conclusions can be drawn, as the study is still in the experimental phase and data collection is ongoing. Nevertheless, some preliminary considerations regarding the strengths and limitations of the research can be outlined. The intervention may represent a step toward an approach to astronomy education in Italian primary schools that is more consistent with the epistemology of science and with constructivist perspectives on learning. In contrast to current instructional practices, which in astronomy remain largely grounded in traditional models and often show limited effectiveness in supporting conceptual restructuring and the development of complex scientific competences, the present design explores alternative instructional pathways. At the same time, disciplinary didactics involves substantial methodological complexity, as it requires the integration of multiple dimensions, including epistemological aspects related to the structure of physical concepts, instructional and methodological choices concerning teaching strategies and activity sequences, and cognitive aspects related to students' intuitive conceptions and processes of conceptual change.

A relevant limitation concerns the assessment instruments adopted, which present constraints in terms of validity. The astronomy test was specifically developed for this study, and, due to limitations related to sample size and intervention duration, it was not possible to conduct a preliminary exploratory factor analysis to examine its latent structure. For this reason, quantitative analyses of test scores should be complemented by qualitative analyses of open-ended responses, allowing for comparisons between experimental groups in relation to the differentiated instructional conditions. From a data triangulation perspective, test results will need to be interpreted alongside qualitative evidence, such as systematic classroom observations, audio or video recordings, and students' written artefacts, in order to better capture the processual nature of learning and to situate students' responses within their instructional context.

An additional point of interest concerns the introduction of concepts, such as reference frames, that are not typically addressed systematically in primary school curricula. This offers an opportunity to explore how students engage with such concepts and how their initial intuitive conceptions may be reorganized through the proposed activities.

Finally, the scope and diversity of the collected data suggest the potential to inform future research on Learning Progressions related to apparent celestial motions and, more broadly, to support further investigations into concepts such as gravity, whose Learning Progressions have traditionally been framed within a Newtonian perspective. In this contribution, however, these issues are not examined analytically; rather, they are outlined as directions for subsequent work, particularly with respect to the integration of alternative theoretical models into instructional design and the investigation of students' cognitive processes through longitudinal and in-depth analyses.

Introduction

This chapter showcases the commitment and creativity of teachers and researchers who strive to improve the quality of science education at both middle and secondary school levels.

Strand 18 examines the two contexts in which science education occurs: middle and secondary school. The studies presented in this chapter provide important insights into the specific challenges and opportunities that arise at these stages of the educational process.

The combined insights presented in this chapter highlight the essential role of teacher education in influencing the global development of science education. By integrating the contributions of researchers, educators, and practitioners, this chapter functions as both a valuable reference and a source of motivation for those dedicated to promoting meaningful science learning experiences in middle and secondary school settings.

We would like to acknowledge the efforts of the authors and conference organizers whose contributions made this proceedings book possible. We trust that the research presented here will support and encourage further dialogue and initiatives in the field of science education.

We encourage readers to engage with the wide range of perspectives presented in this collection and believe that the research included will inspire new ideas and contribute to the advancement of science education.

ESERA 2025 Copenhagen

Facilitating Knowledge Interconnection Through Instructional Prompts In Chemistry Classroom Discourse – An Explorative Qualitative Single-Case Study

Brian Hesse and Katharina Groß
Institute of Chemistry Education, University of Cologne, Germany

Interconnected knowledge structures are widely regarded as a key prerequisite for meaningful learning and the flexible application of subject matter in science education. Although curricula consistently emphasise cumulative and interconnected learning, classroom instruction often remains oriented toward the reproduction of fragmented and isolated knowledge. Against this background, the present study examines how instructional prompts within classroom discourse are related to the levels of interconnection evident in students' responses during chemistry lessons.

The study is based on an exploratory qualitative single-case study conducted in a ninth-grade chemistry class in Germany. Classroom discourse from a teaching unit on redox reactions in the context of electrochemistry was video-recorded and subjected to systematic analysis. Instructional sequences were identified and examined using a combined analytical approach that integrates a categorisation of levels of interconnection with sequential interaction analysis. Initiation, evaluation, and feedback prompts were derived through a deductive-inductive procedure.

The findings indicate that initiation prompts such as "name" and "describe", which occur most frequently in classroom discourse, are predominantly associated with lower levels of interconnection. In contrast, less frequent prompts inviting "assumption" or "explanation" tend to elicit responses characterised by higher levels of interconnection. Moreover, evaluation prompts often function to conclude instructional sequences and may therefore constrain opportunities for sustain cognitive engagement. Feedback prompts, by contrast, frequently extend instructional sequences and serve both regulative and elaborative functions. While feedback often maintains a stable level of interconnection by re-establishing symmetry between initiation and response, it can also be associated with an increase in the level of interconnection. The results further suggest that instructional sequences characterised by stable levels of interconnection may nevertheless allow for substantial depth of content through elaboration within a given level. Overall, the study highlights the importance of the deliberate design of initiation and feedback prompts in classroom discourse and offers insights into how instructional interaction can support cognitive activation and the development of interconnected subject matter understanding.

Keywords: Knowledge Interconnection, Classroom Discourse, Instructional Prompts

Introduction

From a learning psychology perspective, interconnected knowledge structures are considered essential for effective information processing and the development of (personal) competencies (Neumann et al., 2008). Accordingly, the curriculum emphasises interconnected teaching and learning by encouraging students to relate newly acquired knowledge to their prior knowledge through repeated revisiting of subject matter at a progressively higher levels of abstraction across the school years. The long-term objective is to develop chemistry subject matter not merely in an additive manner, but also cumulatively, enabling students to apply their knowledge flexibly across diverse situational contexts (Conference of the Ministers of Education Germany (KMK), 2024).

Despite curricular guidelines in Germany that explicitly promote repetition and increasing abstraction of subject matter (Bruner, 1960; Ministry of School and Education (MSB NRW),

2019), empirical studies report a decline in science performance among German students (cf. Holtmann et al., 2019; Köller, 2024). This discrepancy between curriculum frameworks that account for cumulative learning processes and declining student achievement, which constrains students' ability to meaningfully interconnect subject matter concepts, can be attributed to several factors. First, the hierarchical organisation of subject matter poses particular challenges for students with pre-existing knowledge gaps, making the integration of new knowledge more difficult (cf. Rother & Walpuski, 2020). Second, students often perceive the content taught as a collection of isolated facts, leading to the impression that chemistry instruction lacks coherence (cf. Bernholt et al., 2020; Rother & Walpuski, 2020). Third, students frequently struggle to engage deeply with learning objects due to insufficient cognitive activation in science classrooms (cf. Köller, 2024). Consistent with this, previous studies indicate that science instruction often prioritises reproduction of knowledge, resulting in comparatively low levels of knowledge interconnection (cf. Dietz & Bolte, 2022; Neumann et al., 2008; Podschuweit et al., 2016; Smart & Marshall, 2013; Xu et al., 2024).

Irrespective of country-specific curricular frameworks, cognitively activating and interconnected instruction – characterised by challenging learning tasks and structured teacher-student interactions within classroom discourse – is widely regarded as a key determinant of improved learning outcomes (Neumann et al., 2008; Schreyer & Charalambous, 2024). Against this background, the present study investigates cognitively activating interactions initiated by instructional prompts in classroom discourse as a potential factor influencing the interconnection of school-based chemistry subject matter.

Theoretical Background

Interconnected Learning

Interconnected learning refers to the integration of individual knowledge elements into higher-order cognitive structures through cumulative learning processes (Bernholt et al., 2020). It involves linking newly acquired knowledge to existing prior knowledge, thereby progressively increasing the complexity of learners' knowledge structures through processes of expansion and hierarchisation (Ausubel, 1960; Gagné, 1968; Harms & Bünder, 1999). Such increasingly complex knowledge structure offers several advantages. These include improved retention of interconnected knowledge compared to isolated factual knowledge, more efficient transfer and application of knowledge across different contexts and reduced cognitive effort during knowledge retrieval (Fischer et al., 2007; Mietzel, 2017; Kunter & Trautwein, 2018). Interconnected learning can be differentiated into two forms. Horizontal interconnection refers to interdisciplinary linkages between subject areas, whereas vertical interconnection describes intra-disciplinary connections that build upon one another over time (cf. Fischer et al., 2007). The present research project focuses on vertical interconnection within chemistry education, examining how chemistry subject matter is interconnected through verbal teacher-student interactions in classroom discourse.

Instructional Prompts In Classroom Discourse

Classroom discourse represents one of the most prevalent forms of instructional practices and it "is not merely a conduit for sharing of information […]; it is the most important educational tool for guiding the development of understanding and for jointly constructing knowledge." (Mercer & Hodgkinson, 2008). Within classroom discourse, students are encouraged to articulate their thinking verbally, thereby providing teachers with opportunities to respond through targeted instructional prompts that support learning processes (Kim & Lim, 2025; Lipowsky et al., 2021). Instructional prompts are brief, content-oriented hints, questions, or requests posed by teachers

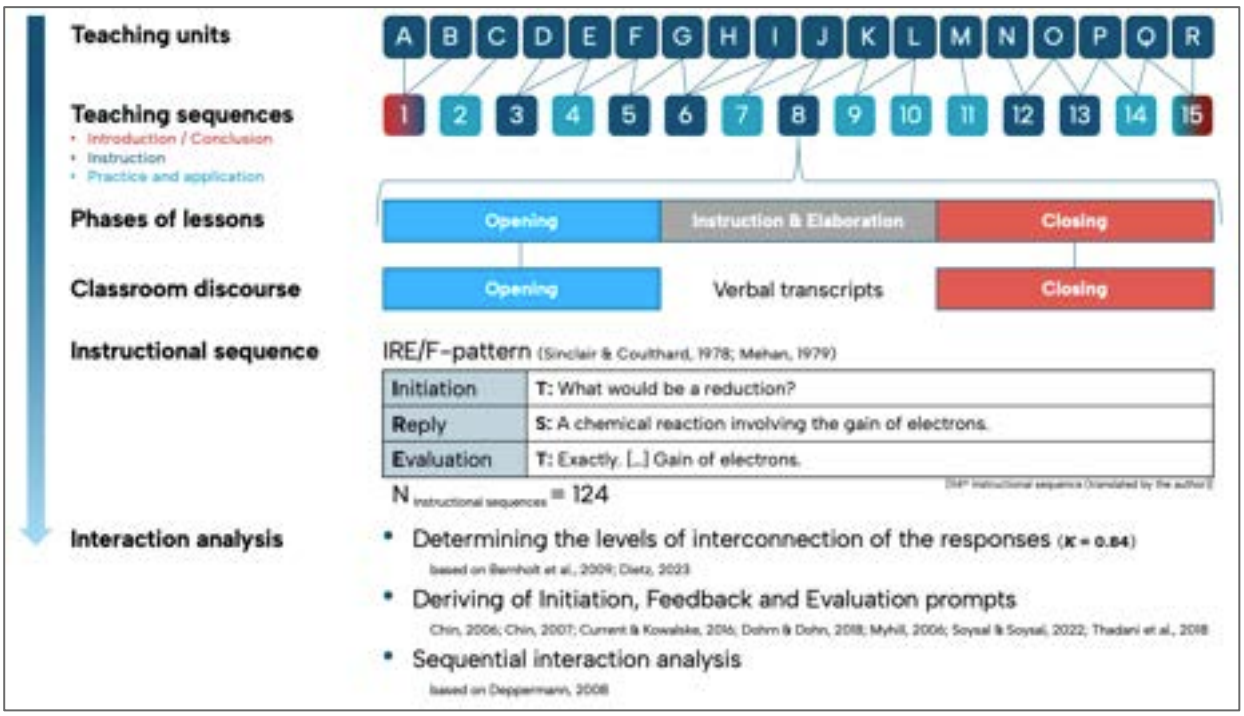
to stimulate students' cognitive or metacognitive processes during classroom discourse without introducing new subject matter. This instructional approach is based on the assumption that students generally possess the relevant conceptual knowledge or procedural skills but may struggle to activate them spontaneously. Instructional prompts thus serve to direct students' attention to subject-relevant aspects and support activation and organisation of existing knowledge (Bannert, 2009; Current & Kowalske, 2016; Wirth, 2009). Despite consistent evidence of low levels of knowledge interconnection in science instructions (cf. Dietz & Bolte, 2022; Neumann et al., 2008; Podschuweit et al., 2016; Smart & Marshall, 2013; Xu et al., 2024), the role of instructional prompts in fostering interconnected knowledge structures, particularly across extended instructional sequences in classroom discourse, remains largely underexplored.

Research Project

Aim, Research Question And Study Design

The overarching aim of this study is to examine cognitively activating interactions in classroom discourse and their relationship to subject-related interconnection in chemistry lessons. To gain insights into authentic teaching practice, the study was designed as an exploratory qualitative single-case study and conducted in a ninth-grade chemistry class at a German Gymnasium over the course of an entire school year (cf. Yin, 2018). Ninth-grade students were selected due to their comparatively advanced prior knowledge, which provides increased potential for the interconnection of subject matter concepts (cf. Bernholt et al., 2020).

The empirical analysis focuses on a teaching unit on redox reactions in the context of electrochemistry (cf. MSB NRW, 2019), which was fully video-recorded. Within this instructional context, the study investigates strategies employed in classroom discourse to foster subject matter interconnection. The analysis is guided by the following research question: Which instructional prompts are used in classroom discourse, and to which levels of interconnection do students' responses lead?



Methodology

A total of 18 lessons, each lasting 45 minutes, were recorded using a two-camera setup. One camera was positioned at the back of the classroom, capturing the teacher and the blackboard, while a second camera was placed at the front of the classroom, focusing on the students. To further enhance the quality of the recorded verbal interactions, the teacher was additionally equipped with a portable audio recorder.

To identify the relevant classroom interactions for analysis, the audio material was systematically pre-structured. First, the 18 recorded lessons were condensed into 15 teaching sequences (Figure 1), representing either the introduction or conclusion of the teaching unit, the development of new subject matter, or the practice and application of previously introduced content. Within these teaching sequencies, the instructional phases of introduction (opening), development (instruction and elaboration), and consolidation (closing) were subsequently identified.

Public classroom discourse initiated by the teacher, occurring primarily during the opening and closing phases, was transcribed. The resulting transcripts were then summarised and segmented into instructional sequences derived from observed interactions and individual utterances. Each instructional sequence constitutes a self-contained unit of content and follows the Initiation–

Figure 1. Data Preparation and Analysis Procedure.

Response–Evaluation/Feedback (IRE/IRF) pattern (cf. Sinclair & Coulthard, 1978; Mehan, 1979).

Figure 1 illustrates an exemplary instructional sequence in which the teacher initiates the interaction with a question, the student provides a response, and the teacher evaluates the response, thereby concluding the sequence. In case of inappropriate or incorrect responses, instructional sequences may be extended through a feedback prompt. In total, $N = 124$ instructional sequences were included in the analysis.

Subsequently, the levels of interconnection present in students' responses were determined. Five distinct levels of interconnection were identified (cf. Bernholt et al., 2009; Dietz, 2023) and grouped into three superordinate blocks. The first block comprises additive knowledge acquisition and includes the two lowest levels: experiential knowledge (Level 1) and factual knowledge (Level 2). Experiential knowledge refers to knowledge derived from students' everyday experiences and their encounters in chemistry lessons (e.g. observing experiments), whereas factual knowledge involves the identification of subject-relevant aspects, technical

Table 1. Category System – Levels of Interconnection Including Selected Examples.

Levels of Interconnection based on Bernholt et al., 2009; Dietz, 2023; (κ = 0.84)		Selected examples
II. Interconnecting to higher-level concepts (core ideas)	Abstraction	T: [...] I simply put it out there that, when a battery is used, chemical energy is converted into electrical energy. For this reason, batteries are also referred to as energy converters. Do you have an idea of what this means? **What does it mean that chemical energy is converted into electrical energy?** S: I'm not completely sure. But chemical energy is when there is a reaction or something like that, and energy is produced. That is **chemical energy to begin with, and then [...] transforming it or using it in such a way that it can be used as electrical energy.** T: Chemical energy has already come up in many other examples. If you think back, for instance, to combustion reactions, we described these as exothermic reactions. In such reactions, chemical energy that is stored in substances is released during a chemical reaction, for example in the form of light and thermal energy. And here we basically have the same situation. In this case as well, chemical energy is stored in a compound, and during a redox reaction it is released in the form of electrical energy [...] – **Abstraction: Energy conversion** [70th instructional sequence (translated by the author)]
I. Interconnecting within the topic	Justified relations	
	Unjustified relations	
0. Additive knowledge acquisition	Factual knowledge	T: [...] **What is reduction?** S: The release of– (T slightly shakes their head) – **the gain of electrons.** T: The gain of electrons, that's right. – **Factual knowledge: Definition** [37th instructional sequence (translated by the author)]
	Experiential knowledge	

terms, or definitions. The second block, interconnection within the topic, consists of two levels, differentiated by whether interconnections are established without justification (Level 3) or with explicit justification (Level 4). The highest level of interconnection is represented by abstraction (Level 5), in which interconnections are established by linking subject-specific content to higher-order concepts. An overview of the levels of interconnection is provided in Table 1.

To assess inter-rater reliability for the high-inferential category system used to classify levels of interconnection in students' responses, 40% of the instructional sequences were independently coded by two raters. This procedure yielded a Cohen's kappa coefficient of $\kappa = 0.84$, indicating almost perfect agreement according to the criteria proposed by Landis and Koch (1977). After the levels of interconnection in students' responses had been established, the methodological approach was extended to include sequential interaction analysis (cf. Deppermann, 2008). Within this analytical framework, initiation, feedback, and evaluation prompts were identified and categorised using a combined deductive-inductive approach (cf. Chin, 2006; Chin, 2007; Current & Kowalske, 2016; Dohrn & Dohn, 2018; Myhill, 2006; Soysal & Soysal, 2022; Thadani et al., 2018).

Results And Discussion

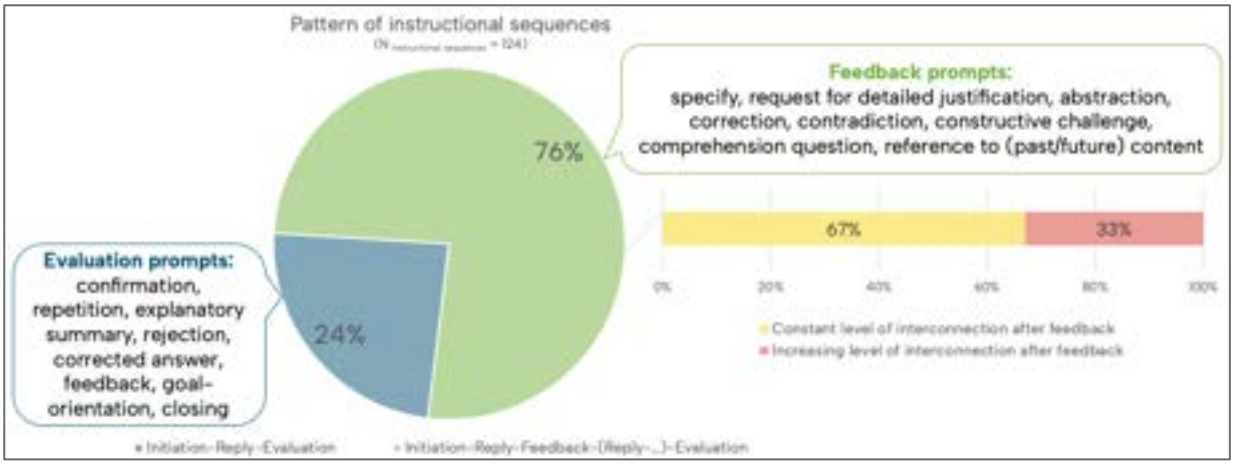
This section presents and discusses the results of the analysis of classroom discourse, with a particular focus on the relationship between initiation prompts, interaction patterns, and the levels of interconnection observed in students' responses. Special attention is paid to the role of evaluation and feedback prompts in shaping instructional sequences and influencing opportunities for cognitive engagement.

Initiation Prompts And Levels Of Interconnection In Students' Responses

The initiation prompts identified during the classroom discourse are presented in the left-hand column of Table 2. For analytical purposes, the levels of interconnection in students' responses were plotted against the respective initiation prompts. Two central aspects emerged from this analysis. First, 57% of the instructional sequences begin with the initiation prompts *name* or *describe*. These prompts predominantly elicit student responses at lower levels of interconnection. In contrast, 10% of the instructional sequences are initiated with the prompt *assume,* and 15% begin with *explain*. Responses following these prompts tend to reach higher levels of interconnection. This pattern suggests that such initiation prompts cognitively stimulate students to engage in more complex reasoning processes, which is consistent with the hierarchical organisation of cognitive processes described in Bloom's taxonomy (cf. Anderson & Krathwohl, 2001).

Table 2. Initiation Prompt and Resulting Level of Interconnection of Student Response.

Level of Interconnection / Initiation Prompts (N instructional sequences = 124)	Experiential knowledge	Factual Knowledge	Unjustified relations	Justified relations	Abstraction	Proportional Initiation Prompts
Name	11%	65%	16%	8%	0%	30%
Describe	35%	18%	35%	12%	0%	27%
Formulate (reaction equation)	0%	7%	86%	7%	0%	11%
Assume	15%	38%	31%	8%	8%	10%
Compare	0%	0%	100%	0%	0%	1%
Justify	0%	25%	0%	75%	0%	3%
Explain	11%	16%	32%	32%	11%	15%
Cognitive Conflict	0%	0%	100%	0%	0%	1%
Evaluate	0%	0%	0%	0%	100%	1%



Second, the results indicate that initiation prompts are systematically associated with specific levels of interconnection. Prompts such as *name* and *describe* primarily address the reproduction of knowledge, whereas prompts such as *explain* are more likely to elicit responses involving higher levels of interconnection. These findings can be interpreted in relation to additive forms of knowledge acquisition. Responses elicited by initiation prompts such as *name* and *describe* frequently focus on the identification of technical terms, definitions, or concepts and therefore reflect additive knowledge building. Such forms of knowledge acquisition may constitute a necessary foundation for subsequent interconnection, as newly introduced subject matter can only be meaningfully related to prior knowledge once it has been explicitly established.

Interaction Patterns: Evaluation And Feedback Prompts

While the previous section focused on initiation prompts and the resulting levels of interconnection in students' responses, classroom interactions are not limited to initiation-response sequences. Rather, they are further shaped by evaluation and feedback prompts, which influence whether instructional sequences are concluded or extended. The following section therefore examines interaction patterns with a particular focus on evaluation and feedback prompts.

Overall, 24% of the instructional sequences follow the three-step Initiation–Response–Evaluation (IRE) pattern (cf. Mehan, 1979), in which the interaction is concluded through a content-related evaluation by the teacher. The evaluation prompts, derived using a combined deductive-inductive approach, are presented in Figure 2.

Figure 2. Proportion of Interaction Patterns, Derived Evaluation and Feedback Prompts, and Achieved Level of Interconnection of Student's Response after Feedback Prompt.

As evaluation prompts bring an instructional sequence to a content-related conclusion and classroom discourse subsequently continues with a new initiation prompt, they may restrict students' ongoing cognitive processes by prematurely terminating the interaction. As a result, opportunities for in-depth engagement with specific content or for further interconnection of subject matter may remain unexploited at particular points in the classroom discourse (cf. Chin, 2007).

In contrast, feedback prompts serve to extend instructional sequences and sustain students' cognitive engagement. When a discrepancy arises between the initiation and the student response, that is, when the response does not meet the expectations implied by the initiation prompt, a feedback prompt is formulated (cf. Naujok et al., 2008). The analysis shows that in 76% of the instructional sequences, interactions are extended through such feedback prompts. Within this framework, students may be asked to specify their response, provide a more detailed explanation, or correct their answer (cf. Chin, 2006). The specific functions of feedback prompts in relation to levels of interconnection are examined in the following section.

Regulative And Elaborative Functions Of Feedback Prompts

An analysis of the levels of interconnection following feedback prompts shows that in 67% of the instructional sequences, the level of interconnection in students' responses remains unchanged. This pattern indicates that feedback prompts predominantly serve to maintain or regulate the level of interconnection established by the initiation prompt, suggesting that initiation prompts largely shape the level of interconnection across an entire instructional sequence.

Within instructional sequences characterised by stable levels of interconnection, feedback primarily fulfils a regulative function by re-establishing symmetry between initiation and response when the initial student response does not align with the expectations implied by the initiation prompt. This form of feedback often involves requests for specification or clarification and supports subject-specific elaboration through the concretisation or expansion of students' responses. The findings suggest that instructional sequences maintaining a stable level of interconnection may nevertheless allow for substantial depth of content, as elaboration and differentiation can occur within a given level rather than necessarily through a transition to a higher level of interconnection.

In the remaining 33% of instructional sequences, feedback prompts are associated with an increase in the level of interconnection in students' responses. This tendency is particularly evident when follow-up questions prompt students to justify, explain, or further elaborate on their initial responses, thereby enabling longer and more complex contributions (cf. Chin, 2006).

Implications And Outlook

The findings of this study have several implications for both the analysis and the design of instructional interaction, as they provide a more fine-grained understanding of how the curricular demand for cognitively activating and interconnection-oriented instruction can be realised through classroom discourse. First, the results underscore the central role of initiation prompts in shaping the level of interconnection across instructional sequences. Initiation prompts such as *name* or *describe* tend to elicit reproductive forms of knowledge. However, rather than indicating superficial engagement, such responses may reflect additive forms of knowledge acquisition, in which technical terms, definitions, and basic concepts are made explicit. This additive knowledge building can be understood as a necessary foundation for subsequent interconnection, as newly introduced subject matter must first be established before it can be meaningfully linked to prior knowledge and integrated into more complex knowledge structures. In contrast prompts that inviting explanation or assumption are more likely to stimulate responses involving higher levels of interconnection. Taken together, these findings suggest that the deliberate formulation of open-ended initiation prompts can support a transition from additive to more cumulative and interconnected forms of knowledge construction over the course of instructional sequences, thereby facilitating the integration of new subject matter into existing knowledge structures (cf. Bernholt et al., 2020; Chin, 2006).

Second, the analysis highlights the differentiated role of evaluation and feedback prompts in shaping instructional interaction. Evaluation prompts tend to conclude instructional sequences and may limit opportunities for sustained cognitive engagement by prematurely terminating ongoing thinking processes. Feedback prompts, by contrast, can be productively integrated into instructional sequences to regulate the alignment between initiation and response and to encourage students to expand, clarify, or justify their contributions. Feedback thus fulfils both regulative and elaborative functions, supporting subject-specific depth of content and, in some cases, facilitating higher levels of interconnection within classroom discourse.

From a methodological perspective, the study demonstrates the value of combining an analysis of levels of interconnection with sequential interaction analysis, as this approach enables a differentiated examination of both cognitive and interactional dimensions of classroom discourse. Building on the present macro-analytical perspective, future research will move towards a fine-grained micro-analysis of classroom interaction. This next step will focus on the detailed examination of the content and structure of interactional sequences, with particular attention to the reconstruction and analysis of students' utterances. Such a micro-analytical approach aims to investigate how students' contributions are interactionally shaped and cognitively activated within instructional sequences and how these processes contribute to the development of a vertically interconnected subject matter understanding. By systematically linking interactional structures with the content-related development of students' reasoning, future research seek to further specify how classroom discourse can support both cognitive activation and the progressive interconnection of subject-specific knowledge.

Inclusive Science Education: Interest In Experimenting And Perceived Self-Efficacy In An Interdisciplinary Teaching Concept

Giulia Pantiri, Thomas Wilhelm, Lea Burkhardt, Volker Wenzel, Arnim Lühken, Dieter Katzenbach and Fatime Beka
Goethe University Frankfurt, Germany

As a design-based research project, the E²piMINT team developed and evaluated an inclusive and interdisciplinary teaching concept for lower secondary schools to promote interest in science and to provide teachers with effective support for lesson planning. Facilitating the cooperation between science education and inclusive education, the project brings together researchers from different fields: subject specific education in physics, biology and chemistry, as well as special education. A core aim of the project is to enable pupils with and without special educational needs (SEN) to learn effectively together through a hands-on teaching approach. Pupils work in groups at learning stations using "Researcher Boxes" to conduct experiments on different topics from the perspective of the three sciences subjects. Two project days on the topics of "colours" and "glueing and sticking" were designed and implemented in the teaching laboratories at the Goethe University Frankfurt with mixed prior ability classes. This first phase was followed by a second phase focusing on the applicability of the concept in school practice. Throughout the study, quantitative and qualitative methods (mixed methods approach) were used to analyse several constructs, such as learners' interest in experimenting as well as perceived experimental self-efficacy in a pre-post-follow-up design. This paper outlines the key features of the teaching materials and presents some preliminary results of the quantitative analysis.

