About These Proceedings

The Proceedings of ESERA 2025 is an electronic publication of revised and extended papers presented at the ESERA 2025 conference, organised by the University of Copenhagen, Denmark, from 25 to 29 August 2025 under the theme *Transitions in Science Education: Sustainability and Digital Advances*. All papers in the e-Proceedings correspond to communications submitted to, and accepted for, the ESERA 2025 conference. All proposals to the conference went through a double-blind review process, with most proposals receiving two reviews and some receiving three, before being accepted to the conference.

A total of 1436 contributions (including 74 symposia) were accepted and presented at the conference, and 228 papers are included in the ESERA 2025 e-Proceedings. Following the call for e-Proceedings (deadline 31 January), 248 extended papers based on conference presentations were submitted; the final selection reflects those that completed the post-conference editorial review.

The authors were asked to produce updated versions of their papers, taking into account the discussion that took place after their presentation and the suggestions received from other participants at the conference. The e-Proceedings present a comprehensive overview of ongoing studies in science education research in Europe and beyond, and represent the current interests and areas of emphasis in the ESERA community. The e-Proceedings contain twenty Parts representing the papers presented across the 20 Strands of the ESERA 2025 conference. For each part, the proceedings list the Strand description used for the conference as well as the per strand sub-themes.

The strand chairs serving for ESERA 2025 co-edited the corresponding Part for each of strands 1 to 20. All formats of presentation used during the conference – oral presentations, interactive posters, workshops, exploratory seminars, and symposia – were eligible to be submitted to the e-Proceedings. The co-editors reviewed the updated versions of the papers submitted after the conference.

ESERA, the editors, and the co-editors do not necessarily endorse or share the ideas and views presented in, or implied by, the papers included in this book.

Parts of the editorial process associated with the conference were supported by generative artificial intelligence (for example, in the thematic clustering of contributions). Editorial responsibility for the contents of these Proceedings rests with the editors and co-editors.

Learning Science: Conceptual Understanding

Co-editors: *Massimiliano Malgieri & Ana Sofia Afonso*

Part 1 / Strand 1 Learning Science: Conceptual Understanding

Science learning from a variety of theoretical and methodological perspectives. Includes theories, models, and empirical results on conceptual understanding, conceptual change approaches to learning in science, methodology for investigating students' processes of concept formation and concept use, and strategies to promote conceptual development.

Sub-themes:

1) Conceptual Change and Cognitive Development in Science Learning
2) Methodologies for Investigating Science Learning
3) Strategies and Interventions for Enhancing Science Learning
4) Models and Theories of Science Learning Processes

Introduction

Strand 1: Learning Science – Conceptual Understanding focuses on the processes through which learners build meaningful understanding in science. Key aspects and topics in Strand 1 include research on conceptual change; theories and models of science learning; methodological approaches to investigating the learning process, including diagnostic questionnaires on student conceptions; and strategies, activities, learning progressions which can improve conceptual understanding.

Research on student difficulties and misconceptions has a foundational role in science education, as the attempts at interpreting the widespreadness, robustness and resistance to change of these alternate conceptions originated research on conceptual change, and guided research on productive educational strategies. Within Strand 1, several contributions addressed this issue. Nyléhn and colleagues highlighted that natural selection is a central concept in evolutionary biology, essential for understanding biodiversity. They investigated how understanding of natural selection develops across increasing levels of biology education, from upper secondary school to university. Their findings showed that understanding improves with educational level; however, persistent misconceptions remain common, even among master level biology students. One such misconception is the belief that evolution is goal-directed or intentional, reflecting teleological reasoning. Ferguson, Tytler, and Kamat reported on a design-based research intervention with multimodal characteristics in the teaching and learning of physical optics in Australian upper primary schools. Their study explored how contemporary pragmatist semiotic perspectives can deepen understanding of key conceptual challenges associated with learning about light and vision. The authors observe how students progress across the sequence from ingenuous conceptions of vision (i.e. "rays from the eye", "sea of light", that is light as a facilitator of vision) to a scientific perspective, and argue that students' common-sense understandings of light can serve as a productive starting point for developing more generalized and epistemically powerful scientific conceptions. Ugwuanyi and Ezema, based on Cognitive Dissonance theory, study the effectiveness of cognitive conflict strategies in eliciting conceptual change about the particulate nature of matter in Nigerian secondary school students. They find cognitive conflict strategies to be significantly more effective than the 5Es educational model in the studied samples, confirming and reinforcing other recent research results.

Traditionally, in formal science education topics are taught separately in the form of units, often disconnected one from the other. However, many researchers argue that teaching two or more related topics at the same time may provide students with a better understanding of both, and in addition reinforce students' productive beliefs about the coherence and interconnectedness of science. Berger, Danzglock and Hänze in their study compared the educational outcomes of teaching the motion of charged particles in electric and magnetic fields as two separate blocks,

or as an interleaved joint sequence. They also compared using both these strategies as mainly individual, or mainly collaborative, work. They found that interleaving strategies are particularly effective in collaborative settings, especially when dealing with complex content. Tampakis and Asimopoulos implemented with prospective primary teachers a teaching–learning sequence on the Earth–Moon system which uses the problem of ocean tides as the focal center for promoting understanding of gravity related concepts. Their results showed that participants progressed from fragmented associations involving the Moon and Sun to a more coherent, gravity-based understanding, reducing competing ideas and consolidating related concepts

The development of scientific understanding can be supported through the use of multiple representations, which help students make sense of complex concepts and potentially overcome persistent misconceptions. In this context, Guilares de Aguiar and Miranda Correia examined the effects of students' prior knowledge and the use of digital resources (i.e., clickable concepts within a concept map) on learning outcomes and cognitive load in the topic of electrical conductivity in metals. Their results showed that the inclusion of clickable digital resources enhanced both factual and conceptual knowledge for learners with low and high prior knowledge, without increasing cognitive load, suggesting a no-overload effect.

Among the possible representations of science, mathematical models hold of course a privileged place, and it is worth investigating how students understand them, and what epistemic value they assign to them. Dohn investigated how biology students understand and apply a fundamental mathematical model in respiratory physiology (the Fick equation), as well as their attitudes toward the use of mathematical expressions in the discipline. The results indicated that many students struggled to articulate their understanding of the Fick principle in precise scientific language, and only a few were able to correctly apply its components in their explanations. Additionally, two contrasting attitudes emerged: some students viewed equations as helpful tools for understanding and remembering concepts, while others perceived them primarily as instruments for numerical calculation in exam preparation. Similarly, Pedersen and colleagues explored students' interactions with models by applying the notion of instrumental genesis. In an empirical study with upper secondary biology students using agar blocks as models of cells to investigate diffusion, the authors demonstrated that this perspective provides a valuable framework for understanding how students appropriate models as epistemic artefacts, thereby supporting the development of modelling practices in science learning.

Finally, Lau Damasceno and colleagues examined conceptual and methodological distortions in pseudoscientific theories. Their empirical study with undergraduate students in a Biological Sciences program revealed that students' analyses of pseudoscience tended to focus predominantly on either conceptual or methodological issues, indicating a partial understanding of the nature of scientific reasoning.

Conceptual Understanding Of Natural Selection Among Biology Students In Upper Secondary School And University Level In Norway

Jorun Nyléhn[1], Ragnhild Gya[1,2], Marte Røssland Henriksen[1] and Maria Kjeilen Steinseide[1]

[1]Department of Biological Sciences, University of Bergen, Norway
[2]Bjerknes Center for Climate Research, University of Bergen, Norway

Natural selection is a core concept of evolutionary biology and modern biological science, and understanding the central parts of the science of life is of uttermost importance for the conservation of nature and biodiversity. We have investigated how the understanding of natural selection develops along with increasing educational level in biology, from upper secondary school to university level. We present our results of a survey of the understanding of natural selection where the Conceptual Inventory of Natural Selection (CINS) was answered in full by a total of 201 participants in three populations of biology students (62 students from upper secondary school, 90 first-year university students and 49 master students). Although the overall understanding of natural selection increased with educational level in biology, the misconceptions decreased to highly different degrees. We discuss 1) misconceptions that were relatively rare in all populations, 2) misconceptions that changed profoundly along with educational levels in biology, and 3) the most common misconceptions which were frequent even at master's level in biology. One example will be discussed in detail in each category. Some misconceptions were rather frequent even at master's level in biology, especially that organisms or mutations are intentional or have goals for the evolutionary changes, and that evolution occurs in single organisms and not at population level. Our conclusion is that these misconceptions should be targeted with interventions and further research.

Keywords: Misconceptions, diagnostic tools, learning progression

Introduction

To understand biology is highly important, especially as natural habitats are destroyed, and the number of species declining (Aleknavičiūtė et al., 2023; Edison et al., 2017). Within biology, evolution and natural selection is a central topic that explains other fields, ranging from ecosystems and biodiversity to human health. To understand evolution means to make sense of biology (Dobzhansky, 1973), how life forms have been developed through many millions of years (Darwin, 1859). Within evolutionary biology, natural selection is a central topic that is particularly hard to understand for many students, even at university level (Athanasiou & Mavrikaki, 2014; Gregory, 2009).

Most of the studies of students' understanding for natural selection are conducted in the USA , and there is a lack of studies from Europe (Kuschmierz et al., 2020). Many misconceptions are known in relation to natural selection (Anderson et al., 2002; Athanasiou & Mavrikaki, 2014; Gregory, 2009). The origins might differ, and some of the misconceptions are also found among teachers and in textbooks (Padian, 2013; Tshuma & Sanders, 2015).

Thus, an investigation of how the understanding of natural selection develops along with educational level in Norway is needed, along with the identification of misconceptions that could

hamper this understanding. We have investigated how the understanding of natural selection changes with education in biology (from upper secondary school to master's level at university), both 1) the overall trend in understanding of natural selection, and 2) identified misconceptions about natural selection at the different levels of education.

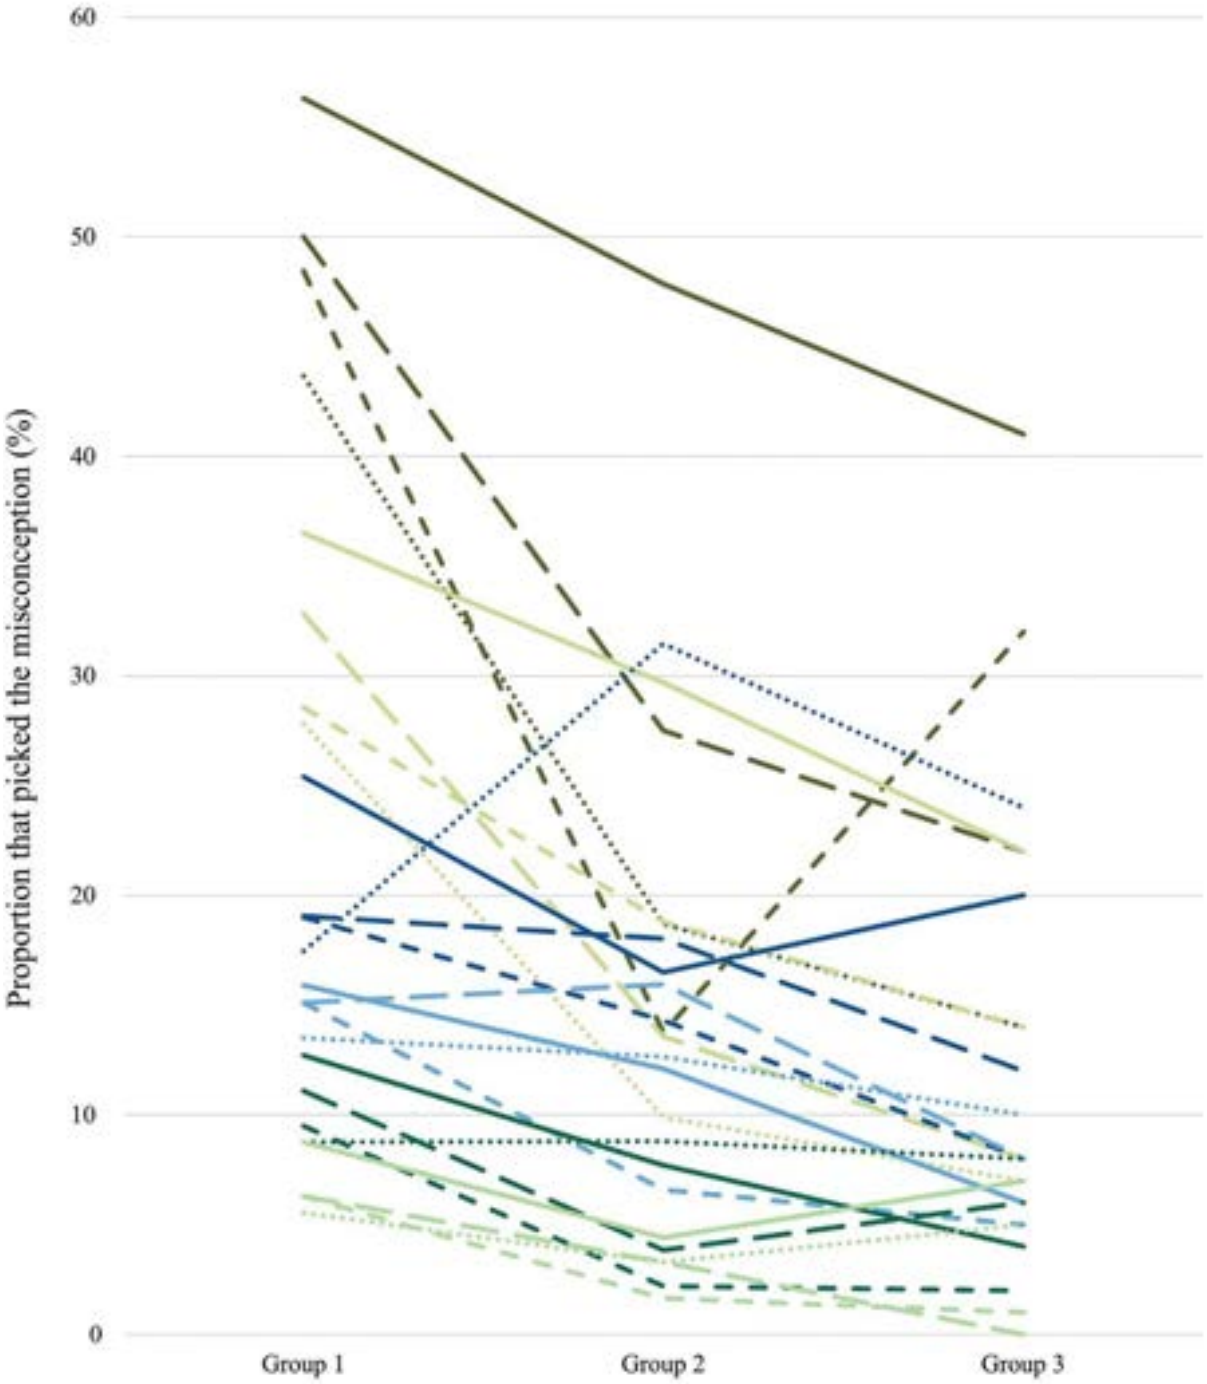
Methods

We have assessed the understanding of natural selection in three populations of biology students (upper secondary school, first-year university students, master level) with the Conceptual Inventory of Natural Selection (CINS) (Anderson et al., 2002). Altogether 201 participants answered all questions (62 students from four upper secondary schools, 90 first-year university students, and 49 master students in biology).

The inventory contains 20 multiple choice items assessing ten interconnected key concepts in natural selection, each key concept is measured with two items. Summarized from Anderson et al. (2002), the ten key concepts tested in CINS are 1) *variation within a population*, which is necessary for natural selection. The genetic part of this is 2) *variation is inheritable*. This variation ultimately comes from mutations in the germ cells, which is 3) *origins of variation*. Population growth in the absence of limitations is called 4) *biotic potential*. In the real world, populations are usually relatively stable around the carrying capacity, called 5) *population stability*. This is commonly a result of 6) *limited natural resources*, causing 7) *limitations in survival*. When limitations in survival are combined with individual variation, the result is 8) *differential survival*. Given time, this will be seen as 9) *changes within a population*; and ultimately, given isolation and evolutionary time, the 10) *origin of species*.

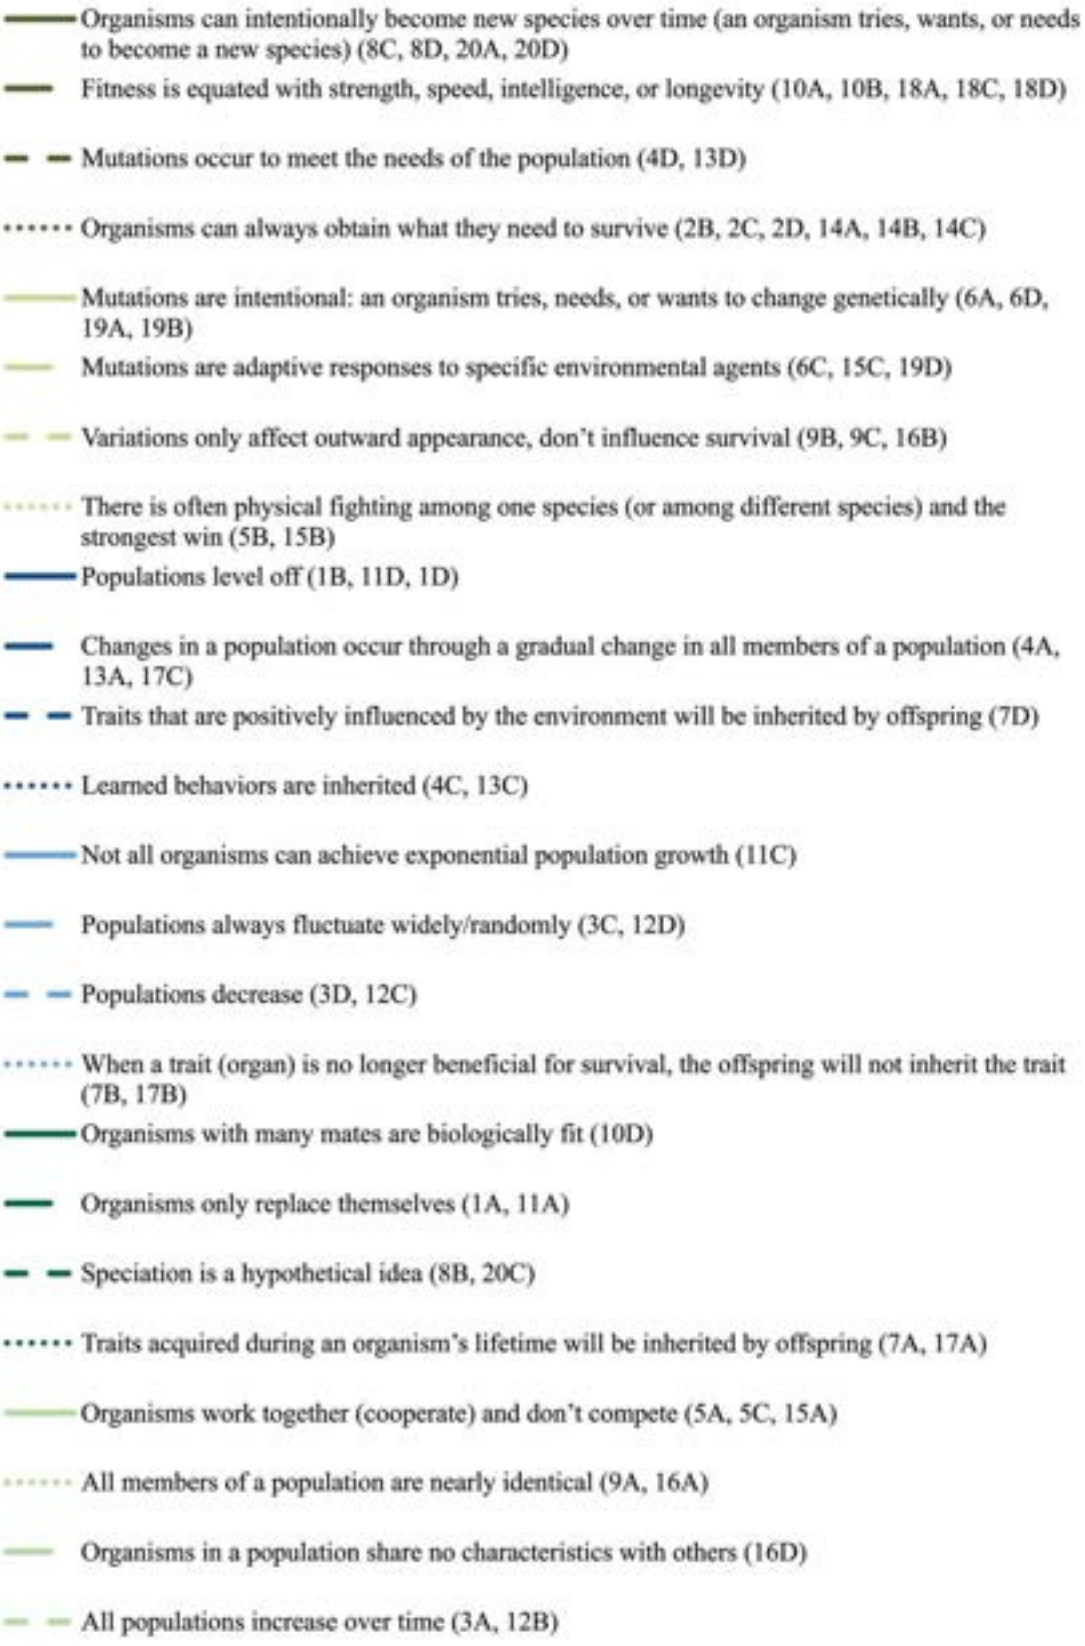
The distractors in CINS target widespread documented misconceptions, for instance 1) *evolution has a goal or fulfills a need*, 2) *the use or lack of use of organs has a direct effect on evolution*, and 3) *fitness equal physical strength*. Altogether 24 misconceptions documented in literature are tested in CINS (Anderson et al., 2002).

Analyses of textbooks in Norwegian schools, both in science and biology, were also undertaken. The contents in all parts relevant for evolutionary biology were analysed. In Norway biology is first taught as a separate topic in upper secondary school, prior education in biology is integrated with chemistry, physics and geology and taught as integrated natural science.



Results And Discussion

Overall, a trend of increasing understanding of natural selection along with educational level in biology was found. There was a rather abrupt and significant change from upper secondary school to first-year students at the university. The maximum score on CINS is 20. The students in upper secondary school had a median of 9 correct answers, while the first-year students scored 13 and the master students scored 14. A small subgroup of master students that have taken an advanced course in evolutionary biology scored, on average,17 correct answers.



We performed a systematic search for studies that have applied CINS. Comparing all result from studies on CINS, including the results from our study, we found a general trend of lower scores reported in upper secondary school (Lucero & Petrosino, 2017) than among first-year students (Pinxten et al., 2020) with some further increase to master level (Athanasiou & Mavrikaki, 2014). Thus, the overall trend is an increased understanding for natural selection along with education in biology.

Figure 1. Changes in misconceptions from upper secondary school (group 1) to first-year university students in biology (group 2) to master's level in biology (group 3). The misconceptions are sorted according to how frequently they appear in upper secondary school (group 1), if similar, they are sorted according to their frequency in the university populations. A) line diagrams (on next page), B) legends (page following line diagrams).

A) Line diagrams of changes in misconceptions

B) Legends. This is a list of the 24 misconceptions tested with CINS. The uppermost are the most common in the present study, the lowermost are the rare misconceptions. The numbers refer to the items, the letters to the distractors, after Anderson et al. (2002).

Furthermore, altogether 23 of the 24 misconceptions tested in CINS decreased along with educational level in our study (Figure 1). However, the misconceptions decreased to highly different degrees, and some of them were frequently found even at master's level in biology. We will first discuss 1) misconceptions that were relatively rare in all populations, then 2) misconceptions that changed profoundly along with educational levels in biology, before we turn to 3) the most common misconceptions which were frequent even at master's level in biology. One example will be discussed in detail in each category.

Relatively Rare Misconceptions

Half of the misconceptions were relatively rare in all the populations we investigated. One example is the misconception that the use and lack of use of organs resulted directly in evolution (Lamarckism). The relatively rare misconceptions might have been found at a higher frequency if we had applied other diagnostic tools than CINS. In a comparison of three methods of investigation (CINS, the open response instrument ORI, and oral interviews), Nehm and Schonfeld (2008) found that the identification of misconceptions depended on the method of investigation. For instance, they reported that Lamarckism was the most common misconception identified with ORI and oral interviews but ranked as the 12th most common based on CINS. Thus, although low scores were obtained for these misconceptions on CINS, they could have been more prevalent using other measurements.

We have compared our results with the other studies we found that report scores for the misconceptions targeted with CINS – Australian 10th graders, (McLure et al., 2020), undergraduate biology majors in USA (Nehm & Schonfeld, 2008) and undergraduate students in Belgium and The Netherlands (Pinxten et al., 2020). Overall, the most frequent misconceptions in our study were also the most prevalent in these studies. This supports that the instrument is crucial in the identification of misconceptions.

In our analysis of school textbooks, we found that some of the rare misconceptions were explicitly targeted. For instance, Lamarckism was frequently explained as a misconception. Such explicit targeting could also have reduced these misconceptions (Gregory, 2009). Such explicit targeting was not found for the misconceptions that were frequent even at master's level in biology.

Misconceptions That Changed Profoundly With Biology Education

Some of the investigated misconceptions changed profoundly from upper secondary school to university level in biology. One example is that fitness equals physical strength, which was found among half the respondents in secondary school in our study, but only 22% of the master students. This misconception is also reported as common in other studies that have applied CINS (McLure et al., 2020; Nehm & Schonfeld, 2008; Pinxten et al., 2020). The term 'fitness' means physical strength outside biology (Gregory, 2009). Such multiple meaning of concepts is known to be problematic and has been discussed in science didactics for decades (Reydon, 2021). Thus, many teachers are probably aware of this and might possibly counteract this misconception through teaching.