Keywords: Inclusive Education, Interest, Self-Efficacy

Introduction

Context And Relevance To Science Education

In recent decades, and particularly since the ratification of the UN Convention on the Rights of Persons with Disabilities in 2009, the German school system has undergone many changes regarding the education of pupils with special educational needs (SEN). During this period, the proportion of pupils with SEN attending regular schools rather than special needs schools (i. e. specifically for pupils with SEN) has increased from 19.8% to 44% in 2020 (Kultusministerkonferenz, 2022). Therefore, there is a need to support this development and the teachers' pedagogical planning with tailored, research-based practical advice. An important challenge for didactic research is to provide teaching formats that enable students with diverse learning needs to work together. Finding a balance between individualised and collective teaching methods is essential in order to allow "learning on the common object" (Feuser, 1982). This standard has yet to be sufficiently achieved in practice. One reason for this can be found in the rare cooperation between science education and special education (Menthe & Hoffmann, 2015; Stinken-Rösner et al., 2020).

Research Framework

The design-based research project E²piMINT fits into this scenario, bringing together researchers from subject specific education in physics, biology and chemistry, as well as special education to develop innovative and inclusive teaching concepts for the secondary school level. The design-based research approach is an effective and flexible combination of theoretical and practical methods, allowing to test the effectiveness of the pedagogical approach during its development

(DBR Collective, 2003; Wilhelm & Hopf, 2014). The project ran from August 2022 to July 2025. During this time, a teaching concept based on existing research, empirical observations and dialogue with teachers from all types of schools was developed. This concept was implemented and tested through practical learning activities in teaching laboratories at the Goethe University and in schools in Frankfurt (Germany) and the surrounding area.

Research Aims And Target Group

One of the project's many challenges is to make interdisciplinary scientific content accessible to all learners, overcoming learning barriers and providing equal support. The project aims to design and produce teaching materials that can be used as directly and flexibly as possible in schools, while also contributing to research in inclusive science education. The effectiveness of the developed teaching concept was tested by evaluating, for example, students' interest in experimenting and perceived experimental self-efficacy, as well as their understanding of the scientific phenomena covered. The project's target group is students in lower secondary level across all school types. The focus is on pupils with SEN, particularly those with learning difficulties, in both regular and special schools. Comprehensive schools ("Gesamtschulen" in German) are of particular interest to the project due to their organisation and purpose. In fact, students at these schools participate in mixed-ability classes and often work using a project-based learning approach, which facilitates the implementation of the collaborative laboratory activities developed in the project.

Method

Research Methods

Table 1: Sample items of the questionnaire.

Scale	Sample Items
Interest in experimenting	*Experiments are boring.*
	I like to carry out set experiments independently.
Perceived experimental self-efficacy	*I can carry out an experiment on my own, without help, using the instructions.*
	I can do experiments even when I'm nervous.

A mixed methods approach combining quantitative and qualitative research methods was used throughout the study. With a questionnaire within a pre-post-follow-up design, the instrument included scales examining how interest in experimenting and perceived experimental self-efficacy changed among learners. The items were adapted to a simplified language given the presence of learners with SEN and were based on validated research instruments. The questionnaire was successfully piloted and adjusted (Fechner, 2009; Hoffman et al., 1998; Schroedter & Körner, 2012; Pantiri et al., 2024a). The final version of the questionnaire consists of eight items related to interest in experimenting and seven items related to perceived experimental self-efficacy, all of which are answered using a five-point Likert scale (from "strongly disagree" to "strongly agree"). To help children with reading difficulties, the Likert scale also included a visual component in the form of a one-to-five-star rating system, similar to those commonly used for reviews. Table 1 shows some examples of items for the two scales, validated in German. English translations are provided as an indication.

The pre-test occurred approximately three weeks before the students participated in the activity; the post-test took place immediately afterwards; and the follow-up test took place approximately

four to six weeks later. Semi-structured group interviews with learners and group observations were used as qualitative research instruments to further investigate their interest, group dynamics and learners' understanding. Given the central role of teachers in the project, their feedback was obtained using a semi-open questionnaire to assess their perspective on the effectiveness of the teaching approach and its applicability in school practice. Analysis of their feedback revealed that the teachers had a high appreciation of the concept, with particular emphasis on the successful alternation of individual and collaborative work, as well as the choice of experiments and materials, which were close to the students' everyday experience. However, this paper focuses on the quantitative results, so the qualitative research is not discussed in detail.

Study Design

In the first research phase, the developed concept was tested and evaluated under controlled conditions in the teaching laboratories at Goethe University Frankfurt (Pantiri et al., 2024b). This was followed by a second research phase in which the effectiveness of the concept was tested in school practice in cooperation with secondary school teachers. The concept is structured as station-based learning, with each station represented by a "Researcher Box", a practical kit containing the necessary materials for the experiments. This allows learners, divided into heterogeneous groups, to work as independently as possible during the experimental phase, helping and supporting each other within their own group, and, in a second phase, between groups. This concept was tested and optimised in design-based research cycles during the 2022/23 school year. Some key features emerged and became established during this time: a) using highly action-oriented and interdisciplinary experiments from physics, biology and chemistry, b) alternating individual and group work phases, c) valuing learner diversity by offering different approaches to the experiments as well as written and video instructions, help cards and additional tasks, d) using alternative methods of fixing and presenting results in the form of collaborative posters.

Two topics were chosen for the activities: "Colours" for grades 5th to 6th and "Glueing and Sticking" for grades 7th to 10th to investigate possible topic-related dependencies. Two sets of seven boxes have been developed for each topic. The "Colours" topic was tested and evaluated in the Goethe University's teaching laboratories in the 2023/24 school year, while the "Glueing and Sticking" topic was tested during the 2024/25 school year. The boxes for both topics were subsequently lent to schools, where teachers could use them flexibly in terms of duration and organisation, but without changing the aforementioned key features. The main study consists of different survey phases, depending on the location of the intervention (at the university or in schools) and on the topic of the activity, as shown in Table 2. These phases are analysed both individually and in relation to each other in the main study. The results presented in this paper focus on the implementation of the activities in the teaching laboratories at the university (Phase 1 and 2).

Table 2: Research design of the main study.

Phase 1 – Sample 1	**Phase 2 – Sample 2**	Phase 3 – Sample 3	Phase 4 – Sample 4
Teaching laboratories (university)		School practice	
Colours	**Glueing and sticking**	Colours	Glueing and sticking
11/2023-04/2024	***11/2024-02/2025***	*06/2024-07/2025*	*03/2025-07/2025*
Age 10-12	***Age 13-16***	*Age 10-12*	*Age 13-16*

Results

This section focuses on the preliminary quantitative results of Phases 1 and 2 (see Table 2), which were obtained by analysing the questionnaire described in the "Research Methods" section. The central research question for this analysis is: Do the activities "Colours" and "Glueing and Sticking" have an influence on students' interest in experimenting and on their perceived experimental self-efficacy? To investigate this question, a one-way analysis of variance (ANOVA) with repeated measures for dependent samples was performed on the quantitative data collected of each topic. In this analysis, time is the only ANOVA-factor: t1 stands for the pre-test, t2 for the post-test and t3 for the follow-up test. The intervention is the laboratory activity. Figure 1 and Figure 2 show the overall data distributions of the two scales per time point in the form of violin and box plots. Figure 1 shows the data for Phase 1 (activity "Colours"), and Figure 2 shows the data for the Phase 2 (activity "Glueing and Sticking"). The significance values and effect sizes resulting from the pairwise comparison (Bonferroni correction) are shown in Table 2 and 3, respectively.

Regarding the topic of "Colours", the median of the interest scale (Figure 1, left) increases from before the laboratory visit ("SL") to after the visit, and decreases again after 4-6 weeks. Both changes are significant, as showed in Table 3. The p-values are in fact <0.05 in both cases (t1 to t2 and t2 to t3) and the effect sizes of the increase and decrease are significant although small (0.2 < Cohen's d < 0.5), indicating a short-term increase of the interest in experimenting (Cohen, 1992). The median of the scale of perceived experimental self-efficacy (Figure 1, right) increases from before the school laboratory visit to after it and slightly decrease up to 4-6 weeks after the activity. The change from t1 to t2 is highly significant (p-value <0.001) with a medium effect size (Cohen's d >0.5), the decrease from t2 to t3 is only slightly significant, and the effect size is not significant at all (Cohen's d <0.2; Cohen, 1992). This indicates a possible score stabilisation up to 4-6 weeks after the activity.

Regarding the topic of "Glueing and Sticking", the median of the interest scale (Figure 2, left) does not increase, but rather decreases slightly over the three time points. However, these changes are not significant, as shown in Table 3, and the effect sizes are negligible. The median of the perceived experimental self-efficacy scale (Figure 2, right) increases slightly from t1 to t2, before decreasing to t3. These changes are also not significant, however, with negligible effect sizes.

Figure 1: Violin and box plots for the IE_EXP and SWE_EXP for the topic of "Colours". 5 corresponds to a high IE_EXP or a high SWE_EXP, 1 to a low one. The sample consists of the same N = 194 pupils in both scales.

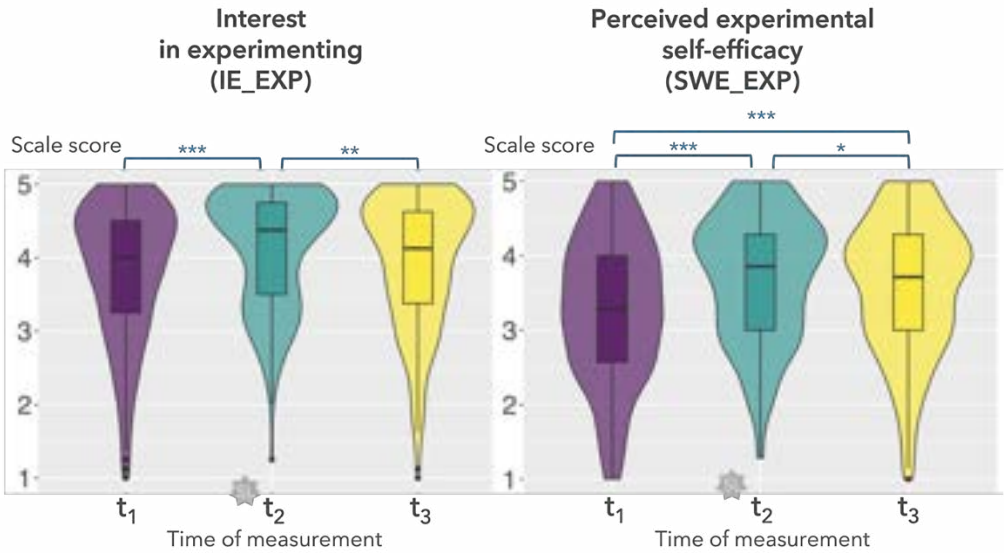

Table 3: Pairwise comparison of the two scales for the topic of "Colours": significance and effect size.

Scale	Time		Significance	Cohens d	Effect size
IE_EXP	t_1	t_2	p<0.001	0.36	small
	t_1	t_3	n.s.	0.14	-
	t_2	t_3	p<0.01	0.25	small
SWE_EX	t_1	t_2	p<0.001	0.51	medium
	t_1	t_3	p<0.001	0.32	small
	t_2	t_3	p<0.05	0.18	-

Figure 2: Violin and box plots for the IE_EXP and SWE_EXP for the topic of "Glueing and Sticking". 5 corresponds to a high IE_EXP or a high SWE_EXP, 1 to a low one. The sample consists of the same N = 142 pupils in both scales.

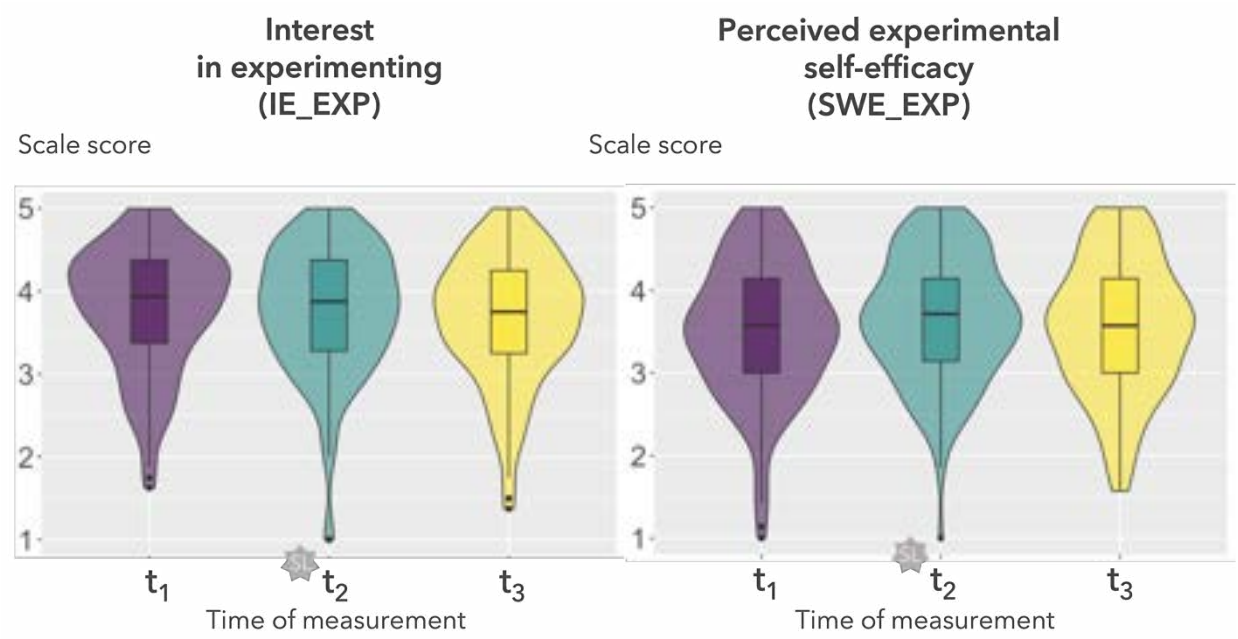

Table 4: Pairwise comparison of the two scales for the topic of "Glueing and Sticking": significance and effect size.

Scale	Time		Significance	Cohens d	Effect size
IE_EXP	t_1	t_2	n.s.	0.04	negligible
	t_1	t_3	n.s.	0.19	negligible
	t_2	t_3	n.s.	0.18	negligible
SWE_EX	t_1	t_2	n.s.	0.19	negligible
	t_1	t_3	n.s.	0.05	negligible
	t_2	t_3	n.s.	0.19	negligible

Discussion of Results and Implications

In summary, these preliminary results show different effects of the two activities. For the topic "Colours", the results suggest a short-term increase in students' interest in experimenting and a possible long-term increase of their perceived experimental self-efficacy. The increase in interest in the post-test results could indicate a positive perception of the laboratory activity "Colours"

and the pedagogical approach about experimenting on which the activity is based. The short-term increase in interest aligns to findings on the effectiveness of a one-off visit to a teaching laboratory (e. g. Pawek, 2009). Regarding perceived experimental self-efficacy, the medium effect size in its short-term increase, despite resulting in a small long-term effect, could suggest an interesting consequence of the intervention, and requires further investigation. To this extent, external factors may have influenced the perceived self-efficacy. Did lessons at school after the visit have any influence? Did the teachers themselves gain self-efficacy in conducting experiments with the class? Were the lessons between the intervention and the follow-up test more experimental or more theoretical? Ongoing additional analyses are therefore investigating the presence of these and other influencing factors, such as the emergence of subgroups in the sample, e. g., gender differences, belonging to a class or type of school, etc.

These results and the related discussion do not apply to the topic of "Glueing and Sticking", for which no significant changes were observed. Further research is needed to better understand these results. One plausible hypothesis for the lack of increase in interest in experimenting and perceived experimental self-efficacy is the difference in participants' age. In fact, as shown in Table 1, the pupils who worked on this topic were aged between 13 and 16 (grades 7th to 10th), while the pupils who worked on the topic of "Colours" were aged between 10 and 12 (grades 5th to 6th). Many studies (see, for example, Habig et al., 2025 for a systematic review) suggest a general decrease in interest in science and science-related topics as age increases. One way to test this hypothesis would be to adapt the "Glueing and Sticking" activity for younger age groups, enabling samples of similar ages to be compared and the topic variable to be better isolated. Another possibility emerges from comparing the results of quantitative and qualitative research analyses. In fact, as mentioned in the "Research Methods" section, semi-structured interviews were conducted with pupils who participated in the activities. An ongoing qualitative content analysis of these interviews investigates possible reasons for growth or lack of growth in the students' interest and perceived self-efficacy.

ESERA 2025 Copenhagen

Making Room Or Falling Into A Trap – Biology Teachers' Conceptions Of Evolutionary Lesson Planning

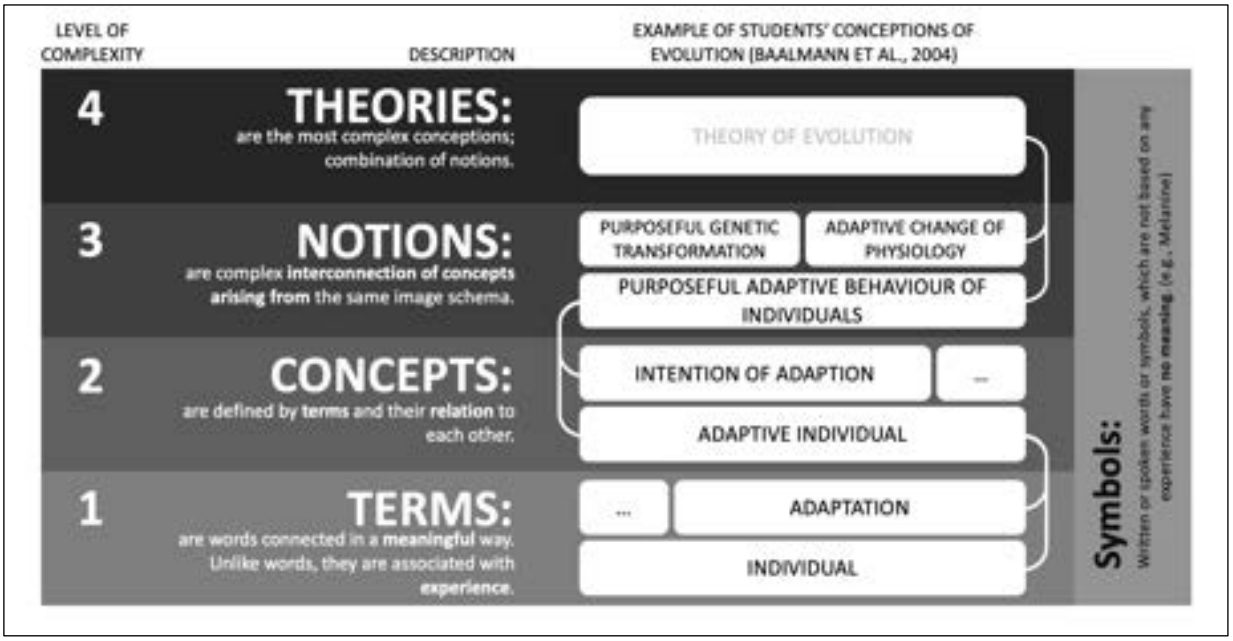
Marleen Schellwald, Malte Michelsen and Jorge Groß
Leibniz Universität Hannover, Germany

From a constructivist perspective, learning environments that address students' conceptions are essential for meaningful learning. The Model of Educational Reconstruction (MER) provides a framework for developing conception-oriented biology instruction by systematically relating students' and scientific conceptions. While the MER has proven effective for designing instructional guidelines and interventions, little is known about how it is reflected in teachers' everyday lesson planning. Semi-structured interviews were conducted with experienced biology teachers (N = 9) focusing on lesson planning for evolutionary adaptation. Data were analyzed using qualitative content analysis combined with systematic metaphor analysis. We examine (1) teachers' conceptions of lesson planning and (2) their conceptions of students' conceptions of evolution. The results reveal contrasting teacher perspectives: while Mrs. Lilly understands students' conceptions both as learning difficulties that need to be addressed and as opportunities for learning, Mrs. Rose primarily views students' conceptions as obstacles to achieving curricular goals. These differences are reflected in distinct metaphorical framings (making room vs. preventing students from falling into a trap) and vary in their alignment with core principles of the MER. The findings highlight that research on students' conceptions must be systematically connected to teachers' professional conceptions in order to inform classroom practice and teacher education.

Keywords: evolutionary theory, students' conceptions, teacher training

Introduction

From a constructivist perspective, creating learning environments addressing students' conceptions is required to foster meaningful learning (Gerstenmaier & Mandl, 1995; Schrenk et al., 2019). A key framework for this is the Model of Educational Reconstruction (MER; Duit et al., 2012), which allows the development of learning environments based on a systematic comparison of students' and scientific conceptions. The MER has proven effective in developing conception-orientated biology instruction on the level of guidelines (e.g. Weitzel, 2024; Kattmann, 2017) and learning interventions (e.g. Zabel & Gropengießer, 2011; Kattmann, 2017). Nevertheless, little is known about the use of the MER in everyday classroom contexts (Hamman & Asshoff, 2014). Additionally, there is limited research on how the MER can be adapted for the design of learning environments for teachers, such as teacher training programmes (Jelemenská, 2012; van Dijk & Kattmann, 2007).



The findings of this study are intended to be used for the development of a professional teacher training program for German secondary school biology teachers, primarily focusing on teachers' individual conceptions of students' conceptions of evolution and their strategies of dealing with them in classroom. In this context, the MER has been adapted for use in teacher education. The theory of evolution was chosen as the biological context because it is characterized by a wide range of students' conceptions (Gregory, 2009; Harms & Reiss, 2019; Zabel & Gropengießer, 2011) causing persistent learning barriers. Furthermore, evolutionary theory plays a central role in understanding biology (Dobzhansky, 1973).

Theoretical Framework

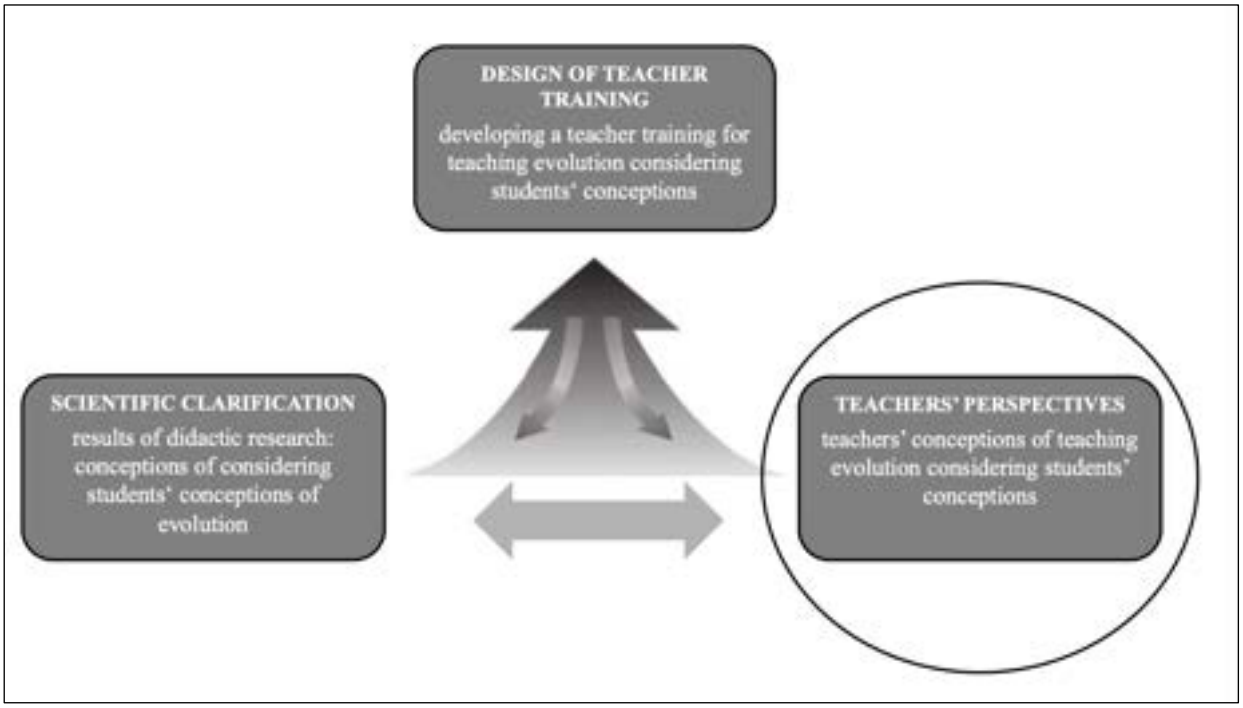
Teaching And Learning Considering Learners' Conceptions

Research suggests that addressing learners' conceptions plays a key role in facilitating conceptual change (Duit & Treagust, 2003; Riemeier & Gropengießer, 2008; Shtulman et al., 2016). We understand conceptions as individual mental constructs. They can be viewed on different levels – ranging from terms and concepts to notions and theories – and differ from symbols (e.g., words), which lack an experiential foundation (see Figure 1).

Figure 1. Hierarchical order of conceptions on different levels of complexity (based on Michelsen et al., 2022) with examples on the topic of evolutional adaptation.

Using evolution as an example, an extensive body of research exists about students' conceptions, learning barriers and strategies that are specifically designed to foster conceptual change (e.g., Bishop & Anderson, 1990; Brumby, 1979; Harms & Fiedler, 2019; Weitzel, 2024; Zabel & Gropengießer, 2011). Despite this substantial research base, evidence from Hartelt et al. (2022) indicates that even practicing secondary school biology teachers struggle to address students' conceptions effectively.

Conceptual Metaphor Theory



Conceptual Metaphor Theory (Lakoff & Johnson, 1980) conceptualizes metaphors as cognitive structures that shape human cognition. In order to make sense of abstract phenomena that are not directly accessible through experience, individuals draw on embodied source domains grounded in bodily and everyday experience (Niebert et al., 2012). Meaning is constructed by mapping these concrete, experience-based domains onto more abstract target domains. For example, evolutionary adaptation is often conceptualized through a goal-directed source–path–goal schema (Gropengießer & Groß, 2019), in which students draw on their experience of moving from a starting point toward a defined destination. This metaphorical framing can lead to interpretations of evolution as a purposeful and directed process, which contrasts with the scientific understanding of adaptation as an undirected population-level process. Considering students' conceptions is crucial in evolution education, as these pre-instructional concepts strongly influence how students make sense of evolutionary mechanisms and thus need to be addressed deliberately in lesson planning. For teachers, knowledge of these conceptions is essential for anticipating learning difficulties, selecting appropriate instructional strategies, and supporting students in developing scientifically accurate understandings. In this study, we examine teachers'

(metaphorical) framings in lesson planning to gain deeper insights into their conceptions of teaching evolution.

Study Framework

The aim of this project is to design a teacher training program that helps teachers adress students' conceptions of evolution, supports their professional development, and strengthens their ability to integrate these conceptions into biology instruction. To this end, we draw on the Model of Educational Reconstruction (Duit et al., 2012), adapted for teacher education (van Dijk & Kattmann, 2007) and further refined for the development of the proposed training program. This study concentrates on investigating teachers' perspectives (see Figure 2).

Figure 2. Study framework: The MER for teacher education, based on the ERTE-Model, developed by van Dijk & Kattmann (2007). The circular mark shows where to locate this study.

Research Questions

- Which conceptions of students' conceptions of evolution can be identified from teachers' lesson planning processes?
- Which conceptions of evolutionary lesson planning can be identified from teachers while planning processes?
- How can teachers' conceptions regarding students' conceptions of evolution be interpreted in the context of the Model of Educational Reconstruction?

Methods

We conducted semi-structured individual interviews with nine practicing biology teachers in Lower Saxony, Germany. Participants had experience teaching evolution and at least three years of general teaching experience. The sample was heterogeneous and included a teacher educator (N = 1), a teacher with a PhD in science education (N = 1), and a career changer with a PhD in biology (N = 1). The participation was voluntary.

The interviews comprised three parts:

1. Teaching evolution: experiences with teaching evolution, lesson planning approaches, and the use of a text on evolutionary adaptation.

2. Lesson planning: planning a lesson on evolutionary adaptation using antibiotic resistance, followed by presentation and explanation of instructional decisions.
3. Teaching and learning: views on teaching roles, learning processes, the consideration of students' conceptions and material selection in planning.

The data were examined using qualitative content analysis (Mayring, 2010) alongside systematic metaphor analysis (Schmitt, 2017).

Results

In order to answer our research questions, we focus on two deductively derived categories: *conceptions of lesson planning* and *concepts of students' conceptions of evolution* (see Table 1). Furthermore, our findings are illustrated using the examples from the interviews with Mrs. Lilly (Interview 8) and Mrs. Rose (Interview 9), both names are pseudonymized.

Table 1. Conceptions of the interviewed teachers Mrs. Lilly and Mrs. Rose regarding the main categories 'conceptions of lesson planning' and 'concepts of students' conceptions of evolution'.

No.	Conceptions of lesson planning	Concepts of students' conceptions of evolution
8 (Mrs. Lilly)	Anticipate students' steps of understanding Making room for students' conceptions	Cause for learning difficulties Chance for learning
9 (Mrs. Rose)	Anticipate students' steps of understanding	Obstacles for test performance Trap

Make Room: Mrs. Lilly

Mrs. Lilly structures her lesson planning using the source–path–goal schema. She describes students as "going through different steps of understanding", starting from "what happened in previous lessons". In this way, she supports students in reaching the "teaching goal – where I want them to go, which curricular competencies I want to address". In addition to the level of learning curricular competencies, Mrs. Lilly addresses the level of understanding evolution, in which students' conceptions "play a big role".

> I know that learners' conceptions of evolution differ significantly from what we see biologically. This means that when it comes to selection or evolutionary processes, we need to look at what conceptions the students already have. What are the learning difficulties we face in this area? Clearly, one of these is active adaptation. (Mrs. Lilly)

For Mrs. Lilly, students' conceptions are "part of every lesson. They are part of the lesson planning, part of the lesson I teach and part of my reflection on the lesson. I give them enough room in all three phases". Additionally, Mrs. Lilly actively diagnoses students' conceptions and encourages students to become aware of their own conceptions. As she states, students "want to learn something and while doing this they find out that reflecting their own conceptions is a part of their learning process". This suggests that she understands students' conceptions both as learning difficulties that need to be addressed, and a chance for students in order to better understand the theory of evolution.

Mrs. Lilly does not perceive the development of curricular competencies and the fostering of evolutionary understanding as incompatible. However, she acknowledges the challenge of addressing both levels simultaneously: "How can I continue my lesson in a way that gives space

to the conception while still achieving my instructional goal? I believe this is one of the most challenging aspects of teaching.

Prevent From Falling Into A Trap: Mrs. Rose

Mrs. Rose structures her lesson planning using the same experience-based referent as Mrs. Lilly, the source-path-goal schema. She also refers to "steps of understanding", and to a "goal orientation: when do I have to be where content-wise". When characterizing her teaching goal, she makes clear, that, in contrast to Mrs. Lilly, she prioritizes the level of learning curricular competencies over the level of fostering understanding of evolution in her lesson planning:

> How adaptations or characteristics change through selection in connection with mutations and random changes in characteristics – that is what they should learn in the basic principle. And once they have understood this, they should be able to complete the tasks in their high school graduation exams more or less successfully. So – that's the goal. So, I'm not talking about something you should internalize because it will make your life better. (Mrs. Rose)

Another major difference compared to Mrs. Lilly lies in Mrs. Rose's understanding of students' conceptions of evolution. She describes them as a "trap that many students fall into, they fall into that thinking pattern". Mrs. Rose characterizes these conceptions as students' "wrong ideas, based on everyday experiences" that she "correct[s] accurately". This suggests that she views students' conceptions primarily as obstacles to achieving teaching goals and exam success. Consequently, Mrs. Rose's views on students' conceptions of evolution lead to a selective consideration of them, depending on the significance for reaching the teaching goal. She reflects: "What happens in my lessons to prevent them from falling into that trap or speak this conception out loud? Or do I want to address the students' conception explicitly so that we can discuss what it actually means?"

Discussion

Mrs. Rose's and Mrs. Lilly's lesson planning processes reveal fundamentally different approaches to students' conceptions.

For Mrs. Lilly, two interconnected notions of planning evolutionary lessons can be identified. Her planning on the level of curricular competencies is structured by a source–path–goal schema. In her view, students' conceptions of evolution belong to a different but equally relevant level — the level of conceptual understanding of evolution. At this level, her lesson planning is metaphorically structured by the idea of *making room* for students' conceptions. The structure of the Model of Educational Reconstruction (MER) supports the diagnosis of students' conceptions, the development of learning environments that foster conceptual understanding, and the reflection of instruction using students' conceptual change as an indicator. This framework thus creates systematic opportunities to integrate students' conceptions into lesson planning. Mrs. Lilly's understanding of *making room* for students' conceptions is therefore consistent with the central principles of the MER.

In contrast, Mrs. Rose clearly prioritizes the level of curricular competency development over fostering a deeper conceptual understanding of evolution. She primarily interprets students' conceptions as obstacles that hinder students from reaching the teaching goal. Consequently, she tends to avoid engaging with students' conceptions, which she metaphorically frames as *traps*. Within this metaphorical framing, students appear unable to leave these traps once they have entered them, suggesting a rather static view of learning. Such conceptions are not compatible with the fundamental principles of the MER, as MER-based learning environments are designed

to support students in transforming their conceptions toward scientifically more adequate understandings.

These two cases illustrate how systematic metaphor analysis can provide deeper insights into teachers' cognitive structures underlying lesson planning. Moreover, the examples of Mrs. Lilly and Mrs. Rose demonstrate that successful conceptual change in classroom practice cannot be achieved by focusing solely on students and their conceptions. Greater attention must also be paid to the teacher level, particularly to how teachers interpret and address students' conceptions during lesson planning and instruction. If teachers' conceptions remain unexamined, research on students' conceptions risks remaining disconnected from instructional practice and therefore offers limited guidance for lesson planning and teaching decisions.

From a different, more cognitive perspective, the growth mindset (Dweck & Yeager, 2019) describes a similarly polarised approach to learning obstacles. On one side of the spectrum, learning obstacles are seen as a threat to the learning process and are therefore avoided. On the other side, learning obstacles are deliberately targeted by teachers, who see the irritation experienced by learners when confronted with them as a learning opportunity.

These different perspectives are particularly important for teacher training, as they could have a significant influence on the professional conduct of future teachers: remaining effective requires a controllable attribution of the causes of learning barriers. A study with math teachers (Copur-Gencturk et al., 2025) could show, teachers struggling with learning barriers in their lessons, attributed them to a lack of prior knowledge, a general inability for dealing with the subject or memory problems - causes which are mostly uncontrollable for a teacher. Their findings suggest that the ways teachers characterize common student struggles are linked to their instructional practices. The findings of the study presented here and the insights of Copur-Genturk et al. (2025) suggest that the investigation of teachers' conceptions of prominent learning barriers of evolution (Zabel & Gropengießer, 2011) should be the next step in the development of a teacher training programme in line with MER.

ESERA 2025 Copenhagen

Visualizing Chemistry: Analyzing Graph Usage In Textbooks And Its Implications For Teaching

Beate Fichtner and Katharina Groß
Institute of Chemistry Education, University of Cologne, Germany

Graphs are central to science and chemistry education, representing abstract concepts and providing alternatives to purely text-based learning. However, their high information density and abstract nature can overwhelm students, potentially leading to cognitive overload. Developing graph competence, the ability to understand and use graphs meaningfully, is therefore essential. While research on graph use and comprehension is established in science education research, chemistry-specific insights remain limited. This study addresses that gap by introducing a graph competence model for chemistry and using it as an analytical lens in a systematic textbook analysis to gain a practice-orientated understanding of graph use in chemistry. Eight German lower- and upper-secondary chemistry textbooks were examined using a category-driven mixed-methods approach, identifying and analyzing 3,550 visual representations. The findings highlight domain-specific characteristics of graph types in chemistry and their distribution across content areas and educational levels, as well as distinct differences in the coverage of graph competence components in tasks between school levels and school types. These patterns point to potential challenges that students are likely to face when engaging with graphs in chemistry and extend previous research on graph use in science education by providing a focused chemistry education perspective. The conference paper introduces the graph competence model and presents selected results that focus on assigning graph related tasks to competence components and levels. Building on these findings, it derives concise implications for teaching graphs in chemistry and for future research on students' graph competence and graph-related difficulties.

Keywords: Graph Competence, Visual Representations, Textbook Analysis

Introduction

Graphs are pervasive in everyday life, science, education, and society. As abstract visual representations, they do not depict objects through direct similarity but through analogical relations between variables, typically with at least one continuous variable. Scales specify the range of possible values a variable can take, thereby enabling the description and interpretation of data based on its position along the axes. In contrast, in realistic pictures the relationship between an object and its representation is directly visible, creating a concrete structural correspondence that is constrained by the two-dimensional nature of the representation (Schnotz, 2001).

From an educational perspective, graphs have an ambivalent role. On the one hand, chemistry's inherently visual nature makes graphs ubiquitous: students encounter them frequently across various areas of chemistry education (Bowen & Roth, 2002; Ring & Brahm, 2020). They are important for visualizing and explaining data and concepts in both theoretical and experimental contexts (Boels et al., 2019; Bowen & Roth, 2002). Consequently, accurate reading, interpretation, and constructing of graphs are essential for acquiring chemistry specific-knowledge. The importance of engaging with graphs is also emphasized in curricula (e.g., Ministerium für Schule und Weiterbildung des Landes Nordrhein-Westfalen, 2022; National Research Council, 2013). On the other hand, prior science education research shows that graphs pose challenges for students due to their abstractness and complexity (Bowen & Roth, 2002; Glazer, 2011; Jahnke, 2020), and that understanding them is far from intuitive for learners (e.g., Ring & Oberrauch, 2024).

To address these difficulties and to realize the learning potential of graphs in chemistry education, graph competence is necessary. Graph competence is the cognitive ability to understand graphs and, based on this understanding, independently solve graph-related tasks involving both information extraction and graph construction (Lachmayer, 2008). Because graph competence is domain-specific, it is essential that learners develop chemistry-specific graph competence to engage meaningfully with graphs and to develop a multimodal understanding of chemical concepts. This competence is not only crucial from an educational point of view but also in students' everyday lives: they need it not only to understand graphs in contexts such as climate change or health statistics, but also to critically question and evaluate the data represented. Nevertheless, despite the importance of graphs in general and graph competence in particular, research on graph competence in chemistry education remains limited, especially with regard to the difficulties learners experience when working with graphs and how instruction can both address these difficulties and foster the learning potential of graphs.

Figure 1. Revised model of graph competence for chemistry (adapted from Lachmayer, 2008). English translations are primarily based on Bernholt and Parchmann (2011) and Von Kotzebue et al. (2015).

Theoretical Framework

Graph competence in chemistry was conceptualized and operationalized on the basis of a model of graph competence originally developed for biology education (Lachmayer et al., 2007; Lachmayer, 2008). This model was then refined to account for chemistry-specific requirements, particularly the characteristics of typical chemistry tasks. It was further adapted using the "Model of Hierarchical Complexity" (Commons et al., 1998), as applied to chemistry by Bernholt et al. (2009). The resulting model shows that competent engagement with graphs involves three core components: "information extraction" from graphs, "construction" of graphs, and "integration" of texts and graphs. Each component is further divided into specific subcomponents. In this study, as these are most relevant to our research question, we focus on the component "information extraction" from graphs and on the newly developed subcomponents "off-reading" and "explanation and interpretation", which are differentiated into levels of increasing complexity (see Figure 1).

Furthermore, graph competence can be differentiated into a domain-general and a domain-specific dimension. These two dimensions are reflected in the graph competence model, where they appear in the respective levels of the component "information extraction" (see Figure 1). The domain-general dimension involves aspects related to the content-independent, formal dimension of graph competence. Since these aspects do not concern the underlying content of the graph, they are relevant across different subjects. This includes, for example, identifying a function value in a graph (level 1) and describing the graph's overall shape (level 2). In contrast, the domain-specific dimension comprises aspects that pertain to the underlying content represented by a graph. This includes, for example, subject-specific interpretations of a function value (level 3), of a single graph (level 4), and of multiple graphs (level 5). These aspects are therefore specific to graph competence within a particular subject domain, in this case chemistry. In this regard, integrated graph competence involves bringing together the formal and the content-related dimensions of graphs. The importance of this integration becomes particularly evident when students explain complex graphs, for example in the context of chemical equilibrium: on the one hand, they must understand the underlying chemical principles (e.g., that the concentrations of reactants and products remain constant at equilibrium), and on the other hand, they must recognize how these principles are represented formally in the graph (e.g., horizontal lines with a slope of zero). This differentiated perspective on graph competence underscores the necessity for students to develop graph competence that specifically reflects the particular characteristics and demands of graph use in chemistry.

Aim and Research Question

The research project aims to address the research gap (see above) by assessing students' graph competence in chemistry and by exploring ways to enhance it through targeted differentiation strategies.

To address the overarching research question, it is first necessary to gain foundational insights into the domain-specific use of graphs in chemistry. The textbook analysis presented in this conference paper serves this purpose and provides practical insights into how graphs are used in chemistry education. Textbooks were selected because they closely reflect the implemented curriculum (Khaddoor et al., 2017; Upahi & Ramnarain, 2019), and their analysis therefore offers valuable information about the content likely addressed during classroom instruction. Moreover, textbooks play a central role for both students, serving as learning resources that enable flexible, self-paced access to content and support individual learning (Chi et al., 2024; Rusek & Vojíř, 2019), and for teachers, functioning as tools for lesson planning and instruction as well as sources of subject-matter information (Meyer & Pietzner, 2022; Vojíř & Rusek, 2022). The main research

question guiding the textbook analysis is therefore: *How are graphs used in chemistry textbooks?* This overarching question is further specified by the following four sub-questions (SQs):

SQ1: *How frequently are graphs used compared to realistic pictures?*

SQ2: *What types of graphs are used?*

SQ3: *In which content areas are graphs most frequently used?*

SQ4: *To which competence components and competence levels do graph-related tasks (line graphs) correspond?*

The present conference paper focuses on SQ4, examining how graph-related tasks are linked to specific competence components and levels. A comprehensive presentation of all results, including findings related to SQ1–SQ3, is provided in Fichtner and Groß (2025a).

Methodology

To address the research question, a systematic coding approach was applied to eight chemistry textbooks, guided by a structured category scheme and informed by the method of graphical analysis (Slough et al., 2010; Khine & Liu, 2017). Building on this established approach, we developed an adapted graphical analysis procedure tailored to our research aim, enabling a systematic and structured analysis of both graphs and realistic pictures in the textbooks.

Eight German chemistry textbooks from North Rhine-Westphalia were selected, representing three major publishers (*Klett*, *Westermann*, and *C.C.Buchner*) and covering both lower and upper secondary education as well as two school types (middle schools, $N = 2$; grammar schools at lower secondary level, $N = 3$; grammar schools at upper secondary level, $N = 3$). One textbook per educational level was chosen from each publisher, allowing for meaningful comparisons across publishers and school types. Table 1 presents the analyzed textbooks by secondary level and school type, along with their abbreviations.

Table 1. Textbooks analyzed in the study, listed by secondary level and school type.

Secondary level, school type	**Name**
Lower secondary textbooks, grammar schools	*Elemente Chemie 7-10*, *Chemie Gesamtband Sekundarstufe I*, *Chemie heute*
Lower secondary textbooks, middle schools	*Prisma Chemie 1/2*, *Blickpunkt Chemie 7-10*
Upper secondary textbooks, grammar schools	*Elemente Chemie Oberstufe*, *Chemie Einführungsphase* (abbreviation: *Buchner H1*), *Chemie Qualifikationsphase* (abbreviation: *Buchner H2*), *Chemie heute SII*

Including textbooks from major publishers and across multiple school types and levels ensures that the sample is representative of materials widely used by chemistry teachers, thereby providing authentic insights into the use of graphs in educational contexts. The only exceptions are that *C.C.Buchner* currently does not publish a middle school textbook and that its upper secondary textbook is divided into two volumes (*Buchner H1* and *Buchner H2*), which were analyzed together to ensure comparability.

For the specific analysis of the textbooks, we first systematically identified 3,550 visual representations (including graphs, realistic pictures, and mixed forms that combine elements of both graphs and realistic pictures). These visual representations were then analyzed using a

category scheme. In the following, we present the part of the analysis that addresses SQ4 (for a full account, see Fichtner & Groß, 2025a).

Regarding SQ4, the graph competence model outlined above plays a crucial role, as it provides the analytical framework for examining the competence components and levels targeted by graph-related tasks and therefore constitutes a central part of the category system. To answer SQ4, we first distinguished between line graphs linked to tasks and those linked to texts (category "Text/Task Assignment"). Second, based on the identified graph-related tasks, we examined whether they aligned with the relevant main competence component, either "information extraction" or "construction". Third, we analyzed the tasks classified as information extraction tasks and coded them according to one of the five competence levels (see Figure 1). To ensure coding reliability, two researchers independently assigned competence levels to 20% of the line graph-related information extraction tasks (n = 74), compared and discussed any discrepancies, and, where necessary, refined the coding scheme, definitions, and examples (Guest et al., 2012; Kuckartz & Rädiker, 2022). Any remaining disagreements were resolved by a third rater using a consensus-based approach. Intercoder reliability, assessed using Cohen's Kappa, indicated a very high level of agreement (κ = 0.946; Balci, 2022; Cohen, 1960; Gamer et al., 2019; Landis & Koch, 1977; The jamovi project, 2024).

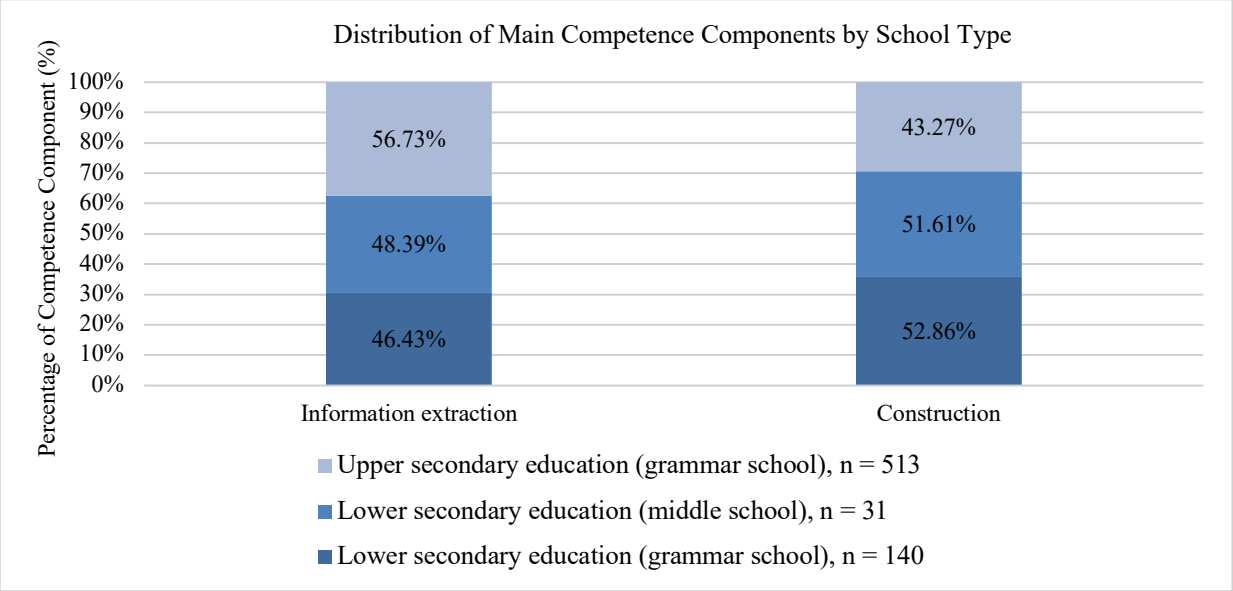
Findings

The results reveal clear differences in the number of graph-related tasks in textbooks depending on school type and educational level. Lower secondary middle school textbooks contain 28 line graphs and 31 associated tasks, corresponding to 1.11 tasks per line graph. In contrast, lower secondary grammar school textbooks include 86 line graphs accompanied by 140 tasks, corresponding to 1.63 tasks per line graph. A further increase appears at the upper secondary level, where 277 line graphs are linked to 513 tasks, resulting in 1.85 tasks per line graph. Thus, task density per line graph increases from lower secondary middle school to lower secondary grammar school textbooks and is highest in upper secondary grammar school textbooks. This pattern implies that learners at grammar schools, and especially at the upper secondary level, encounter line graphs more frequently and engage with them through more tasks than learners at middle schools. It suggests that upper secondary chemical content is particularly well suited to be represented in graph-based tasks and that students at this level are better able to engage with graphs without experiencing cognitive overload. This interpretation is consistent with previous research indicating that graph competence tends to increase with age and grade level (Curcio, 1987; Lachmayer, 2008; Padilla et al., 1986). However, it remains unclear whether students acquire a sufficient level of graph competence during lower secondary education to be adequately prepared for the higher task density in upper secondary textbooks, or whether they instead experience cognitive overload because their graph competence has not kept pace with the increased use of graph-related tasks. This issue is particularly critical for students who transfer from middle school to upper secondary grammar schools, as they have had comparatively few opportunities to develop graph competence through task engagement.

A closer look at the competence components addressed by line-graph tasks reveals a pattern in lower secondary grammar and middle school textbooks (see Figure 2). In both school types, tasks corresponding to the competence component "construction" occur slightly more often than tasks assigned to the competence component "information extraction". This suggests that, at this educational level, graphs are frequently used to support scientific working processes, for example, in the context of experiments. Yet the difference between the two components is small, indicating that both school types foster graph competence that addresses both the construction of

graphs and the extraction of information from them in a comparable way. In upper secondary education, however, this ratio changes, and a shift toward more frequent use of graph-related tasks associated with the competence component "information extraction" becomes apparent (see Figure 2). The focus of the tasks thus narrows, with students increasingly required to extract information from given graphs. A possible explanation is that students in upper secondary education possess more advanced subject-matter knowledge, which enables them to interpret graphs in greater depth regarding the underlying chemical concepts. In addition, this pattern supports the assumption that chemical content at this level is particularly well suited to graphical representation, thereby further encouraging an emphasis on information-extraction tasks.

Figure 2. Percentage distribution of main competence components in graph-related tasks by school type. Percentages represent the proportion of each competence component relative to the total number of competence components within each school type. One unclassifiable graph from lower secondary education (grammar school) is excluded from this visualization.



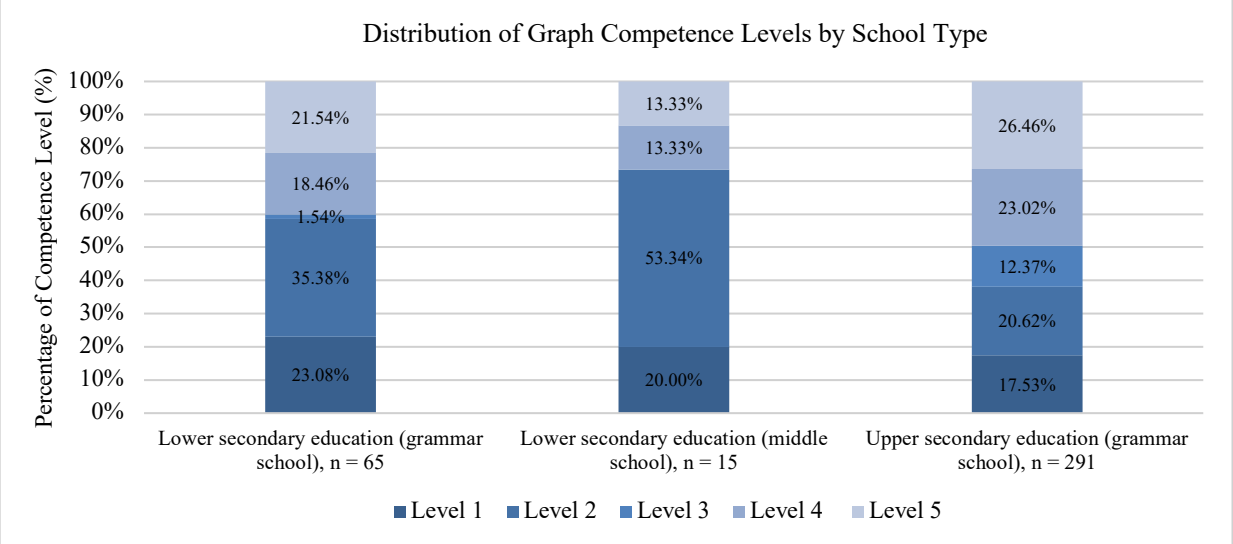


Figure 3. Percentage distribution of graph-related tasks by competence level and school type. Percentages indicate the proportion of tasks within each competence level relative to the total number of tasks analyzed for each school type.

Considering the competence levels within the competence component “information extraction”, learners across all school types encounter tasks that span multiple levels of graph competence and thus demand a range of different cognitive processes (see Figure 3).

Moreover, the discrepancy between school types and educational levels described above becomes more pronounced when the competence levels are considered. In lower secondary middle school textbooks, tasks at level 2 – requiring students to describe graphs – occur most frequently (53.34%), whereas tasks from the other competence levels are comparatively rare. A similar pattern emerges in lower secondary grammar school textbooks, where level 2 tasks also dominate (35.38%), but tasks from the remaining levels appear noticeably more often than in middle school textbooks. In terms of the dimensions of graph competence outlined in the theoretical framework, this indicates a clear emphasis on tasks that address the formal, content-independent dimension in lower secondary education textbooks. In contrast, upper secondary grammar school textbooks exhibit a different pattern, with graph-related tasks distributed more evenly across competence levels, thereby addressing the full range of cognitive demands. Simultaneously, there is a clear emphasis on levels 3–5, which involve more complex tasks and therefore require higher-order cognitive processes. With regard to the dimensions of graph competence, the focus is on tasks that address the domain-specific, content-related dimension, requiring the linking of chemical content knowledge with the form of graphical representation. This raises the question of whether upper secondary education students have developed the multilevel graph competence required to integrate both the formal and the content-related dimensions reflected in the tasks, particularly given that lower secondary education textbooks largely emphasize less demanding, domain-general tasks at levels 1–2. If such competence is insufficient, students may be overwhelmed by the breadth and increasing complexity of tasks in upper secondary education textbooks, potentially leading to cognitive overload (Sweller, 2005) or what Rau (2017) refers to as a representational dilemma. Accordingly, targeted support is needed to ensure that the necessary foundation, active engagement with multilevel graph-related tasks, is developed not only in upper secondary education textbooks but already in lower secondary education textbooks. This is especially important because, without such deep engagement, learners are likely to analyze graphs only superficially and will not fully understand the underlying subject matter (Jahnke, 2020).

Implications

Based on the findings of the study, implications for teaching can be derived. In general, it is important that students are systematically supported and encouraged in developing multilevel graph competence throughout their entire school career – across grade levels, subject matter that is represented in graphs, graph types, and regardless of the type of school they attend. This development can be fostered through the deliberate use of graph-related tasks that reflect the graph competence model in its entirety, including both information extraction and graph construction tasks. Moreover, all levels of the “information extraction” component need to be addressed to ensure that, over time, a sustainable and differentiated multilevel graph competence can emerge.

In order to provide students with adequate support when working on graph-related tasks and to foster their graph competence, it is generally essential that (prospective) teachers recognize the need to explicitly promote graph competence in chemistry lessons rather than relying solely on textbooks. Teachers should explain graphs in a language-sensitive manner, drawing on established quality criteria for instructional explanations in chemistry education (Fichtner & Groß, 2025b). The deliberate and targeted explanation of graphs in classroom practice is particularly important in light of our analysis, which showed that graph captions are

predominantly descriptive and often brief and therefore provide little support for students' comprehension (consistent with prior research, e.g., Bowen & Roth, 2002). Another implication for promoting graph competence directly through textbooks concerns the design, implementation, and use of strategy pages that explicitly outline steps for constructing, describing, explaining, and critically evaluating graphs. These pages provide students with a clear framework for approaching graph-related tasks and help them become aware of the domain-specific features of chemical graphs.

Moreover, appropriate scaffolds should be implemented and adaptively tailored to the specific difficulties that students experience when engaging with graphs. As a prerequisite, it is necessary to first identify the particular challenges that learners encounter when working with chemistry-specific graphs. The second study of the research project addresses this need by examining the difficulties learners face with different types of chemistry-specific graphs using tasks aligned with the levels of the graph competence model. Building on these findings, interventions will be designed that adaptively target the identified challenges and thereby support learners in developing graph competence. In this way, the research project contributes to contemporary chemistry education by fostering students' graph competence in ways that are valuable not only from an educational perspective but also for their everyday lives, particularly for navigating an increasingly data-driven world.

ESERA 2025 Copenhagen

What Comes To Mind When You Think Of Mechanical Engineering?

Corinna Eußner[1] and Melissa Gruber[2]
[1]University of Applied Sciences Karlsruhe, Germany
[2]University of Education Karlsruhe, Germany

*In recent years, there has been a notable decline in the number of first-year students pursuing STEM subjects, particularly in engineering. Consequently, measures have been implemented to promote STEM study programs. These measures focus on investigating the expectations associated with engineering degree programs and the perceptions of prospective students. As part of a study (n=339), the Inspir**ING**® project at Karlsruhe University of Applied Sciences gathered data on how pupils from 8th grade onwards perceived mechanical engineering. The data was collected in 2024 and 2025 and was analyzed using descriptive statistics as well as qualitative content and cluster analysis. While the pupils demonstrated some realistic associations with the subject, the results indicate that pupils currently lack the capacity to comprehend the course in its total breadth of content. This paper outlines survey results and provides an outlook for the future research project.*

Keywords: STEM, mechanical engineering, students' perceptions

Introduction

Recent years have marked a decline in the number of first-year students enrolled in STEM (Science, Technology, Engineering and Mathematics) subjects, particularly those pursuing engineering and technology courses, in Germany (Anger et al., 2024). This decline is of critical concern, particularly in light of the growing shortage of skilled workers. The present shortage is estimated to be approximately 140,000 academically qualified STEM specialists (Plünnecke, 2023). A sustained decline in student numbers is likely to adversely impact Germany's capacity for innovation in the long term and diminish its competitiveness in international comparison (Shambaugh et al., 2017; BDI et al., 2024). A marked downward trend has been observed in the field of mechanical engineering and engineering since 2011, with a decrease in first-year students of approximately 50% (Statistisches Bundesamt, 2025). In response to this decline, a significant number of STEM funding projects are being implemented by federal states, schools, universities and companies.