Overall, the misconceptions that are changing along with educational level could indicate that education works. On the other hand, there might be some underlying differences between our populations. Especially, only a minority of the students in upper secondary school continue with biology at university level, which might have influenced the measured changes.

The Most Frequently Found Misconceptions

Some misconceptions were frequently found even at master's level in biology. One example is teleological reasoning, that evolution is goal-driven or intentional, for instance that mutations do not happen by chance but are induced to solve a need for the organism. Such misconceptions are frequently found in other studies as well (McLure et al., 2020; Nehm & Schonfeld, 2008; Pinxten et al., 2020). However, teleological reasoning has many forms and some of them might be scientifically correct (González Galli et al., 2020).

Thus, we have also undertaken a more fine-grained analysis of the teleological distractors, based on the classification by González Galli et al. (2020). In our study, the distractor including "need to adapt" was frequently chosen, while few students chose that "the lizards wanted to become different in size, so beneficial new traits gradually appeared in the population". None of the students at master's level chose the latter distractor. Thus, the "worst cases" of teleological reasoning were rare and decreasing with education in biology.

Conclusions And Further Studies

Although there is a trend of increased understanding for natural selection along with educational level in biology, there are also highly frequent misconceptions in all investigated populations, even at master's level in biology at university. Thus, we conclude that more explicit targeting of misconceptions on multiple levels of biology studies, as well as more research, are needed.

Specifically, we have planned a follow-up study with explicit targeting of misconceptions. We have also modified two items in the CINS questionnaire for our further use (item 4 and 13, where the distractors "successful behaviors learned by finches/guppies are passed on to offspring" are changed to "successful behaviors learned by finches/guppies are passed on genetically to offspring"). The change is made to specify for the students that genetical changes, and not learning, are meant. Furthermore, we will add other measurements of misconceptions than CINS, for instance interviews of students where they can explain their reasoning verbally.

Material And Embodied Diagramming In Teaching And Learning About Light And Vision

Joseph Paul Ferguson, Russell Tytler and Amrita Kamath
Deakin University, Australia

In this paper, we report on a design-based research intervention in teaching and learning physical optics in upper primary school in Australia, exploring ways in which contemporary pragmatist semiotic perspectives can advance understandings of the significant conceptual issues identified with learning about light and vision. We collaborated with a teacher to design and refine a Year 6 optics learning sequence. We traced the orchestration of material, embodied, and textual/pictorial representational work involved in students 'diagramming' to investigate and explain reflection phenomena and identified challenges students faced in coordinating their common-sense reasoning with the abstract explanatory systems of science. We use Peirce's sign function categories – iconic, indexical, and symbolic – to interpret the nature of this transduction work that leads from immediate personal diagramming experiences to 3D and 2D abstracted diagramming that constitutes the semiotic ecology underpinning canonical scientific optical concepts and practices. We argue that the science classroom ought to welcome students' common-sense understandings of light as the starting point for developing an appreciation for the potentially more epistemically powerful, generalised scientific understandings of light, with students maintaining this common-sense reasoning embedded in practical purposes.

Keywords: material-embodied, optics, reasoning

Introduction

The relationship between light and vision, the study of optics, is an important topic in general science and in physics curricula. This relates to the visual nature of our interaction with the world, and the relevance of optics to explain natural world phenomena and optics-based technologies. Research in the student conceptions area, since the 1980s, has established difficulties for students in recognising light as a tangible entity that travels (Galili, 1996; Guesne, 1985). Several alternative student conceptions of light have long been recognised, including ideas of: 1) light as illuminating objects with the process of vision seen as unproblematic, 2) light as an effect on surfaces or associated with light sources, and 3) vision interpreted through the construct of active looking (Chu et al., 2009; Shapiro, 1989). Selley (1996a; 1996b) developed an influential phenomenological progression in conceptions leading from a 'sea of light' perspective to an 'active sight' egocentric conception to a 'reception' conception of light as travelling and received by the eye. However, such research has focused on the pathways of change from 'naïve' to scientific conceptions but generally has not articulated the mechanisms by which such shifts occur, beyond recommending explicit attention to setting up the conditions for students to recognise the advantage of scientific ideas (Caravita & Halldén, 1994). Nevertheless, the program of establishing canonical science ideas for interpreting phenomena building from these alternative conceptions remains an important aspect of science teaching and learning (Vosniadou, 2020). In particular, these student conceptions present a challenge for teachers in attuning to students' ideas that may make successful learning more difficult and devising approaches that address this need for a shift in perspective (Paçacı et al., 2024).

More recently, attention has shifted away from a purely cognitivist perspective on student conceptual change (Tytler & Prain, 2013; Lemke, 2004) to consideration of the intimate connection between multimodal languages and learning (Kersting et al., 2024; Nielsen & Yao, 2022), including consideration of students starting their learning of light and vision by carefully observing optical phenomena (Fligauf et al., 2022; Sebald et al., 2022). This phenomenological approach values not just the cognitive but also the embodied and material nature of optical experiences. Part of this phenomenological shift has been a pragmatist semiotic perspective that highlights the multimodal nature of students' conceptions of optics. The challenges presented by conventions associated with the ray diagrams of geometric optics (Xu & Prain et al., 2021) are made apparent by this approach, and it becomes possible to explore students' coordination of visual, material, and embodied modes (Prain & Tytler, 2024; Xu & Ferguson et al., 2021) as students undertake diagramming practices with teacher support using iconic, indexical, and symbolic sign functions (Ferguson et al., 2024).

With this recognition of the fundamental role of multimodality in scientific discovery processes and in learning science - including the centrality of bodily and material aspects to such meaning making (Hetherington, 2024; Wilmes et al., 2024) - an alternative framing of conceptual change phenomena has emerged. This approach challenges the purely conceptual versions of knowing, and frames learning as a process of induction into the discursive practices of science (Nielsen & Yeo; 2022; Lemke, 2004). The implication is that conceptual change should not be viewed simply as a shift in mental models or frameworks, but the development of facility with the discursive tools of science which necessarily involves mind and body in integrated ways (Kersting et al., 2021; Kersting et al., 2024). These are the multimodal representations through which concepts are understood and operationalised in science (Tytler et al., 2013). Concepts in science, from this perspective, are semiotic hybrids. To develop new conceptions is a pragmatic matter of learning to use the associated multimodal representations.

In Victoria, Australia, light is included in the Year 5 and year 6 curriculum, Year 9 curriculum, and the Senior Physics curriculum. In this paper, we expand the pragmatist semiotic approach to explore the ways that this may enable new interpretations to emerge of students' engagement with optical phenomena, and the ways in which teachers can support upper primary students (Year 6) to learn key concepts of light and vision through particular optical practices in a guided inquiry setting.

The research questions are:

1. What multimodal sign constructions and transductions are drawn on in developing students' canonical scientific understandings of optics?
2. What roles do common-sense reasoning and diagramming play in developing students' canonical scientific understandings of optics?

Methods

We used a design-based research (DBR) methodology (Brown, 1992; Plomp, 2013) to work with a specialist science teacher (Maja - pseudonym) to create, implement, and refine successive lessons for a learning sequence on light for Grade 6 students (aged 11). Three classes (approximately 30 students each) from this Australian government primary school participated in a range of optical activities as part of this sequence, including tasks to do with the nature of light

and vision, light travel, and reflection from mirrors, which are the focus of this paper. The sequence utilised a guided inquiry, representation construction pedagogy (Tytler et al., 2023).

We collected video/audio of student and teacher interactions and various representational forms in the science classroom. We also collected student artefacts in the form of paper-based and whiteboard-based diagrams of optical phenomena generated in class, and their responses to a pre-test, post-test, and delayed post-test (3-months later).

We employed a micro-ethnographic (Erickson, 2006) approach to the analysis of video/audio records and student artefacts to investigate the semiotic nature of students' diagramming as they engaged with the optical tasks and activated modelling materials with their bodies. We selected examples (Ferguson et al., 2019) of student diagramming that would offer new insights into the nature of this meaning making of optics as supported by Maja's strategic implementation of particular pedagogical moves. We also coded students' responses to the tests in terms of well-known and established optical perspectives: reception of light, sea of light, line of sight, as well as combinations of these, with remaining responses classified as ambiguous. We similarly analysed students' paper-based and whiteboard-based diagrams of optical phenomena in class.

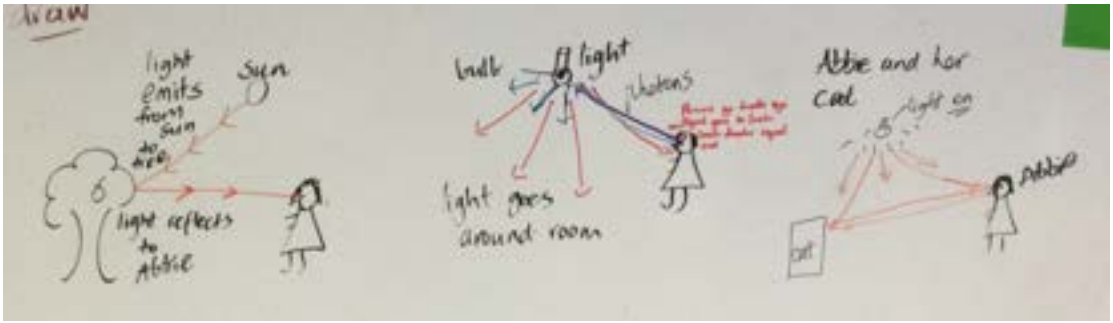
We used Peirce's (1955[1987]) semiotics to analyse the students' artefacts and test responses in terms of their iconic, indexical, and symbolic nature. Peirce proposes that three distinct sign functions underpin all meaning making; 1) *icon* - signify objects by resembling them structurally; 2) *index* - signify their object through a direct epistemic relationship; and 3) *symbol* - signify their objects by some convention that is arbitrary (i.e., socially/culturally endorsed). Such a semiotic approach makes evident that reasoning in the science classroom is not just multimodal – involving all three sign functions that play out in embodied and materials ways (Kersting et al., 2021) – but also transductive – involving switching between and aligning these different sign functions (Prain & Tytler, 2024).

Peirce (CP 1.54)[1] argues that diagrams as a particular arrangement of sign functions are defined by their iconicity. It is through creating and critiquing diagrams that we can become aware of the structural relationships between different parts of objects or different objects within a system. As we propose in Ferguson et al. (2024), teaching and learning in science must prioritise the iconicity of "diagramming" (p. 13) while still appreciating that in reasoning, icons also invariably have indexical and/or symbolic functions.

We also activate Peirce's (1998 [1905]) pragmatism to frame our analyses in recognising that while the method of science is the form of reasoning most able to afford truthful insights into the reality of the world, this is never at the cost of the primacy of common-sense in our daily being in the world through/as habits. Peirce advocates for the importance of "critical common-sensism" (CP 5.439). We need to balance fallibilism and anti-scepticism if we are to really understand and make a difference in the world, in particular in the context of education that ought to be about fostering students to align such perspectives. The implications for the science classroom are that students' alternative conceptions should not simply be dismissed and identified for replacement by canonical science (Strand, 2005). We seek to make use of Peirce's semiotic pragmatism to outline a framing of the teaching and learning of optics that already always starts with valuing

[1] CP x.y = *Collected Papers of Charles Sanders Peirce (1932, 1935)* volume *x*. paragraph *y*.

students' current understandings as the basis, via diagramming, for developing canonical understandings of science.



Findings

Across the activities the teacher, Maja, utilised a representation construction approach that encouraged students to represent and share their views about light and vision. Maja moved students towards a consensus around the scientific view - that we see because of reflected light entering our eyes - through presented accounts of vision, supported by small group and whole class review of student generated ideas.

In the first (diagrammatic) activity, designed to probe student ideas about the relationship between light and vision, there were examples in these Grade 6 responses for all four conceptions of light and vision described by Shapiro (1969), with the sea of light conception predominating. However, following the pre-test, Maja showed a video depicting animal eyes adapted to night vision, explaining this in terms of pupil size and photons streaming into the eye and impinging on the retina. Following this, Maja asked students whether the video had changed their understanding of vision. She drew the Sun, tree and Abbie on the board (representing the first question on the pre-test) and asked for a student volunteer to illustrate what was happening. Subsequently she had students construct responses on the board (Figure 1), which she interrogated with the aim of opening up representational alternatives and moving the class towards a consensus around the scientific reception view (through questioning students' assertions, clarifying ambiguities, and occasionally revoicing).

Maja was playing out the pedagogy we had established in previous projects (Tytler et al., 2023); establishing the ray diagram as a productive sign and modelling its use in constructing explanations. This involved a multimodal orchestration with abstracted visual diagramming, verbal language, and gestures. Maja worked with students to establish a need to explain using arrows - indicating direction of light - and the structural relations between the representation using rays and the geometry of the situation. She did not, however, impose the canonical convention as a strict rule. In this discussion, students sometimes referred to 'photons' so that it seemed that the modelling of light as a stream of photons supported students to take a reception view of vision, possibly because this is a material and therefore less abstract representation than that of rays. The breakdown of student conceptions in response to the 'Abbie and the tree' scenario in the pre-test and post-test (at the end of the sequence) is shown in Table 1.

Figure 1: Board work reflecting Maja's negotiation with students for a consensus view of the relation between light and vision.

Change In Conceptions Of Vision Over The Sequence

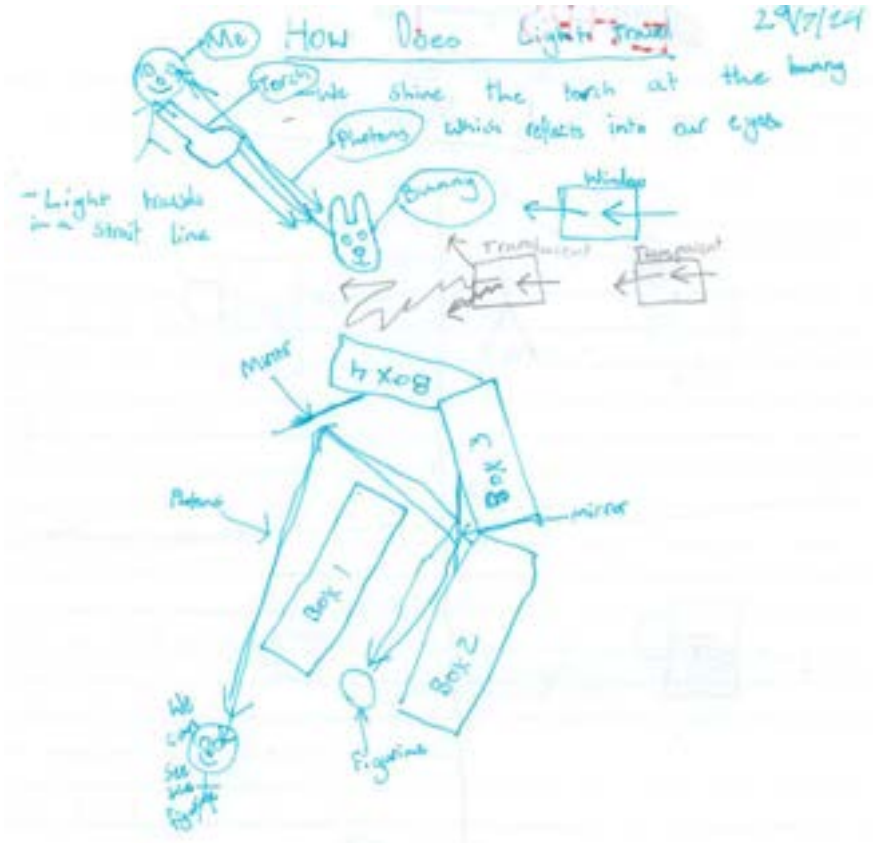
In the pre-test response to representing the way a girl, Abbie, can see a tree with the Sun in the sky, there was a high incidence of a 'sea of light' perspective by which the tree was illuminated by the Sun and so vision was unproblematic. In a 'line of sight' perspective students privileged the act of 'looking' with arrows from Abbie's eyes to the tree. The third perspective amalgamated this with a reception perspective of light from the tree entering Abbie's eyes, and the fourth, scientific perspective, we called 'reception'. These categories, well recognised in the literature, served to allow a tracking of conceptual changes over the sequence. Table 1 shows a growth in students' views of Abbie and the tree from the pre-test to the post-test.

Table 1: Change in student conceptions of how Abbie sees a tree (percentages).

	Sea of light	Line of Sight	Double perspective	Unclear	Reception
Pre-test (N=32)	44	31	6	3	16
Post-test (N=36)	0	22	11	11	56

The Material And Embodied Dimensions Of Understanding Light And Vision

There is a clear movement of student conceptions across the sequence, particularly away from a sea of light view towards the scientific reception view of vision. The line-of-sight perspective was represented by an arrow from the eye to the object, which we interpret to reflect a focus on the active nature of looking. This was a persistent 'alternative conception' for a quarter of students that we will discuss further, below. The 'combination' perspective arose when students drew arrows, or indicated in text, both light entering the eyes and an arrow from the eyes to the object. We now describe and analyse students' responses to the mirror maze and periscope activity.



An understanding of the passage of light involving mirrors and images was developed through two activities, in particular: 1) the design of a 'mirror maze' involving students tracing pathways of light from a torch around the maze and subsequently using the mirror positioning to view a small figurine through the maze; and 2) the design and explanation of a periscope. Video of students working on the mirror maze demonstrated the complex material, embodied and visual representation coordination involved in a scientific account of vision using mirrors. In moving around groups constructing their maze and asking, 'what is happening?', students traced the passage of light through the maze with their fingers, combining this with moving their heads in position to emphasise the act of looking back along the light path. This was translated into diagrammatic form that was effectively a birds-eye view of the light path that allowed clear representation of mirror angles and positions needed. The teacher orchestrated groups to enact these multiple embodied perspectives as part of shared interpretation of their experience. Figure 2 and Figure 3 show students indicating with a finger the passage of light, and their subsequent drawing which reflects a scientific reception view.

Figure 2: Student indicating with their finger the passage of light through a mirror maze.

This use of the finger to trace the light path, we refer to as 'diagramming'. Note that the particular path selected is quite strategic; it is one of many paths of light that reflect from the figurine – the student (Ben) understands the figurine to be a source of reflected light and is actively constructing an embodied/visual representation in 3D space to impose an order on what is experienced and interpreted. The diagram he constructs in his book (Figure 3) is a further extension, in more abstracted form, of this embodied diagramming display.

Figure 3: Ben's visual representation of the light pathway through the maze that allows the figurine to be seen.

Note, in Figure 3, the very particular perspective needed – a top-down view- to make apparent the relationship of the mirrors and eye to the light path, and the reference to photons indicative of a reception model of light.

Ben has achieved a coherent account of the pathway of light that explains mirror images, involving: transduction across his 3D embodied diagramming; his visual experience with the torch and mirror images; his verbal descriptions of light paths, images and photons; and then a symbolic, canonical ray diagram. We consider this as the student mastering the semiotic ecology through which students were working with the task, designed by Maja and the research team as particular arrangements through which understandings of the nature of light would be made possible. The arrangement was intended to 'make things visible' in new ways.

For the next activity, students were given broad instructions about the construction of a periscope using cardboard milk cartons, two mirrors and tape, and challenged to design and construct a periscope with which they could see over a wall. Most students successfully constructed a periscope and drew a diagram to indicate how the mirrors allow its use for seeing. We noticed, however, in engaging with students' ideas and practical interpretations of their mirror maze and periscope designs, a flexible movement between arrows representing directions of 'looking' and arrows representing light paths. In talking with students, we found that they would often draw a line-of-sight diagram and present an ambiguous verbal and embodied explanation of the periscope. On questioning ('is that the light direction?') students would often quickly switch their explanation and diagram to a reception perspective, seemingly demonstrating a capacity to flexibly move between the common-sense line-of-sight view and a canonical science view. Two informative examples of researcher-student interactions are given below.

For instance, a discussion took place with Mark who had drawn his arrows coming from the eye into the bottom of the periscope.

> *Researcher: So ... show us how it works?*
>
> Mark picks up the periscope and points his fingers into the bottom, at the mirror.
>
> *Mark: See the light ... comes through.*

In the subsequent discussion, Mark was ambiguous in specifying where to look, where the light entered, and what you are looking at through the periscope. To clarify this, the researcher pushes the point and asks Mark to imagine the periscope is in a submarine as used to look at a ship. Mark sets up his case to represent water with the periscope poking above the water line.

> *Researcher: So where would the light be going?*
>
> *Mark (again pointing through the bottom): Well if I was seeing the light (then points through the top) and I was seeing the thing here ... it goes down (tracing with his hand into the periscope at the top, down the tube and then out the bottom) and into your eyes.*

Other students, similar to Mark, started their representation of how the periscope works using a line-of-sight frame, but on questioning quickly demonstrated that they understood the pathway of light was the opposite, reflecting light from and object into their eyes. In Mark's case, it seemed that the ambiguity of the term 'looking' (where you look from, what you look at) confused his communication. However, his focus on looking in both these senses could be identified as possibly aligned with his line-of-sight diagram, which shows clearly where he looks from, in the periscope, and what he is looking at.

Table 2 shows the post-test results for students' representations of a mirror maze, and periscope. The persistence of the line-of-sight perspective is clear despite a noticeable increase in scientifically accurate views.

Table 2: Student conceptions in explaining the mirror maze and periscope working (in percentage terms).

	Scientifically accurate (reception)	Line of sight	Combination of reception and line of sight	Ambiguous/confused/ missing arrowheads
Mirror maze (N=36)	14	25	22	39
Periscope (N=36)	25	31	11	33

Discussion And Conclusion

This study has confirmed the findings of earlier research in the conceptual change and phenomenological traditions that identifies tensions between everyday (i.e., common-sense) and scientific (i.e. canonical) accounts of light and vision, and the context dependence of these views. However, building on recent research that demonstrates the epistemic power of students' activating their bodies to entangle with the material environment to realise productive science learning (Hetherington, 2024; Wilmes et al., 2024), we offer some fresh insights into student meaning making processes in optics. We draw on Peirce's pragmatist semiotic perspective to consider the complex orchestration of various representations involved, grounded in a semiotic ecology that consists of practical investigative activities, material-embodied interactions, and textual/pictorial abstractions. These processes combine to afford diagramming as a practice of sign making that moves students from common-sense towards canonical explanatory forms, but without ever entirely leaving behind those common-sense insights.

The common-sense line-of-sight account is shown in our analysis to be supportive of students' successful mirror maze and periscope construction using reasoning that accords an active role to 'looking' around barriers and through the instrument, supported by visual alignment of the mirrors to 'see' each other. We found, however, that in prompting students to explain their periscope constructions, that even when their 2D diagramming (textualisions/pictorialisations) and verbal explanations were caste in this common-sense reasoning (grounded in material and embodied 3D reasoning), when asked about 'light' (as opposed to 'vision') they quickly and naturally shifted their perspective to that of a scientific account. The maintenance by almost 30% of students of this common-sense account in the post test we thus consider as not necessarily implying lack of access to the canonical view, but of students not sufficiently valuing this view or recognising that this was the view sought by the test writers. This implies a need to explore ways in which teachers might best support students to recognise both the common-sense and scientific perspectives but embrace the latter as valuable for a wider set of purposes.

We argue that the iconic and indexical functions of students' diagramming play out in different ways, in that these are mediated to different degrees in different semiotic arrangements. Students' embodied and material diagramming was iconically related to their experience of engaging with

the mirror maze and periscope tasks, as they pointed/gestured to indicate the relationship between their eyes, light source, and toy objects (i.e., structural relations) in each case. This diagramming was also immediately indexical in offering a flexible 3D spatial/temporal indicator of the shining of the torch beams. As such, this common-sense diagramming was contextually grounded for students as they tied their reasoning about light and vision to these particular instances of optical events. The students' paper-based and whiteboard-based diagramming, in contrast, is immediately symbolic as evident in the abstracted forms of the 2D arrows (and other 2D elements) of the ray diagrams, symbolically outlining the structural arrangement of optical elements (iconicity) and the explanatory relationships between these elements (indexicality). As such, this more abstracted and precise scientific diagramming potentially made apparent to students the logic of reflection pathways that apply to light and vision in a more generalisable sense. This was achievable through the idealisation of selected light pathways that strip away other possible but non-relevant light paths and lays itself open to inspection and refinement in ways not possible with the embodied and transient 3D diagramming. Students' common-sense diagramming consistent with the line-of-sight view (e.g. pointing at the mirror in which the figurine is seen) needs to be valued for its practical power but also needs to be brought into question in terms of its scientific explanatory power.

In applying our Peircean pragmatist semiotic framing, we suggest that such a canonical perspective makes possible engagement with the periscope and mirror mazes in even more epistemically powerful ways if students can productively relate these to their common-sense understandings of light and vision. In doing so, the less mediated forms of iconicity and indexicality retain a strong presence in meaning making. In this way, we frame vision and light in the science classroom as an opportunity for students to develop the habits of ray diagramming – that is particular ways of activating the body and material environment - through a process of bridging from common-sense diagramming of structural relations to embodied tracing of light paths, which have iconic and indexical relations to the more abstracted 2D canonical forms. In order to understand vision as underpinned by the nature of light, we need to embrace material, embodied, and textual/pictorial reasoning processes. Our science learning sequences should be designed to reflect these multimodal transduction processes, as we embrace Kersting et al.'s (2021; 2024) call for us science educators to radically reimagine teaching and learning science as first and foremost a matter of bodies and materials.

ESERA 2025 Copenhagen

Improving Students' Conceptual Change In Particulate Nature Of Matter Using Cognitive Conflict Model: Does Cognitive Ability Matter?