Notes

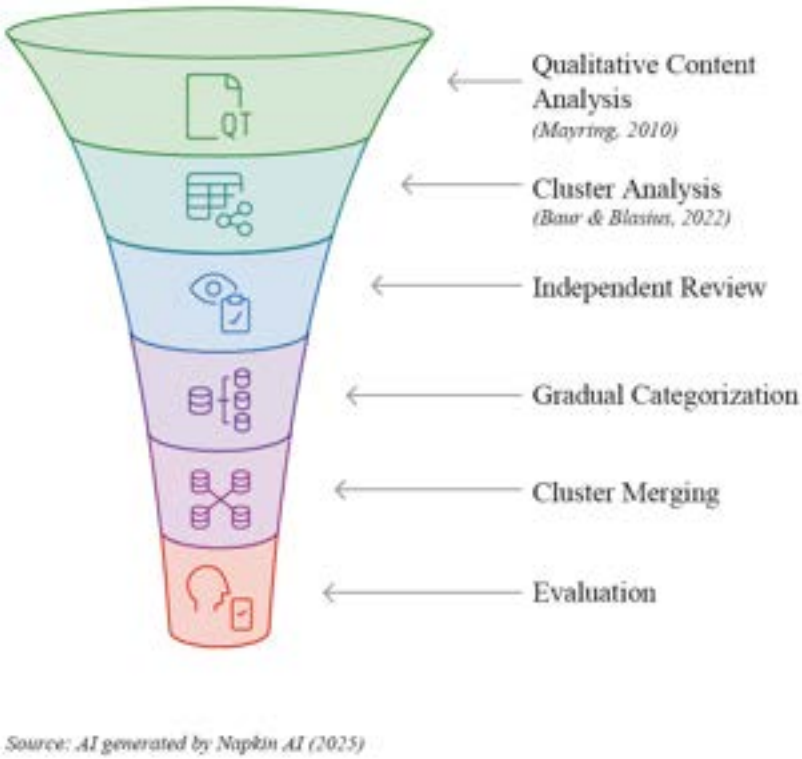
In order to differentiate between students (from 8th grade onwards) and students of engineering subjects at the university, the former are referred to as *pupils*, whereas the latter are described as *students*.

The German word "Maschinenbau" (Mechanical Engineering) is composed of the words "Maschine" (literally meaning: "machine") and "Bau" (literally meaning: "construction").

Background

The Inspir**ING**® project, an elective subject for engineering students, aims to raise pupils' awareness of technology and educate them about technical subjects. The task assigned to students is the design of a teaching unit on a technical experiment of their choosing, which they subsequently implement with pupils from grade 8 onwards. A questionnaire was developed for the purpose of investigating pupils' associations and perceptions of the degree courses in mechanical engineering, mechatronics, computer science and electrical information technology.

The questionnaire is of particular interest as perceptions and ideas are among the sociological factors that influence the decision to choose a field of study (Eccles & Wigfield, 2002). Furthermore, it is imperative to emphasize the pivotal role of attaining a comprehensive understanding of the practical domains associated with a specific degree program, and the cultivation of a realistic perception of the curriculum (Ziegler et al., 2013).



The objective of the survey is to obtain an overview of the associations of pupils with the subject of "mechanical engineering" and to compare them with the real profile of the course. By comparing these perceptions with the actual profile of the course, recommendations for action and potential solutions to improve the image of the Mechanical Engineering program can be formulated. These recommendations will subsequently be implemented into the Inspir**ING**® project and further use of the questionnaire.

Methodology

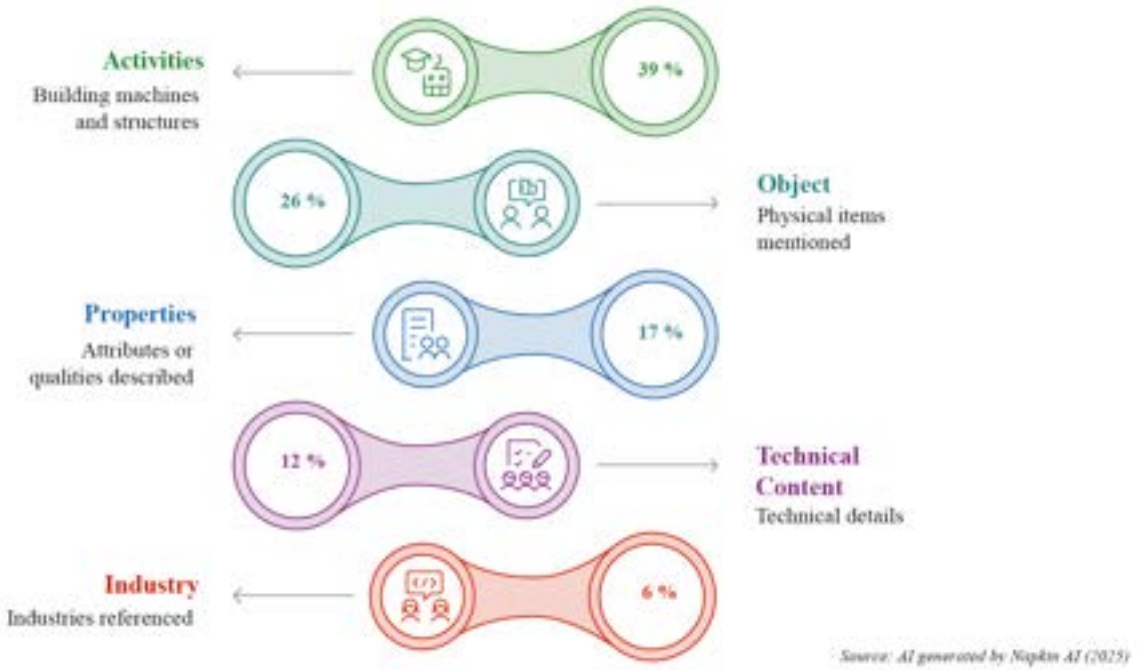
As part of the questionnaire employed in this study, respondents were invited to offer their opinion on mechanical engineering as a subject. This request was made in 2024 and 2025 to pupils in grades 8 and above (n = 339).

As shown in Figure 1 the data analysis was conducted using inductive qualitative content analysis according to Philipp Mayring (2010). This was followed by the implementation of a subsequent cluster analysis (Baur & Blasius, 2022), which was employed to identify clusters within the data.

Figure 1. Overview of the methodological approach

Source: AI generated by Napkin AI (2025)

Initially, the qualitative content analysis was employed to detect meaning structures in the data (Reinders et al., 2022). Qualitative content analysis embeds the material in the contexts of the entire communication, in this case the project and the questionnaire. For the systematic contextualization of the material, it is necessary to define (1) coding units as the smallest possible material component of the text; n the material; (2) context units as the largest possible text component of a category; and (3) analysis units to determine the order of the evaluations. Based on these predefined rules, the material was examined in light of the pupils' opinions regarding mechanical engineering. Following qualitative content analysis, data can either be summarized, explained by reference to additional information and structured by filtering the material according to pre-defined criteria (Mayring, 2015).



In this study, the data was systematically structured with regard to the importance and frequency of occurrence of pupils' opinions on mechanical engineering (Schneijderberg et al., 2022). To ensure the validity as well as the intercoder reliability of the analysis, the data was analyzed independently by two researchers.

In the next step, the pupils' responses were subjected to a process of gradual categorization. Consequently, they were divided into clusters based on their respective similarities. Within each cluster, the respective answers were evaluated regarding their realistic perception of the mechanical engineering degree program. The official study subject description "Mechanical Engineering" of the Federal Employment Agency Germany (Bundesagentur für Arbeit, 2025) was used as a basis for this. The pupils' answers (n = 468) were then evaluated using a three-point scale (1 - very applicable, 2 - applicable, 3 - less applicable). For instance: 3 - build; 2 - build machines, 1 - develop and build machines. These clusters were then successively merged with other similar clusters (Baur & Blasius, 2022). The initial results of this study are presented in the next section, followed by a descriptive illustration.

Findings

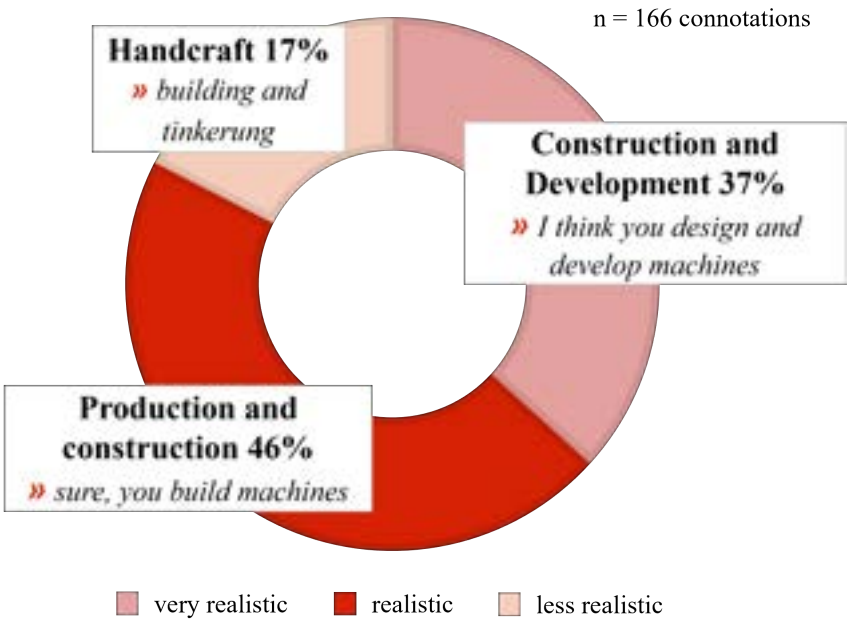
Through qualitative content analysis, the following central categories were identified (see Figure 2): *Objects, Activities, Industry, Properties,* and *Technical Content*. The pupils' perceptions were assigned to these categories without evaluative interpretation or anchoring to real-world or practical applications, ensuring an objective and content-faithful representation of the thematic domains expressed.

Figure 2. Categories identified after the qualitative content analysis

Preliminary results of the content analysis indicate that the largest proportion of pupils' perceptions (39%) falls within the category *Activities*. This finding suggests that pupils primarily associate the field of mechanical engineering with practical actions, processes, or hands-on tasks.

The second most prevalent category, O*bject*, accounted for 26% of associations. This category encompasses concrete artifacts, devices, or technical systems such as machines, tools, vehicles, or electronic equipment, thereby highlighting pupils' engagement with tangible technological artifacts that play a role in engineering contexts.

The category P*roperties* was identified in 17% of perceptions and encompasses descriptive attributes linked to the study of mechanical engineering. These include both positive characteristics (e.g., interesting, exciting, important) and negative perceptions (e.g., demanding, boring, a male-dominated profession), reflecting a range of affective and social associations.



The category *Technical Content* received 12% of the responses, placing it significantly lower than the previous categories. It includes references to particular technical knowledge or disciplinary terminology such as mechanics, electricity, energy conversion, or materials science. While these responses indicate a higher level of subject-specific understanding, they remain relatively infrequent.

Industry is the category with the lowest frequency, accounting for only 6% of associations. Responses in this category are typically associated with companies located near pupils' homes.

Overall, the distribution of responses suggests that pupils predominantly conceptualize technical topics through actions and practical activities. The relatively infrequent responses in the *Technical Content* and *Industry* categories indicate that pupils' understanding of mechanical engineering remains largely superficial, with limited awareness of more profound technical knowledge or real-world industrial contexts.

In order to gain deeper insights into pupils' perceptions of mechanical engineering, a closer examination of the category *Activities* (39%, n = 166) reveals a more detailed breakdown in Figure 3. The chart categorizes pupils' responses into three primary domains: *Production and Construction* (46%), *Construction and Development* (37%), and *Handcraft* (17%). These categories offer valuable perspectives on how pupils conceptualize the field of mechanical engineering.

Figure 3. Distribution of perceptions within the category Activities with clustering into very realistic, realistic and less realistic

Note: Figure created by the author based on original data.

The largest segment of the chart reveals that almost half of the pupils associate mechanical engineering primarily with *Production and Construction*. This finding corroborates earlier observations that pupils frequently link the discipline to practical activities and tangible objects. The statement "sure, you build machines" exemplifies this perspective, thereby underscoring the hands-on, constructive nature of mechanical engineering. This association highlights the pivotal role of practical experiences, experiential learning and the tangible construction of machines and structures in shaping pupils' understanding of the discipline. As these associations are not incorrect but rather superficial, consisting primarily of the course name in German (see chapter **Note** for details), they are categorized in the cluster as *realistic* and not *very realistic*.

The second largest segment C*onstruction and Development* accounts for 37% of the perceptions. Pupils in this category perceive mechanical engineering as a process of designing and developing machines. The representative quote "I think you design and develop machines" reflects a more advanced understanding compared to mere production. This standpoint acknowledges the creative and innovative aspects of mechanical engineering, emphasizing the roles of planning, problem-solving, and technical expertise. These responses are categorized into the cluster *very realistic*, as they not only include object/activity descriptions but also describe processes in mechanical engineering. Nevertheless, it continues to prioritize the tangible outcomes of engineering endeavours rather than the underlying scientific principles or broader industrial context.

The smallest segment *Handcraft* represents 17% of the responses. Pupils in this category associate mechanical engineering with activities like building and tinkering. This perspective emphasizes the manual and craft-based aspects of the field, suggesting that pupils view mechanical engineering as a form of skilled labor involving hands-on work. While this association is valid, it overlooks the complex technical knowledge and theoretical foundations required in modern engineering practices. For this reason, it is placed in the last cluster *less realistic*.

The qualitative content analysis provided an understanding of how pupils perceive mechanical engineering. While practical activities and tangible objects dominate their understanding, there is a need to expand their knowledge base to include technical content and industrial contexts. Closing this gap through targeted educational strategies will be crucial to engage a new generation in studying mechanical engineering and to train versatile and informed engineers.

Outlook

The prevalence of practical and tangible associations in pupils' perceptions of mechanical engineering yields significant implications for STEM education. While experiential learning is essential for fostering interest and engagement, there is a need to broaden pupils' understanding by integrating deeper technical knowledge and real-world industrial applications.

The findings of this study may serve to encourage teachers to expose pupils to typical STEM questions, such as problem-solving tasks, from an early stage. This can raise pupils’ awareness of STEM disciplines and job profiles. In particular, prospects of those pursuing a career in mechanical engineering or recent graduates can be communicated by means of a hands-on approach. Experiments, laboratories, and projects can facilitate pupils in acquiring a more profound understanding of engineering sciences, thereby enabling them to develop a more precise conception of this discipline.

The results of the association questions concerning the degree programs, in particular mechanical engineering, demonstrate the importance and necessity of educating pupils in order to break down stereotypes, incomplete or even misconceptions and create awareness. Inspir**ING**® offers a good platform for this, where students not only inspire enthusiasm for technology, but also report on their personal experiences in the respective engineering degree programs as role models. The “Inspir**ING**® @ work” extension is also planned, in which students will present a technical career path or life plan that shows the path from school to the professional world. This initiative involves collaboration with the university's dual training program and corporate entities. In the future, Inspir**ING**® will also be offered not only for pupils from the 8th grade onwards, but also for kindergarten children in the format “Inspir**ING**® for Kids - Animals, Technology and University” in order to make technology visible and raise awareness of it at an early stage of development.

Uses Of Fault And Fold Models In Geoscience Education: A Case Study In Upper Secondary Education

Boubaker Ghazouani [1,2], Jérôme Santini [1] and Chiraz Kilani[2]
[1]Université Côte d'Azur, France.
[2]Université Virtuelle, Tunisia

Our research addresses the issue of the uses of models and modelling in geoscience education. We conduct a case study on the teaching-learning of tectonic deformations, i.e. folds and faults, in two upper secondary school classes in Tunisia. In these classes, teachers and students use models and modelling. Our aim is to understand how these models are used and how they can help students understand the deformation of the Earth's crust in the context of plate tectonics. To do this, we filmed the entirety of two practical work sessions on folds and faults in each of the two classes. Analysis of our data enables us to characterise the dynamics of knowledge construction through the use of concrete models and modelling during class sessions. This leads us to propose hypotheses of effectiveness concerning the use of models and modelling in geoscience education and to draw implications for the construction of classroom sessions)

Keywords: Models, modelling, geoscience education

General Description

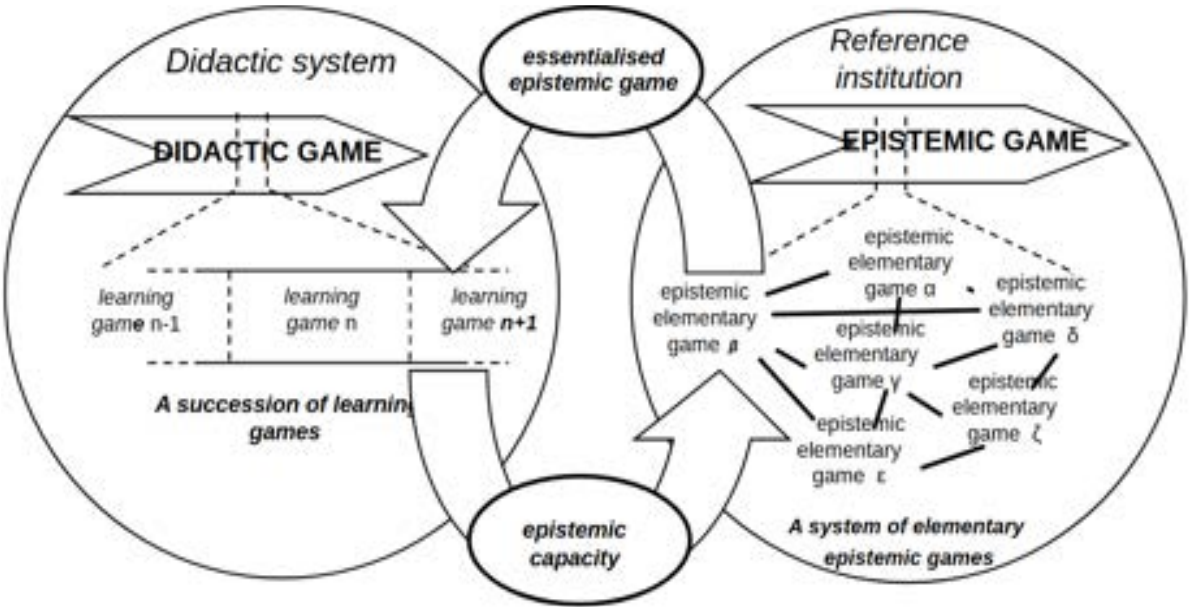
Research in geoscience education covers a variety of contexts and theoretical frameworks (e.g. Francek, 2013; King, 2008; Le Hebel & Fontanieu, 2026; Oh, P. S., 2019; Orion, & Ault, 2007; Santini & al. 2018). It has shown that teaching and learning geological knowledge involves specific difficulties. For example, current geological structures are often perceived as permanent by students, preventing them from conceiving of change over time. Frodeman (1995) points out that the speed at which geological phenomena that are inaccessible to observation occur and unfold is imperceptible on a human scale, given the immensity of geological time. In this sense, Trend (2000) emphasises the difficulty to apprehend the timescales involved and orienting in the space. According to Raab & Frodeman (2002), students encounter difficulties in understanding long timescales and perceive the dynamism of geological processes. In addition to long time frame, the author indicates that even geologists cannot directly conceive of such spans but can understand them through "analogies with everyday experience". For example, geologists "manipulate blocks in their imagination to understand plate tectonics" (ibid., p.72). In relation to the difficulties associated with the size of geological objects, McLaughlin & Bailey (2022) points out that the question of representing space constitutes "a major and recurring obstacle". Therefore, problems of temporal and spatial scales lead educationalists to think of time and macro-space as epistemological obstacles (Bachelard, 2002)-insofar as these two concepts seem completely counterintuitive.

Furthermore, learning about geological phenomena is intrinsically a subject that often excludes direct experimentation as a means of teaching and learning, even for specialists. For these reasons, teachers use models as representations of geological phenomena or modelling activities to teach geoscience (e.g. Santini et al., 2019).

Based on our review of the literature, we note that no research work has been done on the issue of teaching and learning folds and faults in geoscience education, hence the need for the research presented here. In this research context, we addressed the following questions. How is modelling used in teaching and learning about folds and faults? How do models and modelling participate

effectively in the production of the knowledge at stake? How effective are the teaching practices studied in learning how to use models?

Theoretical Elements



The Joint Action Theory In Didactics (JATD)

We situate our work within the Joint Action Theory in Didactics (JATD; Sensevy, 2011, 2019). JATD is part of an action-based approach to didactics. Didactics studies teaching and learning as the functioning of a system composed of three subsystems: the student, the teacher, and knowledge (Hudson & Meinert, 2011). Essentially, the research developed in JATD studies the teaching-learning process as a joint action between students and teachers, i.e. as a mutual adjustment in knowledge during classroom sessions (Tiberghien, 2016). Knowledge is considered to be indissolubly linked to the practices in which it has been forged, in other words the immanence of knowledge and practices (Bloor & Santini, 2023; Santini et al., 2018). Consequently, the study of geoscience education can be understood as the study of how educational practices allow students to approach geological practices.

Game Concepts In JATD

JATD proposes modelling didactic action in terms of games, with reference to Wittgenstein's language game (Wittgenstein 1997) and Bourdieu's social game, which makes human activity seem like a game (Bourdieu1990). In other words, the didactic action can be modelled as a succession of learning games (Sensevy et al., 2005). In this model, didactic action is described as a didactic game in which students and teachers act together in a didactic game through a succession of learning games. To clarify the generic grammar of didactic action, Santini (2021) uses a model of didactic action in a knowledge game model (Figure 1). Learning can then be understood as acquiring new *epistemic capacities*, i.e. capacities with the knowledge at stake, through participation in learning games.

Figure 1: The knowledge game model in JATD (based on Santini et al., 2018).

In JATD, epistemic games are a model of connoisseurs' practices for modelling phenomena of conceptual understanding in the Joint Action Theory in Didactics. In a nutshell, epistemic games model human practice with knowledge. This modelling is based on a theoretical postulate of the immanence of knowledge in human practices. Furthermore, we consider knowledge as a system

of capacities for action, with a certain efficiency in situations. In our knowledge game model, epistemic capacities represent the piece of knowledge in learning games. Under this description, teaching effectiveness is understood as the continuity (Dewey, 1938) between learning games (what the teacher makes students do in order to learn) and epistemic games (what those who know how to do something, the experts, do).

In this paper we focus on learning games. This concept is defined by the transition from one "scene" to another in a teaching-learning sequence, and thus the actualization of new knowledge at stake. These scenes are defined as being connected and self-contained and are generally delimited by an introduction and a conclusion (Sensevy et al., 2015). Learning games are using the concept of didactic contract and didactic milieu.

The Didactic Contract

The didactic contract (Brousseau & al. 2014) constitutes "the set of (specific) behaviours of the teacher that are expected of the student and the set of behaviours of the student that are expected of the teacher". From the perspective of JATD, the didactic contract constitutes a system of rules defining "how to play" and strategic rules for "how to win" in order to play the learning game.

The Didactic Milieu

A learning game is supported by a system of objects that resist the student's actions. This system can be described using the concept of didactic milieu (Sensevy, 2015). The concept of didactic milieu accounts for the set of resources, material and cognitive constraints present in the learning game. This means the milieu is the medium that supports the actions of students and their teachers.

Following Sensevy (2015), we note that didactic milieus and didactic contracts are inseparable, and that a change in the milieu requires a change in the contract.

Models And Modelling In Science Education

Previous researches about models and modelling in science and in science education are numerous. Models are intermediaries between theory and practice (Hacking, 1983). They link objects and events (empirical field) on the one hand, and theories and laws (theoretical field) on the other (Buty et al., 2004).

According to Sensevy et al. (2008), sciences produce explanatory models of the world, but not of the world as it is, but rather of the world as it is reconstructed. Santini et al. (2019) demonstrated that teaching practices can involve representational and/or heuristic uses of concrete models. They concluded that, depending on the uses to which students are exposed, they acquire different understandings of models and modelling in science.

However, Gilbert & Justi (2016) emphasise that models represent not only objects, events or processes in the real world, but also data. Thus, models are partly independent of both reality and theory, as Cartwright (1983) had already pointed out. Gilbert & Justi (2016, p. 22) cite Morrisson and Morgan (1999) who propose that models function autonomously, i.e. they serve as intermediaries between reality and theory. They also consider models to be tools for investigation in scientific practices, as vectors for learning about the world. Morgan (1999) also considers models to represent ideas and have predictive power, which characterises them as active tools in the construction of scientific knowledge.

Following these authors, we think that the problems posed by the use of models and modelling activities ultimately raise fundamental questions such as: what should be explained to students? How can we move from a local scale to a global scale? How can we move from a microscopic explanation to a macroscopic explanation of tectonic deformations?

Methodology

Our research is based on the making and analysis of films of classroom sessions (Tiberghien & Sensevy, 2012). Our research corpus consists of two classes at grade 11 in Tunisia, comprising 30 French-speaking students aged 17 to 18, taught by two teachers T1 and T2. We then filmed the "folds and faults" sessions from start to finish. To analyse them, we followed a methodology close to that described by Kelly (2016) for the study of epistemic cognition in action. Following him we thus proceed in three stages of analysis. After viewing both sessions several times, we transcribed the video recordings in full. The transcripts obtained are used to prepare a synopsis of the classroom sessions, providing a comprehensive overview and conduct an overall analysis of the sessions. We then structured the transcription of the two sessions observed in terms of learning games, which enabled us to carry out detailed analyses and, finally, to reconstruct the unfolding of the knowledge at stake in action.

The transcriptions of the videos were made using the Transana analysis software (Woods, 2025), which helps to understand the interactions between teachers and students, as well as the gestures and attitudes of interest in terms of the knowledge at stake (Badreddine & Buty, 2011). In what follows, we present the analysis and discussion of the results obtained from the transcription of the videos of the classroom sessions.

Results

Each of the two teachers began with the study of pictures of outcrops of folds and faults (Figure 2).

Figure 2. Photographs of various geological outcrops observed in nature.

They asked the students to observe, put forward explanatory hypotheses about the forces responsible for these tectonic deformations and formulate a scientific problem. The students mainly agreed that the strata that are initially deposited horizontally undergo tectonic deformation over geological time under the effect of natural forces.

To test this explanation, the two teachers used concrete models and activities to model folds and faults. It should be noted that both teachers follow the same official curriculum, which entails that their lesson plan is almost the same. We analyse the unfolding of each classroom sessions and model them as a succession of learning games. This method enabled us to construct synopses of the two sessions based on the transcripts and videos, which we present in the table 1 below.

Table 1. Synopsis of the two sessions observe.

Learning games in T1 and T2's sessions	Model used in T1's session	Model used in T2's session
1. Applying two opposing converging forces to a series of flexible plastic rulers	Plastic ruler Flashs Animations	Plastic Ruler
2. Describing the result obtained, put forward a hypothesis to explain the formation of folds and define a fold.		
3. Compiling the document from Activity 1 and determine the properties of the fold.	Video	
4. Observing the following digital simulations and identify the characteristics of each of the two straight folds	Flashs Animations	Photos
5. Applying two compressive forces of increasing intensity to the rigid plastic ruler.	Rigid plastic plate	Rigid plastic plate
6. Giving an interpretation and define a fault		
7. Applying two compressive or stretching forces of increasing intensity to the wooden model on the bench.	Diagram blocks Video sequence from a didactic model	Diagram blocks
8. Looking at the numerical simulations for compression and extension and identify the properties of each type of fault.	flashs Animations	Video
9. Completing the legend for activity games 5 to 8.		
10. Constructing a conceptual, explanatory and summary map of tectonic deformations.		

Table 1 presents T1's and T2's classroom sessions modelled as learning games. We have chosen to examine game 1 of the two class sessions as they share common objectives: understanding and explaining flexible tectonic deformations. We now present an overall analysis of the two sessions and an analysis of an extract from the first learning game in T1's and T2's class.

Analysis Of The First Learning Game In T1's Class

In our study, the teacher described the ruler as a geological layer, and the students described the curved ruler as a layer (Figure 3).

The overall analysis of the T1's session after viewing the filmed session several times, and the full transcript of the video recording, reveals that the knowledge at stake progress rapidly from the pictures to the explanation of the formation of folds in nature. We also note that the division of responsibilities regarding the knowledge at stake between the teacher and the students was generally balanced. The teacher defined the learning game, leaving it up to the students to name the deformation modelled. The activities during the T1's session were generally balanced the same way, with the teacher intervening and the t students following and responding to the interventions of teacher T1. In fact, we note that the naming of the deformation modelled as a fold is not done by the student alone, nor the teacher alone, but a co-construction in joint action, based on the operation of the model. The full transcript of the film recording of the P1 session also shows that the students participated in the development of the didactics milieu. The extract

below illustrates how teacher P1 regulated the didactic milieu. When a student introduced the term "wave-like layers," "folding" or "deformation," the teacher T1 repeated the term and lead the students to explain the formation of folds in the Earth's crust and the conditions for applying the principle of superposition.

Figure 3. Tectonic deformation modelling.

The Determinants Of T1 Teaching Practice

Below we present an analysis of an extract from learning game 1 in the T1's class.

Box 1. Extract from the first learning game in T1's class.

T: what has happened to this layer? Does it remain horizontal?

S: The layer has undulated

S: a downward or upward curvature.

S: it undergoes a deformation

S: the layer is folded

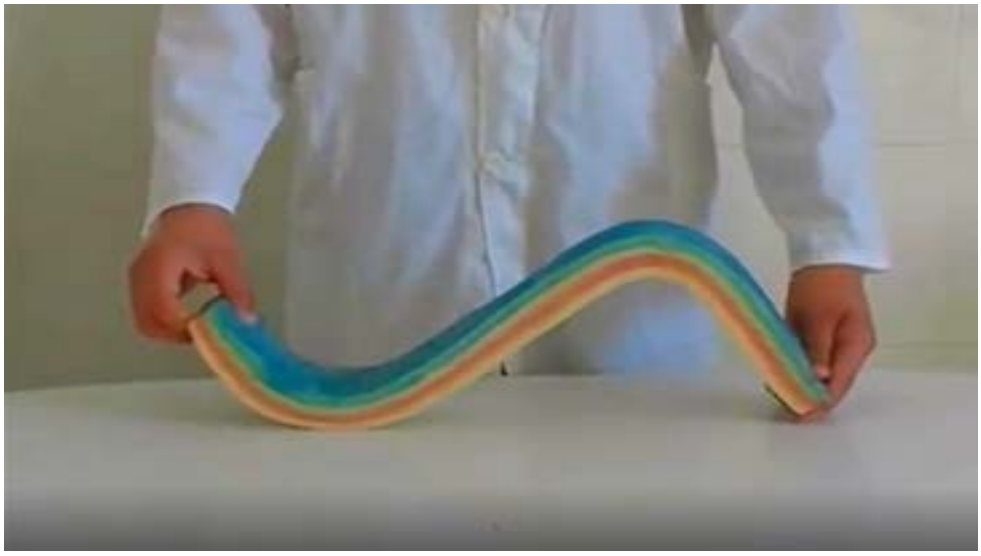
T: very well, the layer is folded under the effect of what?

S: under the effect of lateral compression forces

T: asks the student to add another plastic ruler and to repeat the experiment)

T: What do you find? Can we now apply the principle of superposition?

Analysis of this extract shows a representational use of the model: the model replaced reality, and the students worked on the model as if it were reality. It seems that the model has lost its status as a learning tool and a tool for questioning reality and became a teaching object and objective in itself. We also note a heuristic use of the model: the model was used to reason about the principle of superposition. The model was no longer used simply to represent reality, but to test the validity of the principle of superposition in the case of a fold. The interesting thing about this extract is that it combines a representational use and a heuristic use of the same model.



Analysis of this extract also shows that the students did not spontaneously use the term "fold", even though it was used to describe a photo from the pre-test. Among the previous answers, the teacher echoed "folding" by using "folded". In so doing, he pointed out that "fold" was the expected scientific term. This term can now refer to an experience the students had with the model and was therefore more likely to make sense. However, we note the echo he had given, in a previous turn, to "folding". This gave the students a clue as to how to respond.

In short, Teacher T1 relied on an active teaching strategy rich in interactions (manipulation, question/answer between the two instances of didactic action) guided by his own practical experience. He worked collaboratively with students in an interactive dynamic. We would also point out that teacher T1 did not integrate the use of the model into a global tectonic framework and limits himself to a local explanation.

Analysis Of The First Learning Game In T2's Class

In the first learning game, the teacher described the layers of modelling clay as geological layers, and the students described the curved layers of modelling clay as layers too (Figure 4).

Figure 4. Tectonic deformation modelling.

An overall analysis of the P2 session shows that the advancement of knowledge at stake is mainly due to the teacher. However, T2 slowed down when students encountered learning difficulties. The division of responsibilities about the knowledge at stake was relatively balanced between T2 and the students. T2 seeked to involve the students in the elaboration of the knowledge. He regularly encouraged the students with the words "very good". A global analysis of the session also reveals that teacher T2 was primarily responsible for the evolution of the didactics milieu. Indeed, we note here the main role played by T2 in the establishment and development of the didactic milieu, as he introduced more objects into the environment than the students did.

Using Box 2, we analyse the models used by T2 in the same way as the T1 class above. Analysis of the extract of the first learning game reveals that T2 used interdisciplinarity. Indeed, he reinforced the link between physics and geoscience by citing experiments on wave propagation in physics to help students formulate answers about the undulations of geological layers in order to define a flexible deformation. In addition, he was more comfortable managing interactions in the classroom. We note that T2 mainly used models as representations of reality, and that the heuristic uses of models are limited and brief. Furthermore, T2's attention was focused on student interactions. Indeed, he sought to comply with official curricula while diversifying models. We also note that teacher P2 has not integrated the use of models into a global tectonic framework and limited their uses for local explanations like T1 did.

We analyse all the models used in the same way as the extract above. We find that both teachers predominantly used models as representations of reality. The heuristic uses of models were limited and brief. The models were not placed in a global tectonic framework.

Box 2. Extract from the first learning game in T2's class.

T2: asks a student to apply increasing amounts of compressive force (convergent) to layers of modelling clay of different colours.

S: guided by the teacher, the student carries out the demonstration experiment for their classmates.

[Deformation of the layers initially placed horizontally].

T: what did you observe?

S: Under the effect of the compressive forces, the layers do not remain horizontal.

T: Yes, excellent answer.

T: What did they undergo?

S: The layers underwent undulation, a curvature directed upwards and downwards.

T: Very good, so by simulating this experiment, what is the nature of the rocks in the slide? S: Plastic. S: Elastic. S: Flexible.

T: When the rocks are flexible, what do we get?

Discussion And Conclusions

The analysis of didactic actions shows that teaching practice can involve representational uses of concrete models, where study of the model replaces study of the phenomenon itself.

We think that allowing students to use models more heuristically should help them to better understand geological phenomena and the usefulness of models. For example, in the extract analysed, students could have been asked to argue why the principle of superposition cannot be applied here. In this way, students could have learnt that a model can be used to test a theoretical principle.

We note that teachers followed the textbook, but not everything was determined by the textbook in the construction of the sequence. In fact, the teachers choosed the same object as the rule and varies a flexible or rigid property to encourage comparison between the two models.

In conclusion, it seems that the models used were not integrated into a global tectonic framework, which made impossible to know where the forces exerted come from. This seems to us to be a necessary part of geoscience education at the upper secondary level. It would thus be possible to link the various models used in a global tectonic framework to explain the forces they bring into play. In the excerpt analysed, this would lead to make explicit the pressure of the hands on each edge of the ruler within the framework of a convergence regime. In addition, despite the same official programme, analysis of the action shows that similar models were not exactly used in the same way in the two classes. We think that this difference in the uses of the models may determine part of the effectiveness of their teaching.

Introduction

Strand 19 of ESERA focuses on teaching and learning in higher science education, encompassing research and practice across various curricular, pedagogical, and sociocultural aspects of science beyond K-12. Given the academic structure of higher education, the themes covered in this strand are typically discipline-based, such as Chemistry, Physics, and Pharmaceutical Science, but also inter- and transdisciplinary, such as STEMM (science, technology, engineering, mathematics, and medicine) and involving HASS (humanities, arts, and social sciences).

Overview

The ESERA 2025 conference theme, "Transitions in Science Education: Sustainability and Digital Advances," invites us to reflect on how profound ecological and technological transformations are actively reshaping higher education. In Strand 19, the contributions centred on how higher education navigates these shifting landscapes as they prepare the next generation of scientists, educators, and citizens to combat environmental crises, and adapt to the rapidly advancing digital technologies that shape modern learning.

The research papers presented in this strand show how transitions between academic, professional, and/or civic realms can be navigated from five perspectives. These perspectives include examining the cross-disciplinary boundaries of environmental (ocean) literacy, evaluating the entrepreneurial framing of chemistry topics for teacher education, and assessing the evidence-based digital tools used to scaffold students through high-stakes academic transitions, characterising students' learning-goal orientations and motivation in the analytical chemistry laboratory, and tracing how students perceive and coordinate multiple visual representations of electric fields. Collectively, they show how science teaching and learning at the university level can embed rigorous disciplinary knowledge with real-world technological, societal, and ecological relevance to support the transitions students face in higher education.

The ocean environment is an integral part of the Earth's interconnected global ecosystem. Despite its immense scale and capacity to buffer changes, the ocean faces severe environmental challenges. Under the prism of Sustainable Development Goal 14 of the Agenda 2030 focusing on conserving and sustainably using the oceans, seas and the marine resources, and the United Nations Decade of Ocean Science for Sustainable Development (2021-2030), the present study attempts to highlight the persisting deficit in the Ocean Literacy field by focusing on two major categories of university students: those enrolled in Science and Humanities disciplines. Based on current research, the study argues that both fields can support ocean protection and sustainable management of its resources as content science knowledge is only one dimension that leads to pro-environmental attitudes and behaviour. In this regard, a structured questionnaire was administered to 495 university students from eight Science and Humanities Departments in Greece and Italy. The results showed low to moderate content knowledge, favouring science students, as expected, but common misconceptions were present. However, all students showed satisfactory pro-environmental attitudes and behaviour. These findings suggest that not only natural science experts, but anyone interested in the ocean can be receptive to scientific concepts, even if unfamiliar, such as those in ocean sciences.

Keywords: Ocean Literacy, Science students, Humanities students

Introduction

Marine and Aquatic Education has its roots in the environmental movement of the 1960s and 1970s, while its necessity had already been underlined and studied in parallel with the progress in Environmental Education, following a similar path in the 1970s and 1980s (Mogias et al., 2022). However, in the mid-1990s, a lack of ocean-related subjects was realised in the US formal science education standards, and the need for a more comprehensive framework to encourage the inclusion of ocean sciences emerged (Payne et al., 2022).

The concept of Ocean Literacy (OL) was defined in the early 2000s as an "*understanding of the ocean's influence on humans and our influence on the ocean*" (Cava, 2005). A series of workshops brought together governmental and non-governmental organisations, educators, scientists, and policymakers to define important concepts about the ocean and its resources. This effort led to a comprehensive framework with a set of seven principles and, initially, forty-four

concepts about ocean issues. An updated version added a forty-fifth concept almost a decade later (NOAA, 2013). The framework also included a pedagogical guide for teachers to use ocean content in teaching science from kindergarten to high school. It gave recommendations about when and how to insert ocean concepts into the K-12 science curriculum. These guidelines are now widely accepted and have inspired many initiatives worldwide. Although OL started as a knowledge concept, it has evolved into a multi-perspective approach, aiming at a society that understands, values, and cares for the ocean (Glithero et al., 2024). Current research in OL suggests several dimensions: awareness, knowledge, attitude, communication, behaviour, activism, emotional connections, access and experience, adaptive capacity, trust and transparency. These should also be considered when designing OL initiatives and interventions (McKinley et al., 2023).

To this aim, the 2030 Agenda for Sustainable Development, adopted by all United Nations Member States in 2015, included 17 Sustainable Development Goals (SDGs), among which a stand-alone goal focusing on the ocean (i.e., SDG 14) has been a major achievement for the global ocean community. In parallel, the United Nations declared the Decade of Ocean Science for Sustainable Development (2021-2030), seeking to contribute to the achievement of SDG14 and to extend its scope to fill the gap from "*the ocean we have*" to "*the ocean we want*". The concept of OL is central to operationalising Challenge 10, which aims to "*ensure that the multiple values and services of the ocean for human well-being, culture, and sustainable development are widely understood, and identify and overcome barriers to behaviour change required for a step change in humanity's relationship with the ocean*" (UNESCO-IOC, 2021).

Towards this direction, assessment and enhancement of OL issues among university students, the youngest active citizens who should use ocean knowledge and skills of ocean issues to communicate about the ocean in a meaningful way and make informed and responsible decisions, is required. This study aims to assess the levels of specific OL dimensions, such as knowledge, attitudes, and behaviour of university students coming from different disciplines of Science and Humanities Departments, and to reveal the potential needs and gaps while giving proper recommendations for mainstreaming ocean science issues into formal higher education.

Materials And Methods

A cross-discipline study was conducted on students attending eight Departments from four Universities in two European countries, Greece and Italy (Figure 1). The Departments were grouped into two general discipline fields, Science and Humanities; the total sample comprised 495 students. Table 1 shows the distribution of students by country, discipline, and gender. Two main hypotheses were tested regarding ocean sciences issues: (a) students enrolled in Science disciplines prevail, regarding ocean content knowledge, over students enrolled in Humanities, and (b) content knowledge strongly affects pro-environmental attitudes and behaviour.

A structured questionnaire to investigate knowledge, attitudes, and behaviour toward ocean sciences issues was developed according to previous research (e.g., Mogias et al., 2015; 2019) following the OL Framework (NOAA, 2013) and administered to students in the spring semester of 2024. The research tool contained demographics, a knowledge scale with 32 close-ended questions, and an attitude and behaviour scale with 10 statements each, following a 5-point Likert scale, revealing the degree of participants' agreement. Descriptive (relative frequencies, mean values, and standard deviations) and inferential statistics (t-tests and One-Way ANOVAs) were implemented using SPSS v.29; a probability value of 0.05 or less was predetermined as the significance level.

Figure 1. Location of the University Departments per country.

Results

Of the 495 students comprising the total sample of the study (almost two-thirds females), 48.3% emerged from Greek and 51.7% from Italian University Departments; accordingly, 58.6% had enrolled in Science while the rest in Humanities disciplines. Table 1 reveals in detail the sample distribution of the study. All students seem to choose the Internet as their primary source of information regarding environmental issues (4.08±0.987 and 3.83±1.027 for Science and Humanities students, respectively), while the former group also seem to prioritise the university faculty (3.61±1.112), academic textbooks (2.77±1.219), and scientific papers (2.69±1.320); on the contrary, TV appears to be the Humanities students' next highest preference (2.85±1.152), followed by friends and family (2.64±1.059) (Figure 2).

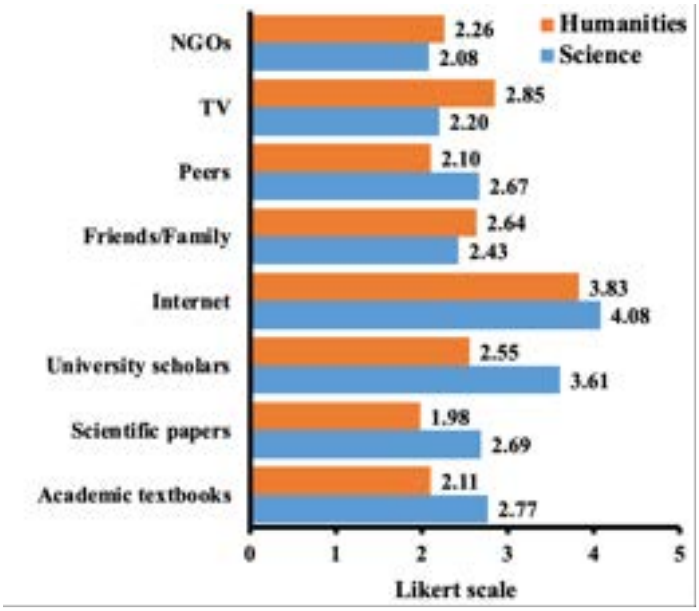
Table 1. Sample distribution of the study.

Country	Department	Discipline	Number of students (N)	Gender (%)	
				males	females
Greece	Marine Science	Science	85	49.4	50.6
	Environment	Science	56	42.9	57.1
	Primary Education	Humanities	55	16.4	83.6
	Education Sciences in Early Childhood	Humanities	43	2.3	97.7
Italy	Natural Sciences	Science	52	52.9	47.1
	Geological Sciences	Science	97	50.5	49.5
	History & Culture	Humanities	24	35.4	64.6
	Classical Philology & Italian Studies	Humanities	83	21.1	78.9

Students coming from both fields were found to possess rather low to moderate levels of ocean sciences content knowledge (mean score 16.60±5.278 for Science and 11.57±4.389 for Humanities students) but, at the same time, very positive attitudes and behaviour towards relevant issues (Figure 3). A statistically significant difference between the two discipline groups was recorded only for the content knowledge dimension ($p \leq 0.001$) (Figure 3a), while this was not the case for the other two dimensions; on the contrary, a statistically significant difference is depicted between attitudes and behaviour for each group ($p \leq 0.05$ and $p \leq 0.001$, respectively), with the former scale clearly prevailing (Figure 3b). Figures 4 and 5 reveal that despite the existing differences between the two main categories of students, they present comparable depictions in terms of the questionnaire items; more specifically, focusing on the content knowledge items, we

detect that almost the same questions were hard and, respectively, the same ones were easy to correctly answer (Figure 4).

Figure 2. Mean values of the preferred information sources. by Science and Humanities students



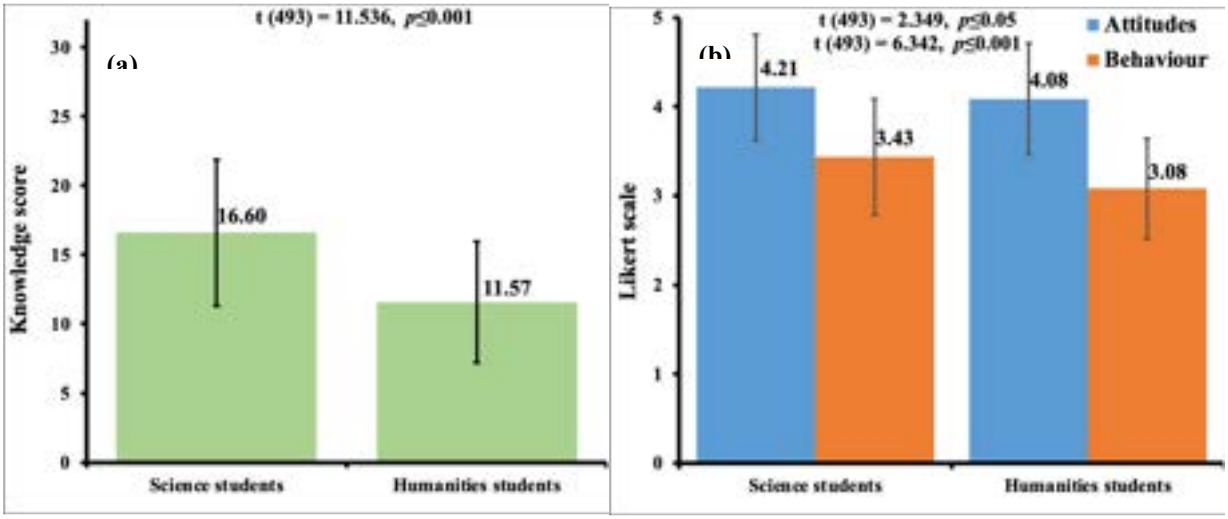


Figure 3. Mean knowledge (a), and attitudes and behaviour (b) values of Science and Humanities students

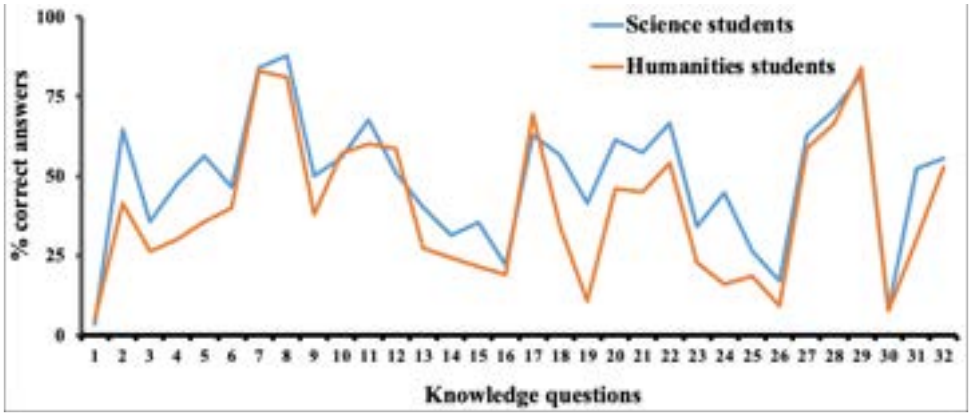
The common most difficult to answer items were questions 1, 16, 26, and 30, referring to the interconnection of all sea basins (mean value 3.4 and 4.9% for Science and Humanities students, respectively), the ocean's role in the global carbon cycle (22.1 and 19.0%), the vital role of estuaries (16.9 and 9.3%), and the basic sources of oil spills (8.0 and 7.8%); the common easiest questions to answer were 7, 8, and 29, referring to the transportation of several materials through rivers and watersheds to the ocean (mean value 84.1 and 82.9% for Science and Humanities students, respectively), the evidenced existence of seas and lakes million years ago in present-day terrestrial surfaces (87.9 and 81.0%), and the modern society's influence on the ocean (81.7 and 83.9%) (Figure 4). In terms of the other two scales, namely attitudes and behaviours, our findings portray amazing similarities between the two groups of students when depicting their level of agreement across all statements; more specifically, the attitude statements fluctuated between 3.72 (±1.054) and 4.48 (±0.768) (Figure 5a, Table 2), while the behaviour statements between 2.29 (±1.221) and 4.68 (±0.793) (Figure 5b, Table 3).

Figure 4. Fluctuation of correct answers provided by Science and Humanities students regarding the knowledge scale of the research tool.



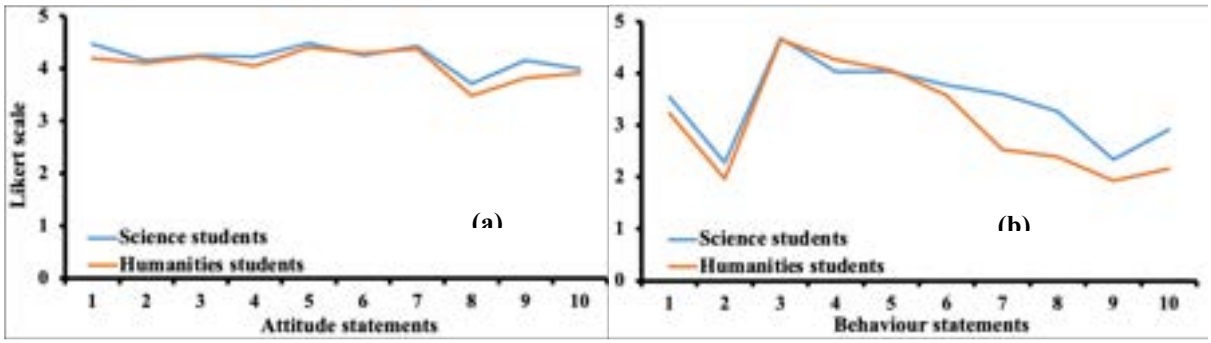


Figure 5. Fluctuation of values provided by Science and Humanities students regarding the attitudes (a) and behaviour (b) scales of the research tool.

Discussion

The aim of this study was not to compare students based on their nationality, nor among the Science and, respectively, the Humanities Departments. Our main interest focused on assessing the potential existing gaps between students attending these two scientific fields, primarily in ocean content knowledge, and whether these gaps could, and to what extent, influence their pro-environmental attitudes and behaviour. The results revealed low to moderate knowledge of ocean sciences issues in favour of Science students as expected, sharing the same misconceptions, while they exhibited positive attitudes and behaviours. These findings are in line with the existing literature (e.g., Koulouri et al., 2022; Mogias et al., 2019; 2022) targeting several populations, such as primary and secondary school students, and pre-service teachers, among others.

Our findings confirmed our first hypothesis regarding ocean content knowledge levels, based on the nature of the students' disciplines, but rejected the second one regarding knowledge impact on other OL dimensions such as attitudes and behaviour, as Humanities students with a comparatively decreased content knowledge exhibited almost equal positive attitudes and behaviours to their Science peers. Results of this study indicate that the involvement of other dimensions, such as emotional connections, access and experience, adaptive capacity, trust, and transparency, could promote pro-environmental attitudes and behaviour as these were portrayed by the work of McKinley et al. (2023). Moreover, modern teaching and learning require multi-perspective approaches (e.g., scientific, historical, geographic, among many others) that promote interdisciplinary, inclusive, and intercultural competencies (e.g., Santoro et al. 2017). Furthermore, the inter- and multi-disciplinarity that connects freshwater, marine, education, and social scientists is an acknowledged way of communicating complex ocean issues (Mokos et al., 2022).

The White Paper for Challenge 10 of the UN Ocean Decade, referring to "*Restoring Society's Relationship with the Ocean*", emphasises the major societal transformations needed to create a sustainable and equitable future (Glithero et al., 2024). Behaviour changes in personal, emotional, and cultural connections with the ocean are necessary beyond conventional scientific methods and proper science communication under the prism of Education for Sustainable Development (ESD), climate education, and global

citizenship.

Table 2. Mean values and standard deviations (sd) portraying the sample's level of agreement in the attitude scale.

	Attitude statements	Science students		Humanities students	
		mean	sd	mean	sd
1	I believe that human life is inextricably linked to the ocean	4.47	0.773	4.20	0.819
2	I feel frustrated with the overexploitation of marine resources at risk of depletion (e.g., fish)	4.16	1.017	4.11	0.956
3	I am concerned that human activities carried out on land (e.g., industries, agriculture) significantly affect the health of the marine environment	4.25	0.851	4.22	0.874
4	I feel frustrated when the leaders of several countries postpone the necessary measures to protect the ocean	4.23	1.104	4.05	1.167
5	I feel frustrated that sensitive marine ecosystems will be lost if humans do not change their behaviour towards the marine environment	4.48	0.768	4.40	0.718
6	I believe that humans are responsible for the extinction of many marine species	4.25	0.840	4.29	0.901
7	I believe that all of us, regardless of whether we live near the ocean or far from it, are responsible for protecting it	4.42	0.752	4.38	0.860
8	I feel personally responsible for protecting the ocean	3.72	1.054	3.48	1.162
9	I would like to get to know the marine environment better so that I can protect it and contribute to its future conservation	4.17	0.997	3.82	0.999
10	I would like to contribute to the protection of the marine environment, although I feel that I cannot do much on my own	3.99	0.988	3.91	0.974

In conclusion, attempting to provide an answer to the dilemma already presented in the title of the present study, we should all agree that current environmental issues require multi-perspective and innovative approaches. The concept of OL aims to connect ocean science and ESD through behavioural change initiatives and the adaptation of a systems approach. Continuing to invest almost exclusively during the past decades in experts' education proved not to be the best practice; what we need is to create a universal culture for the general public, which will eventually guide us to active citizenship. Only in this way will we be able to understand that the vitality of the ocean is inextricably connected to our survival, and thus collaborate towards its conservation, protection, and sustainable management of its resources.

Table 3. Mean values and standard deviations (sd) portraying the sample's level of agreement in the behaviour scale.

	Behaviour statements	Science students		Humanities students	
		mean	sd	mean	sd
1	With my lifestyle I try to reduce the impact I have on the environment in order to protect the ocean	3.54	0.931	3.22	1.084
2	I participate in organized social actions for the protection of the marine environment (e.g., beach cleaning)	2.29	1.221	1.97	1.026
3	I collect my trash when I'm on the beach	4.68	0.793	4.65	0.750
4	I avoid playing with marine organisms, even for a few minutes when I am on the beach	4.04	1.241	4.27	0.998
5	I recycle and reuse plastic, as it has a significant negative impact on the marine environment	4.03	1.027	4.07	1.050
6	I am opposed to the construction of houses and hotels on the beach, as it negatively affects the coastal and marine environment	3.78	1.224	3.57	1.153
7	I explore the diversity of marine life when I get the chance to do so	3.60	1.242	2.54	1.190
8	I encourage my family and friends to learn more about the marine environment and how to protect it	3.27	1.317	2.40	1.136
9	I know enough about the ocean and the problems it faces, but I still don't change my daily habits to protect it	2.34	1.025	1.93	0.910
10	I motivate my friends to learn more about how to protect the ocean	2.91	1.198	2.17	1.067

What Are Students' Learning Goal Orientations In The Analytical Chemistry Laboratory?