Christian Sunday Ugwuanyi[1] and Marcus Jideofor Ezema[2]
[1] Faculty of Education, University of the Free State, Bloemfontein, South Africa
[2]University of Nigeria, Nsukka, Nigeria

Over the years, Nigerian students' poor performance in Physics has been a major worry to Science Educators, especially those in Physics Education. Some researchers have implicated a lack of conceptual understanding of Physics concepts as one of the major causes of students' poor performance in the subject. However, research is scarce on the conceptual change levels of students with respect to physics concepts especially particular nature of matter. Anchored on cognitive conflict theory, this study adopted a pre-test-post-test non-equivalent control group design. A sample was 195 senior secondary one students SS1 in four intact classes participated in the study. Conceptual Change Test (α = .71) and Test of Logical Thinking (α = .81) were used for data collection. The conceptual change test was used to account for the possible students' naive conceptions (alternative conceptions) on the topics. After the treatment sessions, data collected before and after were analysed using percentage and analysis of covariance. The results showed that the use of cognitive conflict significantly improved the conceptual change of students than the 5E instructional model. It was also revealed that cognitive ability had a significant influence on students' conceptual change in particulate nature of matter. This implies that understanding students' initial levels of conception is very important to teachers and stakeholders for students' sound conception of concepts.

Keywords: Conceptual change, cognitive ability, cognitive conflict

Introduction

In Nigeria, senior high school scientific curricula mandate that all science students take biology, chemistry, and physics in addition to the general courses (mathematics, English language, civic education, and a trade topic) (Oladejo et al., 2023). Due to their substantial contributions to the quality of life in a variety of fields, including healthcare, communication, agriculture, environmental protection, nutrition, transportation, and energy production, science and technology have emerged as critical components of sustainable development on a global scale (United Nations, 2015). However, it has been sadly observed that Scientific literacy, which is essential for scientific advancements, is still low in Nigeria (Oladejo et al., 2023). Specifically, over the years, Nigerian senior secondary school students have consistently performed extremely poorly in physics (Ario, 2024). Reports on pupils' achievement in the West African Senior School Certificate Examination (WASSCE) in physics suggest poor performance of male and female students (Ogbaga et al., 2024). Furthermore, Zudonu et al. (2024) noted that the students' achievement in physics and chemistry which are the major concern of science educators has remained poor over the years as a result of misconceptions and other related factors. According to Madu and Orji (2015), misconceptions are false beliefs or concepts that come from prior information learnt from school or from experiences in daily life. Ideas whose meaning deviates from what is widely acknowledged by scientific consensus are referred to as misconceptions (Cardoso et al., 2020). It was determined that misconceptions are influenced directly by instructor preparation and training as well as student conduct (Guerra-Reyes et al., 2024). Guerra-Reyes et

al. (2024) further found that the primary contributing factors are the consistent use of the didactic transmission-reception model, the impact of students' everyday experiences, the decontextualization of the material being addressed, the inadequate development of research skills, the use of ineffective teaching strategies, texts that are overly formulaic, and exaggerated schemas. In the same vein, Trisniarti et al. (2020) found that assumptions, reasoning, intuition, and associative thinking are frequently the root causes of misconceptions.

In the natural sciences of which Physics is a part, misconceptions can stem from a number of different places. They might result from wrong interpretations of commonplace events, false information obtained from unofficial media sources, or cultural customs. Even in the face of direct, structured instruction, these beliefs become deeply ingrained in students' minds and pose significant obstacles since they are resistant to change. This phenomenon not only makes it difficult to learn new information, but it can also have a negative impact on students' attitudes toward science education by lowering their motivation and level of interest (Guerra-Reyes et al., 2024). The complexity and difficulty of the subject matter (Nugroho, 2021), the kind of instructional materials used, the degree of student engagement (Madaiton et al., 2022), as well as taking into account personal beliefs and prior knowledge (Dorsah & Okyer, 2020), are some of the factors that can affect the development of critical conceptual understanding. These components may play a role in the development of misconceptions, which are personal beliefs and understandings that defy recognized scientific definitions (Blonder & Mamlok-Naaman, 2019). Reconstructing intuitive ideas is necessary to build a more solid scientific conceptual framework in order to gain a thorough knowledge of difficult and contentious scientific concepts (Arabeyyat et al., 2022).

Based on the above, it becomes imperative that science subject especially Physics should be taught using conceptual change models in order to improve students' conceptual understanding. One of the most important objectives of science education, specifically in physics, is to improve students' conceptual understanding of scientific concepts (Laurenty et al., 2021; Wibowo et al., 2017). Therefore, before beginning the learning process, teachers must have a thorough understanding of the preconceptions or assumptions that pupils hold (Samsudin et al., 2024). It has been observed that the impact of cognitive conflict is typically limited, and even after receiving research-based training, students' naive beliefs or misconceptions often continue in some form (Hull & Hopf, 2022). Thus, this research anchoring on the cognitive dissonance theory sought to find out the effect of conceptual change model on students' conceptual understanding of particulate nature of matter.

Theoretical Framework

Cognitive Dissonance Theory By Festinger (1957)

Cognitive conflict model is a part of psychological theories of conceptual change. Festinger (1957) proposed the Cognitive Dissonance Theory (CDT) and suggests that cognitive inconsistency leads to a motivational state that promotes regulation, which comes mainly through a change of opinions or behaviours. Cognitive Dissonance Theory underpins the perception of incompatibility between two cognitions, which can be defined as any element of knowledge, including attitude, emotion, belief, or behaviour. Festinger (1957) opinions that non-fitting relations among cognitions generate a state of discomfort termed dissonance, which is generally

considered as involving negative arousal, that motivates people to cope with this situation, typically by adjusting one cognition to the other.

Festinger (1957) used the term *dissonance* to refer to three different entities: the theory itself, the triggering situation and the generated state. For better understanding, these terminologies can be seen as: the trigger as *inconsistency*, the evoked arousal as *cognitive dissonance state* (CDS) and the theory itself as *cognitive dissonance theory* (CDT). To substantiate the homeostatic nature of dissonance, Festinger drew a connection to hunger: when people are deprived of food, they feel hungry and find ways to cope with it. However, as if the same construct defined food deprivation and hunger, Festinger used the term dissonance for both the triggering relation and the state of discomfort that occurs. Therefore, cognitive dissonance model holds that contradicting cognitions act as a driving force that pushes the learner to acquire new thoughts or beliefs, or to modify existing beliefs, in order to reduce conflict between cognitions.

It is penitent to note that critics have observed that cognitive dissonance theory is subjective and goes with some questions of doubt. Hence, it cannot be objectively measured. This is because individuals function differently. Since what may trigger dissonance in Mr A may not in Mr B. Therefore, most of the issues raised in this theory are linked to cognitive conflict instructional model. This is because in cognitive conflict instructional model, conflicts arising from anomalous situation are resolved before conceptual change will occur. Cognitive conflict instructional model allows students to develop conflict with their own thinking, and it is through this conflict that the students develop their own meanings or at least seek to resolve the conflict. Implementing a cognitive conflict approach has been reported in studies on different concepts such as temperature and heat (Madu & Orji, 2015), acid-base material (Labobar, Setyosari, Degeng & Dasna, 2017), light materials (Wartono, Batlolona & Putirulan, 2018) and courses in computational physics (Akmam et al 2018). Cognitive conflict helps the assimilation process becomes more effective and meaningful in the intellectual formation of learners. It helps learners reflect on explanations of phenomena they learned.

Cognitive Conflict And Conceptual Change

Wartono et al. (2018) found that cognitive conflict strategies can be used to reduce misconceptions that lead to increased student learning achievement. Labobar, Setyosari, Degeng and Dasna (2017) revealed that students had misunderstanding of the concept before, but decreased after treatment with cognitive conflict strategy. Madu and Orji (2015) found that the cognitive-conflict-based physics instruction improved students' conceptual change in heat and temperature over the traditionally designed physics instruction. Orji (2013) revealed that cognitive conflict instruction significantly enhanced students' conceptual change on heat and temperature. In a related research, it has been demonstrated how well students' conceptual mastery was improved by combining the cognitive conflict technique with discovery model physics learning resources (Gunawan et al., 2021). Similarly, it has been revealed that augmented reality with cognitive conflict models significantly improve students' scientific literacy (Mufit & Dhanil, 2024).

From the reviews, none of the studies reviewed investigated the effect of cognitive conflict on students' conceptual change and self-efficacy in particulate nature of matter concepts. It is on this note that the present study sought to investigate the effect of cognitive conflict on students' conceptual change in particulate nature of matter.

Methods

The study adopted a quasi-experimental design; specifically, pre-test-post-test non-equivalent groups design using a sample size of 195 senior secondary one students in four intact classes, in Bwari Area Council of FCT, Abuja. The sample was arrived at using a purposive sampling technique. Particulate Nature of Matter Conceptual Change Test (PNMCCT), and Test of Logical Thinking (TOLT) were used for data collection. The instruments were properly validated by three experts: Two from Physics Education, one from Measurement and Evaluation, all from the Department of Science Education, University of Nigeria. After trial testing, the reliability of PNMCCT was determined to be .71 using Cronbach's Alpha formula, while the reliability of TOLT has been documented by the developers and its reliability was found to be .81 using Cronbach's Alpha method. The reliability index of the three instruments showed that the instruments are reliable.

Ethical approval from the conduct of the research was issued by the Faculty of Education research committee on ethics of the University of Nigeria. Besides, informed consent forms were given to the participants to fill out and sign before the commencement of the treatment. Prior to the administration of the treatments, the students were given PNMCCT and TOLT as pre-test and baseline assessment. The scores from TOLT were analysed and used to categorize the students into different levels of cognitive ability. Two groups of senior secondary one students were exposed to cognitive conflict and 5Es instructional models respectively. The treatment periods which were facilitated by the use of cognitive conflict and 5Es lesson plans lasted for a period of six months. After the treatment sessions, the PNMCCT was administered to both groups of students as post-test. Thereafter, the pre-test and post-test scores were organized and subjected to data analysis. Percentage and analysis of covariance were used for data analysis while the hypotheses were tested at 5% probability levels.

Results

Research Question One: What are the mean conceptual change scores of students taught particulate nature of matter using cognitive conflict instructional model and those taught using 5E instructional model?

Table 1: Mean analysis of conceptual change scores of students taught particulate nature of matter using cognitive conflict instructional model and those taught 5E instructional model.

		Pre-test		Post-test		
Group	**n**	**Mean**	**SD**	**Mean**	**SD**	**Mean gain**
Cognitive Conflict Model	98	33.00	1.34	79.76	2.54	46.76
5E Instructional Model	97	32.45	1.66	71.67	4.65	39.22

It can be seen from Table 1 that students taught particulate nature of matter using cognitive conflict instructional model had a higher post-test conceptual change mean score (M = 79.76, SD = 2.54) than their counterparts taught using 5E instructional model (M = 71.67, SD = 4.65). indicating the efficacy of cognitive conflict.

Table 2: Analysis of covariance of the effect of cognitive conflict instructional model and 5E instructional model on students' conceptual change.

Source	Type III Sum of Squares	df	Mean Square	F	Sig.	Partial Eta Squared
Corrected Model	321.099[a]	6	53.516	13.960	<.001	.308
Intercept	3630.619	1	3630.619	947.079	<.001	.834
CC Pre Score	4.007	1	4.007	1.045	.308	.006
Instructional Model	100.721	1	100.721	26.274	<.001	.123
Cognitive Ability	140.325	2	70.163	18.303	<.001	.163
Instructional Model * Cognitive Ability	9.010	2	4.505	1.175	.311	.012
Error	720.696	188	3.833			
Total	1161050.000	195				
Corrected Total	1041.795	194				

a. R Squared = .308 (Adjusted R Squared = .286)

Table 2 revealed a significant effect of the cognitive conflict model on students' conceptual change in the particulate nature of matter, $F(1, 188) = 26.274$, $p < .001$.

Table 3: Mean analysis of conceptual change post-test scores of students of different cognitive ability levels.

Cognitive Ability	n	Mean	SD
High	26	76.04	1.32
Average	72	76.00	1.54
Low	97	74.24	2.76

Table 3 shows that students with high cognitive ability had higher mean conceptual change score ($M = 76.04$, $SD = 1.32$), followed by the average cognitive ability students ($M = 76.00$, $SD = 1.54$), and the low cognitive ability students ($M = 74.24$, $SD = 2.76$). Besides, Table 2 revealed that there is a significant influence of cognitive ability on students' conceptual change in particulate nature of matter. Table 2 also revealed that there is no significant interaction effect of instructional model and cognitive ability on students' conceptual change, $F(2, 188) = 1.175$, $p = .311$.

Discussion Of Findings

This research has shown that cognitive conflict model is very effective in improving students' conceptual change in Physics concept like particulate nature of matter. Besides, cognitive ability of the students is a major factor that determine students' conceptual understanding of Physics concept. This result may have been this way because of the instructional relevance of cognitive conflict model. The cognitive conflict model offers an effective framework for teaching that fosters deeper learning and conceptual transformation in a variety of subject areas. The paradigm, which has its roots in constructivist theory, asserts that when students identify inconsistencies between new knowledge and their preexisting mental models, meaningful learning takes place. It thus becomes imperative that Physics teachers should be better positioned to make effective use of cognitive conflict model during the implementation of Physics curriculum.

Buttressing this finding, Wartono et al. (2018) found that cognitive conflict methods can help students learn more effectively by lowering misconceptions. According to Labobar, Setyosari, Degeng, and Dasna (2017), students' conceptual misunderstandings decreased following cognitive conflict strategy treatment. According to Madu and Orji (2015), students' conceptual understanding of heat and temperature was enhanced by cognitive-conflict-based physics training compared to traditionally planned physics instruction. According to Orji (2013), students' conceptual understanding of heat and temperature was much improved via cognitive conflict education. Combining the cognitive conflict strategy with discovery model physics learning resources has been shown to improve students' conceptual mastery in a comparable study (Gunawan et al., 2021). Similarly, it has been revealed that augmented reality with cognitive conflict models significantly improve students' scientific literacy (Mufit & Dhanil, 2024).

More recent studies are in agreement with the finding of this research. For example, It has been found that integrating the cognitive conflict model with the STEM method is advised to enhance students' conceptual knowledge because it may link concepts to practical applications and encourage cognitive reflection through conflict situations (Nabila et al., 2025). Similarly, Research revealed that students' scientific and digital literacy were impacted by the cognitive conflict model-cognitive conflict method combined with mobile learning (Makhrus & Hidayatullah, 2025). According to Makhrus et al. (2025), pupils who were exposed to the cognitive conflict model improved their critical thinking abilities more than those in the control group.

This research has therefore contributed to the field for Physics Education in the Nigerian context through the empirical verification of the effectiveness of cognitive conflict model on students' conceptual change in particulate nature of matter. This is for the fact that no such study has proved that prior to the conduct of this research.

Conclusion And Recommendation

Based on the findings of this research, the researchers concluded that cognitive conflict instructional model is an effective method for enhancing students' conceptual change in particulate nature of matter. Besides, cognitive ability of the students is a major determinant of students' conceptual change when exposed to conceptual change model. It was therefore

recommended that Physics teachers should be better equipped in order to adopt cognitive conflict model in the teaching of Physics concepts.

Acknowledgment

The researchers appreciate all those who participated in this study for their honest and impactful participation.

Understanding Forces In Magnetic And Electric Fields Through Interleaved Practice And Collaboration

Roland Berger[1], Maria Danzgloc[2] and Martin Hänze[2]
[1]University of Osnabrück, Germany
[2]University of Kassel, Germany

A method of learning content frequently used in mathematics and science is to first teach one concept in a block and subsequently a second concept in another block. However, several studies have shown this blocked study of one concept at a time to be less effective than intermixing the two concepts in an interleaved study sequence. Yet, Mielicki and Wiley (2022) found that interleaved practice in mathematics was less effective when studying complex concepts. To address the role of complexity in physics education, we adopted the motion of charged particles in electric and magnetic fields as complex physics concepts. In our study 380 students studied this topic in a 2 (blocked vs. interleaved) × 2 (working in dyads vs. individually) - design while playing a serious computer game. As dependent variables we assessed their academic performance in an immediate post-test, as well as a follow-up test 8 weeks later to probe for lasting learning. The analyses revealed no main effects for both problem sequencing and work form in the post-test as well as the follow-up test. However, for both tests, we found a significant interaction that demonstrates the benefits of practicing interleaved problems collaboratively. In conclusion, we conclude that interleaving gains strength in collaborative settings, particularly in learning complex concepts. This result is supported by the concept of the "collective working memory" (Kirschner et al., 2018), which claims that collaborative learning reduces individual cognitive load and fosters subsequent learning.

Keywords: Interleaving, Collaboration, Game-based learning

Introduction

A method of learning content frequently used in mathematics and science instruction is to first teach one concept in a block and subsequently teach a second concept in another block. However, several studies have found this blocked study of one concept at a time to be less effective than intermixing the two concepts in interleaved practice. For example, Ziegler and Stern (2014) report that sixth graders gained a deeper understanding not when the addition and multiplication of variables were presented blocked, but when they were presented interleaved. The students in the interleaved study condition made more errors during training but performed better than students in the blocked study condition on the follow-up tests. From the perspective of cognitive load theory, acquiring conceptual knowledge through interleaved study imposes a higher cognitive load on students, as they must constantly switch between concepts. This switching requires learners to repeatedly retrieve each concept anew, which demands significantly more cognitive effort. However, this repeated retrieval strengthens knowledge structures and ultimately leads to improved learning outcomes. Thus, interleaving can be seen as a form of "desirable difficulty" (as called by Bjork and Bjork, 2011), making the learning process more challenging but more effective in the long term. This effectiveness has been proven in many studies (see the metaanalytic study provided by Brunmair and Richter, 2019).

In this paper two research gaps are addressed. First, the natural sciences of physics, chemistry, and biology are important domains in education at schools and universities. Despite this prominent role of science education, the number of studies on interleaving is small (Richter et al.,

2022). Second, Brunmair and Richter's (2019) meta-analysis shows evidence, in particular, for the effectiveness of interleaving in inductive learning; however, there have been only a few studies to date that deal with interleaved practice with educationally relevant and complex materials. As areas of further research, the authors highlight the need for investigations on educationally more relevant and complex materials, which are underrepresented in existing studies on interleaving.

To address these research gaps, our study focuses on the movement of charged particles in electric and magnetic fields as important concepts in higher physics education. This topic is characterized by its inherent complexity, because students have to deal with multiple theoretical, highly interwoven constructs at the same time, namely force, velocity, and the direction of fields. Furthermore, the deep structural differences between electric and magnetic fields are significant large. Hence, students often confuse electric and magnetic fields (Maloney et al., 2001) and mistakenly apply principles of one field to the other (Scaife & Heckler, 2010; Guisasola, Almudi & Zubimendi, 2004). In addition, because the Lorentz force that governs the charged particles' motion in magnetic fields affects all three dimensions simultaneously, students find it difficult to visualize the relationship between movement, field and forces (Aubrecht & Raduta, 2005; Kustusch, 2016). While interleaved practice could benefit long term learning success, such complexity risks cognitive overload. Mielicki and Wiley (2022) found that interleaved practice was less effective in complex scenarios. Yet, it remains unclear whether the complexity of physics concepts, such as the motion of charged particles in electric and magnetic fields, hinders the effectiveness of interleaved practice.

According to Mullins, Rummel and Spada (2011) students' collaboration is particularly beneficial if the learning material requires elaborative learning activities. From the perspective of cognitive load theory, complex and demanding concepts like the three-finger rule are characterized by high conceptual element interactivity that might hinder learning due to cognitive overload. Kirschner, Sweller, Kirschner & Zambrano (2018) hypothesize that the use of collaborative learning can reduce element interactivity and thus cognitive load. According to the cognitive interdependence principle, appropriate collaborative learning introduces a "collective working memory". That is, various interacting elements can be distributed among the working memories of the different group members, thus reducing cognitive load on a single working memory. In other words, collaboration becomes a scaffold for individuals' knowledge acquisition processes. Furthermore, during collaborative learning, some information comes from other students rather than other sources and that information is likely to become available exactly when it is needed, resulting in a decreased load and increased learning. To evaluate Kirschner et al.'s hypothesis in the present study we examine the role of collaboration and its interplay with interleaving.

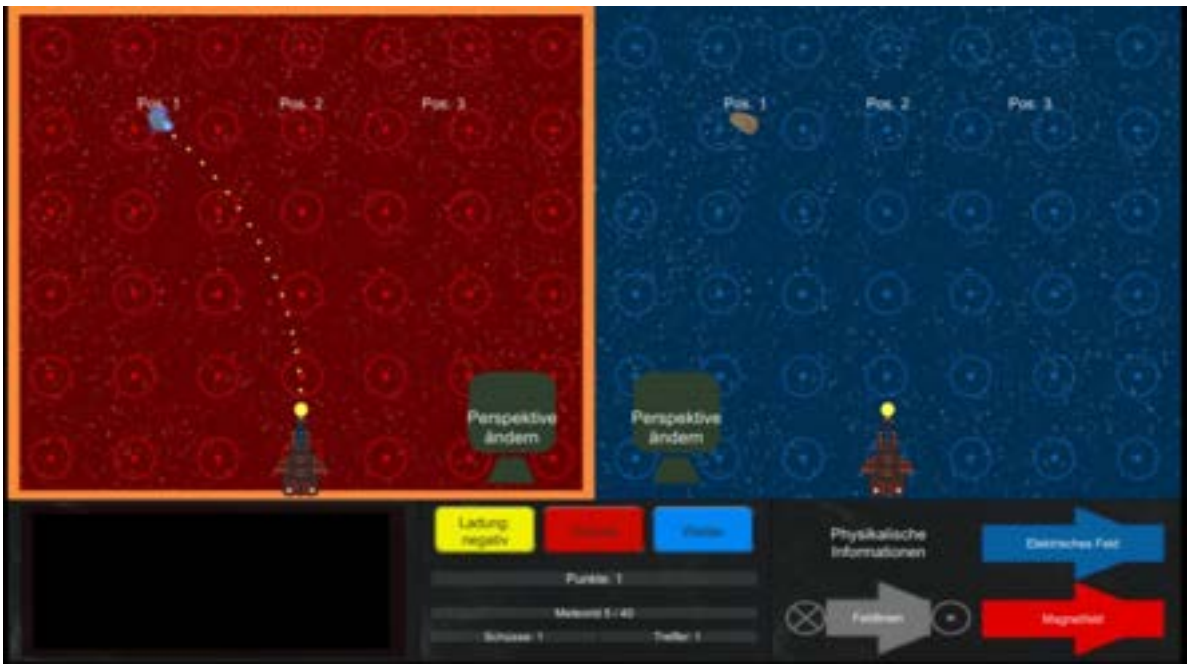
Hypotheses

Based on the theoretical background we assume main effects of sequencing and collaboration:

H1: Students working collaboratively on exercises will achieve a higher learning success a) immediately after the learning phase, as well as b) delayed after 8 weeks than students who learned individually.

H2: Students working on exercises in an interleaved sequence will achieve a higher learning success a) immediately after the learning phase, as well as b) delayed after 8 weeks than students who learned in a blocked sequence.

Furthermore, we assume an interaction effect:



H3: The difference between students who learned collaboratively compared to students who learned individually is greater in the interleaved than in the blocked sequence a) immediately after the learning phase, as well as b) delayed after 8 weeks.

Method

Learning Environment

We have developed a computer-based learning game called “Eraser” (cf. Berger, Kulgemeyer & Lensing, 2019). The objective of the game is to use charged projectiles to shoot down meteorites passing a spacecraft in electric or magnetic fields. “Eraser” is well-suited for simultaneous comparison, because it presents the movement of a charge carrier in a magnetic field on one half of the computer screen and the movement in an electric field shown on the other half of the screen (Figure 1).

Figure 1. Screenshot of the learning game “Eraser”. The active situation is framed in orange. In the interleaved condition, the magnetic field (left) can be compared with the corresponding electric field (right) to detect differences between both concepts.

Participants And Experimental Design

Thirty-one 12th-grade physics classes in the Osnabrück and Kassel regions in Germany with a total of 430 students participated in the study in 2023 and 2024. Prior to the study, students were taught both concepts, the electric and the magnetic field, by their regular teachers. The physics classes were randomly assigned to working in dyads or individually (independent variable “Work form”: collaborative or individually, respectively). In addition, in classes assigned to the collaborative work form the students were randomly paired in dyads. The students in each class were randomly assigned to one of the two conditions (independent variable “Sequence”: blocked or interleaved, respectively). In the data analyses, we considered 380 students with complete data on all variables.

Procedure

The lesson lasted 90 minutes. Students first completed a pre-test (15 minutes). Then, students were introduced to the learning game. During the practice with the learning game in the blocked condition, students saw 18 situations with magnetic fields followed by 18 situations with electric fields. In the interleaved condition, both fields were juxtaposed. In this condition, magnetic fields were on the left and electric fields on the right of the screen. The gameplay lasted 45 minutes. Afterward, students completed a questionnaire on cognitive load and intrinsic motivation, followed by a post-test (20 minutes). About 8 weeks later, they completed another questionnaire on subject interest and a follow-up test to assess learning durability.

Dependent Variables And Scale Analysis

Academic performance

The pre-test encompasses 9 multiple-choice items (magnetic field 4 items, electric field 5 items; cf. Berger et al., 2019). Example items are attached in the appendix. The post-test encompassed the items from the pre-test, and additionally 4 transfer items, covering superimposed electric and magnetic fields. The follow-up test was identical to the post-test. The Cronbach's alpha coefficients were $\alpha = .82$ for the pre-test, $\alpha = .87$ for the post-test, and $\alpha = .89$ for the follow-up test.

Self-report scales

To explore the underlying mechanisms, we assessed intrinsic motivation, cognitive load, and subject interest (as a control variable):

- Intrinsic Motivation: Measured with 3 items (Berger & Hänze, 2009), Cronbach's $\alpha = .77$.
- Cognitive Load: Measured with 2 items (Leppink et al., 2013), Cronbach's $\alpha = .82$.
- Subject Interest: Measured with 4 items based on Horstendahl (1999), covering relevance, positive feelings, and the intrinsic character of interest (Krapp, 2002), Cronbach's $\alpha = .86$.