Silvia Wehmeier
University of Graz, Austria

This study explored students' learning goal orientations in the analytical chemistry laboratory to gain insights on students' motivational patterns and how these vary by gender and cohort. Using the SELLMO-ST scales, the study assessed 273 students across five different cohorts. Learning goals emerged as the most prominent orientation, indicating high intrinsic motivation, while performance-approach goals exerted moderate influence. Performance-avoidance and work-avoidance scores were relatively low, suggesting that most students actively engaged with laboratory tasks. Gender differences revealed slightly higher performance-avoidance tendencies in female students, reflecting a stronger fear of failure. Overall, all student cohorts showed high learning goals which may arise from a shared enjoyment of the practical aspects of the laboratory course. Three distinct student profile groups were identified: 49% students with a strong focus on learning (profile 1), 32% students which combined learning with a performance-approach (profile 2), and 19% students with a high tendency to performance-avoidance and work-avoidance (profile 3). These findings highlight the importance of fostering intrinsic motivation and tailoring laboratory experiences to address diverse motivational patterns in chemistry laboratory education.

Keywords: Undergraduate Teaching, Laboratory, Motivation

Introduction

Research in chemical education has explored how students feel when learning chemistry and how this may be influencing how they perform. (Flaherty, 2020) One aspect is students' learning goals orientation, which play a crucial role in shaping their motivation, emotional engagement, and academic success. Learning goals are rooted in achievement goal theory (Urdan & Kaplan, 2020) which is closely linked to self-determination theory (Ryan & Deci, 2000). Both theories emphasize the interplay between intrinsic and extrinsic motivations in shaping students' engagement and success. It categorizes goals into mastery goals, which focus on developing competence and understanding, and performance goals, which emphasize demonstrating competence relative to others (Elliot & McGregor, 2001). These goal orientations are closely tied to emotional experiences, as students' motivations influence their perceptions of success and failure. Intrinsic motivation, linked to mastery goals, fosters adaptive behaviours like persistence and deep learning, alongside positive emotions such as pride and enjoyment. Conversely, extrinsic motivation, often associated with performance goals, can lead to anxiety and surface-level learning, particularly when driven by performance-avoidance goals and fear of failure (Pekrun, 2006). Studies in students' learning goal orientation in chemistry lecture-based courses indicated students were motivated both intrinsically and extrinsically. (Lewis, 2018; Naibert et al., 2024) While these studies have explored motivational patterns in lecture-based chemistry courses, there is limited understanding of how these dynamics play out in laboratory settings.

Aim

Our observations in the analytical chemistry laboratory course indicate that while some students dedicate significant effort and aim for excellence in mastering the analytical chemistry laboratory course, others are primarily driven by grades or prioritize merely completing tasks with minimal effort. Therefore, this study explored students' learning goal orientation in the analytical chemistry laboratory, using the Scales for Assessment of Learning and Performance Goals

(SELLMO-ST; Spinath et al., 2002). Grounded in achievement goal theory, SELLMO-ST measures four distinct orientations: learning, performance-approach, performance-avoidance, and work-avoidance goals. Learning is one goal orientation and is associated with intrinsic motivation and a focus on personal growth and understanding. Performance-approach goals emphasize outperforming others and receiving recognition, while performance-avoidance goals are driven by a fear of failure and avoiding appearing. The following research-questions were explored: (1) What are student learning goal orientations in the analytical chemistry laboratory? (2) What is the influence of gender on motivation profiles? (3) What difference in motivational patterns do students show between cohorts?

Method

Participants

The practical laboratory course for analytical chemistry is part of different science curriculums at an Austrian university. Participant students included first-year Chemistry (n = 71), third-year Molecular Biology (n = 84), second-year Environmental System Sciences (n = 47), and second-year pre-service Teacher Education (n = 14). Additionally, fourth-year students (n = 57) of the advanced analytical chemistry course took part in this study. Altogether, 273 students (58% female, 41% male and 1% diverse) participated in the study. The study was conducted with the approval of the university ethics committee and in accordance with established ethical guidelines. Participation was voluntary, and written informed consent forms from the students were collected. SELLMO-ST questionnaire return was > 95%.

Learning Goal Orientation

The student version of the Scales for the Assessment of Learning and Performance Goals (SELLMO-ST; Spinath et al., 2002) was used to evaluate academic goal orientations in the analytical chemistry laboratory courses. The SELLMO-ST instrument consists of 31 items, categorized into four scales starting with “In the analytical chemistry laboratory course, it is important for me…” : Learning (8 items, e.g., '... to learn something interesting'), Performance-approach (7 items, e.g., '... to get better grades than others'), Performance-avoidance (8 items, e.g., '... to hide if I know less than others'), and Work-avoidance (8 items, e.g., '... to finish my studies with little effort'). Items are rated on 5-point Likert scales ranging from "totally disagree" (1) to "totally agree" (5). Cronbach's alpha was 0.85 for the learning goal orientation scale, 0.84 for the approach-achievement, 0.89 for the avoidance-achievement and 0.89 for the work-avoidance scale, indicating good reliability. The SELLMO-ST questionnaire was administered in the analytical chemistry laboratory on the first day of each practical course. Answering the SELLMO-ST questionnaire took approximately 10 minutes. Data were analysed using IBM SPSS Statistics (Version 28).

Results & Discussion

(1) What Are Student Learning Goal Orientations In The Analytical Chemistry Laboratory?

Table 1 shows the descriptive statistics for the SELLMO-ST scales, assessing the different learning orientation goals in the analytical chemistry laboratory. Overall, the results show a highly pronounced learning orientation and, in comparison, less pronounced values for performance-approach, performance-avoidance, and work-avoidance.

This suggests that most students prioritize developing competence and understanding in their laboratory work, reflecting high levels of intrinsic motivation. Some students are motivated by external validation and competition in the laboratory setting, though it is not the primary driver

for most students. The low performance-avoidance goals score indicates that most students experience relatively low levels of anxiety-driven motivation. Further, the low work-avoidance score shows that most students are willing to engage actively in laboratory tasks. This is a positive outcome, as learning goals are typically associated with adaptive learning behaviours and deeper engagement (Ryan & Deci, 2000). Furthermore, recent research by Liu (Liu et al., 2025) underscores the intricate relationships between motivation, emotions, and academic success in chemistry education.

Table 1: Descriptive statistics SELLMO-ST Scales (1 low to 5 high).

SELLMO -ST Scale	Mean	SD	α
Learning Goals	4.32	.59	.85
Performance-Approach	2.76	.75	.84
Performance -Avoidance	2.22	.87	.89
Work-Avoidance	2.02	.86	.89

(n = 273). M (mean) and SD (standard deviation), Cronbach's α.

The relationship between the SELLMO-ST goal orientation scales is presented in Table 2. The learning goals scale strongly associated with positive motivational patterns, including a positive correlation with performance-approach goals, and a negative correlation with work-avoidance. This suggests that students focused on learning goals are less likely to avoid effort and may also seek some level of recognition. There was no significant relationship with performance-avoidance, indicating that fear of failure does not strongly align with intrinsic motivation. The performance-approach goals scale positively correlated with performance-avoidance goals, indicating that students driven by competition may also experience fear of failure. This could be interpreted as the risk of critic versus appreciation, which in turn could be met by the feedback-style from laboratory teachers. An expected weak positive correlation with work-avoidance, suggesting a minimal connection between competition-driven motivation and effort minimization. In contrary, fear-driven motivation is often linked to disengagement and reduced effort is reflected in the moderately correlation of performance-avoidance with work-avoidance.

Table 2: Bivariate correlation SELLMO-ST Scales of goal orientation.

SELLMO Scale	2.	3.	4.
1. Learning	.202 (<.001)	-.049 (.420)	-.388 (<.001)
2. Performance-Approach		.588 (<.001)	.091 (<.137)
3. Performance-Avoidance			.423 (<.001)
4. Work-Avoidance			-

Note: *r* (p)

(2) What Is The Influence Of Gender On Motivation Profiles?

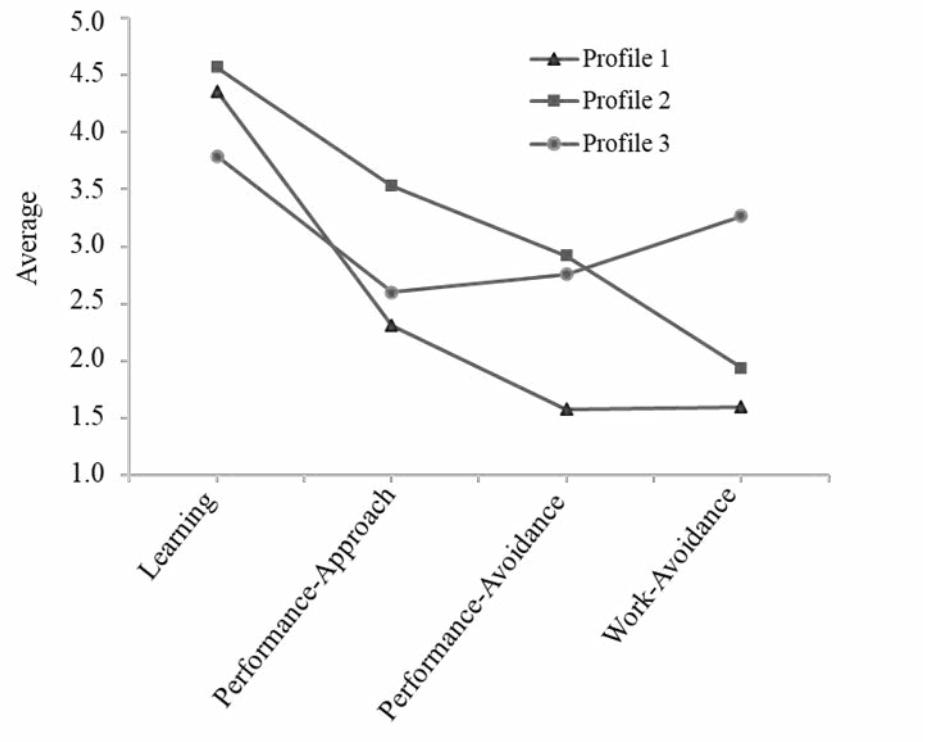
Key findings from the descriptive statistics in Table 3 indicate that female and male students had comparable mean scores for learning goals. This similar motivation may arise from a shared enjoyment of the practical aspects of the laboratory course and the self-selection involved in university program enrollment. Additionally, no significant differences were observed between genders in performance-approach or work-avoidance scores, which may be attributed to the laboratory setting's emphasis on teamwork and collaboration, helping to minimize motivational variation. However, there was a significant difference on performance-avoidance goals between female and male students. This pattern may reflect a stronger fear of failure among female students. Addressing this issue could involve maintaining a supportive laboratory environment that fosters confidence and reduces anxiety, where students feel comfortable expressing ideas without fear of negative judgment, and emphasizing the learning process through meaningful feedback.

Table 3: Descriptive statistics SELLMO-ST Scales (1 low to 5 high) for genders .

	M (SD)			
	Learning	Performance-Approach	Performance-Avoidance	Work-Avoidance
Female (n = 158)	4.34 (.19)	2.81 (.81)	2.36 (.93)	2.02 (.93)
Male (n = 111)	4.28 (.52)	2.70 (.65)	2.01 (.71)	2.01 (.74)
$t(267)$ =	.912 p = .363	1.15 p = .253	3.28 p = .001	.067 p = .946

M (mean) and SD (standard deviation), t = independent sample t-test.

(3) What Difference In Motivational Patterns Do Students Show Between Cohorts?



The motivational patterns from the five student cohorts are shown in Table 4. The key finding was between the Chemistry and Environmental Systems Sciences cohorts, where statistical differences were found for the mean scores for the learning scale ($t(116) = -2.73$, $p < .01$), performance-approach ($t(116) = -4.51$, $p < .001$), and performance-avoidance ($t(116) = -2.64$, $p = 0.009$), though not for work-avoidance ($t(116) = 1.68$, ($p = .096$). Suggesting less emphasis on competence and recognition in the analytical chemistry laboratory course, which may be influenced by the interdisciplinary focus of the Environmental Systems Sciences. These findings highlight the importance of tailoring laboratory experiences to student cohorts. Figure 1 shows three generated profiles (K-Means) from the student cohorts in the analytical chemistry laboratory. Profile 1 consist of 48,7% (n = 133), the second profile of 31,5% (n = 86), and the third profile of 19,7% (n = 54) students. The profile groups 1 and 2 show high learning goal orientation and low work-avoidance tendencies. Profile 1 demonstrates minimal influence from performance-oriented goals (either approach or avoidance) compared to profile 2, which shows moderate performance orientation. Profile 3 characterizes a high tendency to work-avoidance and performance-avoidance with a lower learning goal orientation compared to the other two profiles.

Table 4: Descriptive statistics SELLMO-ST Scales (1 low to 5 high) for student cohorts.

Student cohort	M (SD)			
	Learning	Performance-Approach	Performance-Avoidance	Work-Avoidance
Environ. System Sciences (n = 47)	4.03 (.62)	2.37 (.67)	1.90 (.70)	2.15 (.83)
Pre-Service Teacher (n = 14)	4.22 (.35)	2.60 (.76)	2.05 (.80)	2.70 (1.62)
Molecular Biology (n =84)	4.38 (.53)	2.79 (.79)	2.29 (.96)	1.84 (.77)
Chemistry (n = 71)	4.37 (.69)	2.95 (.68)	2.30 (.84)	1.89 (.83)
Advanced Analytical Chem. (4th year) (n = 57)	4.41 (.44)	2.80 (.72)	2.31 (.85)	2.13 (.69)

M (mean) and SD (standarddeviation)

Figure 1: Mean values of the learning goal orientation scales, learning, performance-approach, performance-avoidance and work-avoidance. Profile 1 (n = 133), Profile 2 (n = 86), Profile 3 (n = 54).

Conclusion

This study revealed that students in the analytical chemistry laboratory predominantly demonstrate intrinsic motivation, supported by strong learning goals, moderate performance-approach tendencies, and mostly low avoidance behaviors. This motivation may stem from the shared enjoyment of the practical aspects of laboratory course work and the students' self-directed choices in selecting their university programs. Gender differences revealed that female students experienced a stronger fear of failure, which could be addressed by maintaining a supportive laboratory environment and emphasizing the learning process through meaningful feedback. Additionally, the findings suggest that laboratory experiences for the interdisciplinary Environmental System Sciences cohort could be further refined to enhance meaningful learning by providing targeted feedback that emphasizes the relevance of laboratory tasks.

Acknowledgement

The author would like to thank all participating students and Prof. Manuela Paechter for the valuable discussions.

ESERA 2025 Copenhagen

Supporting First-Semester Chemistry Students: Development And Evaluation Of A Two-Phase Digital Learning Unit In Redox Chemistry

Jasmin Kneuper, Sebastian Henke and Insa Melle
TU Dortmund University, Germany

STEM degree programs, such as chemistry, are associated with a range of challenges, with mathematical content areas posing particularly significant difficulties for students (e.g., Averbeck et al., 2018; Seymour & Hunter, 2019; Ye et al., 2024). However, in the context of redox chemistry, such content is fundamental to achieving a deeper understanding of chemical relationships.

This project aims to develop, implement and evaluate a two-phase digital learning unit designed to support first-semester chemistry students in understanding mathematical-chemical concepts and tackling related tasks in redox chemistry. In the first phase, students engage independently with interactive educational videos. In the second phase, they work on exercises and are provided with one of three different digital support measures.

The effectiveness of the intervention will be analysed primarily in terms of improvements in content knowledge. Additionally, student evaluations regarding the attractiveness and usability of the learning unit as well as cognitive load will be considered. Other aspects included in the evaluation are logfile analysis, students' written assignments, and video recordings of the training phase.

Keywords: Higher Education, Postsecondary Education, Undergraduate Teaching

Introduction

Chemistry is considered one of the most challenging subjects for students at university (e.g., Childs & Sheehan, 2009). This is evidenced by the high dropout rates reported internationally in STEM degree programmes such as chemistry, which show a rising trend. Academic performance issues disproportionately often lead to early dropouts (e.g., Heublein et al., 2022; Seymour & Hunter, 2019).

Students enter higher education with diverse initial conditions, such as varying levels of prior knowledge and mathematical skills. However, these factors are among the key determinants of subsequent learning success (Averbeck et al., 2018). The content covered during the first semester forms the foundation for learning as part of a cumulative acquisition of knowledge. Consequently, there is an acute need for targeted measures to support first-semester students in mastering subject-specific challenges.

Thematic areas with high mathematical components appear to present particular difficulties for first-year students (Hoban et al., 2013; Potgieter et al., 2008; Ye et al., 2024). These include redox chemistry, which is taught in the first semester. Topics such as balancing redox reaction equations and applications of the Nernst equation are especially challenging (Potgieter et al., 2008). This is emphasised by numerous misconceptions and difficulties documented in the literature (see overviews by Duit, 2009; Horton, 2007). These include, for example, the concept of oxidation in general, difficulties identifying reducing and oxidising agents (e.g., Brandriet & Bretz, 2014), misinterpretation of oxidation numbers, and general struggles with setting up and balancing redox reaction equations (e.g., Potgieter & Davidowitz, 2011). Although extensive research highlights

learners' challenges in understanding redox chemistry, relatively few studies provide concrete suggestions for addressing these issues and evaluate their effectiveness (Goes et al., 2020).

Our objective is therefore to design, implement and evaluate a learning unit focused on redox chemistry that aims to help learners deal with their difficulties.

Research Design And Method

The developed two-week learning unit comprises two main phases. In the first phase, students engage with educational videos that have been designed according to research-based principles for maximising learning success (Kulgemeyer, 2020) and that have been enhanced with interactive *H5P* elements to promote active learning (e.g., Brame, 2016). They then attend two seminars, 135 minutes in total, where they work on exercises (training phase). During this time, the students are assigned to one of three different digital support measures. In a previously conducted qualitative study, the primary difficulties faced by first-semester students in redox chemistry were identified (Kneuper et al., 2025b). Based on these findings, worked examples (WE), flowcharts (FC) and brief solutions (BrS) were designed to help students deal with these difficulties in the training phase. It is important to emphasise that all students receive identical exercises in terms of content, and the allocated time for completing these tasks is consistent across all groups.

WEs present learners an experts' solution to a given problem, including the final answer. This allows students to understand and learn from this model approach (e.g., Atkinson et al., 2000). To encourage self-explanation (*self-explanation effect*) and promote the transition from learning with WEs to solving tasks independently, each thematic area includes a progression: an elaborated WE with self-explanation prompts, followed by a faded WE where learners complete specific solution steps independently, and finally open-ended tasks (e.g., Atkinson et al., 2000; Atkinson et al., 2003; Wittwer & Renkl, 2010).

FCs provide visual representations of workflows required to solve various problems or complete tasks and therefore serve as strategic tools (Işık, 2024; Yuriev et al., 2017). The FCs offered are structured around sub-goals and encourage procedural checks (Ye et al., 2024).

BrS show students the final answer, but do not provide any information or guidance on how to solve the problem/task. This enables them to check their solution, though they do not receive any process-related support. A more detailed description of the three support measures can be found in Kneuper et al. (2025a).

One focus of our research is to examine how the content knowledge of the students who take part in our study develops:

> Q1: To what extent do the educational videos affect the students' content knowledge?
>
> Q2: To what extent does the training affect the students' content knowledge, depending on the support measure offered?

Additional aspects investigated in this study, though not covered within this paper, include students' evaluations of the learning unit, the influence of personal variables on the development of content knowledge (e.g., gender or science motivation) and detailed analysis of students' interactions with WEs, FCs or BrSs.

To address Q1 and Q2, a knowledge test was developed that covers the conceptual basis of redox reactions as well as applications, such as reasoning with the Nernst equation. The test was validated through an ongoing exchange with the professor who gave the introductory chemistry lecture in the first semester. It consists of 27 multiple-choice single-select items (MC) and six

open-ended items. The MC items are internally consistent (α = .810), while a scoring scheme for the open-ended items is under development.

The content knowledge test is administered at three different times: at the beginning of the learning unit (pre), after engaging with educational videos (mid), and upon completion of seminar exercises (post). To answer question Q2, participants are assigned to one of three statistically comparable intervention groups based on their prior knowledge levels (pre-test content knowledge, MC items) and gender.

First Results of Iteration 1

In the winter semester 2024/25, a first iteration was conducted with $N = 90$ first-semester students (chemistry, chemical-biology and chemistry teaching), of whom 79 students (44 females, 34 males, 1 not specified) participated completely in the intervention and where therefore included in our analysis. Table 1 provides an overview of the initial results from the content knowledge test, addressing research questions Q1 and Q2. It should be noted that this analysis only considers the MC items; the evaluation of open-ended items is still pending.

Table 1. Development of the students' content knowledge (MC items) based on the intervention group (*$p < .001$).**

Group	Time	*n*	*M*	Mean Difference	Effect Size (part. η^2)	95%-CI
Worked Examples	pre	26	.437	.164***	.702	[0.104, 0.224]
	mid		.601			
	mid	26	.601	.105***		[0.051, 0.160]
	post		.707			
Flowcharts	pre	27	.420	.148***	.629	[0.091, 0.205]
	mid		.568			
	mid	27	.568	.019		[-0.026, 0.064]
	post		.587			
Brief Solutions	pre	26	.466	.127***	.499	[0.051, 0.202]
	mid		.593			
	mid	26	.593	.048		[-0.004, 0.101]
	post		.641			
All	pre	79	.441	.146***	.593	[0.111, 0.182]
	mid		.587			
	mid	79	.587	.057***		[0.028, 0.087]
	post		.644			

To examine the development of content knowledge within each group, a one-way ANOVA and post-hoc tests with Bonferroni-correction were performed separately for each group (WE/FC/BrS). The results are summarised in Table 1: Significant increases in content knowledge from 'pre' to 'mid' were observed across all groups, with large effect sizes. From 'mid' to 'post', significant improvements were detected exclusively in the WE group, whereas no significant changes were found for the FC and BrS groups.

Interaction effects between intervention groups (WE/FC/BrS) and time (pre/mid/post) on content knowledge development were determined by a mixed ANOVA with Greenhouse-Geisser correction. A significant interaction effect between time and group was detected with a moderate effect size ($F(3.70, 140.43) = 3.32$, $p = .015$, partial $\eta^2 = .080$). Table 1 shows that the increase in content knowledge from mid to post is highest in the WE group and lowest in the FC group, suggesting that the WEs are more effective in facilitating learning than the FCs.

Discussion & Outlook

The preliminary findings of this study indicate that the learning unit is well-suited for first semester students (see also Kneuper et al., 2025a) and that the educational videos are effective in supporting learning. Moreover, among the support measures compared, worked examples appear to be the most effective. A more detailed analysis is currently being carried out, incorporating the remaining content knowledge data (open-ended items), task processing data, generated logfiles, and video recordings from the training phase. To this end, appropriate coding manuals are being developed. Combining these sources of information is expected to provide valuable insights into developing effective learning opportunities for complex content areas in higher education. Furthermore, a second iteration in the winter semester 2025/26 is planned to increase the sample size.

ESERA 2025 Copenhagen

Representational Competence In The Context Of Electric Fields: An Eye-Tracking Study

Larissa Hahn[1], Andreas Müller[2] and Pascal Klein[1]
[1]Physics Education Research, University of Göttingen, Germany
[2]Faculty of Science, University of Geneva, Switzerland

Multiple visual representations can significantly enhance learning and understanding of scientific concepts. However, for visual representations to be effectively used in learning, learners need representational competences, i.e. abilities to interpret and fluently coordinate multiple representations. Therefore, to design effective multi-representational learning materials, it is essential to understand representational competence and how learners retrieve and process information from visual representations. In this article, we present a study that explores representational competence in the context of electric field representations. In the study, 38 university science students completed a test including two different visual representations of electric fields, namely equipotential line diagrams and field line diagrams. In each task, they were asked to evaluate characteristics of the electric field shown, with some tasks requiring inter-representational coherence formation and others not. During task completion, students' eye gaze was recorded. Analyses revealed that while students demonstrated strong visual understanding of individual representations, they struggled to integrate these representations as shown by low response accuracy and confidence while perceiving high item difficulty and indicating high cognitive invest. Moreover, initial conclusions about students' visual strategies for handling the representations could be revealed.

Keywords: Non-Verbal Representations, Eye-Tracking, Process Skills

Theoretical Background

Visual representations play a crucial role in science and science education. Being able to use and switch between different representations is essential for understanding scientific concepts (Rau, 2017). However, to truly benefit from visual representations in learning, students need representational competences—knowledge and skills required to use visual representations for reasoning and problem-solving (Klein et al., 2017). These competences consist of two aspects: visual and connectional understanding (Rau, 2017). Visual competences involve intra-representational coherence formation, i.e. knowing how individual representations work, what information they convey, and how they connect to scientific concepts (Seufert, 2003). Connectional competences involve inter-representational coherence formation which incorporates the ability to connect and flexibly switch between different visual representations (Seufert, 2003).

Because visual representations are important in scientific communication, many researchers highlight the need to develop representational competences to help students grasp complex scientific ideas (De Cock, 2012; Rau, 2017). Therefore, numerous studies geared towards characterizing students' representational competences in science learning (e.g., Kohl & Finkelstein, 2005; Rau, 2018).

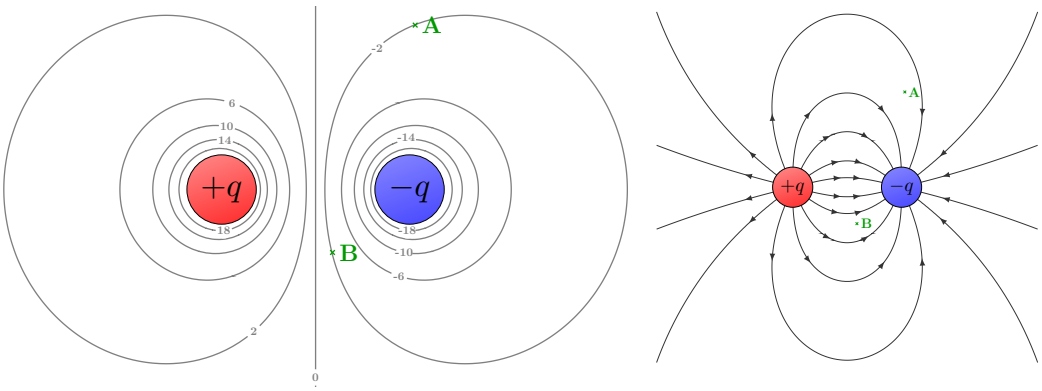
From the perspective of cognitive psychology, it is important to understand how learners retrieve information from one or multiple visual representations to design effective learning materials. Since these retrieval processes are difficult to observe directly, eye tracking, i.e. analysis of eye movements, provides valuable insights into how learners handle visual representations (Ubben et al., 2018). For example, in previous studies from science education research, analyses of gaze

behaviour revealed representation-specific visual strategies (Hahn & Klein, 2025) and processes of information extraction from different representations (Susac et al., 2023).

The Present Study

This study focuses on visual representations of electric fields, specifically equipotential line diagrams and field line diagrams. Equipotential line diagrams represent the electric potential, and field line diagrams depict the electric field, i.e. its magnitude and direction (Figure 1). Previous research identified numerous learning difficulties related to the interpretation of such electric field representations (Bollen et al., 2017; Campos et al., 2023, Küchemann et al., 2021). For instance, students confused characteristics of field lines and equipotential lines, and they failed to recognize field line density as an indicator of the field's magnitude (Bollen et al., 2017). Since electric field representations are crucial in undergraduate physics, understanding representational competences is key to developing multi-representational learning materials.

Research Aims



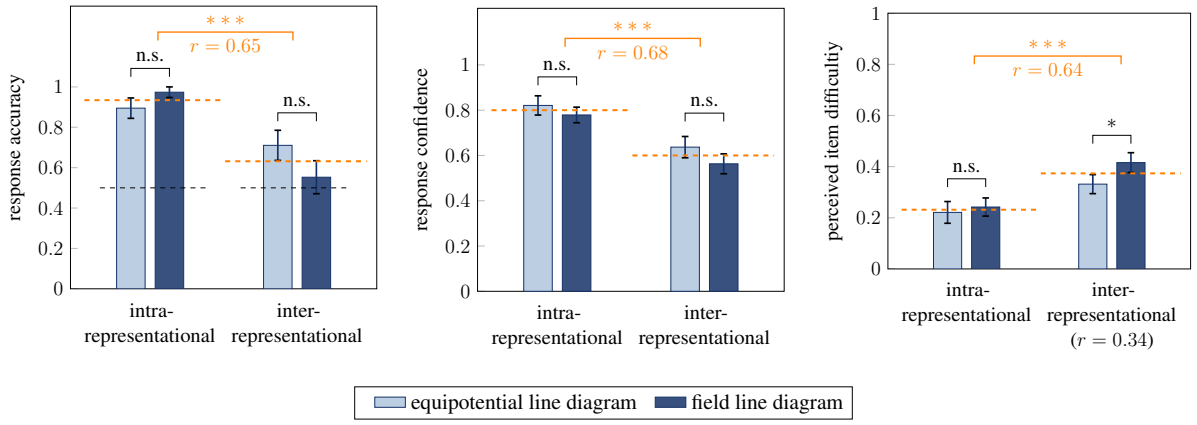
The current study takes an exploratory approach to investigate students' representational competences in using electric field representations. The following objectives are focused: (1) characterizing students' ability—their visual and connectional understanding—to handle electric field representations and (2) identifying visual strategies employed by students when processing electric field representations. To achieve these objectives, the study triangulates gaze data during representation processing and performance measures, i.e. students' response accuracy, response confidence, and perceived item difficulty.