All self-report scales used 8-point ratings, anchored at "not applicable at all" (1) and "completely applicable" (8). The scales are provided in the appendix.

Results

In order to account for students' interdependence within dyads and within physics classes we ran nested analyses of variance with SPSS Statistics version 27. An example for the SPSS syntax can be found in the appendix. Only students without missing data were taken into account.

Academic Performance

With the pre-test as covariate we got the adjusted means (with standard deviations in brackets) in percent of maximum score for the post-test and the follow-up test as depicted in Table 1.

Table 1. Academic performance (standard deviations) in percent of maximum score for the post-test and the follow-up test with the pre-test as covariate.

Sequence	*Work form*	*n*	*Post-test*	*Follow-up test*
Blocked	Individual	96	51.6 (22.8)	41.6 (26.6)
Blocked	Collaborative	96	53.4 (25.0)	42.4 (27.5)
Interleaved	Individual	93	48.6 (26.0)	35.6 (23.0)
Interleaved	Collaborative	95	59.5 (25.7)	45.6 (29.3)

With regard to the post-test we did not find an effect for sequence (F (1, 213) < 1, p = .49), a marginal effect for work form (F(1, 37) = 3.14, p = .085) and a significant interaction effect (F(1, 211) = 4.21, p = .041), which suggests an advantage for learning collaboratively, especially when students work in the interleaved sequence. With respect to the follow-up test 8 weeks later we found a similar result: There was no effect for sequence (F (1, 352) < 1, p = .50), no effect for work form (F(1, 46) = 1.76, p = .19), but again a significant interaction effect (F(1, 353) = 4.75, p = .030).

Learning Experiences

The means (and standard deviations in brackets) for intrinsic motivation (adjusted with subject interest as covariate) and cognitive load are depicted in Table 2.

Table 2. Learning experiences (standard deviations). Intrinsic motivation is adjusted with subject interest as covariate.

Sequence	*Work form*	*n*	*Intrinsic motivation*	*Cognitive load*
Blocked	Individual	96	5.60 (1.69)	3.70 (1.59)
Blocked	Collaborative	96	5.86 (1.53)	3.82 (1.75)
Interleaved	Individual	93	5.32 (1.70)	3.90 (1.40)
Interleaved	Collaborative	95	5.83 (1.28)	3.08 (1.46)

For intrinsic motivation we found no effect for sequence (F(1, 219) < 1, p = .35), a significant, but small effect for work form (F(1, 33) = 4.17, p = .049, d = .24), and no interaction effect (F(1, 220) < 1, p = .45). For cognitive load we found no significant effect for sequence (F(1, 222) = 2.67, p = .10), no effect for work form (F(1, 37) = 1.78, p = .19), but a significant interaction effect (F(1, 223) = 8.21, p = .005). In particular, during interleaved practice the cognitive load when working in dyads is smaller by Cohen's d = 0.57 compared to individual work.

Discussion

Using the learning game “Eraser” to study the motion of charged particles in electric and magnetic fields, we conducted a study to assess the role of both sequencing (blocked or interleaved) these concepts, and work form (collaborative in dyads or individual) for learning success.

With respect to the variable work form the findings does not provide significant support for hypothesis H1. While there are marginal advantages for collaborative learning in dyads compared to individual work in the post-test, no effect is observed in the follow-up test. Working in dyads is associated with increased intrinsic motivation. Therefore, the learning environment appears to be more suitable for collaborative task engagement, which fosters intrinsic motivation, even though this does not correlate with clear performance benefits in the tests.

With respect to the variable sequencing, we did not find any effect at all, neither for the post-test nor the follow-up test 8 weeks later. Thus, hypotheses H2 is not supported. Several studies attest that interleaving has a stronger positive effect on category learning in comparison to blocking. However, in the present study learners must not only categorize a problem but also adapt the solution procedure to the given type of problem, e.g. to use the three-finger rule for a magnetic field that is perpendicular to the direction of motion. Hence, the problem is demanding due to its inherent complexity. Our results and this interpretation is in accordance with the work of Mielicki and Wiley (2022), who also did not find a benefit of interleaving in the mathematical context of combinatorics, where students must not only be able to accurately categorize problems but also to map these problems to corresponding solution procedures, which must be remembered as well as correctly executed.

However, as expected from hypotheses H3, we found interactions between work form and sequencing in the post-test, as well as in the follow-up test. More precisely, working on interleaved problems collaboratively is most beneficial for learning. The concept of collective working memory (Kirschner et al., 2018) postulates that collaboration can contribute to the fact that a student receives help from their partner exactly when they encounter difficulties in solving a task. For instance, the partners can spur on each other to demonstrate and visualize the complex three-finger rule, which may then result in better anchoring its correct usage in memory. This may have supported recall in the post-test and particularly in the follow-up test. The intensive and active use of the visual representation of the three-finger rule with their hands might also help reduce cognitive load. This interpretation is consistent with our finding of a significantly reduced cognitive load with medium effect size in dyads compared to individual work. To strengthen these interpretations, we are currently analysing the audio recordings of the work done in dyads.

In the present study, we used as learning objectives challenging rules regarding the direction of force on moving charge carriers in electric and magnetic fields. An unanswered question is whether more pronounced differences between interleaving and blocking would arise when practicing even more abstract and comprehensive concepts, such as the distinction between force equilibrium on one object and interaction between two objects as described by Newton's laws. In the case of these topics, the assignment of different examples to the two concepts is significantly less clear than in the case of electric and magnetic fields. It is challenging to categorize the problems concerning force equilibrium and interaction law. If, in such cases, both the categorization and the choice of an appropriate problem-solving strategy are challenging, the

interleaving may then show its particular strength in emphasizing the differences between different concepts to a greater extent (Rohrer, Dedrick, Hartwig & Cheung, 2019).

a) The figure shows a positive charge q approaching a homogeneous electric field between the plates of a capacitor at a constant speed $\vec{v}$.

How does the positive charge move after entering the electric field?

❑	It is deflected upwards.
❑	It is deflected downwards.
❑	It is deflected into the paper plane.
❑	It is deflected out of the paper plane.
❑	It continues to move without deflection.

b) The figure shows a positive charge q approaching a homogeneous magnetic field between the poles of a magnet at a constant speed $\vec{v}$.

How does the positive charge move after entering the magnetic field?

❑	It is deflected upwards.
❑	It is deflected downwards.
❑	It is deflected into the paper plane.
❑	It is deflected out of the paper plane.
❑	It continues to move without deflection.

ESERA 2025 Copenhagen

Exploring Tidal Phenomena: A Focus On Gravitational Dynamics Between Earth And Moon

Panagiotis Tampakis, Stefanos Asimopoulos
University of Thessaly, Greece

Teaching ocean tides has received limited research attention, despite providing a rich context for introducing key concepts in Astronomy and Physics through modelling, Nature of Science discussions, thought experiments, and multiple representations. The key explanatory mechanism is the gravitational Earth–Moon interaction. Although gravity has been extensively studied in Science Education, its specific role in explaining this mechanism remains underexplored, largely due to associated cognitive challenges. This study reports findings from implementing a gravity-focused teaching–learning sequence on the Earth–Moon system with 16 prospective primary teachers from the University of Thessaly (Greece), aiming to support their development of a well-structured explanation of ocean tides. The results show that participants progressed from fragmented Moon/Sun associations to a gravity-based understanding, reducing competing ideas and consolidating related concepts. These findings suggest tides can function as an effective anchor for modelling and multiple representations.

Keywords: Learning environments, science education, pre-service teacher education

Introduction

Teaching core astronomy concepts is pedagogically important because these ideas connect with students' everyday experiences and can support engagement in scientific inquiry and explanation. However, they are often cognitively demanding, and students frequently rely on intuitive, experience-based explanations that may be internally coherent yet diverge from scientific accounts, particularly when coordination of reference frames and understanding of gravitational interaction in the Earth–Moon system are required (Plummer et al., 2016). Over recent decades, science education research has therefore examined students' ideas and learning progressions, alongside the design of instruction and assessment tools that support conceptual change in astronomy. Across this work, studies repeatedly converge on a relatively stable set of topics, including the shape of the Earth and gravity, the day–night cycle, the causes of the seasons, the phases of the Moon, and foundational ideas about the Solar System and stars (Lelliott & Rollnick, 2010).

Against this backdrop, the present study focuses on tides as a productive context for foregrounding Earth–Moon gravitational interaction and the system's dynamical relations as a central explanatory mechanism. Tides are defined as the periodic rise and fall of sea level, shaped primarily by the gravitational attraction of the Moon (and the Sun) in combination with the dynamics of the Earth–Moon system and the Earth's rotation about its axis. Although the periodic pattern is salient, a mechanistic explanation requires linking ideas from astronomy, Newtonian mechanics, and elements of fluid mechanics.

Despite their relevance and visibility, tides are often not understood in depth. While students commonly associate tides with the Moon, substantial cognitive demands arise when accounting for gravity as an action-at-a-distance and for the Earth–Moon system as a two-body system rotating about a common centre of mass (barycentre). In this respect, the international literature

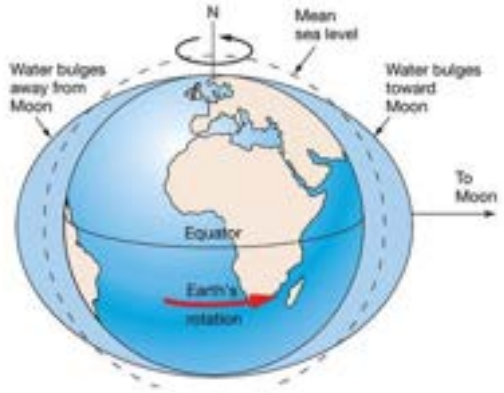
contains relatively few studies that explicitly exploit the two-body relationship in teaching about tides, with instruction often remaining at a simplified level that constrains opportunities for deeper understanding (Ucar et al., 2011).

More broadly, research has documented persistent alternative conceptions about gravity, including difficulties with action at a distance, treating gravity as an intrinsic property linked to motion, and limited recognition of interactional reciprocity as formalised in Newton's third law. Additional patterns include an "absolute" sense of "down", associations between gravity and the atmosphere, and beliefs that gravity is confined to the Earth rather than operating in space and on other celestial bodies (Baxter, 1989; Ruggiero et al., 1985). These conceptions constitute functional mental models and typically require targeted instructional support to be reorganised. Tides, as a phenomenon arising from lunar gravitational attraction acting on the Earth, offer a context for challenging the view that gravity is bounded by the atmosphere or has a purely local character.

Related difficulties have also been reported regarding the concepts of gravity, weight, and mass. Students may not treat weight as the gravitational force acting on a body, instead separating weight from gravity; weight is sometimes linked to air or atmospheric pressure, treated as a property of objects, and confused with mass, while mass may be conflated with volume (Holding, 1987; Mullet & Gervais, 1990; Ruggiero et al., 1985). Because explaining tides requires distinguishing between the amount of matter (mass) and the gravitational force in a given field (weight/force), the phenomenon can support the consolidation of these distinctions through empirical examples and modelling.

Difficulties are also evident in students' representations of the Earth–Moon system. Many adopt geocentric or hybrid models, attribute incorrect orbital paths to the Moon, or assume that the Moon is visible only at night (Dunlop, 2013; Gulbin & Hakan, 2016). The barycentre concept is particularly challenging: the Moon does not orbit the Earth alone; rather, both bodies orbit their common centre of mass. Without this idea, accounts of tides remain fragmented. The existence of two tidal bulges—at the sublunar point and its antipode—requires attention both to spatial variation (the gradient) of the gravitational field across the Earth and to accelerations associated with rotation about the barycentre.

The present study forms part of a wider research programme that explores the didactic potential of tides for teaching key concepts in astronomy and Newtonian mechanics. It aims to elicit pre-service primary teachers' ideas about the nature of gravity and its relation to weight and mass, as well as core characteristics of a two-body system, with the goal of supporting a more scientifically compatible explanation of the simultaneous formation of two antipodal tidal bulges. The paper presents a teaching–learning sequence structured around the Static Tide Model, incorporating experimentation, thought experiments, and simulations, and reports outcomes in terms of movement from fragmented links towards a more coherent, mechanistic account.



In sum, tides provide a context for connecting concepts that are often taught separately (gravity, motion, reciprocity of forces, two-body systems, barycentre) and for engaging learners through modelling to explain complex phenomena. Given the limited research base on tides within science education (Ucar et al., 2011), this study contributes empirical evidence on how a targeted sequence built around the Static Tide Model can challenge alternative conceptions and strengthen conceptual understanding, positioning tides as a productive phenomenon at the interface of everyday experience and theoretical explanation.

Methodology

The study adopted a qualitative, interpretive design and drew on the teaching experiment methodology (Komorek & Duit, 2014) to trace the development of pre-service teachers' mental models of concepts and phenomena related to gravity and the Earth–Moon system—conceptual resources that are central to explaining tides. The sample comprised eight pairs of third- or fourth-year students from the Department of Primary Education at the University of Thessaly, recruited through convenience sampling. Participants engaged in hands-on tasks, simulations, and structured thought-experiment scenarios intended to support movement from initial, simplified accounts towards more scientifically compatible explanations, with particular emphasis on conceptualising the Earth and the Moon as a two-body system rotating about their common centre of mass (barycentre). Data were collected via written questionnaires, video recordings of the sessions, and observation sheets completed by external observers. The dataset was analysed qualitatively, guided by the trustworthiness criteria of Guba and Lincoln (Lincoln, 2001).

The teaching sequence was designed to support understanding of gravity, the mass–weight distinction, and the dynamical relationship between the Earth and the Moon. It began with elicitation questions (e.g., "What keeps the Earth and the Moon together?") to surface participants' initial ideas and orient discussion towards gravity as an interaction acting at a distance. Participants were then asked to define "force" in terms of observable changes in an object's motion or shape. Next, weight was introduced and explicitly differentiated from mass through practical activities using scales and spring balances. Participants measured mass in kilograms and weight in Newtons and considered that weight can vary across different planets—and, more subtly, across different latitudes on Earth.

Figure 1. Static Tide Model.

Subsequent activities focused on falling-object situations on Earth and on the Moon, together with variants of thought experiments in which the Earth, the Moon, or the Sun is momentarily "stopped". These tasks were intended to foreground that gravity operates throughout space and is implicated not only in the perceived up–down direction but also in motion, including orbital motion. Short video clips of parabolic flights (including ESA material and footage from a small private aircraft) were used to connect the experience of weightlessness to the type of trajectory followed. Participants then explored computer simulations in which gravity could be "switched off", enabling them to observe the resulting changes in the trajectories of satellites and other bodies. To introduce the centre of mass (barycentre) in an embodied way, participants used everyday objects (e.g., a hand axe/hatchet) to identify balance points and relate them to rotation about the centre of mass. Slow-motion video of a thrown hatchet provided a concrete analogue

of rotation about the centre of mass, supporting discussion of barycentric motion in the Earth–Moon system. Additional computer simulations were used to examine further features of this motion, including the relatively stable location of the centre of mass with respect to the Earth. Finally, participants were asked to refine a Static Tide Model (Figure 1) by incorporating the Moon's orbital motion around the Earth, aiming to produce a more coherent and physically grounded account of the phenomenon.

Results

An analysis of participants' ideas about the causes of tides indicates that, although most participants (N=14) recognised the role of the Sun and the Moon, their responses did not articulate a coherent explanatory model—even at a qualitative level—in which gravity is treated as the underlying mechanism (Table 1).

Table 1. Responses regarding the cause of tides.

Responses	Frequencies (N=16)
Associated with the Sun & the Moon	14
• **Magnetic field**	3
• **Gravity**	3
• **Movements**	3
• **Temperature - Sun or Moon**	2
• **Change in density**	1
• **Change in pressure**	1
• **Supernatural force of the Moon**	1
I do not know	2

In addition, although only a small number of participants (N=3) initially referred to gravity as the factor through which the Sun and the Moon generate tides, responses shifted when a more specific question focused exclusively on the Earth–Moon relationship. In this case, the proportion increased, with 13 participants identifying gravity as the primary factor governing the interaction (Table 2). Six of these participants first referred more generally to attractive forces, but later became more specific and explicitly mentioned gravity; two also included magnetic forces as contributing to the Earth–Moon interaction. One participant attributed the interaction solely to magnetic forces, whereas two did not appear to have formed a stable mental model of this relationship. Taken together, differences between responses to the two questions point to the fragmentary and heterogeneous nature of the models in use, even within the same overarching context (i.e., the Earth–Moon–Sun interaction underlying tides).

Table 2. Responses on how the Earth and the Moon interact.

Responses	Frequencies (N=16)
The Earth and the Moon interact through:	
• **Gravity**	11
• **Gravitational and magnetic forces**	2
• **Magnetic forces**	1
• **No response**	2

Regarding the concept of gravity itself (Table 3), all participants correctly recognised gravity as a force, and many described it as attractive (N=11) and acting at a distance (N=7). However, participants struggled to specify between which bodies gravity acts. At the outset, no participant provided an explicit answer to this question. During subsequent discussion with the researcher, the idea began to emerge that gravity operates between all material bodies. The development of a model aligned with the dominant scientific account, however, appeared to be constrained by another alternative idea: for five participants, gases were the only bodies that do not interact gravitationally, possibly reflecting an assumption that "material bodies" include only solids and liquids. In addition, a substantial proportion of participants (N=10) believed that bodies of different mass (e.g., the Earth and the Moon) exert forces of different magnitude on each other. This likely reflects limited appreciation that the gravitational interaction depends on both masses and constitutes a characteristic application of Newton's third law. Overall, although gravity may appear straightforward in its classical description, adequate understanding requires attention to learners' alternative ideas in underpinning concepts, which helps to explain persistent difficulties in teaching and learning it.

Table 3. Reported characteristics of gravity.

Responses		Frequencies (N=16)
Gravity is a force		16
• **attractive**	11	
• **never repulsive**	7	
Acts at a distance		7
Bodies of different mass exert forces of different magnitude		10
Does not act between gaseous bodies		5

Furthermore, analysis of the interview data highlights a localised view of gravity in participants' thinking (Table 4). Gravity was often considered to be active only when one is on a celestial body (primarily the Earth, and within the limits of its atmosphere), while appearing absent in the space

in between. While all participants acknowledged gravity on Earth, this was not the case for the Moon for nearly one third of them. Initially, five participants stated categorically that there is no gravity on the Moon, citing videos of astronauts "floating" or drawing on the idea that gravity exists only where there is an atmosphere.

Table 4. Initial responses on where gravity exists.

Responses		Frequencies (N=16)
Gravity is present everywhere on Earth		16
On the Moon		
Gravity exists		8
No gravity, because:		5
• **Astronauts floating**	3	
• **Lack of atmosphere**	1	
No response		3
In space		
Gravity exists		5
No gravity, because:		11
• **No readings on a scale or spring balance**	7	
• **Astronauts floating**	4	
• **Lack of atmosphere**	1	

Following the teaching episode, however, 12 participants referred to lunar gravity, and six explicitly noted that it is weaker than Earth's. When the discussion turned to the space between the Earth and the Moon, the majority (N=10) initially spoke of an absence of gravity, referring mainly to the lack of readings on a scale or spring balance (N=7), astronauts floating (N=5), and the lack of an atmosphere (N=1). As the episode progressed, participants' views shifted markedly: 14 then stated clearly that gravity exists there as well, and eight suggested that it would be reduced due to increased distance from the Earth or the Moon. These findings underline the influential role of images and videos of astronauts moving on the Moon or in spacecraft orbiting the Earth, which can create an impression of negligible gravitational influence and may contribute to the alternative view that the gravitational field extends only to the limits of Earth's atmosphere.

Additional difficulties were observed in relation to participants' understanding of the direction of the gravitational field. In the thought experiment in which a tunnel passes through the Earth's centre and a ball is released to fall through it, around one quarter of participants produced different predictions depending on whether the tunnel connected the two poles or two diametrically opposite points on the equator. Thus, a ball dropped from the North Pole was expected to exit from the "bottom" of the Earth, whereas if it were dropped from the opposite side of the same tunnel, it would reach the centre and return. In the case of an equatorial tunnel, the ball was

expected to move towards the centre, but with lower speed compared to being released from the North Pole in the other tunnel.

Even greater confusion emerged when participants were asked to describe the ball's motion after it reaches the centre (Table 5). For the majority (N=12), the ball stops there, either because the absence of a "centre" was interpreted as the absence of gravitational force (and therefore of motion and speed), or because all forces were believed to be concentrated there and thus to "hold" the ball stationary. Two alternative ideas are therefore evident: first, that motion without force is impossible (N=4); and second, that the role of the centre of mass of a spherical body as a centre of symmetry within Newtonian mechanics is not recognised. Instead, it is treated as the location where all forces are present (N=3), while its "absence" (because the tunnel passes through it) is taken to imply the absence of gravity (N=8).

Table 5. Initial responses regarding the motion of a ball falling through a tunnel passing through the Earth's centre

Responses		Frequencies (N=16)
The ball comes to rest at the centre because of:		12
• **Absence of forces there**	8	
• **Maximisation of forces**	3	
Depends on latitude		3
Oscillates about the centre		1

Particular difficulties also arose when participants were asked to determine the up–down direction on Earth and in space, since in all responses—at least initially—the criterion used was unclear. For example, when asked to draw where a ball held by people at different locations on Earth would fall, 10 of the 16 did not appear to recognise the role of the Earth's centre: six had difficulty specifying the plane perpendicular to which the ball would fall; two stated that gravity is directed towards the centre but did not represent this in their drawings; and for two others the up–down direction was defined independently of the planet itself, using criteria such as the up–down direction of the page. These findings—possibly reflecting an association between the gravity vector and geographic coordinates or reliance on experiential rules (e.g., "down" defined by the head–feet direction)—indicate the absence of an external, non-egocentric frame of reference, as well as a limited internalised vector model of gravitational force directed towards the planet's centre of mass.

To examine how participants relate gravity to planetary motions, two thought experiments were discussed. In the first, the Earth was assumed to be alone in the universe, moving in some way, and then—hypothetically—stopped for a short period. The question was what would happen next (Table 6). Of the 16 participants, only seven answered that the Earth would remain at rest; five suggested it would continue the same motions as before (with two claiming these motions would be slower), and four argued that it would fall "down". In the second thought experiment, the Moon was assumed to move together with the Earth; both bodies were stopped, and then only the

Earth was released. Based on initial responses, six predicted motions of the Earth towards the Moon; four expected the Earth to continue exactly the same motions as before; three suggested it would remain at rest; and three struggled to provide a prediction. These patterns suggest that many participants did not conceptualise gravitational force as an interaction acting at a distance between material bodies, nor did they understand its role in generating or sustaining the motions of celestial bodies.

Table 6. Initial responses on what the Earth would do as the only celestial body if it were momentarily stopped

Responses		Frequencies (N=16)
Continues its previous motion		5
• **In exactly the same way**	3	
• **More slowly**	2	
Falls 'down'		4
Stops all motion		7

Finally, none of the participants initially recognised that the Moon does not simply orbit the Earth; rather, the Earth–Moon pair, as a system, rotates about their common centre of mass (barycentre), which lies within the Earth. Consistent with the above, participants did not appear to appreciate the role of the Earth–Moon mass ratio in shaping the type of motion the system exhibits. This may reflect one-sided geocentric representations in school science textbooks and limited opportunities for empirical exploration of the reciprocity of gravitational interactions. Moreover, addressing such a complex topic presupposes access to relevant physical concepts or phenomena (such as tides), which remain largely absent from the Greek school curriculum.

Conclusions

The findings indicate that participants recognised the main celestial bodies implicated in tides (the Sun and the Moon), yet they typically lacked a coherent explanatory model in which gravity functions as the organising mechanism. This matters because gravitational interaction is the mechanism that integrates the elements of the phenomenon into a mechanistic account; without it, explanations remain partial. The fragmentary nature of responses—even across closely related questions—suggests the absence of an integrated account of Earth–Moon interaction and, by extension, tides. Instead, participants appeared to draw on loosely connected fragments of personal explanations that were not sufficiently functional for scientific reasoning.

A second key result concerns the sensitivity of responses to problem framing. When asked about the broader Earth–Moon–Sun context, few participants explicitly foregrounded gravity. However, when the focus narrowed to the Earth–Moon relationship, most identified gravity as the primary factor. This pattern suggests that multiple mental models may be available and that their activation depends on contextual cues and task formulation. Alternative ideas also persisted, including attributing the Earth–Moon interaction to magnetism, which can obstruct understanding of why the bodies interact and how tides arise from that interaction.

With respect to gravity itself, most participants described it as an attractive force acting at a distance. Nevertheless, many struggled to specify between which bodies it acts and to generalise the interaction to all material bodies, including gases. A further persistent difficulty concerned Newton's third law and the reciprocal character of interaction. Limited understanding of action–reaction and of the dependence of gravitational force on both masses appeared to underpin the erroneous idea that "the larger body exerts a greater force on the smaller". Such interpretations constrain the construction of a consistent explanatory model and help explain why apparently "simple" classical descriptions of gravity remain difficult to learn.

A particularly salient pattern was the attribution of a "local" character to gravity: it was often treated as operative only on celestial bodies (especially on Earth and within the perceived limits of its atmosphere), while being assumed absent in space. Visual representations—especially images and videos of astronauts floating—seemed to reinforce the idea of "zero gravity" beyond the atmosphere. This underlines the need for explicit teaching to distinguish weightlessness/floatation from the absence of gravity and to explain how orbital motion can produce such experiences despite gravity's presence.

Closely connected to this was difficulty in conceptualising the direction of the gravitational field and the meaning of "up–down". For several participants, direction criteria were egocentric (linked to body orientation or the page's orientation), rather than anchored in an external frame of reference centred on Earth's centre of mass. The absence of an internalised vector model likely contributed to inconsistencies when the reference point changed across the Earth's surface, aligning with difficulties in drawing or reasoning about gravitational direction at different geographic locations.