Design And Methods

The study involved 38 university science students (20.9 ± 2.1 years, 68% male), most of whom were pursuing bachelor's or master's degrees in physics (3.5 ± 2.3 semester of study). Almost all participants were currently enrolled in or had taken a course on electrodynamics (95%). In the study, students completed a test on electric field representations, judging the magnitude, direction, and potential of fields shown as equipotential or field line diagrams. Some tasks required inter-representational coherence formation (e.g., judging electric potential using a field line diagram; in the following referred to as inter-representational coherence formation items), while others required interpretation within the same representation (intra-representational coherence formation items; Figure 1). The test included three scenarios commonly encountered in undergraduate electrodynamics courses, namely a point charge near an uncharged metallic plate, a symmetrical dipole (Figure 1), and an unsymmetrical dipole. After completing a task, participants moved to the solution page and provided their solution as well as a retrospective think-aloud explanation of their reasoning. Additionally, students rated their response confidence and the perceived difficulty of each item. During test assessment, students' gaze behavior was recorded using a Tobii Pro Fusion eye tracker (sampling frequency 120 Hz).

The following analyses focus on the symmetrical dipole scenario (Figure 1). To evaluate students' representational competences, response accuracy, response confidence, and perceived item difficulty were compared between intra- and inter-representational coherence formation items. These comparisons were conducted for tasks involving equipotential and field line diagrams of the symmetrical dipole, addressing the field's magnitude and potential. Moreover, gaze data during task processing was analysed by referring to the fixation count on the diagram. For analyses, performance measures and gaze metrics were subjected to non-parametric paired comparison analyses. Pearson correlation coefficient r and odds ratio OR are referred to as measures of effect size by following the interpretation of Cohen (1988).

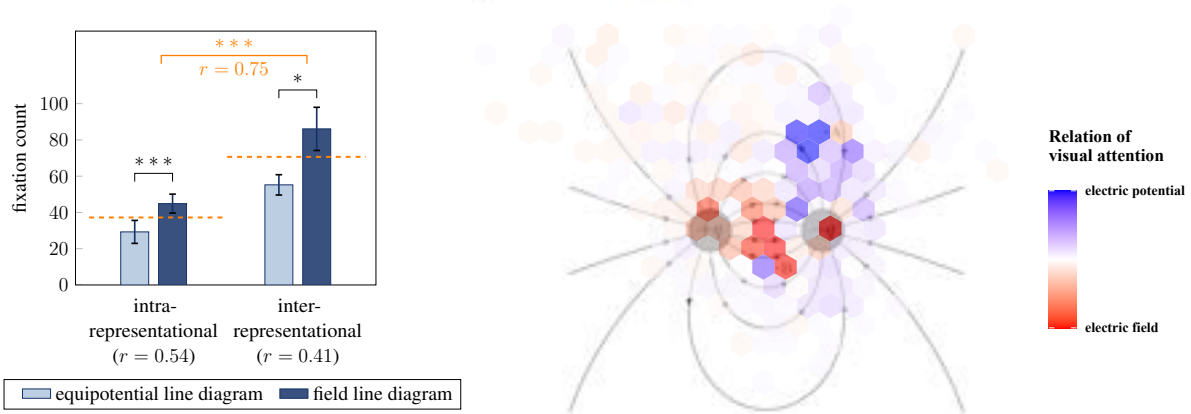
Figure 1. Equipotential line diagram (left) and field line diagram (right) of a symmetric dipole (positive charge $+q$, negative charge $-q$). Two tasks were posed for each diagram: "Decide in which of the indicated points, A or B, (1) the electrical potential / (2) the magnitude of the electric field is higher". For the left diagram, the first question involves intra-representational coherence formation, while the second question requires imagining the corresponding field lines (inter-representational coherence formation item). For the right diagram, those task requirements apply vice versa. The points A and B are identically placed in all diagrams, ensuring isomorphic representations. While the electric field's magnitude is higher at point B (higher field line density), both points share the same electric potential.



Results

When comparing students' response accuracy between intra- and inter-representational coherence formation items of the symmetrical dipole, a large-sized effect was observed ($z = -4.01$, $p < 0.001$, $r = 0.65$; Figure 2 left, orange). Students achieved lower scores on the inter-representational coherence formation items (0.63 ± 0.38) compared to the intra-representational coherence formation items (0.93 ± 0.17).

Regarding students' response confidence and perceived item difficulty of the symmetrical dipole scenario, similar effects were observed (Figure 2 middle and right, orange). For inter-representational coherence formation items compared to intra-representational coherence formation items, students were less confident in their answers ($z = -4.18$, $p < 0.001$, $r = 0.68$) and reported higher item difficulty ($z = 3.93$, $p < 0.001$, $r = 0.64$), with large effect size, respectively. Notably, students found it more challenging to judge the field's potential using the field line diagram than to determine the field's magnitude from the equipotential line diagram ($z = -2.07$, $p = 0.039$, $r = 0.34$), representing a medium-sized effect.



Gaze data analyses revealed that students fixated more often on the diagrams during inter-representational coherence formation items compared to intra-representational coherence formation items ($z = 4.63$, $p < 0.001$, $r = 0.75$), with large effect size (Figure 3 left, orange). Across both item categories, students showed significantly higher fixation counts for tasks involving the field line diagram than for those with the equipotential line diagram ($z = -3.29$, $p < 0.001$, $r = 0.54$ for intra-representational coherence formation items; $z = -2.52$, $p = 0.012$, $r = 0.41$ for inter-representational coherence formation items), with large and medium effect size, respectively.

Figure 2. Students' response accuracy (left), response confidence (middle), and perceived item difficulty (right) for symmetrical dipole items. Performance indicators are compared between intra-representational coherence formation items and inter-representational coherence formation items (means for both item categories in orange) using sign tests for response accuracy and Wilcoxon signed-rank tests for response confidence and perceived item difficulty. Comparisons between items involving equipotential line diagrams and field line diagrams are conducted using McNemar tests for response accuracy and Wilcoxon signed-rank tests for response confidence and perceived item difficulty (∗ / ∗∗∗ / n.s. statistical significance $p < 0.05$ / $p < 0.001$ / not significant, effect size r, black dashed lines indicate guessing probability, error bars represent 1 SEM).

When the equipotential line diagram of the symmetrical dipole was presented, response accuracy did not differ between the intra- and the inter-representational coherence formation task ($p = 0.07$). However, students allocated significantly more visual attention to the equipotential line diagram when evaluating the field's magnitude compared to its potential ($z = -3.87$, $p < 0.001$, $r = 0.64$).

Figure 3. Students' fixation counts on the diagrams for symmetrical dipole items (left) and visual attention difference pattern when processing the field line diagram (right). Left: Fixation counts are compared between intra-representational coherence formation items and inter-representational coherence formation items (means for both item categories in orange) and between items involving equipotential line diagrams and field line diagrams using Wilcoxon signed-rank tests (∗ / ∗∗∗ statistical significance $p < 0.05$ / $p < 0.001$, effect size r, error bars represent 1 SEM). Right: Hexagons illustrate differences in students' visual attention when analysing electric potential (blue) versus field magnitude (red) in the field line diagram. Colour intensity represents the magnitude of attention difference between the two tasks.

In contrast, when students were shown the field line diagram of the symmetrical dipole, students achieved significantly lower scores (0.97 ± 0.16 versus 0.55 ± 0.50; $\chi^2(1,38) = 12.50$, $p < 0.001$, $OR = 17$) and fixated significantly more often on the diagram ($z = -3.93$, $p < 0.001$, $r = 0.64$) when they judged the field's potential compared to its magnitude. Students' gaze patterns also revealed task-specific attention distribution within the field line diagram (Figure 3 right). When determining the field's magnitude, students predominantly focused on the charges and the field lines surrounding point B. Conversely, when assessing the field's potential, their attention was directed toward point A and the area around the negative charge.

Discussion And Outlook

When handling electric field representations, students demonstrated lower response accuracy, reported lower confidence, perceived higher item difficulty, and allocated more visual attention to the representations when inter-representational coherence formation was required compared to items that involve intra-representational information extraction. These findings align with frameworks from cognitive psychology that distinguish between two facets of representational competences: visual understanding of a single representation and connectional understanding of different representations (Rau, 2017; Seufert, 2003).

In the context of electric fields, these results suggest that students possess strong visual understanding of equipotential and field line diagrams. Contrary to prior studies, no difficulties in associating field line density with the field's magnitude were observed (Bollen et al., 2017). Instead, students exhibited targeted focus on the field lines around the point with higher field magnitude. Moreover, nearly all students correctly judged the field's magnitude from the field line diagram, which implies that their visual strategies were guided by top-down processes rather than by surface features of the diagram, indicative of advanced visual expertise.

However, consistent with earlier research on electric fields, students encountered significant challenges in connectional understanding (Campos et al., 2023). Specifically, when tasked with assessing the field's potential from a field line diagram, their performance was hardly above guessing probability, they reported high item difficulty and showed high cognitive invest. While students performed well in judging the field's magnitude from a field line diagram, these findings suggest a specific lack of representational competence in relating field lines to electric potential. To shed light on students' difficulties and reveal expertise characteristics, further analyses will focus on students' reasoning and comparisons between high- and low-achieving students.

Improving Problem-Solving Skills Using Entrepreneurial STEM Intervention

Aybuke Pabuçcu-Akiş and Nil Orhan-Özteber
Dokuz Eylul University, Türkiye

This study aims to provide an example for potential future interventions in the context of entrepreneurship and sustainability and enhance problem-solving skills with an entrepreneurial STEM intervention. Fourteen senior pre-service chemistry teachers (PTs) worked in five small groups, each developing a distinct STEM project (e.g., making soap from used cooking oil). For each project, the groups were required to identify relevant Sustainable Development Goals (SDGs) and prioritize social entrepreneurship. Data was collected using the Interpersonal Problem-Solving Inventory (pre and post) and PTs' reflection forms (post). The quantitative data indicated that the implemented STEM activity significantly impacted the sub-dimensions of negative approach to interpersonal problems, low self-confidence, and unwillingness to take responsibility in PTs' interpersonal problem-solving skills. The qualitative data pointed to the changes in participants' capability of making connections between chemistry and everyday life. PTs have stated that they have gained valuable experience in laboratory practice and project writing, both of which would contribute highly to their career. In addition, some of the PTs have stated that the intervention improved their entrepreneurial skills. Lastly, the study contributes to the field by bringing authenticity to STEM education by incorporating social and green entrepreneurship and supporting students' problem-solving skill development.

Keywords: *Entrepreneurial STEM, problem-solving, social entrepreneurship*

Introduction

Recently, STEM education has begun to focus on various topics, including sustainability and entrepreneurship. When the research on entrepreneurship is reviewed, it is commonly viewed as financial entrepreneurship in education rather than other types, such as social, innovative, and sustainable entrepreneurship. While financial entrepreneurship focuses on monetary expectations through performing different activities such as starting a business and selling a product or a service with profit (Hisrich & Peters, 2002), social entrepreneurship focuses on social change and cultural issues rather than monetary expectations (Barberá-Tomás et al. 2019), and green entrepreneurship focuses on solving environmental problems using sustainable processes (QAA, 2018). Currently, the integration and implementation of entrepreneurship in STEM education is a new area with a limited number of studies. The current study aims to integrate enterprise education and STEM education while promoting social and green entrepreneurship. Enhancing entrepreneurial STEM education is important because entrepreneurial thinking and practices are essential for fostering sustainable, collegial, and collaborative interactions that enable innovative STEM practices (Abd-El-Khalick et al., 2011). One of the common features of STEM education and entrepreneurship is their focus on generating solutions to real-life problems. In this regard, entrepreneurial skills such as problem solving and creativity play a crucial role in enhancing the understanding of the relationship between STEM and real-world contexts (Bicer et al., 2017; Sarı et al., 2022; Kaya-Capocci et al., 2024). Moreover, although there are studies indicating that entrepreneurial STEM activities positively affect students' problem-solving skills, there is a need for an increase in the number of such studies (Sarı et al., 2022; Kaya-Capocci et al., 2024). This study investigated the effects of Entrepreneurial STEM activities on students' problem-solving skills through the implementation of activities structured according to the nine-step Engineering Design Process proposed by Hynes et al. (2011). Previous research highlights Engineering Design

Process–based STEM practices as effective pedagogical tools for fostering 21st-century skills, including problem-solving abilities (Hacıoğlu et al., 2016), and for enhancing students' conceptual understanding (Tatlı, 2022).

Methodology

The research questions (RQs) of this study are:

1. How do PTs' problem-solving skills change following an entrepreneurial STEM intervention?

2. What do PTs think about the effectiveness of the intervention they've completed?

Participants

This study was conducted as part of a lesson titled "Service to Community" at a public university during the first semester of the 2024-2025 academic year. Fourteen PTs participated in the study.

Research Tools

While PTs' reflection form (post) was used to collect qualitative data, the Interpersonal Problem-Solving Inventory (pre and post) was used to collect quantitative data.

Interpersonal Problem-Solving Inventory (PSI)

The scale was developed by Çam and Tümkaya (2007) to assess interpersonal problem-solving skills. The scale consists of 50 items and yielded a five-factor solution: Negative approach to interpersonal problems, Constructive approach to interpersonal problems, Low self-confidence, Unwillingness to take responsibility, and an Insistent-persevering approach. It has been determined that the inventory applies to university students between the ages of 18 and 30. While the Cronbach's alpha internal consistency values of the subscales ranged from .67 to .91, the test-retest stability coefficients varied from .69 to .89.

Reflection Form

Following the completion of the intervention, the pre-service teachers (PTs) individually completed a reflection form. The form included two open-ended questions designed to explore their perceptions and experiences regarding the intervention (see Table 5). The questions were reviewed by two field experts to ensure their comprehensiveness and appropriateness.

Intervention

The intervention was conducted over 12 weeks during the first semester of the 2024–2025 academic year. After completing the PSI, the pre-service chemistry teachers (PTs) were organized into small groups and asked to identify problem situations related to the United Nations' Sustainable Development Goals (SDGs). The Sustainable Development Goals (SDGs) addressed by Group 1 are presented in Table 1. During the intervention, each group developed a distinct social entrepreneurship–oriented STEM project. The projects were: (1) Sustainable Soap Production from Used Cooking Oil, (2) Removal of Heavy Metals from Simulated Water Using Eggshell Powder, (3) Bioplastic Protective Face Masks from Banana Peels, (4) Eco-Friendly Soap Sheets, and (5) Smart Edible Films and Coatings with Natural Spoilage Indicators. The problem scenarios of the five social entrepreneurship projects are presented in Table 2. In addition, the learning objectives of the Group 1 project are provided as an illustrative example in Table 3.

Throughout the implementation of the STEM activities, students followed the nine-step Engineering Design Process proposed by Hynes et al. (2011), which includes: (1) problem identification, (2) problem research, (3) generation of possible solutions, (4) selection of the most appropriate solution, (5) prototype development, (6) testing and evaluation, (7) sharing and

reflection, (8) redesign, and (9) finalization. After the intervention, all PTs completed the PSI again and submitted reflective forms.

The SDGs related to Group 1's project are presented in Table 1.

Table 1. SDGs of Group 1's Project.

No	Goal(s)
4	Quality Education (Target 4.7)
6	Clean Water and Sanitation (Target 6.3)
12	Responsible Consumption and Production (Target 12.4 & 12.5)
14	Life Below Water (Target 14.1)

Table 2. Groups' Social Entrepreneurship Interventions and Identified Problems.

Grup	Project Titles and Problem Statements
1	Sustainable Soap Production from Used Cooking Oil This project aims to produce an environmentally friendly cleaning product by recycling used cooking oil, thereby reducing water pollution and promoting sustainable waste management practices
2	Removal of Heavy Metals from Simulated Water Using Eggshell Powder The project focuses on mitigating the risks of heavy metal contamination in wastewater by employing waste eggshells as an eco-friendly, low-cost, and sustainable adsorption material.
3	Bioplastic Protective Face Masks from Banana Peels This project aims to reduce environmental pollution caused by disposable face masks by producing biodegradable bioplastic protective face masks from waste banana peels as a sustainable alternative.
4	Eco-Friendly Soap Sheets The project focuses on developing portable, biodegradable soap sheets as a sustainable alternative to conventional wet wipes, thereby reducing environmental pollution and promoting responsible consumption.
5	Smart Edible Films and Coatings with Natural Spoilage Indicators The project focuses on developing biodegradable edible films and coatings integrated with natural indicators to monitor the spoilage of meat and meat products, thereby enhancing food safety and reducing packaging-related environmental impacts.

Table 3. Learning Objectives of the Group 1 Project

Subject Disciplines	Learning Objectives
Chemistry	- Explain acid–base reactions.
Technology	- Provide examples of interdisciplinary applications of computational thinking.
Mathematics	- Determine an unknown quantity when the ratio of two quantities is given.
Engineering	- Develop and use sketch drawings to support idea generation and problem-solving during the engineering design process. - Gather qualitative and quantitative experimental data. - Document and analyse observations.
Social Entrepreneurship	- Recognize the role of interpersonal communication in social entrepreneurship. - Analyse the social responsibilities of entrepreneurs. - Propose strategies for spreading knowledge, products, and services for societal benefit.

Data Analysis

Quantitative data were analysed using the SPSS 22 package program. The Wilcoxon test was applied separately for each of the five sub-dimensions of the Interpersonal Problem-Solving Inventory. For a significant difference between the pre-test and post-test, the sigma value must be less than 0.005.

The qualitative data were analysed through content analysis. The codes were developed by two researchers. Each form was assigned a code by researchers individually, and these codes were compared to see whether there would be any disagreements. Through these discussions, the variance of 2% between the coders was resolved. The inter-rater reliability for the coding is 98%. The initial letters ‘PT’ and a number from 1–14 was given to each preservice teacher (i.e., PT-16).

Findings

The current study revealed the following findings related to the RQs, respectively.

RQ1—Investigating PTs’ Problem-Solving Skills

In the inventory, which consists of five sub-dimensions, each sub-dimension was separately subjected to the Wilcoxon test, and sigma values were obtained (see Table 4). When examining the sigma values, it was found that the intervention created a significant difference in the sub-dimensions of the Negative approach to interpersonal problems, low self-confidence, and unwillingness to take responsibility. However, it did not create a significant difference in the sub-dimensions of constructive approach to interpersonal problems and insistent-persevering approach.

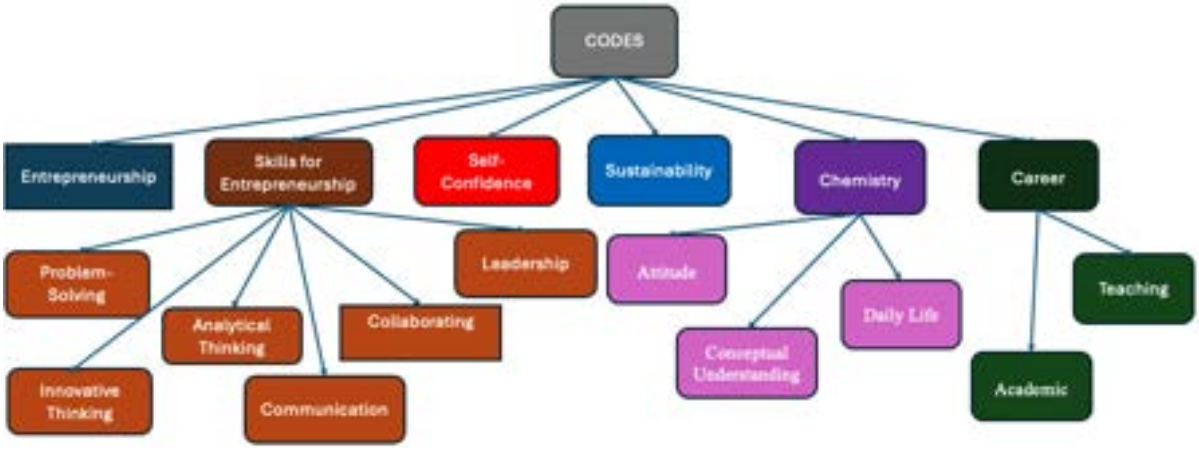

Table 4. The sub-dimensions and sigma values.

The Sub-dimensions	Asymp. Sig. (2-tailed)
Negative approach to interpersonal problems	0.001
Constructive approach to interpersonal problems	0.182
Low self-confidence	0.002
Unwillingness to take responsibility	0.004
Insistent-persevering approach	0.889

RQ2—Investigating Pts' Experiences And Feelings Of The Intervention

To respond to RQ2, PTs' opinions about the intervention were investigated through interview questions, and their opinions were classified under six major codes (see Figure 1 and Table 5).

Figure 1. Concept map for the codes of the study.

The results showed that the intervention strengthened PTs' entrepreneurship potential and the different skills necessary for Entrepreneurship. Besides, some PTs believed that the intervention helped improve their self-confidence. In addition, approximately 25% of PTs stated that the intervention improved their understanding of chemistry, attitudes toward chemistry, and their sustainability awareness by helping them to make connections with the world. Figure 3 shows that problem-solving is the most developed skill (see Figure 3). Furthermore, most of the PTs believed that this intervention was helpful to promote their future careers in both academic and teaching means (see Figure 4).

Table 5. Reflection forms' questions & example excerpts.

• **Interview Questions**
• What are your opinions about the effectiveness of the project you were involved in? • Do you think this project will be helpful later in your career?
Entrepreneurship *"These experiences have encouraged me in what I can achieve in Entrepreneurship. I will continue to take part in entrepreneurship interventions in the future that both generate financial and social benefits (PT-4)*
Skills for Entrepreneurship & Self-confidence • **Problem-Solving** *"The project improved my problem-solving skills, now I am more adept at using search engines and I am better at researching." (PT-1)* • **Collaboration** *"This project improved my teamwork and collaboration skills" (PT-10)* • **Innovative Thinking & Analytical Thinking** "*Trying to find solutions to environmental problems has improved my innovative and analytical thinking skills*" (PT-10) • **Communication & Leadership & Self-confidence** *"In this project, I was the team leader, in this way, I improved my communication and leadership skills and increased my self-confidence (PT-10)*
Sustainability "*Seeing that we can contribute to the environment by repurposing waste materials has increased my interest in and awareness of sustainability. In the future, I am to take part in interventions that focus on developing more sustainable solutions.*" (PT-9)
Chemistry • **Attitude & Conceptual Understanding & Daily Life Connection** "*Realizing the chemical properties of the eggshells makes chemistry more real and meaningful for me. I realized how effectively the eggshells we usually dispose of can be used in addressing the significant use of removing heavy metal accumulations, that pose a risk to human health. This allows me to use chemistry in my daily life, and this allows me to recognize I enjoy this subject. Once again, we learned new elimination methods for pollution, such as phytoremediation".* (PT-9)
Career • **Academic Experience** "*This project provided me with the opportunity to conduct scientific research. In this regard, I believe it has contributed to my academic and career development." (PT-10)* • **Teaching Experience & Sustainability** *"The knowledge I've gained in this experience will be useful in my teaching life. For example, I can teach my students about making soap from used cooking oils, as well as about information on sustainability." (PT-8)*

Figure 2. Percentage of codes for the first question from the form.

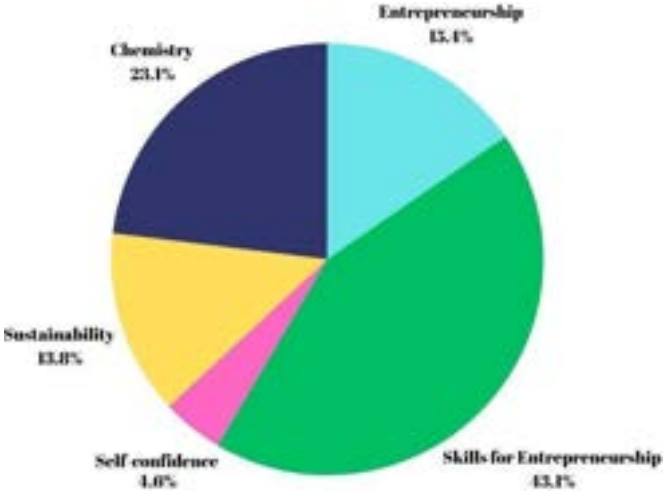

Figure 3. Percentage of sub-categories for "Skills for Entrepreneurship".

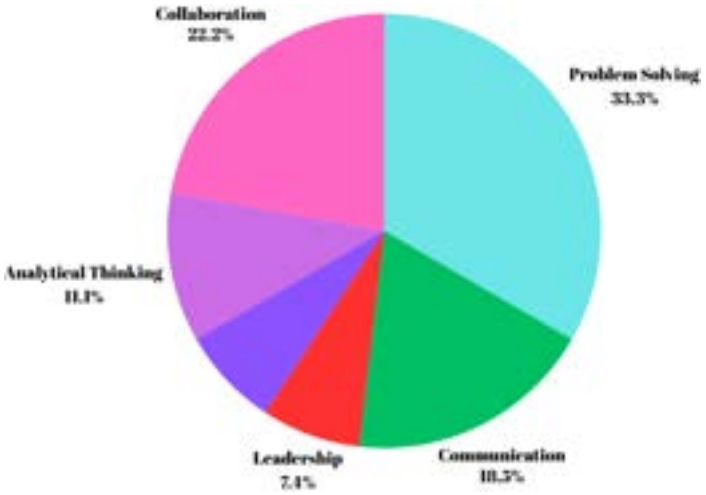

Figure 4. Percentage of codes for the second question from the form.

Discussion & Conclusion

The study aimed to increase PTs' problem-solving skills within the context of entrepreneurial STEM education. In the current study, qualitative data showed that 33.33% of PTs believed the effectiveness of the intervention to improve their problem-solving skills. A review of the literature on educational research reveals that studies examining problem-solving skills have generally focused on no more than three sub-dimensions (Kaya-Capocci et al., 2024). However, in the present study, the Interpersonal Problem Solving Inventory developed by Çam and Tümkaya (2007), which conceptualizes problem-solving skills across five sub-dimensions and considers three sub-dimensions insufficient for an in-depth analysis, was employed. This approach enabled a more comprehensive examination of the effects of Entrepreneurial STEM activities on problem-solving skills across five distinct sub-dimensions. Examining the results of the interpersonal problem-solving inventory, which constitutes the quantitative data, a significant difference was observed in three out of the five sub-dimensions, while no significant difference was found in the other two. The sub-dimensions with a significant difference were negative approach to interpersonal problems, low self-confidence, and unwillingness to take responsibility. The sub-dimensions without a significant difference were constructive approaches to interpersonal problems and an insistent-persevering approach. The negative approach to interpersonal problems dimension refers to intense negative emotions and cognitions, such as helplessness, pessimism, and sadness experienced when individuals encounter a problem (Çam & Tümkaya, 2007). The finding that STEM activities reduced PTs' negative perceptions toward problems supports the assertions of Topsakal et al. (2022). This positive shift may be attributed to students' learning how to systematically approach and solve problems by following the Engineering Design Process during STEM activities. The unwillingness to take responsibility reflects a reluctance to assume responsibility in problem-solving situations, while the low self-confidence dimension represents insecurity regarding one's ability to solve problems (Çam & Tümkaya, 2007). In the present study, positive changes were observed in both the unwillingness to take responsibility and low self-confidence sub-dimensions. These findings suggest that learning how to address a real-life problem within Entrepreneurial STEM activities may enhance PTs' self-confidence, enabling them to take greater responsibility in the problem-solving process.

The qualitative data also showed that some PTs believed that this intervention positively affected Entrepreneurship. Besides, they also stated the intervention was useful to improve some crucial skills (communication, leadership, innovative thinking, analytical thinking, and collaboration) and self-confidence, which are related to becoming and succeeding as an entrepreneur. In addition, it seems that the intervention presented here was effective in improving PTs' understanding of the chemistry topics and attitudes toward chemistry by helping them to make connections between real-world and chemistry knowledge. Lastly, we believe that the study is going to add a unique contribution to the related literature because it seems to be helpful to increase PTs' sustainability awareness.

Foreword

The strand Methods and Methodological Aspects in Science Education Research (or informally, "the methodology strand") is a slim but important part of the ESERA conference. Other strands employ a rich array of techniques and arguments in their studies, but for this strand, the primary focus is on the methods. Authors may use their work to showcase a methodological advance, to promote an existing technique to the community, or to invite critical discussion of their analysis structure and choices. Method is the key focus of this theme, while it can be integrated into a range of science education contexts set up in other themes.

In this year's proceedings, the methodology strand has two chapters. The first, by Sundstrom and collaborators, uses temporal exponential random graph models to quantify the existence and growth of structure in student collaboration networks in university science courses. The second, by El Karkri and collaborators, uses a Solomon Four-Group Design to probe for the effect of pre-test sensitisation in secondary school science courses. Both studies are quantitative in focus, and both recommend further use of their tools in the science education research community. Temporal network models allow for the adaptation of popular pretest/post-test designs to incorporate network effects, and the Solomon Four-Group Design gives principled attention to the often-neglected question of pretest effects that may damage the precision or reliability of findings.