The thought experiments (a tunnel through the Earth; abrupt "stopping" of the Earth or the Earth–Moon system) surfaced additional alternative ideas. Some participants assumed that gravity becomes zero at the Earth's centre and therefore motion ceases; others assumed that forces are "concentrated" there, holding the ball stationary. These responses indicate uncertainty about the role of the centre of mass and about equilibrium/oscillation around it. Similarly, several participants treated motion as requiring a continuous force, underestimating inertia and the role of initial velocity in the absence of external forces.

Regarding celestial motion, participants often struggled to connect gravity (as an action-at-a-distance interaction) with the generation and maintenance of trajectories. The idea that the Earth–Moon pair rotates about a common centre of mass was largely unfamiliar, and geocentric accounts lacking reciprocity dominated. This appears to reflect a broader difficulty in treating gravitational interaction as a two-body relation with reciprocal consequences, rather than as the one-sided action of a larger body on a smaller one.

The designed teaching–learning sequence aimed to support a gradual shift from simplified, alternative models towards more integrated, scientifically compatible explanations of tides and the underpinning concepts. Through experiments, structured thought scenarios, animations, video, and simulations, participants progressively distinguished mass from weight; recognised gravity as attractive and distance-dependent; and reconsidered the assumption that gravity vanishes in the region between the Earth and the Moon. They also developed a view of the Earth and Moon as a dynamical two-body system rotating about a common centre of mass. Refining an existing Static Tide Model by incorporating the Moon's dynamical motion supported a more coherent account of the simultaneous formation of two tidal bulges and functioned as a bridge

towards scientifically compatible conceptual understanding. Overall, the results position tides as a productive phenomenon for linking concepts often taught separately (gravity, reciprocity of forces, inertia, two-body systems, barycentre) and for engaging learners with modelling as a means of explanation.

Methodologically, the study is limited by a small, focused sample (N=16) and by data generated within a specific instructional sequence; generalisation should therefore be cautious. Future work should examine the durability of conceptual change over time and across contexts (e.g., other departments, in-service teachers, upper secondary students), as well as transfer into authentic classroom practice. Interdisciplinary connections with Geography or Earth Sciences may further enhance relevance by foregrounding tidal effects in coastal regions. Finally, cross-cultural studies could explore how interpretive resources shape understandings of tides and the outcomes of comparable interventions.

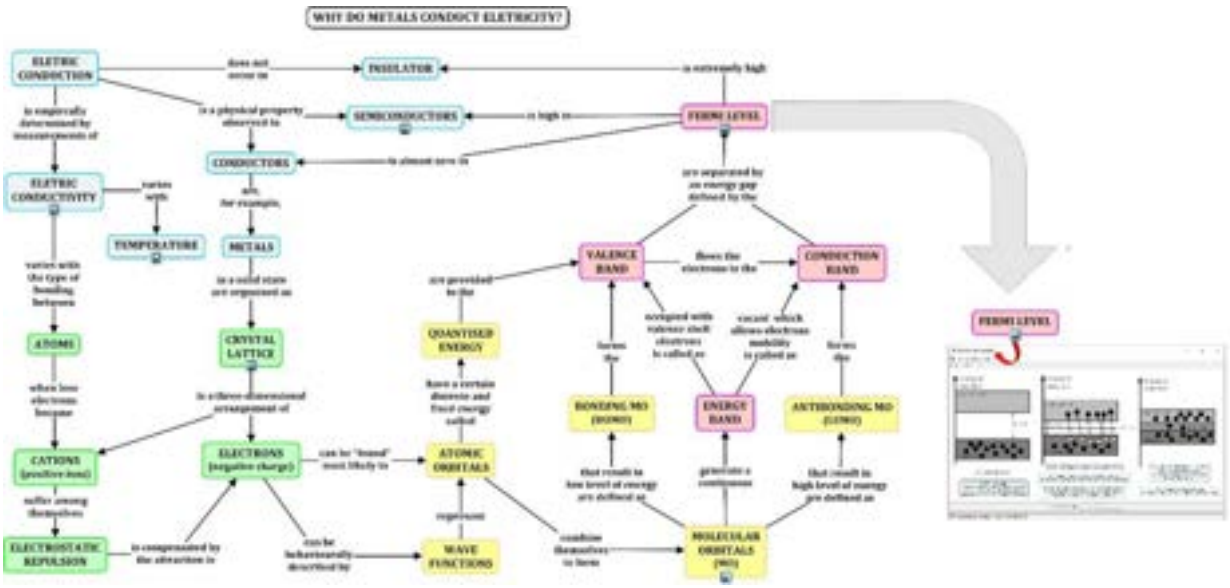
Learning Chemistry Through A Concept Map With Clickable Digital Resources (Hypermedia Map)

Joana Guilares de Aguiar[1] *and Paulo Rogério Miranda* Correia[2]
[1]Universidade Federal Fluminense, Brazil
[2]Universidade de São Paulo, Brazil

Although concept mapping is not new in science education, a few studies systematically evaluate it as a multimedia and hypermedia study material. Seemingly, several factors may influence the effectiveness of meaningful learning. This study investigated the effects of students' prior knowledge and the use of digital resources (i.e., clickable concepts on the map) on learning outcomes and cognitive load. A chemical macroscopic event – electrical conductivity in metals – was chosen to be represented in a teacher-prepared map used as study material. According to Mayer's Cognitive Theory of Multimedia Learning, hypermedia materials may foster schema construction; however, for lower prior knowledge learners, it could lead to a cognitive overload due to a high demand of essential processing on the verbal channel. A 2 x 2 pre-test-to-post-test design was adopted to investigate the effect of map type (Plain map vs. Hypertext map) and learners' prior knowledge (Low vs. High) on test performance and mental effort ratings for understanding the topic. The participants were 77 undergraduate students treated following APA ethical guidelines for human research. The results showed that the Hypertext map-type group had a higher performance with a lower mental effort than the Plain map group. Surprisingly, no prior knowledge effect was found. Adding clickable digital resources on the map enhanced factual and conceptual scientific knowledge for both groups of learners (low and high prior knowledge), indicating a no-overload situation.

Keywords: Digital Resources. Higher Education. Multimodal Learning.



Theoretical Framework And Purpose

Concept maps or Cmaps (Figure 1) have been described in the literature as a pedagogic tool that supports meaningful learning (Novak, 2010) because they are organised similarly to the knowledge structure in memory (Ausubel, 2000). They can also incorporate multiple sources of information, including verbal/textual and visual/pictorial. Both features facilitate accessing and integrating information processes, which scaffold meaningful learning (Paivio, 1990).

Although using Cmaps is not new in education, a few studies systematically evaluate them as media and hypermedia study material (Chang, Hwang, & Tu, 2022). Moreover, several factors seemingly influence the effectiveness of learning through Cmaps, such as the learners' Prior Knowledge (PK) (e.g., Amadieu et al., 2009; Simonsmeier et al., 2021) and the use of Digital Resources (DR) resulting in a hypermedia map (e.g., Chiou, Tien, & Lee, 2015; Fatawi et al., 2020).

According to the Cognitive Theory of Multimedia Learning (Mayer, 2009), hypermedia materials, such as concept maps with clickable concepts (Figure 1), may foster schema construction. However, for lower PK learners, this could lead to cognitive overload due to a high demand of essential processing on the verbal channel, which means selecting and organising relevant information in the limited working memory.

Figure 1: Teacher-prepared concept map used as study material (on the left-hand). The hypermedia map was prepared by adding six clickable digital resources on the concepts (see an example on the right-hand).

The present study investigated the effect of learners' PK and the use of DR on learning outcomes and mental effort through concept mapping instruction. If adding DR is responsible for fostering learning, participants in the hypermedia map group are expected to have higher performance (Hypothesis 1a) and lower mental effort (Hypothesis 1b) than the plain map group. On the other hand, if adding extra information on the map would lead to an overload situation, the low PK group is expected to have lower performance (Hypothesis 2a) and higher mental effort (Hypothesis 2b) than the high PK group.

Methods

A 2 (Prior Knowledge: Low, LK *vs.* High, HK) x 2 (Map type: Plain Map, PM *vs.* Hypertext Map, HM) factorial design was adopted, resulting in four conditions: LKPM group (n = 16), LKHM group (n = 24); HKPM group (n = 18) and HKHM group (n = 19). The participants were 77 undergraduate Chemistry students (51% female, M_{age}: 22.1) treated following APA ethical guidelines for human research. The data collection procedure occurred during a university-level class (approximately 60 minutes) of a natural science course as follows.

- *Step 1 - PK test (5 min)*: students were asked to judge a 25-statement questionnaire about the chemical content as correct/incorrect, considering +1 for correct judgments and -1 for misjudgments (-10 to +10 scale). Example of statements: In metals, there is not actually a bond, only a weak interaction (false); metals have atoms spatially organised in the form of a crystalline lattice (true). The questionnaire was peer reviewed to eliminate dubious information. The internal consistency analysis of the items revealed satisfactory results for Cronbach's alpha, with a value of 0.762.
- *Step 2 - Pre-test (10 min)*: six multiple-choice questions assessed factual knowledge, and four written questions assessed conceptual knowledge. Overall performance was given by the sum of both tests (0-10 scale). Example of multiple-choice question: "In a metal, electrostatic interaction occurs between: (A) Cations and anions; (B) Protons and electrons; (C) Cations and electrons (CORRECT); (D) Protons and anions; (E) Neutral atoms". Example of a written question: "Why are metals good conductors of electricity?"

- *Step 3 - Navigating on the Cmap (20-30 min)*: the digital plain Cmap was prepared by the teacher to explain conductivity in metals (Figure 1). To understand this phenomenon, the learners must grasp chemical concepts regarding the types of materials (insulators, semiconductors and conductors) and macroscopic aspects of electrical conduction (blue concepts in Figure 1); the reticular model for crystalline structure of metals (concepts in green); the Theory of Molecular Orbitals, HOMO and LUMO formation (concepts in yellow) and the Band Theory of Solids and Fermi level (concepts in pink). The hypermedia map was prepared by adding six DR on the map, which means six clickable concepts that pop up images and further explanation about the topic (see Figure 1). The DR was: images, tables, audio explanation, videos, simulation and animation. The concepts that received the DR were: electric conduction, temperature, semiconductors, crystal lattice, molecular orbitals and Fermi level (Figure 1).
- *Step 4 - Mental effort rating (5 min)*: students were asked to rate their mental effort (Paas et al., 2003) to navigate and understand chemical content on the Cmap by using a 9-point Likert scale (from 1 = very, very low to 9 = very, very high).
- *Step 5 - Post-test (10 min)*: the students were asked to answer six multiple-choice questions (retention test) and four written questions (transfer test). Overall performance was given by the sum of both tests (0-10 scale). The post-test was different and more difficult than the pre-test.

Results And Discussion

A 2 (Prior Knowledge: LK vs. HK) x 2 (Map Type: PM vs. HM) ANOVA and independent t-tests were conducted using SPSS 24.0 (IBM, USA) on pre-test and post-test overall performance and their difference (i.e., gain of knowledge) and mental effort ratings (Table 1).

One-way ANOVA confirmed that PK test scores were higher for HK participants (M = 4.97, SD = 2.13) than for LK ones (M =- .60, SD = 2.29), $F(1,75) = 122.01$, $p < .001$. As expected, HK participants outperformed LK on pre-test, $F(1,75) = 9.24$, $p < .005$. Concerning post-test performance, the ANOVA confirmed that neither PK nor map type affected the post-test scores, $F(1,75) = .02$ and .03 (both ps > .05), respectively. On the other hand, it was a main effect of adding DR on the map, considering the gain of knowledge. The HM group gained more factual and conceptual knowledge than the PM group, $F(1,75) = 3.82$, $p < .05$, $\eta^2 = .15$ (medium effect size). Yet no significant difference emerged between the groups considering their level of PK, $F(1,75) = 1.70$, *n.s*.

There is some evidence that offering a Cmap as hypermedia study material fostered learning, confirming Hypothesis 1a. As the level of PK did not affect students' performance, it was inferred that adding DR on the map did not lead to an overload situation, refuting Hypothesis 2a.

The ANOVA showed a main effect of students' PK on mental effort. LK students reported higher mental effort (M = 7.24, SD = 1.00) to navigate the map and understand the topic than HK students (M = 4 .93, SD = 1.40), $F(1, 75) = 6.05$, $p < .05$, $\eta^2 = .08$ (medium effect size). This confirms our Hypothesis 2b. Yet no significant difference emerged between the groups considering the use of DR, $F(1,75) = .02$, *n.s*.

Table 1: High and low PK participants' means (SD) of pre-test, post-test, knowledge gain and mental effort for each Cmap type.

	Low Prior Knowledge (LK)		High Prior Knowledge (HK)	
	Plain Map (PM)	*Hypermedia Map (HM)*	*Plain Map (PM)*	*Hypermedia Map (HM)*
PK test scores	-.12 (2.12)	-.92 (2.38)	5.00 (2.37)	4.95 (1.93)
Pre-test	2.44 (1.54)	1.96 (1.22)	3.61 (1.94)	2.82 (1.33)
Post-test	4.13 (1.94)	4.29 (1.70)	5.06 (1.64)	5.00 (1.97)
Gain of knowledge	1.69 (1.65)	2.33 (1.90)	1.44 (1.76)	2.18 (1.78)
Mental effort	8.04 (.48)	6.43 (1.38)	4.04 (1.38)	5.81 (1.42)

Interestingly, a marginal PK x map-type interaction was found considering mental effort, $F(1,75) = 3.81$, $p = .05$, $\eta^2 = .05$ (small effect size). Whilst for LK learners, adding DR to the map has decreased mental effort, $t(38) = 4.47$, $p < .05$, for HK learners, adding DR increased it, $t(35) = -3.13$, $p < .05$. Moreover, a high PK on the topic was critical to decrease the mental effort required to understand the content on the plain map (LKPM *vs* HKPM, $t(32) = 11.00$, $p < .001$). However, no difference was found for those who studied the hypermedia map (LKHM *vs* HKHM, $t(41) = 2.21$, *n.s.*). These results are partially in line with our Hypothesis 1b.

These results suggest that for LK students, the Cmap used as hypermedia study material leads to higher performance with lower mental effort. Considering a no-overload situation, they were able to select relevant information and organise it as presented without imposing a high cognitive demand on their limited working memory. Consequently, they can use some free cognitive resources for schema construction (i.e., learning).

For HK learners, the increase in mental effort can be explained by generative processing, which means actively engaged in the learning process. This is only possible due to the automated schemas in long-term memory, which can be retrieved and integrated with new knowledge presented in the material. These results showed no evidence of an overload situation nor the expertise reversal effect (Kalyuga et al., 2003), which means, "instructional techniques that are highly effective with inexperienced learners can lose their effectiveness and even have negative consequences when used with more experienced learners" (p. 23).

Final Remarks

Although Cmaps have been used for the last five decades in Science Education, a few studies systematically evaluate them as a teacher-prepared media and hypermedia instructional material. Firstly, ensuring a well-designed digital Cmap (readability, layout and content accuracy) is critical for learning with a hypermedia map. In this study, using the Cmap with clickable DR fostered learning regardless of the level of learners' PK. However, for a higher learning outcome,

we need to be aware of its impact on knowledge acquisition, avoiding cognitive overload and the expertise reversal effect.

ESERA 2025 Copenhagen

Learning A Respiratory Model – Undergraduate Understanding Of And Attitudes Toward The Fick Equation

Niels Dohn
Aarhus University, Denmark

This study examines how second-year biology students in an animal physiology course understand and apply the Fick equation, a fundamental mathematical model in respiratory physiology, and their attitudes toward the use of mathematical expressions in the discipline. Seventy-one students completed a written assignment designed to assess their understanding of the Fick principle, followed by a questionnaire exploring their attitudes toward mathematical models in physiology. Results indicate that many students struggled to articulate their understanding of the Fick principle in precise scientific language, with many answers being vague or colloquial. While some students referenced the Fick equation, only a few correctly applied its elements in their explanations. Additionally, misconceptions about alternative oxygen-binding pigments, such as myoglobin or hemocyanin, were prevalent. The questionnaire revealed two distinct student profiles: one with a positive attitude toward models, finding equations helpful for understanding and remembering concepts, and another with a negative attitude, viewing models mainly as tools for numerical calculation in exam preparation. The findings suggest that while students recognize the importance of models in physiology, they struggle to translate mathematical representations into scientifically accurate conceptual knowledge. This supports previous research on the fragmentation of mathematical and disciplinary knowledge. This study highlights the need for improved instructional strategies to help students translate mathematical models into scientifically accurate conceptual knowledge.

Keywords: Attitudes, conceptual understanding, undergraduate learning

Introduction

Representational models are central to science education, where they are used to abstract and simplify complex real-world phenomena, rendering them more amenable to analysis. Such models frequently include mathematical representations, which play a crucial role in scientific reasoning and problem-solving. Despite their importance, research has consistently documented substantial challenges for students in applying mathematics meaningfully within scientific contexts A recurrent issue is the fragmentation of mathematical and disciplinary knowledge, which impedes students' ability to integrate concepts and develop coherent understandings (Towns et al., 2019). As a result, mathematical representations are often perceived as purely algebraic or symbolic tools, encouraging procedural manipulation of variables rather than conceptual interpretation (Taber, 2009; Tsui & Treagust, 2013).

These difficulties are also evident in physiology. Prior studies have reported persistent student misunderstandings of physiological and respiratory models (Michael et al., 1999; Modell, 1997). In line with these findings, our observations suggest that students frequently struggle to conceptualize the Fick equation, a foundational mathematical model in respiratory physiology.

Against this backdrop, the present study focuses on students' attitudes toward the Fick equation as a mathematical model, with particular attention to how the model is used in practice. Attitudes are commonly understood as the feelings, beliefs, and values individuals hold about science as an object and are typically conceptualized as a multifaceted construct comprising affective,

cognitive, and behavioural components. This includes enthusiasm for and enjoyment of science, perceptions of science, views on the societal contributions of science and scientists, and orientations toward engagement with science, such as interest in science-related careers (Osborne et al., 2003). However, attitudes are rarely examined in relation to epistemic dimensions of the discipline, such as the nature of biological knowledge or the epistemic status of models (e.g., whether they are explanatory, predictive, or heuristic). Consequently, students' resistance to mathematical models may be misinterpreted as affective in origin, when it is instead epistemically grounded (Aikens et al., 2021).

This study therefore examines how biology students interpret and apply the Fick equation as a mathematical model in physiology and explores their attitudes toward the use of mathematical expressions within the discipline. The study is guided by the following research questions:

1) How do biology students apply Fick's principle to solve a given assignment?

2) What attitudes do students express toward the use of mathematical expressions in physiology?

Method

Our target group consisted of second-year undergraduate biology students enrolled in an animal physiology course. The course included lectures, theoretical exercises, and laboratory sessions. The Fick principle had been covered in the previous lecture and was revisited during the lecture in which the study took place.

For the study, we developed a pen-and-paper format comprising a written assignment and a brief questionnaire. The written assignment was designed to assess students' understanding of the Fick principle and the extent to which they utilized the Fick equation. The assignment posed the following question:

"Some Antarctic fish lack haemoglobin in their blood entirely. It has been observed that these fish have larger hearts compared to closely related species with haemoglobin. Provide a brief explanation for this."

The Fick equation was provided at the top of the assignment, but its use was not explicitly required. Students were instructed to keep their textbooks closed while answering.

To explore students' attitudes toward mathematical models in physiology, we designed a questionnaire consisting of nine items, which students completed immediately after the written assignment.

A critical analysis of these items indicated that they capture multiple constructs beyond affective attitude. Specifically, some items reflect epistemic engagement and perceived utility (e.g., "The Fick principle is easier to understand when expressed as an equation than when described in words"), others measure self-efficacy (e.g., "I understand the Fick principle well enough to explain it to other students"), while several items capture instrumental motivation or behavioral intention (e.g., "I focus on the text and usually skip the equations") or disciplinary identity (e.g., "Equations do not belong in a physiology textbook"). Recognizing these distinctions is important for interpreting survey responses, as apparent "attitudes" may in fact reflect epistemic beliefs, confidence, or task-specific engagement rather than stable affective dispositions.

Analysis

Fifty-two students (73%) completed the assignment, while 19 students (27%) did not participate. The responses were reviewed by two researchers and analysed to address the first research question. The answers were categorized and quantified for further analysis.

The unit of analysis comprised individual student responses to the assignment, based on their handwritten answers. A structured qualitative content analysis was conducted following Mayring's (2015) procedure. First, categories were defined to capture analytically relevant features of the responses, specifically the degree of conceptual correctness and the presence of identifiable misconceptions. Second, explicit coding rules were established to ensure consistent delineation between categories and unambiguous assignment of each response segment to a single category. Third, anchor examples were selected to exemplify typical manifestations of each category, illustrating both accurate reasoning and recurring patterns of misconception.

Of the 71 questionnaire responses, all were deemed valid for statistical analysis. Reliability, measured as internal consistency, was calculated using Cronbach's alpha, yielding a value of 0.71. To ensure consistency in the analysis, negatively worded statements about models (items 2, 5, 7, and 8) were recoded.

Due to the relatively small sample size, advanced statistical analyses were not meaningful. Our primary aim was to examine how responses were distributed across the individual items and to identify the overarching conclusions that could be drawn from these patterns. The results are therefore presented as response distributions to facilitate straightforward interpretation.

Results

The results revealed that many students struggled to articulate their answers in clear and concise scientific language. A correct answer would include the following reasoning:

The arterial oxygen concentration (CaO2) is low in fish lacking haemoglobin, leading to a reduced arteriovenous oxygen difference. To ensure sufficient oxygen transport, the cardiac output (Q) must be increased. This can be achieved by a higher heart rate (fH) and/or a larger stroke volume (Vs). The most critical factor is the larger stroke volume, which is facilitated by a larger heart.

However, many student responses were vague and imprecise. Thirty-nine students (54%) provided answers referencing the need to "pump a greater blood volume," but these were often formulated using colloquial rather than scientific language. Representative examples include:

"Could be because more 'liquid' must be pumped around than if it had been blood, because the 'liquid' does not contain so much oxygen".

"Haemoglobin binds oxygen very efficiently. Without haemoglobin, a greater heart is required to get the same amount as with haemoglobin".

"With a great heart blood is pumped around faster. And therefore, more oxygen is also pumped around in the body of the fish".

While these answers are not entirely incorrect, they lack scientific precision. The students seem to exhibit an intuitive grasp of the concepts but face challenges in translating their understanding into scientifically accurate language. This imprecision does not necessarily indicate a

misunderstanding of the Fick principle but rather highlights difficulties in expressing conceptual knowledge in a formal scientific context.

Only 4 responses (6%) explicitly incorporated elements from the Fick equation. For instance:

"A larger heart enables better circulation of body liquid (blood), which is necessary when the fish lacks haemoglobin which binds oxygen. Stroke volume, Vs, enters the Fick principle. The greater Vs → the greater VO_2".

Table 1. The results are expressed as a percentage of the total number of students who replied to the questionnaire (n = 71)

	Item	Strongly agree	Agree	Disagree	Strongly disagree
1	When I prepare for lectures in physiology, I spend a considerable amount of time trying to understand equations	8	42	39	11
2	When I prepare, I focus on the text and usually skip the equations	21	36	31	12
3	The Fick principle is easier to understand when expressed as an equation than when described in words	3	40	50	7
4	It is easier to remember the Fick principle when it is presented as an equation	23	58	17	2
5	I can only use the Fick equation when I can insert values	9	44	29	18
6	I understand Fick principle well enough to explain it to other students		18	46	36
7	I am only trying to understand the equation because it is curriculum	12	30	38	20
8	In my opinion, equations do not belong in a physiology textbook		6	25	69
9	Understanding and using equations in physiology is part of scientific literacy	69	29	2	

Additionally, 11 students (16%) suggested that the fish might use alternative oxygen-binding pigments, such as myoglobin or hemocyanin, instead of haemoglobin. These responses reflect misconceptions. For example:

"They have myoglobin or something like that, which can only bind 1 oxygen, and more blood therefore has to be pumped to give the same amount of oxygen to the body".

"The Fish have hemocyanin(?) in their blood. This transports oxygen and also has to be pumped around the body to the tissue; perhaps hemocyanin cannot carry as much oxygen as haemoglobin?

(The haemoglobin molecule binds 4 oxygen atoms, but I don´t know how much hemocyanin binds!)".

These examples show that students are reasoning sensibly and attempting to integrate prior knowledge with the question. For instance, they understand that myoglobin has fewer oxygen-binding sites than haemoglobin and hypothesize that this could necessitate increased blood flow. However, their factual knowledge is incorrect, as fish blood does not contain myoglobin or hemocyanin. This misunderstanding leads to flawed conclusions.

Overall, these findings suggest that while students' conceptual models align with those presented in lectures, exercises, and textbooks, errors in factual recall and imprecise language hinder their ability to provide scientifically accurate explanations.

The analysis of the questionnaire revealed that the students could be divided into two nearly equal groups, each characterized by a distinct profile.

The first profile represents students with a positive attitude toward models. These students view themselves as actively engaging with models, finding them helpful for understanding and remembering concepts. Specifically, they report that the Fick principle is easier to comprehend and recall when expressed as an equation rather than in words.

The second profile represents students with a negative attitude toward models. These students tend to skip equations in their textbooks, viewing the Fick equation as merely a tool for numerical calculations. Their primary motivation for understanding the Fick principle is limited to exam preparation.

Interestingly, this negative attitude is inconsistent with responses to items 8 and 9 on the questionnaire. In item 8, nearly all students disagreed with the statement that models do not belong in a physiology textbook, and in item 9, most agreed that understanding and using equations in physiology is integral to scientific literacy. This apparent contradiction suggests that while students acknowledge the importance of models as an ideal aspect of physiology and scientific literacy, their everyday experiences with models in lectures and exercises may not align with this ideal.

Discussion

This study examines how undergraduate biology students interpret and apply the Fick equation as a mathematical model in respiratory physiology, and how they articulate their epistemic stance toward mathematical formalisms within the discipline. Consistent with prior research documenting the fragmentation between mathematical and disciplinary knowledge (Towns et al., 2019) and students' tendency to operationalize equations as procedural algorithms rather than conceptual representations (Taber, 2009; Tsui & Treagust, 2013), our findings demonstrate that the majority of students failed to mobilize the Fick equation as an explanatory framework – even in contexts where its application was explicitly warranted.

RQ1: How Do Biology Students Apply Fick's Principle To Solve A Given Assignment?

Although most students produced responses that were compatible with the intended explanation (e.g., "a greater volume must be pumped"), only a small minority explicitly grounded their reasoning in the structure of the Fick equation. This pattern indicates that many students relied on informal physiological intuition rather than using the equation as a representational model

linking oxygen uptake (VO_2), cardiac output (Q), and the arteriovenous oxygen difference (CaO_2–CvO_2). The equation thus failed to function as an epistemic tool for explanation, remaining largely implicit or entirely absent from students' reasoning processes.

Importantly, the widespread vagueness and colloquial phrasing should not be interpreted as conceptual failure. Instead, it may reflect a recurring educational bottleneck: students may recognize the causal logic of oxygen transport but struggle to articulate it in concise scientific language and to map that logic onto formal representations. This aligns with the idea that representational competence involves not only "knowing the content" but being able to translate between verbal, conceptual, and mathematical forms (Kozma & Russell, 1997). Thus, the main barrier appears to be representational integration rather than a complete lack of physiological understanding.

At the same time, responses containing alternative oxygen-binding pigments (e.g., myoglobin, hemocyanin) reveal that misconceptions do play a substantive role for a notable subset of students. These answers were often framed through seemingly coherent reasoning ("fewer binding sites → lower oxygen transport → increased pumping"), suggesting that misconceptions were not random errors, but plausible reconstructions based on fragmented prior knowledge. This supports earlier work showing that students may hold internally sensible but scientifically inaccurate models of physiological mechanisms (Michael et al., 1999; Modell, 1997). Here, factual inaccuracies about oxygen carriers led students to build explanations that were structurally reasonable yet physiologically invalid – illustrating how misconceptions can be reinforced by otherwise productive mechanistic thinking.

Taken together, these findings suggest a heterogeneous landscape: while students' explanations often reflect partial conceptual alignment with teaching materials, their performance is constrained by (1) limited use of the equation as a conceptual scaffold, (2) imprecision in disciplinary discourse, and (3) discrete yet consequential misconceptions that derail otherwise plausible reasoning.

RQ2: What Attitudes Do Students Express Toward The Use Of Mathematical Expressions In Physiology?

The questionnaire data reveals two nearly equal attitudinal profiles: one group positioned equations and models as cognitively supportive (supporting comprehension and retention), whereas the other positioned them as obstacles or as purely instrumental for calculation and exam performance. This division resonates with the literature on students' procedural orientation toward mathematics in science: for a substantial cohort, equations remain symbolic artefacts to be manipulated or avoided, rather than representations of relationships in biological systems (Redish & Kuo, 2015).

However, a key finding is that the "negative" profile did not reflect wholesale rejection of models. Students who reported skipping equations nevertheless tended to endorse the normative legitimacy of models in physiology textbooks and acknowledged that using equations is part of scientific literacy. This discrepancy suggests that resistance may not be rooted in anti-scientific affect or motivational deficits but rather in epistemic and experiential factors: students may accept the principle that models should function as explanatory resources while simultaneously experiencing them as disconnected from understanding in pedagogical practice. This interpretation aligns with Aikens et al.'s (2021) argument that what appears to be negative attitude

may instead reflect students' perceptions of the epistemic role that models are afforded in teaching – whether models are treated as explanatory resources or merely as formalities attached to numerical exercises.

Consequently, students' attitudes appear to be shaped by how mathematical representations are positioned within the instructional context. If the Fick equation is primarily encountered as something to "plug numbers into," students may reasonably conclude that it is not a tool for thinking, but as an assessment hurdle. Conversely, students who experienced the equation as a compact summary of causal structure were more likely to report it as meaningful and memorable. Attitude, then, is not simply an individual trait but plausibly an outcome of students' repeated encounters with what counts as "doing physiology" across lectures, exercises, and examinations.

Implications: The Fick Equation As A Model Rather Than A Formula

Across the dataset, the central pattern indicates that students often possess fragments of correct reasoning but fail to integrate these consistently with the formal mathematical model. This finding directly instantiates the problem articulated in existing literature: the fragmentation of mathematical and disciplinary knowledge (Towns et al., 2019) and the reduction of equations to procedural tools (Taber, 2009; Tsui & Treagust, 2013). The Fick equation appears to function as a boundary object (Star & Griesemer, 1989) that some students successfully employ to coordinate conceptual domains, while others perceive it as an external mathematical demand imposed upon physiological reasoning.

A plausible educational implication is therefore that instruction should make the epistemic status of the equation explicit: not only what it is, but what it is for. If the Fick equation is framed as a representational model that explains why changes in CaO_2, Q, fH, and Vs matter, students may be better positioned to move from intuitive statements ("pump more") to mechanistically grounded explanations ("reduced CaO_2–CvO_2 requires increased Q, primarily via increased Vs enabled by a larger heart"). At the same time, the misconceptions observed indicate the need for targeted conceptual clarification of oxygen carriers and their distribution across taxa, because incorrect recall can produce coherent but incorrect explanatory pathways.

Conclusion

In response to the research questions posed, we find that undergraduate biology students predominantly approach the assignment through intuitive physiological reasoning but rarely deploy the Fick equation explicitly as an explanatory model; furthermore, a subset of students' reasoning is undermined by misconceptions concerning oxygen-binding pigments. Attitudinally, students divide into two approximately equal cohorts – those who experience equations as conceptually generative scaffolds and those who perceive them as calculational or examination-driven obstacles – yet even students in the latter category largely acknowledge the disciplinary legitimacy of mathematical modelling. This constellation of findings suggests that students' difficulties and resistance may stem less from mathematics aversion per se than from how mathematical representations are positioned and operationalized within physiology pedagogy: as epistemic tools for mechanistic reasoning, or as symbolic formalism for algorithmic manipulation.

ESERA 2025 Copenhagen

Models As Artefacts From The Perspective Of Instrumental Genesis

Mathilde Kjær Pedersen[1], Maria Kirstine Østergaard[2], Morten Misfeldt[1] and Uffe Thomas Jankvist[2]
[1]Departmen of Science Education, University of Copenhagen, Denmark
[2]Danish School of Education, Aarhus University, Denmark

In science and science education, models play an essential role. Scientific models have a representational aspect, but they also serve other epistemic practices for the agents that are manipulating and using them, such that models can be seen as human-made epistemic artefacts. We see a parallel between an agent's use of models and of technologies. The instrumental approach focusses on the relation between cognition and the use of technology considered as a materialized artefact through instrumental genesis. Instrumental genesis is the complex process of an artefact becoming an instrument with a certain purpose for the user through the user's cognitive and practical interactions with the artefact. This paper explores the possibilities of applying the notion of instrumental genesis to students' interactions with models as artefacts. We present an empirical example of Danish upper secondary school biology students conducting an experiment on diffusion. Using agar blocks as a model for cells, the purpose of the exercise was for the students to learn about diffusion in cells. The analysis of the empirical example indicates that the perspective of instrumental genesis can provide a valuable terminology for understanding students' use of models as epistemic artefact. Furthermore, knowledge of instrumental genesis may help structuring learning activities to support students' development with models, considered as a form of modelling genesis.

Keywords: Science models, epistemic artefacts, instrumental genesis

Introduction

In a first approximation, models can be seen as the appropriation of materiality to serve epistemic purposes. Similarly, technology is an appropriation of materiality to serve pragmatic purposes. This paper addresses the interplay between these two perspectives on interactions with materiality. In philosophy of science, the so-called artefactual view on the nature of models (e.g., Knuuttila, 2011) considers models as epistemic artefacts, which involves a triadic relation between the agent, the model, and the represented part of the world. In this sense, the representative aspect of a model occurs when the model is used by an agent (Giere, 2010). From the artefactual view, models are human made artefacts materialized serving many epistemic functions other than representing the world. It is in the interaction with models, such as producing, manipulating and using models that scientists can generate knowledge (Knuuttila, 2011). For the teaching and learning of science, epistemic functions of models are essential (Taber, 2017), as models in education have a didactical purpose based on an intension for the learning. This means that in learning situations, we can also consider models as epistemic artefacts that the students are to learn with. We find it interesting to study students' cognitive processes when interacting with models as epistemic artefact. To do this, we analyse an empirical example of a biology experiment on diffusion in cells, where students are studying the relation between cell size and diffusion rate.

Considering models as artefacts may create a parallel between the use of technology and models for epistemic purposes. One theoretical perspective on the relation between technology and cognition from educational research is the instrumental approach (Verillon & Rabardel, 1995). In mathematics education research, the notion of instrumental genesis (Guin & Trouche, 1998) builds on the instrumental approach and provides a framework for studying students' interaction with artefacts in learning situations. Instrumental genesis is the lengthy process of interacting with and learning from an unknown artefact such that it becomes an instrument with a specific purpose for the student (Guin & Trouche, 1998). Therefore, we find it relevant to study students' work and interactions with scientific models as artefacts by addressing the following question: *What possibilities to study students' interactions with scientific models as epistemic artefacts may the perspective of instrumental genesis offer?*

We address this question by applying the theoretical notion of instrumental genesis on the empirical example from a Danish upper secondary school biology class.

Empirical Example: Diffusion In Cells In Upper Secondary Biology

The chosen empirical example stems from a project on models and modelling in STEM education, where we have observed upper secondary teaching in biology, physics and chemistry for the past year. In a 1st year biology class of Danish upper secondary school (corresponding to grade 10 or 11), the students were learning about diffusion in cells. We observed one of the activities, which revolved around an experiment designed to explain the relation between the size of a cell and the degree of diffusion across the cell membrane. This experiment was well-known to the biology teacher who previously had run the experiment with other 1st year biology classes. The students followed written instructions for executing the experiment and did a written report on the experiment afterwards.

The students worked in small groups, immersing three different sized cubes of blue-coloured alkaline agar into vinegar (see Figures 1a and 1b), and leaving them for exactly five minutes. Subsequently, the cubes were cut in halves (see Figure 1c), making it possible to measure how far into the cube the vinegar had diffused, and thus calculate the ratio between the surface area and volume of the cube, and the volume of the diffused area. The students were then asked to write a report on the experiment and their findings, including their reflections on the use of models in the experiment as well as in the theory connected to the topic.

Figure 1a. The three alkaline agar blocks before they are put into vinegar.

Figure 1b. The three agar blocks in vinegar.

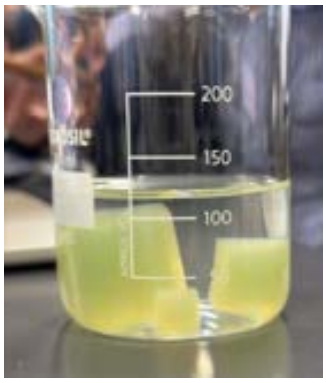

Figure 1c. The three agar blocks cut into halves after the diffusion of vinegar.

Models As Epistemic Artefacts

Viewing models as human-made epistemic artefacts makes it possible to nuance the complexity of the links between models and reality. One of the links is that models are simplified representations of reality based on some selected criteria (Gilbert, 2004). In addition to representing, models may be used to perform other epistemic practices such as "making simplifications and idealization; conceptualizing imagined (or non-observable) objects or processes; supporting arguments, explanations, and predictions" (Gilbert & Justi, 2016, p. 23). Therefore, models may be seen as external artefacts, which play an important role in thinking and learning, when using and producing them. Thereby, models are seen independently from the real-world target systems (Knuuttila, 2011), and the relation between the model and the subject using the model becomes essential. This view on models is highly relevant in an educational context, as models, such as 2-D illustrations, 3-D figures, symbolic formulas, animations, and laboratory exercises, all play a central part for learning science. Students' access to study, conceptualize, explain and investigate scientific phenomena often is through educational science models.

Instrumental Genesis

In the notion of instrumental genesis, an artefact is an either physical or symbolic materialized object that a student or user encounters for the purpose of handling a given task or situation. Instrumental genesis is the cognitive process of interacting with the artefact to become familiar with it and with ways of using it such that it becomes an instrument for the specific task or situation. Through this interaction students learn from the artefact and develop knowledge about the given situation and its objects and phenomena (Guin & Trouche, 1998). The interaction is two-way directional in the sense that the student is influenced by the artefact and its configuration and limitations, named instrumentation. On the other hand, the student reads their own anticipations and intentions into the artefact and makes use of the artefact in an individual way, named instrumentalization. To interact with an artefact, students make use of *techniques*. A technique is a way of solving a task or handling a situation, based on reasoning and previous experiences and routines (Artigue, 2002). These techniques can either be of pragmatic or epistemic value. The pragmatic value is related to the technique's productive potential such as providing answers and facts. The epistemic value concerns the technique's contribution and support to the learner's cognition such as understanding the scientific object and processes involved (Artigue, 2002). A pragmatic technique when using a computer algebra system in mathematics could be to solve an equation efficiently without the technique supporting an understanding of why the result is correct or how to solve that type of equation in general. An epistemic technique could be to use the computer algebra system to do multiple calculations or manipulate a variable to look for patterns of why a certain relation is valid, where it is rather the process behind the result than the result itself that is of interest. The value of the applied technique is often related to the given instructions and the types of tasks, and sometimes pragmatic techniques may be used as part of or as precursor to epistemic techniques.

We suggest that a similar distinction between techniques can be applied to students' work with scientific models. Pragmatic techniques involve using models to obtain specific results, such as perform measurements, read off values or predictions. In contrast, epistemic techniques involve using models to explore relationships, mechanisms, assumptions, and limitations in order to develop understanding of underlying processes and systems of the phenomena represented. By identifying students' techniques for using models, we can gain insight into how students engage

with models as epistemic artefacts. Focusing on students' techniques for applying models in science education provides a lens to study their interactions with models, as it is the students' cognitive processes and their interactions with the models that ultimately determine what students take from the models.

Method

The presented empirical example was selected because the students work with concrete artefacts in the form of agar blocks, which function as models of cells or, more precisely, of cell sizes. In this way, the experiment itself constitutes a model of the relationship between cell size and diffusion. The example provides an empirically rich setting for analysing students' interactions with models, as the agar blocks are initially unfamiliar and require the students to develop techniques for using them efficiently for the experiment. This makes it possible to examine how students' pragmatic and epistemic techniques emerge and develop over the course of the activity, and to explore whether the notion of instrumental genesis can serve as an analytical lens for studying how models function as epistemic artefacts, namely, tracing how an artefact becomes a meaningful model for understanding the underlying relationship.

The observation of the example was carried out by the first and the second author. All observations were video recorded with two classroom cameras. The data collected from the observations are field notes, video and audio recordings of classroom teaching and of group work and student products.

As part of the analysis of the empirical example, we identified the main activities of carrying out the experiment, such as cutting and treating the agar blocks of the three sizes, doing measurements and calculations after the experiment, and discussing their results in relation to the given question of cell size and diffusion rate. These activities include the students' techniques for treating the agar blocks and the experiment as models for cells and diffusion. Thus, analysing what the students do with the materials and for what purposes indicate whether a technique is pragmatic in the sense of solving a specific task of the experiment, or epistemic in the sense of supporting knowledge about the size of a cell. This means that also the students' way of talking about the materials and the activities are part of their techniques.

Furthermore, the students were asked to discuss their results and to explain how the experiment can account for the relationship between cell size and diffusion in their written reports. Analysing the written discussions provides access to the students' reflections on the experiment as an artefact and makes it possible to examine how the experiment comes to function as an instrument for understanding the relationship between cell size and diffusion through the students' engagement with it. The reflections make visible how students interpret the model, how they attribute meaning to it, and how they derive information that is relevant for the phenomenon under study. In this way, the written reports provide insight into the ongoing process of instrumental genesis.

In analysing the written reports, the distinction between pragmatic and epistemic techniques is not used as a categorical coding of students' responses, but as an analytical guideline for relating the written work to the students' activities during the experiment. When students' written responses are primarily oriented towards reporting results obtained in the experiment, this points to the role of pragmatic techniques, insofar as the focus is on accomplishing the experimental task and presenting outcomes. When, on the other hand, students discuss their results in relation

to the experimental materials and the underlying process of diffusion, this points to the role of epistemic techniques, as the model is used to reason about and make sense of the relationship between cell size and diffusion. Importantly, both orientations may be present within the same written response, and it is precisely the interplay between pragmatic and epistemic techniques across activities and reflections that is of interest in analysing the process of instrumental genesis.

Instrumental Genesis In A Biological Experiment

When the students began the experiment, they had been introduced to its purpose and to the material of alkaline agar blocks and the chemical reaction happening between the agar and the vinegar. Yet the students were still rather unfamiliar with the material they were to work with, in particular the alkaline agar. At first, the students studied the agar and talked about how it felt weird and if it smelled, which indicates that this material was simply an artefact for the students.

In the following process of using vinegar, measuring cups, knives and rulers, the students developed techniques to work with the agar blocks in a way that made sense for the experiment of studying diffusion in cells. The first activities of the experiment were to measure and cut the agar blocks into the right sizes as well as to measure the diffusion and calculate the percentage of the volume that had changed colour were at this point. These activities all included techniques of pragmatic value, namely, dealing with the artefact to provide the results of the difference in diffusion between the three cubes. All the groups found that the smallest agar cube had the largest percentage of changed colour. However, this result may not be that interesting in and by itself for the biology content but needed to be elaborated on by why it is so, and what it reveals about cell size.

In the entire experimental activity, the techniques of pragmatic value serve to produce results and to familiarize students with the artefact of the agar. Techniques of epistemic value, in turn, involve in this case to relate the results of the percentage of changed colour to the relation between the surface area and volume of the agar cube, as well as to infer that the results can be transferred to the context of cells, such that it support understanding of the relationship between cell size and the degree of diffusion across the cell membrane. Importantly, the epistemic techniques are dependent on pragmatic techniques, as the latter provide the empirical basis and experiences upon which epistemic reasoning can build. This connection is seen in the students' written reports.

One group wrote that the experiment showed that:

> The larger agar blocks will have a slower diffusion of vinegar, which is related to the fact that in the larger agar blocks, there is a greater distance that the vinegar molecules must move. […] The most favourable block is the smallest, since its surface area is quite large in relation to the volume, which makes it more permeable to the vinegar and thus more effective." (Our translation from Danish)

The excerpt merely reports upon the results of the agar blocks, which refers to many of their techniques with pragmatic value. They concentrate on the sizes of the agar blocks and which of these there is most favourable to obtain the vinegar. Thus, the genesis of agar blocks as models for cells seems omitted at this point. Yet there is still some understanding of how diffusion is related to size and more importantly to the relation between volume and surface area, which is a central point for the experiment. Then later in their discussion they wrote that agar blocks:

> [...] make it possible to measure how far a substance such as colour that can be simulated as a nutrient can penetrate the block, visualizing the effect of diffusion. They are transparent and easy to manage, making it easier to observe and measure how the diffusion proceeds. […] it was probably chosen not to use real cells, as they would be too small and difficult to observe in detail under a microscope without advanced equipment. The agar block is therefore a practical alternative to simulate why diffusion works in cells. (Our translation from Danish)

This reflection indicates techniques of epistemic value connecting the experiment to the biological context of cells, where the agar blocks turned into an instrument like measuring cups, knives, and rulers, for the purpose of carrying out the experiment and to conclude upon the size of cells and their diffusion. Yet, whereas the other instruments only had pragmatic purposes to execute the exercise, the agar block also had an epistemic purpose to explain and investigate the relation between diffusion and cell size. Similar processes of the agar blocks becoming models or instruments for studying cells were seen in the other students' work during the observation and in the written reports. In the empirical example given, it is easier to recognize the instrumentation, i.e., the influence from the artefact and the setup of the exercise on the students, than how the students' own anticipations and expectations shape the artefact. Through the process of cutting the agar block into the right sizes, observing the change of colour, measuring the differences, and calculating the volume of diffusion, the students got familiar with the artefact of the agar, meaning that they could begin to reflect upon the specific artefact in relation to the diffusion in cells, which we see in their written work.

Discussion

The example from the biology class illustrates that the diffusion of the agar blocks becomes a model for understanding the diffusion of cells through the students' instrumental genesis of the agar blocks. The perspective of instrumental genesis can provide a terminology to understand how models can be understood as artefacts in teaching and learning situations in science. The distinction between artefact and instrument emphasizes the epistemic process of dealing with an artefact to understand and investigate the represented scientific phenomenon. The notion of technique can point the attention to the actual use of the artefact, which indicates the two-way influence between the artefact and the user. The analysis indicates that students instrumentalize models by thoroughly working and dealing with them in different ways using both techniques of pragmatic and epistemic values. In the empirical example, the agar is a physical artefact serving as a model in the interaction with the students, illustrating this complex relation between artefacts as models and models as artefacts. Other kinds of models, such as 2-D illustrations, 3-D figures, and animations, also build on simplifications and idealizations, and the students still need to study a model as an artefact before they can apply it in meaningful ways. Therefore, we find that the instrumental approach also may be fruitful in such situations, which of course require further investigation. Yet the analysis with instrumental genesis indicates that students' interactions with models could be a *modelling genesis*. The lengthy and complex process of instrumental genesis may imply that the genesis of a scientific model as a learning tool also is a complex process, which should be considered when presenting models in science teaching. Moreover, in mathematics education instrumented techniques often have merely pragmatic value and no epistemic value (Artigue, 2002). This is not necessarily the case for the application of models as artefacts but may indicate that the distinction is fruitful when considering for what purposes

certain models are introduced. The transfer of the instrumental approach from mathematics to biology or broader science education remains underexplored, particularly with respect to how the notion of techniques can be meaningfully reinterpreted in relation to science models and practices. Based on the analysis and discussion, we find that it may be interesting to investigate further to what extent knowledge of instrumental genesis is transferable for studying students' modelling genesis.

Conceptual And Methodological Distortion In Pseudoscientific Theories: How Do Undergraduate Students Recognise These Problems?

Pseudoscience is an issue that is widely disseminated in society. Its strategies involve mimicking elements of the sciences, but they can present various problems of reasoning. Thus, we aimed to analyse the understanding of undergraduate students in Biological Sciences about the conceptual and methodological distortions presented in the following pseudoscientific constructs: Flat Earth (FL); Intelligent Design (ID); Blood Type Diet (BD); Epigenetic Modulation to Eradicate Diseases (EM); and Homeopathy (HO). The information analysed was collected from an activity developed with 51 students on the Biological Sciences degree course at a Brazilian public university. From our analysis, we identified that the students recognized conceptual distortions in pseudoscientific statements as a type of concept parameters alteration or concept emptying. With regard to methodological distortions, they identified the use of a method unsuited to the issue and the inability of pseudoscientific practices to provide scientific proof. Furthermore, we observed that even though the students brought up other problems with pseudoscience reasoning, they focused mainly on the conceptual or methodological ones. We would argue that in order to understand pseudoscience, science education that considers science as a social practice should be provided, as this would help people to understand science as a social practice.

Keywords: Qualitative Research, Pre-service Teacher Education, Science Education, Undergraduate Learning.

Introduction

Pseudoscience's acceptance is strongly related to one's distorted conceptions of science and scientific activity, and, as both teachers and students have shown these types of distorted conceptions, there is an urgent need to raise discussions on the subject (Rodrigues et al., 2019).

Authors such as Shermer (2011) and Pilati (2018) describe that pseudosciences generally seek to mimic characteristics of scientific practice. It is common, for example, for these pseudosciences to distort scientific theories or present methodological processes that are inconsistent with their claims.

The growing presence of pseudoscientific discourses in media and everyday life reinforces the importance of developing critical scientific literacy among students. When individuals lack a clear understanding of how scientific knowledge is produced, validated, and communicated, they may become more susceptible to accepting claims that superficially resemble science but lack empirical and methodological rigor. Therefore, fostering critical analysis skills becomes a central objective of science education, enabling students to evaluate evidence, recognize fallacies, and question unfounded assertions.

Another point regarding pseudoscience is the discussion about the need to establish criteria for demarcating science from pseudoscience. For Fasce and Picó (2018), it is essential to define such criteria. However, some criteria may not be sufficient for the desired differentiation, since there are multiple areas of knowledge within the sciences themselves, with diverse methodological issues and internal processes that are receptive to criticism, making a "universal" demarcation unfeasible.

In this sense, Olivé (2004) argues that demarcating the boundaries between science and pseudoscience is not a simple matter and involves aspects that go beyond the methodological characteristics of the sciences. From this perspective, he also argues that it is not necessary to categorically demarcate science and pseudoscience, but rather to provide the population with elements to understand pseudoscience based on the philosophical, epistemological and sociological aspects related to its propositions.

From this perspective, rethinking science teaching to make science explicit as a social practice (Longino, 2002) can offer tools for a better understanding of both science and pseudoscience. Considering these discussions, this work aims to analyse the understanding of undergraduate students in Biological Sciences about the conceptual and methodological distortions presented in pseudoscientific constructions.

Methodology

This paper presents a qualitative research (Erickson, 2012) that aimed to analyse the activities carried out by fifty-one students from the Biological Sciences degree course at a public university in the state of São Paulo, Brazil. The activity was carried out in groups of up to five people, totalling 20 groups. Each group received a text with statements that supported and statements that refuted one of the following five pseudosciences: Flat Earth (FL); Intelligent Design (ID); Blood Type Diet (BD); Epigenetic Modulation to Eradicate Diseases (EM); and Homeopathy (HO) (Fasce & Picó, 2018). Thus, each pseudoscience was analysed by four groups. The groups were instructed to identify the main reasoning problems contained in the claims that supported the pseudoscience. We selected the groups that, in addition to identifying the reasoning problem, justified their response, totalling 16 groups. From this organization and selection, our categories of analysis emerged.