Integrating advanced methodology and data analyses make an important contribution to science education issues. We envisage that these advanced methodological considerations will gain increasing attention among researchers who work in different issues and disciplines in science education. For instance, the temporal exponential random graph models, which show student networks in physics education research in this conference proceeding, will interest researchers in chemistry and biology education. The Solomon Four-Group Design, which attends to students' scientific reasoning in different experimental conditions in this proceeding, will interest scholars working on experimental design that advances students' nature of science and scientific practices. We believe that papers in this strand will extend our discussion on how to advance science education using methods. In the future, science education researchers will continually derive methodological frameworks based on the designs discussed in the two chapters. We thank the authors for their work, and look forward to the next stage in the conversation of methodological advances and practices in the field of science education research.

ESERA 2025 Copenhagen

Measuring Classroom Network Dynamics with Temporal Exponential Random Graph Models

Meagan Sundstrom[1], Adrienne Traxler[2] and Eric Brewe[1]
[1]Drexel University, United States of America
[2]University of Copenhagen, Denmark

Interacting with peers has been shown to positively correlate with undergraduate science students' performance and sense of belonging. Correspondingly, a growing number of physics education research studies have examined patterns of peer interactions using social network analysis. Time-dependent student networks are of particular interest, as they illuminate the ways in which student communities form. Existing studies of time-dependent student networks, however, rely on descriptive measures and/or simple statistical tests that do not account for other variables that may explain classroom network dynamics. In this study, therefore, we demonstrate the use of temporal exponential random graph models (TERGMs), a form of multiple regression for time-dependent network data. We apply TERGMs to pre- and post-semester peer interaction networks from two introductory physics courses in the United States taught using different active learning pedagogies: Peer Instruction (i.e., small groups of students answer poll questions during lecture) and SCALE-UP (i.e., small groups of students work on problem solving and laboratory activities in a classroom specifically designed for group work). We find that students form connections with small groups of three peers in both courses. In SCALE-UP, however, students are also unlikely to form connections that create long chains. These results are not extractable from the descriptive network measures alone, suggesting that TERGMs (or other similar models) are necessary for measuring classroom network dynamics.

Keywords: Network Analysis, Collaborative Learning, Pedagogy

Introduction

According to the participationist framework, learning occurs as people engage with their surrounding community (Packer & Goicoechea, 2000). Collaborating with others allows for learners to revise upon their own thinking and co-construct understanding. In university-level physics classrooms in particular, researchers have demonstrated that social interactions with peers positively correlate with student outcomes such as academic performance, attitudes, and persistence (Bruun & Brewe, 2013; Dou et al., 2016; Zwolak et al., 2017).

Social network analysis (SNA) is an increasingly popular tool for analyzing peer interactions among physics education researchers (Grunspan et al., 2014). Many SNA studies administer a network survey to students, asking which peers they interact with about their physics course, at one point in time and use a combination of descriptive statistics, regression methods, and exponential random graph models (ERGMs) to make claims about patterns in the resulting interaction network (Bruun & Brewe, 2013; Commeford et al., 2019; Sundstrom et al., 2022b; Crossette et al., 2023; Pulgar et al., 2023). Other SNA studies examine how student interaction networks evolve over time by administering several network surveys throughout a physics course and analyzing changes in the resulting networks (Brewe et al., 2010; Bruun & Bearden, 2014; Commeford et al., 2021; Sundstrom et al., 2022a, Wolf et al., 2022). Such "time-dependent" student networks illuminate the ways in which student communities develop in a classroom and how classroom instruction may impact student network development.

The existing studies of time-dependent student networks, however, have exclusively relied on descriptive statistics (e.g., network density) and/or simple statistical tests (e.g., t-tests) to make claims. These methods are limited because they do not allow for hypothesis testing: they measure

the effect of one variable at a time without accounting for other variables that may explain why networks change over time. More sophisticated tools, therefore, are necessary to make more nuanced claims about time-dependent student networks.

In this study, we expand upon the SNA methods that have been applied in physics education research to meet the methodological needs of time-dependent networks described above. We use temporal exponential random graph models (TERGMs)–a form of multiple regression for time-dependent network data–to measure network dynamics in two university-level, introductory physics courses taught using different active learning pedagogies. We aim to address the following research question: What types of peer interaction network structures form in different active learning environments in physics?

Methods

Data Collection

We use data from two courses at different institutions in the United States that were collected as part of a prior research project (Commeford et al., 2021). The first was an introductory physics course at Drexel University containing 116 students. The course contained one combined lecture section and several smaller laboratory and recitation sections. The lecture component was taught in a large lecture hall using "Peer Instruction," where the instructor asked students to discuss and respond to clicker questions. The second was an introductory physics course at North Dakota State University containing 71 students. The course was taught using the "SCALE-UP" pedagogy, where all students were in one course section that blended lecture, laboratory, and recitation activities. The course took place in a large room designed for group work: there were several round tables where students sat, and whiteboards were placed along the perimeter of the room.

In each course, the instructor administered an online network survey at the beginning and end of the semester. Students responded to the following prompt: "Please choose from the list of people that are enrolled in your physics class the names of any other student with whom you had a meaningful interaction in class during the past week, even if you were not the main person speaking." Below the prompt was an alphabetized course roster with associated check boxes, from which students could select as many names as they wanted. For the Peer Instruction course, the pre- and post-survey had response rates of 42% and 58% of enrolled students, respectively. For the SCALE-UP course, the pre- and post-survey had response rates of 70% and 66% of enrolled students, respectively. Responses made by students who did not consent to participating in the research were excluded from our analysis.

Data Analysis

We created undirected networks using the survey responses, with nodes representing students and edges representing a reported interaction between two students (regardless of which student reported the interaction on the survey), to reduce possible impacts of missing data due to non-respondents. We calculated several descriptive measures for each network, as in prior work (Commeford et al., 2021), to characterize its structure:

- Density: the proportion of all possible edges in the network that we observed
- Transitivity: the number of two-paths (e.g., student A is connected to student B and student B is connected to student C) that are closed (e.g., students A and C are connected)
- Giant component: the number of nodes that are contained in the largest connected cluster of nodes.

We then applied TERGMs to the data to measure whether different network structures (e.g., transitivity) are more (or less) likely to form in our observed post-semester networks than we would expect if the pre-semester networks evolved randomly. We used separable TERGMs in particular, as they model two distinct processes of network evolution: (1) formation–the tendency for new edges to form over time and (2) persistence–the tendency for edges formed early on to remain in the network over time (Krivitsky & Handcock, 2014). In line with our research goal of identifying the types of network structures that form in active learning classrooms, we only examine the formation process in this study.

Table 1. Predictor variables included in TERGMs.

Variable	Description	R syntax
Edges	The number of edges in the observed network.	edges
Chains	The number of two-paths (e.g., student A is connected to student B and student B is connected to student C) that are open (e.g., students A and C are not connected).	gwdsp(decay=0.5, fixed=TRUE)
Transitivity	The number of two-paths (e.g., student A is connected to student B and student B is connected to student C) that are closed (e.g., students A and C are connected).	gwesp(decay=0.5, fixed=TRUE)
Degree Distribution	The distribution of the number of edges connected to each node.	gwdegree(decay=0.5, fixed=TRUE)

We ran one TERGM for each of the two courses using the predictor variables listed in Table 1 and the "tergm" package in R. We included these particular variables because we expected them to vary between the Peer Instruction and SCALE-UP classrooms based on prior work (Commeford et al., 2019; Commeford et al., 2021). For example, we expected that chains would be more likely to form in Peer Instruction classes, as students typically sit in long rows of chairs in stadium style lecture halls, than in SCALE-UP classes, where students work in small groups at a round table.

Both models exhibited sufficient goodness-of-fit: the observed networks and a set of networks simulated from the resulting models had similar structural properties (Hunter et. al., 2008).

Results

Figures 1 and 2 show the pre- and post- semester networks for the Peer Instruction and SCALE-UP courses, respectively. Table 2 contains descriptive measures for each network. The Peer Instruction network does not appear to change much over time. In both networks for this course, the majority of students are connected in the giant component, which contains a combination of chains and closed triangles. Quantitatively, the density and transitivity values are similar for the pre- and post-networks. The SCALE-UP pre-network contains some isolated small groups of students and a few edges that bridge together these groups. The SCALE-UP post-network, on the other hand, contains more edges (the density increases) and more strongly connected small groups (the transitivity increases) than the pre-network.

Figure 3 and Table 3 show the coefficient estimates for the TERGMs applied to the observed networks. Odds ratios that are greater (less) than one and significant indicate that the network structure represented by the predictor variable is more (less) likely to form in our observed network than we would expect if the pre-network evolved randomly.

Figure 1. Pre- (left) and post- (right) peer interaction networks for an introductory physics course taught using Peer Instruction. Nodes represent students and edges represent self-reported, in-class peer interactions.

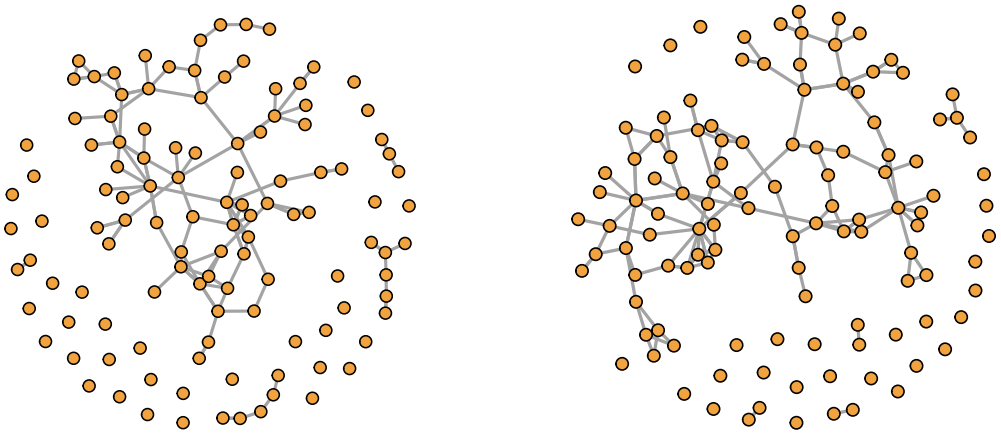

Figure 2. Pre- (left) and post- (right) peer interaction networks for an introductory physics course taught using SCALE-UP. Nodes represent students and edges represent self-reported, in-class peer interactions.

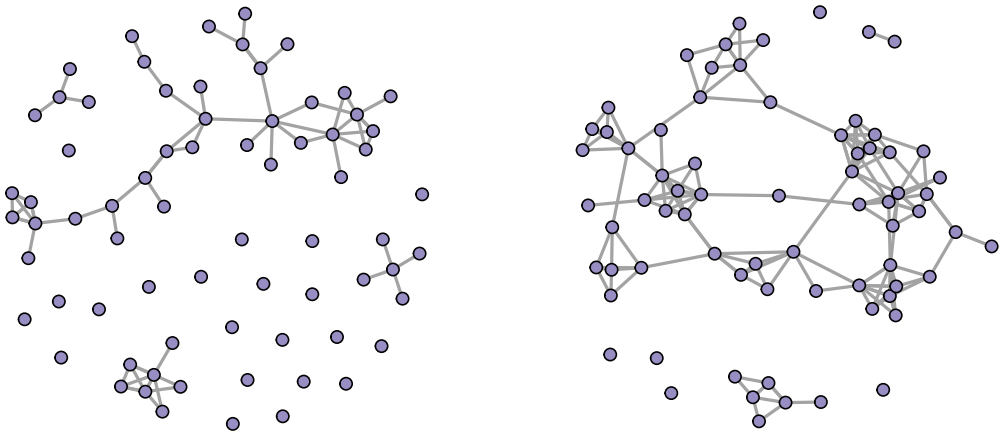

Table 2. Descriptive measures for the four networks.

	Peer Instruction		SCALE-UP	
	Pre	Post	Pre	Post
Nodes	116	116	71	71
Edges	135	159	71	176

Transitivity	0.209	0.231	0.327	0.517
Giant component	67	80	34	58

In the Peer Instruction course, the only significant effect is transitivity: edges forming closed triangles are significantly more likely to form in our observed network than we would expect at random. Notably, this result is after controlling for the other effects included in the model and despite the raw transitivity values of the pre- and post-networks being similar (Table 2). The non-significant effect of degree distribution means that edges are not more likely to form if they create either a highly skewed degree distribution (i.e., with many students having few connections and a few students having many connections) or a very uniform degree distribution (i.e., with all students having a similar number of connections).

In the SCALE-UP course, we find that chains are significantly less like to form than we would expect at random and that edges that form closed triangles are significantly more likely to form than we would expect at random. Similar to the Peer Instruction course, we find no significant effect of degree distribution.

Figure 3. Coefficient estimates for TERGMs. Error bars represent 95% confidence intervals and asterisks indicate statistical significance (*$p < 0.001$).**

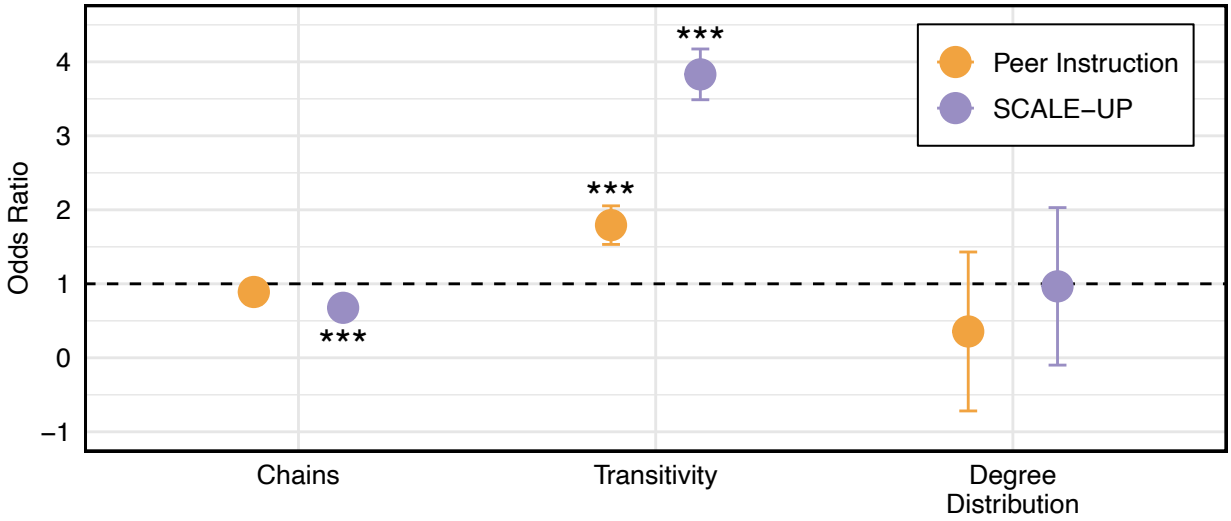

Table 3. Coefficient estimates for TERGMs. SE indicates standard error and asterisks indicate statistical significance (*$p < 0.001$).**

Discussion and Conclusion

We have characterized the dynamics of student networks using a statistical tool not yet applied in physics education research: temporal exponential random graph models. Results indicate

structural differences in the types of connections students form with their peers in two introductory physics courses taught using different active learning pedagogies. In a Peer Instruction course, students form connections with small groups of three peers. In a SCALE-UP course, students also form small group of three peers, but they are unlikely to form connections that create open chains.

We recommend for other education researchers to use TERGMs or similar models (e.g., stochastic actor-oriented models) when conducting time-dependent network studies, moving beyond descriptive and/or simple statistical approaches. In this study, for example, we found that after controlling for other effects in the model, some changes in network structure identified in the TERGMs differed from the descriptive statistics alone.

ESERA 2025 Copenhagen

The Critical Role of Pre-test Sensitisation and the Solomon Four-Group Design in Science Education Research: A Transition From Uncertainty to Necessity

Mourad El Karkri, Antonio Quesada, and Marta Romero-Ariza
University of Jaén, Spain

Pre-test sensitisation (PS) is a critical concern in science education research, as it can influence participants' responses to interventions and potentially distort study outcomes. When students are pretested, they might gain insights or knowledge that allow them to answer correctly during subsequent assessments, thereby affecting the validity of the results (Pan & Carpenter, 2023). Two studies, undertaken a Spanish-Moroccan team of researchers, were conducted in secondary schools over two consecutive academic years (2021–2022 and 2022–2023), both utilising the Solomon Four-Group Design (SFGD) as a tool to detect PS (Campbell & Stanley, 1966; Solomon, 1949). Despite this shared framework, a notable divergence emerged in the results: the first study revealed no evidence of PS, while the second clearly shows sensitization. This difference led to new considerations and perspectives, raising essential questions about the role of PS in science education research. Should it be regarded as a prestigious methodological element, or is its inclusion always necessary? These findings challenge established perceptions and highlight the need for a critical reflect on the methodological significance of PS.

Keywords: Pre-test sensitisation, Solomon Four-Group Design, Quasi-experimental studies.

Theoretical Background

Numerous studies across different fields provide evidence supporting the presence of PS, demonstrating its impact on learning processes, attitudes, mental health interventions, and behavioural intentions (Hoogstraten, 1980; Lana & King, 1960; Spence et al., 2009; Spirito et al., 1988; Swanborn & De Glopper, 1999).

Conversely, many studies have reported the absence of PS, showing no significant effects on attitude change, behavioural measures, family interaction patterns, self-efficacy, or stress management scores (Jordaan et al., 2018; Kazdin, 1973; Lana, 1959; Parsons & Alexander, 1973; Rosa-Castillo et al., 2023; Rubel et al., 2010; Spence & Blanchard, 2001).

A nuanced perspective on pre-testing is offered by Hollins et al. (2023), who challenged the assumption that pre-testing universally enhances memory. Their findings suggest that pre-testing benefits are limited to specific guessed information, providing a more detailed understanding of its role in memory. Similarly, Pan & Carpenter (2023) demonstrated that the pre-questioning or pre-testing effect can enhance learning, even when initial tests include incorrect answers, through the use of various educational materials.

Taken together, these studies illustrate that while PS may not always manifest, its potential to influence participant responses remains substantial. This is particularly relevant in contexts where pre-tests and post-tests share identical formats, differing only in content and numerical measurements. Although the evidence does not provide definitive conclusions, it strongly indicates that PS is a plausible factor warranting careful consideration in research design and interpretation.

Research Questions

This study seeks to address two interrelated questions concerning the phenomenon of PS in science education research through two implementations conducted in different secondary schools. First, it investigates whether PS might occur in science education contexts, examining its potential influence on research outcomes. Second, it explores whether PS should be considered as another aspect while research design, something that must be considered and accounted for, whenever possible to ensure methodological rigour.

Research Design And Methods

The Solomon Four-Group Design (SFGD) received its name from Richard Lester Solomon (born in 1918, passed away in 1995) and consists of four different groups of participants, each subjected to a different experimental condition, as outlined in Table 1:

Table 1: Structure of the Solomon four-group design (Campbell & Stanley, 1966).

Groups	Assignment	Pre-test	Treatment	Post-test
Group 1 (Experimental & Pretested)	Randomly	O1	Yes	O2
Group 2 (Control & Pretested)	Randomly	O3	No	O4
Group 3 (Experimental and Non-Pretested)	Randomly		Yes	O5
Group 4 (Control and Non-Pretested)	Randomly		No	O6

The treatment in both studies was planned as five sessions focusing on getting students familiar with reason patterns related to making a fair test with variable control. These lessons were inspired by those offered within the Cognitive Acceleration through Science Education, a broadly implemented program in various countries across Europe, America, Australia, and Asia (Adey et al., 2004). The pre-test and post-test used in the studies were composed of 10 questions extracted from activities, examples, and applications from CASE program, designed to be completed within 1 hour.

Findings And Interpretation

Tables 2 and 3 present the SFGD for each study. Table 2 features a larger number of participants with a more balanced distribution across the four groups compared to Table 3. This difference arises from the availability of the study samples.

Despite the less balanced sample in the second study, normality was verified before proceeding with parametric analysis, using IBM SPSS Statistics (version 26). The Shapiro-Wilk test confirmed normality in Study 1 for both the treated group ($p = 0.469$) and the untreated group ($p = 0.240$). Similarly, in Study 2, it indicated normality for the treated group ($p = 0.496$) and the untreated group ($p = 0.254$), supporting the assumption of normality and the use of parametric methods.

Table 2. Distribution and composition of the Solomon four-group design in the 2023 Study.

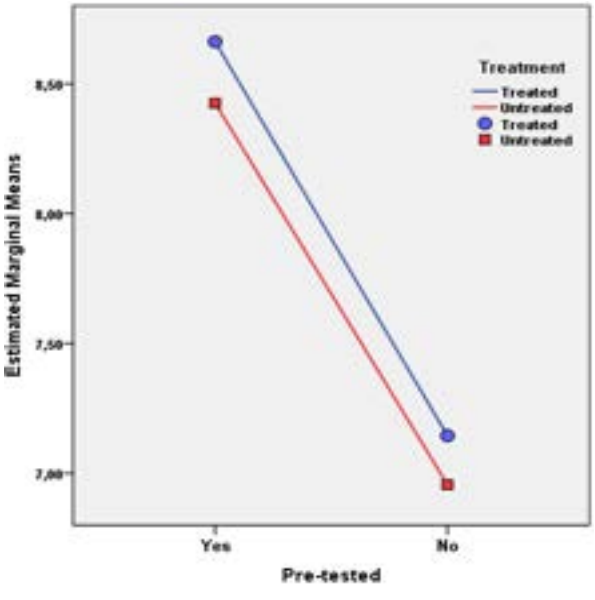
Groups	Frequency	Percentage
Experimental 1	31	25 %
Control 1	23	18 %
Experimental 2	38	30 %
Control 2	34	27 %
Total	126	100 %

Table 3. Distribution and composition of the Solomon four-group design in the 2022 study.

Groups	Frequency	Percentage
Experimental 1	9	10 %
Control 1	25	29 %
Experimental 2	17	19 %
Control 2	37	42%
Total	88	100 %

To visualise the interaction between the variables, we generated Two-Way ANOVA interaction plots, which are not commonly used or shown in comparable studies. In this approach, the quantitative variable Post-test Scores were set as the dependent variable, while the two qualitative variables, Pre-test Scores and Treatment, were assigned as fixed factors. This method produced the two interaction graphs displayed below (Figures 1 & 2), illustrating the effects of pre-testing and treatment on the Post-test Scores.

Figure 1. Interaction between pre-testing and treatment on post-test scores in study 1 (2023).



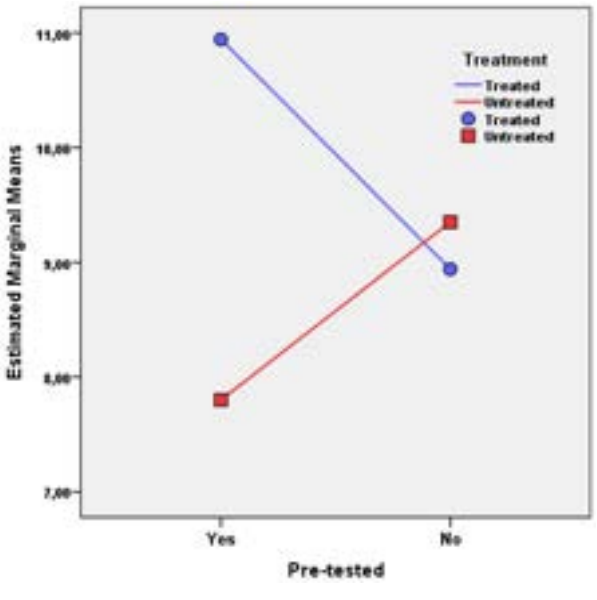


Figure 2. Interaction between pre-testing and treatment on post-test scores in study 2 (2022).

Before giving interpretation of plots, some details need to be clarified. A line in an interaction plot does not represent a mathematical function. Instead, it is a visualization of group averages calculated from a statistical model. Each line connects these averages to make trends easier to interpret. The end points of the line correspond to the estimated marginal means for each condition, providing a clear summary of the data for different groups.

Each line shows how the dependent variable (Post-test Scores) changes with the independent variable (Pre-test Scores) for a specific group (Treated or Untreated). The lines connect estimated

marginal means from the statistical model and are straight, reflecting assumed linear relationships. This simplifies group comparisons and emphasizes trends, even if real-world relationships are not strictly linear.

When lines in an interaction plot intersect, it means there is an interaction effect between variables. The effect of the treatment on the outcome depends on the condition of another variable (pre-test). Crossing lines show that the effect changes or reverses between conditions, while parallel lines indicate no interaction, meaning the effect is consistent across all conditions.

Based on these reflections, In Study 1 (Figure 1), the lines are nearly parallel (in general, no intersection), indicating that there is no interaction between pre-testing and treatment. This shows that treatment effects were consistent and unaffected by pre-testing.

In contrast, in Study 2 (Figure 2), the lines are non-parallel (in general, they intersect), indicating a significant interaction between pre-testing and treatment. This demonstrates how pre-testing influenced treatment outcomes, highlighting the variability of PS effects.

Future Directions In Adoption

By repeating the same experiment with the SFGD, we gain a broader perspective on the phenomenon of PS itself. This repetition allows us to determine whether PS consistently occurs, consistently does not occur, or varies depending on specific conditions. If the findings suggest variability, it implies that PS cannot be generalised across studies. Consequently, this variability underscores the necessity of accounting for PS in every research design to ensure methodological rigour and accurate interpretation of results.

Historically, the Pre-test-Post-test Control Group Design, now viewed as a fundamental element of the "traditional" or "usual" approach to two-group experimental studies, was once considered a prestigious and innovative methodology (Huck & McLean, 1975). Similarly, the Solomon Four-Group Design, often described as prestigious due to its ability to detect and account for PS, deserves a reassessment of its role in educational research.

It is time to recognise this design not just as a specialised tool for select studies but as an essential approach for designing and conducting experiments in education. Adopting the Solomon Design as a standard methodology could significantly enhance the precision and reliability of findings, especially in contexts where the effects of pre-testing cannot be ignored.

The absence of PS, as observed in Study 1 does not imply that researchers should revert to the usual two-group design of. Instead, it may encourage the adoption of a more rigorous approach, such as parametric analysis and meta-analysis, as proposed by Braver & Braver (1988). However, this lack of PS should not lead to a disregard for the Solomon Four-Group Design. Despite its perceived complexity, this design remains invaluable, particularly in fields like educational research, where the influence of PS should not be overlooked.

Reflections Following Conference Feedback

In light of the notes and discussion generated by attendees during the presentation of this work at the ESERA Copenhagen 2025 conference, it became clear that the topic of pre-test sensitisation (PS) continues to raise important methodological questions in science education research. The central purpose of the present article is therefore to foreground the significance, and in some contexts the practical necessity, of considering PS when designing and interpreting experimental or quasi-experimental interventions. Even when PS is not consistently observed across studies, its potential to shape participants' responses can influence the magnitude and interpretation of treatment effects. For this reason, the article argues that PS should not be treated as a marginal

issue, but rather as a plausible source of variation that warrants explicit attention whenever research conditions make it possible.

The discussion with attendees also brought out a practical question that many researchers face, which is how the analysis should proceed when a study includes a pretest, when it does not, or when it includes both conditions, as in the Solomon Four-Group Design. Put simply, attendees wanted to know what changes in the analytic strategy from one situation to another, and how to choose the most appropriate route for estimating treatment effects without drawing conclusions that the design cannot support. This ambiguity was subsequently addressed more extensively in a methodological contribution published in Review of Education (El Karkri, Quesada, & Romero-Ariza, 2025a), where the procedures and decision steps are clarified in a systematic manner, including guidance on how to proceed under the presence or absence of PS and how to select appropriate analyses for different types of outcome variables.

Attendees also commented on the uneven distribution of participants across groups in Study 2 (Table 3). The concern was not only about balance in principle, but about what such imbalance might mean for statistical power, the reliability of estimates, and the interpretation of the interaction term. Rather than treating this as a minor limitation, it was used to sharpen the methodological discussion and to explain more clearly how these issues can be handled and reported transparently. This line of critique was taken forward in a later empirical paper published in Brain Sciences (El Karkri, Quesada, & Romero-Ariza, 2025b), which examines the second study in greater depth and discusses its implications in a more detailed way. Taken together, the conference feedback and the follow-up publications help to clarify why PS deserves attention, how it can be analysed carefully, and how design-related concerns can be strengthened through systematic follow-up work. It was also suggested that Table 1 should clarify the random allocation of participants to groups. Attendees also noted that Table 1 should clarify the random allocation of participants to groups, and this has now been reflected in the revised version.

Acknowledgement

We are grateful to Dr Martin Riopel (Department of Didactics, Faculty of Education Sciences, University of Quebec in Montreal, Canada) for his comments during the presentation and for subsequent discussions afterwards, which contributed to enriching this work. We also acknowledge Dr Ahmad Qablan (Faculty of Education, United Arab Emirates University, Al Ain, United Arab Emirates).