Although there were other reasoning problems related to pseudoscience, such as the use of authorities from outside the domain of science or from another area, the focus of this analysis was on the "conceptual distortion" reasoning problem, defined in the activity as the "appropriation of an existing concept in the wrong way, use of valid theories and knowledge to give the impression of veracity, However, the concepts are misrepresented, either by emptying the concept or by altering some fundamental parameters" and "methodological distortion" described as "using a method that is inappropriate to the problem and does not provide credible answers", as these were the reasoning problems most identified by the groups.

As a data analysis methodology, each author of the study, based on the theoretical framework selected in the construction of this study, identified the elements in the responses of the student groups. Subsequently, in a collective meeting, the authors evaluated the classifications made and validated the analyses, proposing a consensus among the categories that will be presented in the discussion section of the results.

Results And Discussion

In this work, we have analysed all the answers prepared by the 16 selected groups, and although the problems of conceptual distortion and methodological distortion occur in all the pseudoscientific practices listed, considering the length of this work, we have chosen to present only a few examples to illustrate our results.

Regarding the student groups' responses to conceptual distortion, the answers were organized into two categories: Fundamental concept parameters alteration; and Concept emptying.

Of the 16 groups, 8 characterized conceptual distortion as fundamental concept parameters alteration, so passages were included that indicate that pseudoscientific constructions mimic scientific concepts that already exist in the sciences in order to induce veracity.

In the case of ID, a conceptual distortion would be to state that mutations, which are key aspects of the Synthetic Theory of Selection, are deleterious and do not generate major evolutionary innovations, i.e. the innovation would result from the increase in the number of bases in the DNA sequence. Group 9's answer describes that the conceptual distortion comes from the fact that the ID considers mutation only as a deleterious characteristic.

> “They use concepts in an incomplete way, [mutations] can be deleterious, but they can also not be.” (Group 9’s response to ID).

The random changes (mutations) generally damage the genetic code, but there is a possibility that these mutations can contribute to innovative or improved biomolecular functioning, even if there is no clarity on the fitness gains that each evolutionary step (mutation) can bring.

The text mentions that “the dilution (of the homeopathic remedy) generally follows a scale, such as the decimal scale (1 : 10) or the centesimal scale (1 : 100), where each dilution stage is accompanied by succussion to potentiate the remedy effect”. Commonly used in laboratory areas, succussion (agitation) is a concept to describe the process of stirring to homogenize a mixture, a standard process in the production of various medicines. Group 6 was able to identify the conceptual distortion presented in the statements:

> “It uses the concept of vigorous agitation as an enhancer of a state of agitation of the molecules.” (Group 6's response to HO).

For Goldacre (2015), this statement is an attempt to associate with pre-existing scientific concepts, so when students signal this term, they recognize a false relationship between the concept and its real application.

Of the 16 groups, 8 characterize the conceptual distortion as Emptying the concept, including passages that indicate pseudo-scientific constructions that cite an accepted scientific concept but completely change its meaning. BD uses the concept of the ABO blood group system to propose dietary adjustments for individuals based on the premise of ancestral genetic inheritance (Cusack et al., 2013). As highlighted by the groups, the claims of this pseudoscience are not supported, as there is no relationship between blood type and the indication of the best “diet” for healthy individuals.

> "[...] each blood type carries information about the behaviour of our ancestors [...]. Weight loss would be associated with a reduction in the consumption of ultra-processed foods and an increase in the consumption of fruit and vegetables" (Group 11's response to BD).

The strategy adopted by BD of using the concept as scientific jargon with the intention of inducing a more scientific language, according to Pilati (2018) and Shermer (2011), is quite common in pseudosciences. Something similar occurs in EM, in which it is claimed that it is possible to modulate genes through food in order to eliminate diseases in their descendants.

> "The idea of a healthy diet, because it's known that healthy diets prevent diseases" (Group 9's response to EM)

Therefore, the claim that "changing our diet can lead to a global reprogramming of the chemical signals that reach our cells and activate (or deactivate) our genes" is an understatement of what epigenetic modulation really is.

In relation to the responses from the 16 groups, only 13 of them identified methodological distortion. The answers were organized into two categories: Use of a method unsuited to the problem, identified by 9 groups; and Inability to provide scientific proof, identified by 4 groups.

Thus, the category Use of a method unsuited to the problem included responses justifying the reasons why a particular method was not sufficient to support the pseudoscientific claims.

In the case of HO, the groups signalled that although they follow some tests to publish their results, they often ignore important steps with the control groups to understand the efficacy of their drugs.

> "The work done (on homeopathy) that corroborates this is not distinguishable from the placebo effect, so there are no methodological criteria that allow the questions asked to be answered." (Group 6's response to HO)

According to Goldacre (2015), homeopathy does not use publicly recognized standards to prove the results of its medicines and is also opposed to these allopathic processes. Thus, when they call a homeopathic medicine effective, they are unable to differentiate its results from the well-known placebo effect.

In the Inability to provide scientific proof category, the discussion on ID came up. This pseudo-scientific practice has created a method to justify the action of "higher forces" to create more complex organisms.

The concept of Specific Complexity is considered by its creators to be a tool for probabilistically identifying signs of ID. It is therefore possible to demonstrate the inability of evolutionary mechanisms to select or generate highly complex systems, inferring that there is design (superior forces).

> "The concept of specific complexity. They create it (specific complexity) as a method to validate what they themselves say" (Group 10's response to ID)

Although group 10 did not delve into the specifics of pseudoscience, they recognized that the specific complexity (superior force) is not verifiable, and was only developed to validate the claims made by the ID.

Similarly, Shermer (2011) describes that although it is the practice of the sciences to propose new methodologies, these new methodological proposals need to be validated by scientific communities, something that pseudosciences don't do.

Conclusion

Based on the research's analysis, we observed that conceptual distortions were understood by these students as a process of fundamental concept parameters alteration or as concept emptying. In addition, when they analysed the methodological distortions presented by pseudoscientific practices, they identified the use of a method that was inappropriate to the problem proposed by these practices or the inability to provide scientific proof based on the method chosen by a given pseudoscience.

Student groups' interpretations indicate that it is possible to discuss epistemological aspects of pseudosciences without necessarily creating universal demarcation criteria, as proposed by Olivé (2000). We observed that even though they brought up other aspects, the students focused mainly on conceptual or methodological ones. In addition, we infer that the focus given to concepts during school and university training could make this aspect closer to the students' reality, and therefore easier to analyse. Something similar may have occurred as a methodological distortion, since these aspects are normally associated with compulsory subjects in the curricula of Biological Sciences courses in Brazil.

Thus, we believe that our activity gave students the opportunity to analyse other reasoning problems that explore epistemological elements of science. Therefore, we advocate providing science education that considers science as a social practice (Longino, 2002), as this would help people understand the epistemological, philosophical and social elements that surround the processes of science construction, which would help them identify pseudo-scientific constructions in society.

Finally, it should be noted that, as this is a qualitative study, our results refer to the class analysed and may serve as a parameter for future discussions on pseudoscience, such as the psychological and social reasons that lead people to believe in pseudoscientific practices.

Reclaiming Attention To Attitudinal Dimensions In Science Education

Strand 2 focuses on science learning as a multidimensional endeavour extending beyond conceptual understanding. Research in this strand examines how learners think, feel, value, experience, and interact while engaging with science-related issues. It brings together theoretical, methodological, and empirical work addressing the *cognitive, affective, aesthetic*, and *social dimensions* of science learning, while building on the longstanding tradition of attitudinal research in science education. Indeed, research within the strand draws on cognitive science, educational psychology, and the sociology of education. The contributions included in this volume reflect the breadth of research represented within the strand. Collectively, they demonstrate that learners' interests, emotions, values, identities, aesthetic experiences, and social interactions are integral components of engagement with science.

Across different educational levels and countries, including Spain, Germany, Denmark, Turkey, and Italy, the contributions explore how these dimensions shape learning processes and how educational interventions can support more meaningful and sustained participation in science. Learning is examined in diverse settings, including classrooms, out-of-school laboratories, natural environments, and collaborative educational programmes and interventions. *Authenticity* emerges as a particularly important aspect of science education. Learning environments that connect scientific ideas to real-world contexts, societal challenges, or personally meaningful experiences are shown to support engagement and participation. This emphasis on authenticity aligns with broader efforts in science education research to bridge the gap between *school science* and learners' *lived experiences*.

A prominent theme across the contributions concerns the *affective dimensions of science learning*. Several studies investigate factors that influence learners' interest, motivation, self-efficacy, and beliefs about learning. These papers address the longstanding challenge of maintaining and strengthening learners' engagement with science across educational stages. They highlight the importance of designing learning experiences that connect scientific content to learners' interests, experiences, and perceptions of relevance. The findings suggest that affective factors are central to participation, persistence, and achievement in science learning.

Another significant theme is *the role of emotions in scientific thinking and inquiry*. The contributions extend affective research by examining epistemic emotions associated with knowledge construction, problem solving, and scientific discovery. This focus reflects growing recognition that emotions are closely intertwined with cognitive processes. Curiosity, surprise, uncertainty, satisfaction, and other epistemic emotions influence how learners engage with scientific questions, evaluate evidence, and construct explanations. The development of analytical tools for identifying and visualising such emotions also points to emerging methodological innovations in this area of research.

A further theme concerns the *aesthetic dimensions of science education*. While aesthetic engagement has received less attention than affective outcomes, several contributions highlight

the potential of sensory and experiential forms of engagement with science-related issues to strengthen learners' connections with science. These include supporting appreciation of biodiversity and encouraging reflection on relationships between humans and other living beings.

Taken together, the contributions in this strand present science learning as a complex process involving cognition, emotion, aesthetics, values, identity, and social participation. As a whole, the volume advances understanding of science learning beyond narrow cognitive perspectives. The contributions offer valuable insights into how science education can support learners in engaging meaningfully and responsibly with science in contemporary society. Therefore, the strand *Learning Science: Cognitive, Affective, Aesthetic, and Social Aspects* is well positioned to contribute to ongoing discussions about the future directions of science education research.

ESERA 2025 Copenhagen

Factors Influencing The Aesthetic Appreciation Of Biodiversity: An Exploratory Study With Pre-Service Teachers

António Almeida[1], Irene Prieto [2] and García Fernández [3]
[1]Instituto Politécnico de Lisboa /EDUNOVA.ISPA / CICS.NOVA, Universidade Nova de Lisboa, Portugal
[2]University of Castilla-La Mancha, Faculty of Education of Cuenca, Spain
[3]University of Castilla-La Mancha, Faculty of Education of Ciudad Real, Spain

The present study aimed to explore the factors influencing the aesthetic appreciation of landscapes with relevant biodiversity, emphasizing the role of scientific knowledge. To achieve this, a questionnaire was administered to a group of pre-service teachers of a Portuguese institution. Participants were asked to rate their preferences for four landscapes with different biodiversity using a Likert scale and to provide justifications for their choices. Two landscapes featured native vegetation, while the other two included exotic and invasive vegetation. The teachers were divided into two groups, with only one group participating in a session focused on the scientific exploration of the landscapes prior to completing the questionnaire. The results showed that the group attending the session demonstrated a greater preference for landscapes with native vegetation, more frequently using scientific arguments to justify their aesthetic appreciation. Nevertheless, other important factors influencing landscape appreciation were identified, such as the presence of specific characteristics of the species and the participants' familiarity with the presented landscapes. Thus, deepening scientific knowledge about biodiversity and engaging directly with landscapes appear to positively influence participants' preferences. The link between higher aesthetic appreciation and the desire for nature preservation seems plausible, although further research is needed.

Keywords: Aesthetic Appreciation, Biodiversity, Pre-service teachers

Introduction

Recent research has increasingly highlighted the emotional and perceptual benefits associated with natural environments. Empirical evidence suggests that natural landscapes, particularly those with minimal human interference, tend to elicit stronger emotional responses (Bethermy & Corraliza, 2019). Within landscapes, specific environmental features play a decisive role in determining preferences, as the presence of water and vegetation is consistently associated with higher levels of appreciation, whereas predominantly sandy or rocky environments tend to receive lower preference ratings (Corraliza, de Frutos & Moll, 2023).

According to Tieskens *et al.* (2017), nearly all rural areas in Europe have been shaped or modified by human activity and can be regarded as cultural landscapes, many of which are now recognized as cultural heritage, indicating that the concept of a "natural landscape" scarcely exists outside a few highly restricted areas. Even in ostensibly natural landscapes, the presence of exotic species is common, further demonstrating that the "human touch" is nearly ubiquitous.

Understanding the factors that influence the aesthetic appreciation of biodiversity can be relevant to uncovering the reasons that motivate people to act in favour of nature preservation. This knowledge can also be valuable for both pre-service and in-service teachers, as it can assist in defining strategies to foster positive attitudes toward nature among students.

According to Carlson (2009), there are two forms of aesthetic appreciation, regardless of the object in question. One of them can be referred to as "free beauty," where the individual simply appreciates the object based on its formal characteristics. The other form, known as "dependent beauty," assumes that knowledge about the object is fundamental to its appreciation. This second

form, although controversial in the field of aesthetics, is particularly relevant to science education, as it links the appreciation of a natural object to the scientific knowledge one has about it.

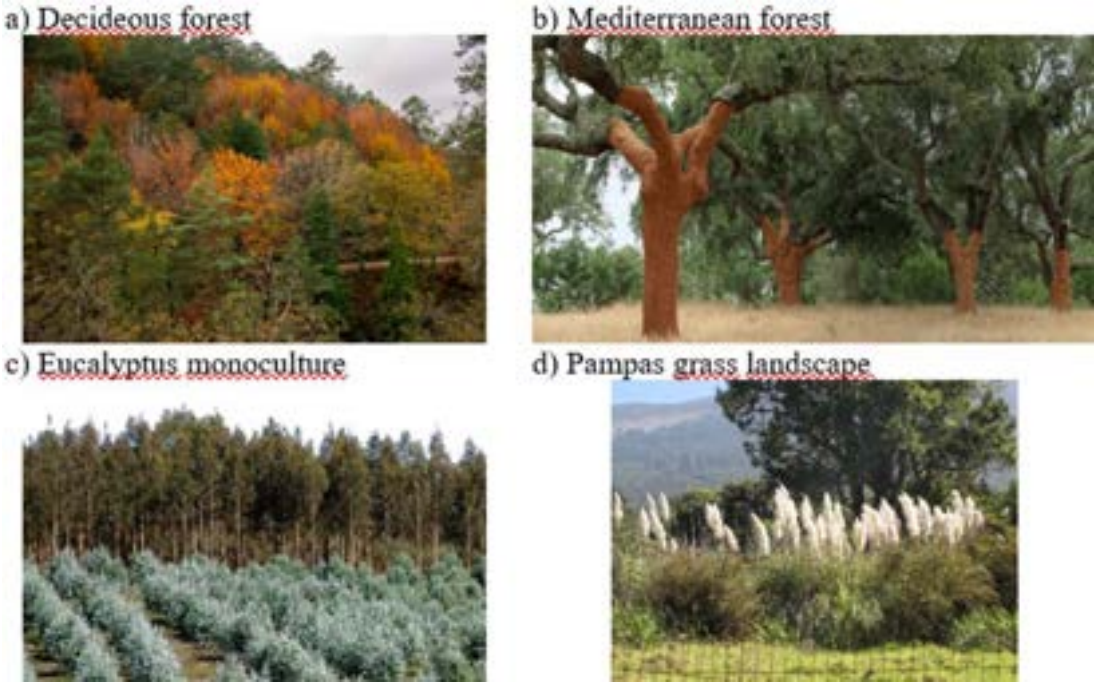
This perspective, supported by diverse authors such as Frank Muir, Aldo Leopold, and Holmes Rolston, all leading figures in the field of environmentalism, is based on the following principle: the more we know, the more we can observe, admire, appreciate, and ultimately, strive to preserve. As Rolston III (1995) explains, this knowledge allows one to find beauty where it was not previously perceived: "when you understand the harshness of an arid or an alpine climate, you will find the plants' clinging to life aesthetically stimulating" (p. 378).

For this reason, Thompson (1995) argues that the appreciation of nature cannot rely solely on subjective elements but must also include objective elements that underpin this appreciation. From this perspective, the aesthetic appreciation of nature requires scientific knowledge, particularly in fields such as geology, biology, and ecology. This knowledge can also help put destructive events, such as fires, into perspective. According to Brady and Prior (2020), understanding their importance to forest ecology allows us to recognize the value of something that was previously seen only as a force of destruction, turning vibrant landscapes into desolate ones.

The Present Study Area

The present study involved pre-service teachers from a higher education institution in the Lisbon metropolitan area, Portugal. It aimed to achieve the following objectives:

1. To identify the factors that may influence the aesthetic appreciation of landscapes with diverse biodiversity elements.



2. To examine the influence of scientific knowledge on the appreciation of landscapes and of the biodiversity elements they contain.

3. To discuss strategies that enhance the aesthetic appreciation of nature, which may prove significant in motivating for its preservation.

Methodology

The present study had an exploratory nature due to the lack of similar research at least in Portugal. A total of 93 pre-service teachers participated (83 – 89.2% female), all enrolled in primary education training courses (master's degree), with a mean age of 23.9 years (SD = 6.067). The data collection instrument was a questionnaire that, in addition to sociodemographic information, presented four photographs of landscapes with varying biodiversity characteristics. Two of the photos featured native Portuguese vegetation: a) A deciduous forest typical of northern Portugal, minimally affected by human intervention; b) A Mediterranean forest (known as *dehesa* or *montado* in Portuguese), a centuries-old human-shaped landscape where nature is sustainably managed. The other two photos depicted exotic and invasive vegetation: c) A eucalyptus monoculture, a tree from Australia that depletes the soil and prevents the establishment of other plant species. Despite these negative impacts, it is widely cultivated due to its rapid growth and is used for paper pulp and timber in the construction industry; d) A landscape dominated by pampas grass (*Cortaderia selloana*), a plant from South America introduced for ornamental purposes that has become invasive due to its rapid propagation (Figure 1).

Figure 1. The four landscapes (a,b,c and d) appreciated by the pre-service teachers.

After the presentation of each photo, the questionnaire included the following questions: 1. According to your preference, rate this landscape on a scale of 1 to 5, where 1 means "I do not like it" and 5 means "I like it very much"; 2. Justify your answer. The questionnaire was validated by two experts in Didactics of Science and considered appropriate for the outlined objectives. The students were randomly divided into two groups (G1 = 48 and G2 = 45), and all completed the questionnaire. However, the students in G2 participated in a prior 45-minute session during which the landscapes were analysed from a scientific perspective. In this session, the main species present in each photo were identified, along with their classification as native or exotic. Additionally, the positive and negative impacts of these species on ecosystems and humans were analysed. For each landscape, the median and mean values of the preference ratings were calculated for each group. To determine if the differences in appreciation were statistically significant, the Mann-Whitney U test was applied with a significance level of 0.05. The justifications provided by the students were subjected to content analysis and categorized according to the nature of the reasons given. The incidence of the different reasons across the two groups was counted and presented in percentages.

Results

The degree of preference expressed for each landscape by each group (median, mean, and standard deviation) is summarized in Table 1, along with the verification of statistically significant differences.

Table 1. The appreciation of the four landscapes by the two groups of participants.

	Median		Mean		SD		
	G1	G2	G1	G2	G1	G2	*p.*
Landscape 1 - Decideous forest	4	5	3.97	4.40	0.956	0.914	0.01
Landscape 2 - Mediterranean forest	3	4	3.14	3.73	1.110	1.268	0.01
Landscape 3 - Eucalyptus monoculture	3	3	3.16	2.73	0.974	1.175	0.04
Landscape 4 - Pampas grass landscape	4	3	3.68	3.26	1.013	1.213	0.09

The results show that participants in G2, who attended the scientific session on landscape analysis, exhibited a stronger preference for landscapes dominated by native vegetation than those featuring exotic and invasive species. The differences between the groups were statistically significant for three of the four landscapes. The exception was the landscape dominated by pampas grass, which still received a higher median score (four, instead of three) in the group that did not attend the session.

The analysis of the participants' justifications from both groups is presented briefly due to space constraints. For Landscape 1 (Deciduous Forest), the responses were predominantly positive. The variety of colours in the landscape was the most frequently cited reason for landscape appreciation by participants in both groups (G1: 72.9%; G2: 57.8%). Additionally, several participants in G2 noted that it represented an ecosystem with native vegetation of high biodiversity (27.9%). The few negative justifications highlighted only one issue: one participant from each group mentioned the excessive vegetation density.

While predominantly positively appraised, Landscape 2 (Mediterranean Forest) also elicited some negative aspects from the participants. Significantly, 20% of G2 participants emphasized the integration of natural and cultural elements within the landscape, a perspective not expressed by G1 participants. The familiarity of the landscape was mentioned by participants from both groups (G1: 8.3%; G2: 20%). In G1, 16.6% of respondents identified the cork oak (Quercus suber) as a beautiful tree, whereas 11.1% of G2 participants emphasized the tree's tolerance of other species. Negative aspects were more prominent in G1, where 20.8% of the participants stated that stripping the tree of its bark reduced its beauty, and 18.8% considered the landscape ordinary. Interestingly, no G2 participant deemed the cork oak's debarking process as negative. This may be because in the session it was highlighted that cork harvesting is a key factor in the preservation of this species in Portugal.

Landscape 3 (Eucalyptus monoculture) received the most negative appreciations, especially from G2 participants. Among G2 respondents, 35.6% pointed out that eucalyptus is an invasive species that depletes resources (soil and water) and is highly flammable, reasons mentioned by only 4.2% of G1 participants. In G1, 29.6% described the landscape as monotonous with little colour variation. Positive justifications highlighted the symmetry in the arrangement of the trees in both groups (G1: 4.2%; G2: 11.1%), with an additional 10.4% of G1 participants noting that the landscape conveyed tranquillity.

Landscape 4 (Pampas grass landscape) garnered more positive than negative assessments from both groups, with this trend being more evident among participants in G1. In G1, 22.9% highlighted the beauty of the pampas grass, a justification also noted in G2 (13.3%). Both groups appreciated the variety in the landscape (G1: 16.7%; G2: 11.1%). Negative justifications were primarily provided by G2, which pointed to the presence of an invasive species (20%) or mentioned its toxicity (4.4%).

Discussion And Conclusions

The study findings demonstrate that scientific exploration of landscape characteristics significantly enhances their aesthetic appreciation. Differentiating between native, exotic, and invasive species, coupled with understanding their ecological and human impacts, proved highly influential. Consequently, this research underscores the crucial role of scientific knowledge in appreciating landscapes and emphasizes the need for a deeper understanding of natural aspects within both classroom settings and outdoor experiences.

Nevertheless, this knowledge is not the only factor contributing to such appreciation. The features of the observed species, referred to as "free beauty" in the introduction section, also played a role

and seem to explain the high appreciation of pampas grass by both groups, though more markedly in the group that did not experience the scientific exploration of landscapes. In essence, the aesthetic appeal of this invasive species seems to somewhat diminish its perceived negative impacts. Therefore, future educational exploration of the present issue should place greater emphasis on the detrimental consequences of this species.

Experiential factors exert both positive and negative influences on landscape appreciation. Familiarity, when associated with positive past experiences, can significantly enhance appreciation. Conversely, when perceived as excessive and lacking novelty, familiarity can have a detrimental effect. While less frequent, some participants expressed feelings of insecurity in landscapes perceived as visually enclosed, a phenomenon previously documented in other research (Ulrich, 1993; Kirillova *et al.*, 2014). The perception of human intervention in landscapes proved to be a nuanced factor, eliciting both positive and negative responses from participants, with no significant differences between groups. This was exemplified by the presence of some symmetry in the arrangement of eucalyptus trees, which was appreciated differently by individuals.

As stated initially, this study is exploratory in nature, but it appears to confirm the importance of scientific exploration for a more effective appreciation of landscapes and biodiversity in general. This aspect should receive special attention in the training of science teachers. The connection between increased knowledge and the desire to preserve nature requires further and more targeted investigation, but the present study suggests that this relationship may be plausible.

Theories Of Intelligence And How They Depend On Students' Definition Of Intelligence

Laura Goldhorn[1], Thomas Wilhelm[1] and Verena Spatz[2]
[1]Goethe-University Frankfurt, Germany
[2]Technical University of Darmstadt, Germany

The theory of growth and fixed mindsets provides a framework for understanding how beliefs about intelligence influence learning and academic performance. A growth mindset reflects the belief that intelligence can be developed through effort and persistence, whereas a fixed mindset views intelligence as innate and unalterable. To identify whether individuals have a more growth-oriented or more fixed view, the Theories of Intelligence Scale (Dweck, 2000) is used in most reported studies. This scale contains statements like, "You have a certain amount of intelligence and really can't do much to change it." However, we consider it a limitation that these mindset surveys often ask for students' views on the malleability versus fixedness of intelligence but do not define intelligence itself. The present study investigates how German middle-school students' definitions of intelligence may influence their physics-specific mindset. In addition to the mindset survey, students were asked about their definition of intelligence, and the findings reveal distinct differences that are in line with a similar study by Limeri et al. (2020). Students associating intelligence with knowledge were more likely to agree with growth mindset statements, potentially reflecting the perceived adaptability of knowledge. In contrast, those defining intelligence as ability demonstrated more variability in their mindset responses, suggesting differing perceptions of the fixedness or malleability of abilities. Additionally, reasoning power emerged as the most common definition of intelligence, highlighting its role as a widely recognized yet complex concept within cognitive performance. The study contributes to refining the theoretical understanding of mindsets and supports the need for further exploration of how definitions of intelligence influence the measurement of mindsets and what this implies for measuring and interpreting students' learning attitudes, particularly in subject-specific contexts.

Keywords: Belief Measurement, Educational Psychology, Learning Theories

Motivation

The concept of growth and fixed mindsets provides a framework for understanding how individuals perceive their abilities and potential. These mindsets are grounded in beliefs about the nature of intelligence and abilities, that people hold unconsciously. A fixed mindset is characterized by the belief that intelligence is innate, while a growth mindset reflects the idea that intelligence can be developed through effort and learning. These unconsciously held beliefs can significantly influence students' engagement in learning and show an impact on academic outcomes (Dweck, 2000; Yeager & Dweck, 2020). Success in school is not solely dependent on mindsets, however, students with a fixed mindset tend to give up more easily when faced with difficulties or setbacks. In contrast, students with a growth mindset are more likely to choose challenging tasks (Rege et al., 2021) and exhibit a mastery-oriented behaviour in learning situations (Blackwell et al., 2007). Some studies even show better academic results for students with a growth mindset (Paunesku et al., 2015). In general, a growth mindset can be considered supportive in an academic context.

While the majority of mindset research focuses on beliefs about general intelligence, some studies suggest that mindsets can manifest in specific domains (e. g. Hong et al., 1999). Particularly, in STEM fields, a tendency towards a more fixed view has been reported (Dweck, 2008; Leslie et al., 2015; Rattan et al., 2012), which aligns with similar psychological concepts such as the 'talent habitus' (Archer et al., 2020). However, whether the studies target a general or domain-specific

mindset, they usually inquire about beliefs related to intelligence. Mindset questionnaires typically include items like "You have a certain amount of intelligence and really can't do much to change it" (Dweck, 2000), which assess beliefs about the malleability versus fixedness of intelligence but do not define intelligence itself.

Limeri and colleagues (2020) conducted a study with undergraduate students, analysing their definitions of intelligence in relation to their growth mindset scores. They found a significant difference in students' mindset scores based on a dichotomous definition of intelligence: students who defined intelligence as knowledge were more likely to believe in the incremental nature of intelligence than those who defined it as abilities. This may lead to inaccurate mindset assignments, as students who define intelligence as knowledge might answer growth mindset items affirmatively but not exhibit the behaviour patterns typically associated with such a mindset (Limeri et al., 2020). In another study, researchers compared first year STEM students' answers to the typical mindset questionnaire based on the *Theories of Intelligence Scale* depending on their level of agreement to different definitions of intelligence (Diederich & Spatz, 2024). And Sun et al. (2021) observed differences in surveyed mindset patterns when students referred to the model of fluid or crystalline intelligence. The conclusion is similar: measuring mindset based on the Theories of Intelligence scale may not lead to reliable mindset assessment depending on students' intelligence definition.

This research focuses on domain-specific mindsets in physics with the aim to gain a better understanding of subject-specific beliefs. Therefore, a physics-specific mindset questionnaire has been developed and evaluated. This tool contains items of the *Theories of Intelligence Scale* but also incorporates questions about students' beliefs regarding *Giftedness in Physics* and the impact of *Effort in Physics* on learning success. Using these scales, students can be classified into three mindset types: a physics-specific growth mindset (which supports growth mindset statements related to intelligence, giftedness, and effort in physics), a fixed mindset based on general intelligence beliefs, and a fixed mindset based on giftedness in physics (the belief that physics talent predicts success in learning the subject). Students whose answers do not fit any of the three mindset categories are classified into the mixed mindset type (Goldhorn et al., 2023; Goldhorn et al., 2022). Due to the design of this survey instrument, our physics-specific mindset research does not focus on students' intelligence beliefs alone, but these beliefs remain a key element. The influence of students' definitions of intelligence in this context, however, is still unknown.

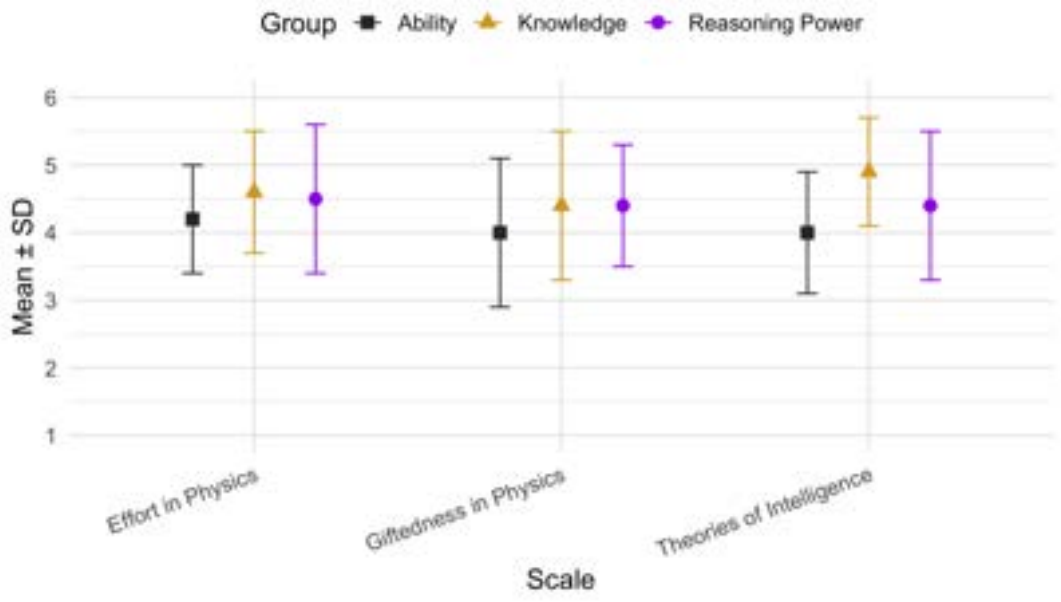
Research Method

The data presented here aims to investigate differences in students' physics-specific mindset patterns based on their definition of intelligence and is part of a paper-based growth mindset intervention study with N = 210 participating German middle-school students. Before they got to work on the intervention material, students completed the physics-specific mindset questionnaire (Goldhorn et al., 2023) and were asked to define intelligence. First, they answered a single-choice item with the following options: "Intelligence is the sum of what I know," "Intelligence is what I can do," and "Intelligence is reasoning power." The first two options are based on the study by Limeri et al. (2020), while the option about reasoning power is derived from interview studies conducted during the development of the physics specific mindset questionnaire (Spatz & Goldhorn, 2021). In the second step, students were given the opportunity to write their own definition of intelligence if none of the provided options aligned with their understanding.

Results

To simplify the following report and discussion of the results, the intelligence definitions are categorized as reasoning power, knowledge, and ability. A total of N = 191 students answered

the single-choice item about intelligence: 55 % agreed with the definition of reasoning power, 25 % chose the option ability, and 20 % selected knowledge. For N = 98 students, the intelligence item could be matched with the growth mindset questionnaire.



Only the items of the Theories of Intelligence Scale contains the term ‘intelligence’, therefor possible influences of students’ intelligence definitions are expected to appear mainly on this part of the mindset questionnaire. Table 1 presents the mean values and standard deviations for all three scales (Likert scales from 1 to 6, higher values indicating a more growth mindset) that are part of the mindset questionnaire (see Goldhorn et al. (2023) for more details of that mindset questionnaire and the items used). Figure 1 provides an additional visual display on possible group differences based on the mean values and standard deviations.

Table 1: Comparing mean values and standard derivations for each scale of the mindset questionnaire, according to students' intelligence definitions.

Mindset scale / Intelligence definition	Theories of Intelligence ($\boldsymbol{M \pm SD}$)	Giftedness in Physics ($\boldsymbol{M \pm SD}$)	Effort in Physics ($\boldsymbol{M \pm SD}$)
reasoning power	4.4 ±1.1	4.4 ± .9	4.5 ± 1.1
knowledge	**4.9 ± .8**	4.4 ± 1.1	4.6 ± .9
ability	**4.0 ± .9**	4.0 ± 1.1	4.2 ± .8

As expected, a one-way ANOVA reveals a significant effect of students’ intelligence definition, $F(2, 95) = 3.89$, $p = .024$, $\eta^2 = 0.76$ for the *Theories of Intelligence Scale*. Post-hoc comparisons using the Bonferroni correction show that students who define intelligence as knowledge ($M = 4.92$, $SD = .83$) score significantly higher ($p = .002$, $d = .90$) than students who define intelligence as ability ($M = 4.03$, $SD = .95$), i.e. they believe more in the changeability of intelligence. For the other scales, no statistically significant differences can be reported.

Figure 1: Visual display of the mean values and standard deviations of the three scales Effort in Physics, Giftedness in Physics and Theories of Intelligence according to students’ intelligence definitions.

The participating students could also describe intelligence in their own words, and 31 students took that option. Eighteen of them added their own description to their chosen option, for

example, two student who chose *reasoning power* wrote "IQ score" as their own description of intelligence. In general, students' descriptions of intelligence show a broad variety in their perception of intelligence. They include different perspectives from "intelligence is the ability to learn something new and how fast you can learn" to "intelligence means being smart" and "intelligence means how distinctive your brain is".

In our research regarding physics-specific mindsets the mindset questionnaire is used to assign students to different mindset types (see Goldhorn et al. (2023)). To examine possible influences of students' definition of intelligence on those mindset assignments, Table 2 presents the mindset distributions based on students' intelligence definitions. From all N = 98 students, 41 % were assigned to the physics-specific growth mindset, 17 % aligned with the criteria for the fixed mindset 'general intelligence', and 13% identified with the fixed mindset 'giftedness in physics'. The remaining 29% were classified as having a mixed mindset. Slightly more than half of the students who define intelligence as knowledge (53 %) are assigned as holding a growth mindset, while only 24 % of the students who define intelligence as ability are sorted to this mindset group. This difference would support the findings of Limeri et al. (2020) how students' definition of intelligence may shift their mindset assignment, still it is not statistically significant in the presented study.

Table 2: Mindset distribution sorted by students' intelligence definition. Numbers in brackets show the actual numbers of students, N = 98.

Mindset distribution / Intelligence definition	growth mindset (40)	fixed mindset 'general intelligence' (16)	fixed mindset 'giftedness in physics' (14)	mixed mindset (28)
reasoning power (56)	45 % (25)	20 % (11)	9 % (5)	26 % (15)
knowledge (17)	**53 %** (9)	6 % (1)	12 % (2)	29 % (5)
ability (25)	**24 %** (6)	16 % (4)	28 % (7)	32 % (8)

Discussion

Nearly half of the participating students agreed with one of the two concepts of intelligence (knowledge or ability) suggested by Limeri et al. (2020). And sorting students by this dichotomous differentiation of intelligence definition shows a significant difference on how they answered on the *Theories of Intelligence Scale*. The knowledge group is scoring higher (M = 4.92, SD = .83) than the ability group (M = 4.03, SD = .95), which means, these students answer more towards a growth mindset on that part of the mindset questionnaire (see Table 1 and Figure 1). This result aligns with the findings of Limeri et al. (2020). They explained that students who define intelligence as knowledge tend to agree with growth mindset items because it is a common understanding and also the students' experience that knowledge increases over time and can be expanded from any current state. On the other hand, students who define intelligence as abilities show more variation on the mindset scale, depending on whether they view abilities as more fixed or more malleable, which explains more variety on the *Theories of Intelligence Scale* and therefor a lower mean value. Limeri and colleagues conclude that measuring students' mindsets using only the *Theories of Intelligence Scale* might lead to incorrect assignment for those who define intelligence as knowledge. Our sample supports this hypothesis, as the knowledge group scores higher on the theories of intelligence scale and has relatively more students assigned to a physics-specific growth mindset.

The mindset distributions based on students' definition of intelligence (see Table 2) shows differing percentages for the knowledge and the abilities group. Within the knowledge group, there are relatively more students assigned to a growth mindset compared to the abilities group. The student numbers are very small, and the occurring differences are not statistically significant, but they do align with the result about a tendency towards a growth mindset for those students who define intelligence as knowledge. Also, the higher number of students with a *fixed mindset (giftedness in physics)* compared to those with a *fixed mindset (general intelligence)*, especially for students who define intelligence as abilities, supports the findings about a more fixed view of abilities in STEM fields that has been reported by Dweck (2008), Leslie et al. (2015) and Rattan et al. (2012).

The differing scores on the *Theories of Intelligence Scale* related to students' definition of intelligence as knowledge versus intelligence as abilities is the main finding of the presented research. Still, the intelligence definition with the highest level of agreement is reasoning power. This might be equivalent to analytical intelligence and is a very common understanding of intelligence, especially since it aligns with what can be measured in IQ testing (Carpenter et al., 1990). However, there is no specific data on how students really refer to reasoning power and if it is a concept that can be aligned with the mindset theory. From the 31 students who wrote their own description of intelligence the main result is that they show a broad variety and do not refer to a similar concept of intelligence. To clarify students' perception of the word intelligence more qualitative research is needed.

Conclusion

Students' definitions of intelligence seem to influence how they respond to typical mindset statements, such as those found in the *Theories of Intelligence Scale*. In particular, students who define intelligence as knowledge may occur as having a growth mindset, since their perception of intelligence aligns with an incremental concept. But answering the mindset items based on that does not mean they truly believe in an incremental theory of developing one's individual potential. Mindsets are a powerful predictive tool, especially when students can be shifted to a more growth mindset approach to academic learning through mindset interventions. However, to effectively do this, the commonly used instrument with its sole focus on intelligence, should be critically evaluated. Based on our research, domain-specific scales that do not use the term 'intelligence' appear more reliable for identifying students (domain-specific) mindsets and there are no statistically significant differences in a mindset assignment based on all three scales as we propose in our research (Goldhorn et al. (2023)). This finding highlights the importance of using mindset measures that do not focus exclusively on intelligence.

The present study is a small sample, but it supports the hypothesis proposed by Limeri et al. (2020) and Sun et al. (2021): students' definitions of intelligence do matter when investigating mindset and warrant further exploration to ensure all the possibilities regarding mindset research.

ESERA 2025 Copenhagen

Enhancing Students' Interest And Self-Efficacy In Science Through A Large-Scale Teaching Program

Mikkel Bergqvist[1] and Mathias Osmundsen[2]
[1]LIFE Fonden, Denmark
[2]Rambøll, Denmark

Globally, a lack of student interest in science education remains a critical challenge, particularly among primary and secondary students. This poses difficulties in fostering scientific literacy and meeting workforce demands for scientific competencies. Existing programs that enhance interest and self-efficacy often lack scalability, requiring significant resources and time commitments from schools and teachers. To address these limitations, a large-scale teaching program was developed with the aim of improving science education. In 2024, over 135,000 students participated in this program. We study one of the teaching units that are part of the program. The teaching unit includes a 1.5-month in-school teaching unit as well as a one-day out-of-school lab activity and is based on an inquiry and Socio-Scientific Issues approach. It aims to increase student interest, engagement, and self-efficacy in science. A quasi-experimental difference-in-differences design evaluated the unit's impact across 1,951 students in 189 classes. The results show medium effects on situational interest (0.64 SD) and students' ability to relate science to societal challenges (0.55 SD). Confidence in mastering content-specific tasks showed large effects (0.98–1.59 SD), though improvements in general motivation and broader scientific competencies were limited. The study shows that it is possible to develop a scalable approach to science education that combines minimal preparation time from teachers with significant improvements in student outcomes. However, the study indicates that a 1.5-month program alone is insufficient to significantly improve students' general motivation for science or develop general scientific competencies. Future impact evaluations will explore different possibilities for improvement.

Keywords: Interest. Self-Efficacy. Student Engagement

Context And Relevance

Students' lack of interest in science education remains a significant global challenge, particularly among primary and secondary school students. The lack of interest in science poses challenges both in terms of motivating and strengthening students' general scientific literacy and in educating enough students with scientific competencies to meet workforce demands (Griethuijsen et al., 2015).

While various educational programs have demonstrated effectiveness in enhancing students' interest and self-efficacy in science, these interventions often face critical limitations: they are resource-intensive, lack scalability, and demand substantial time commitments from schools and teachers. These constraints often result in participation being limited to a small, self-selecting group of motivated educators and schools, making it difficult to generalize findings or achieve widespread impact.

A recently funded program, organized externally from schools, has developed science teaching units to address these barriers. Unlike many traditional programs, this initiative is designed to be scalable and accessible, reducing demands on teachers' time and resources. This model enables broad participation across diverse schools and student populations. In 2024, more than 135,000 students participated in a teaching unit, most of them in middle or lower secondary schools.

As part of the grant, an ambitious impact evaluation strategy has been developed. The first evaluation was conducted on one of the teaching units targeting 9th-grade students. The teaching unit, based on an inquiry-based approach, consists of a 1.5-month in-school activity and a one-day follow-up out-of-school lab event. The evaluation measured effects on 9th-grade students' interest and self-efficacy in science across different student groups, including those traditionally less motivated in science. Evaluating whether a large-scale science program can effectively improve students' interest and self-efficacy in science is crucial for understanding how more students can access high-quality science education.

Research Questions

The research questions are:

1. Can the teaching unit improve students' situational interest and general motivation for science?
2. Can the teaching unit enhance students' content-specific self-efficacy and their self-efficacy in conducting experiments?
3. Are the program's effects consistent across different student demographics and academic backgrounds?
4. What lessons can be drawn about the scalability of high-quality educational interventions?

Theoretical Framework For The Development Of Outcomes

The impact evaluation is based on seven survey scales measuring students' interest and motivation for science, and science self-efficacy. The survey scales were developed and validated following the seven steps recommended by the Association for Medical Education in Europe (Artino et al., 2014). These steps include a thorough literature review of international research, expert validation by science researchers, cognitive interviews with students, and statistical validation. Our scales draw from established science education research and are adapted to a domestic school context. The scales were statistically validated using the Rasch model with pilot data collected in 2023 (Rambøll, 2024).

Situational Interest

Two scales measure students' situational interest in science lessons. These are based on Hidi and Renninger's (2006) four-phase theory of interest development and inspired by Linnenbrink-Garcia et al.'s (2010) Situational Interest Measures survey instrument. The two scales measure the first two phases of the theory. Are students more inclined to participate and more engaged (called Triggered situational interest), and do they find the teaching unit more relatable and meaningful (called Maintained situational interest) than their regular science lessons.

General Motivation For Science

Two scales measure students' broader motivation for science, focusing on intrinsic and extrinsic motivation. These scales are based on Ryan & Deci's (2020) Self-Determination Theory and adapted from validated scales developed by Makransky et al. (2020) students in grades 4–9 in the relevant country.

Content-Specific Self-Efficacy

Two scales measure students' confidence in mastering the specific academic content covered in the teaching unit. The items broadly align with the program's learning objectives and national science curriculum goals. The scales draw on Albert Bandura's (1997) concept of self-efficacy and related studies (e.g., Fidan & Tuncel, 2021).

Self-Efficacy In Conducting Experiments

This scale measures students' self-efficacy in conducting experiments and evaluates whether the teaching unit impacts their more general scientific inquiry skills. The scale is inspired by Hu et al.'s (2022).

Research Method And Data

The impact evaluation employs a robust quasi-experimental difference-in-differences (DiD) design. In the intervention group, students' interest and science self-efficacy are measured both before and after participating in the teaching unit. Similarly, in the control group, students are measured twice within the same timeframe as the intervention group. The effect is calculated as the difference in outcome development between the intervention and control groups. The design employs a kind of 'wait-list' design, where the control group consist of classes that has enrolled but had not yet started the teaching unit. This approach was used to avoid self-selection bias. Pre-scores show no substantial difference between the control- and intervention groups.

The DiD estimator is calculated using a simple regression model (a two-way fixed-effects model): $Yit = \beta i + \beta t + \rho Tit + uit$

where T equals 0 for the control group and 1 for the intervention group, uit represents the unobserved error term, and βi and βt are individual and time fixed effects. The parameter ρ captures the average causal effect of the teaching unit. As a sensitivity analysis, we tested a model that controlled for students' background variables (gender, ethnicity, grades, parental education, and income). The results did not yield substantially different results compared to the simpler model.

The dataset includes 1,951 students across 189 classes, with each student completing the survey twice. The analytical sample does not differ significantly from the entire population of 9th-grade students in the relevant country.

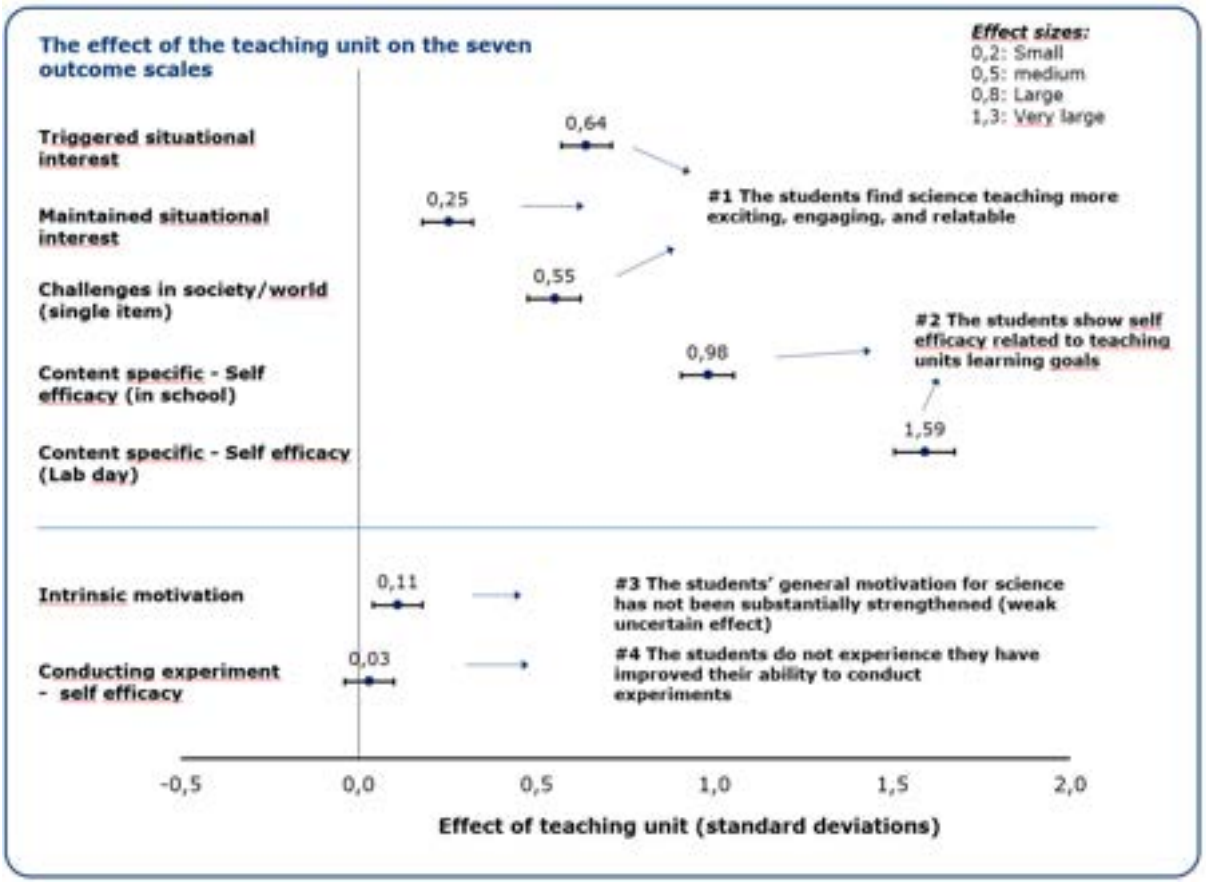
Findings

Figure 1 (next page) shows the results of the impact evaluation.

Improved Interest, Engagement, And Relevance

Students taught in the teaching unit were more interested and showed a greater desire to participate in science lessons compared to students in the control group (Triggered situational interest, medium effect: 0.64 SD). Additionally, students found that the teaching unit, more than regular science lessons, could be related to daily lives (Sustained situational interest, small effect: 0.25 SD). When directly asked if the teaching could be related to societal or global challenges, there was a medium effect (0.55 SD).

Weak Improvement In General Motivation For Science



Despite students finding the teaching unit far more engaging and relevant than regular science lessons, it did not substantially enhance their broader motivation for science (Intrinsic motivation, small uncertain effect: 0.11 SD).

Enhanced Content-Specific Self-Efficacy

Students demonstrated greater confidence in their ability to perform science-related tasks, linked to the teaching units learning objectives (Content-specific self-efficacy, large effect: 0.98–1.59 SD). This outcome is not surprising, as the design does not ensure that the control group worked on the same topic as the intervention group. Other effect studies typically show effects on outcomes that relate directly to the teaching units learning goals (Slavin et al., 2014).

Nevertheless, the effect sizes suggest that students generally achieve the nationally established objectives addressed by the program.

Figure 1: Results Of Impact Evaluation. Standardized effect estimates from regression models, with cluster-robust standard errors at the class level. Lines indicate 95% confidence intervals around point estimates (n=3,876 observations). Source: Rambøll, 2024.

Lack Of Improvement In Conducting Experiment Self-Efficacy

Students did not assess they had improved in their ability to conduct experiments. Regarding the development of broader scientific competencies, such as inquiry skills, either the teaching program was not sufficient, or different approaches are needed.

Equity Across Student Groups

Subgroup analyses revealed that the improvements in situational interest applied across various groups, including students of different genders, ethnic backgrounds, academic performance levels, and socioeconomic statuses. However, students with higher initial academic performance showed slightly greater gains in content-specific self-efficacy.

Discussion Of Findings And Implications

The study shows that it is possible to develop a large-scale science program for teachers that requires minimal preparation time and increases students' interest, participation, and engagement in science. This effect was measured on a representative group of schools and students, and the results demonstrate that the increased interest and engagement in science benefited all student groups, including those who traditionally show less interest in science.

The study indicates that a 1.5-month program alone is insufficient to significantly improve students' general motivation for science or develop general scientific competencies. Future impact evaluations will explore whether multiple teaching units can achieve more general and long-term effects, incorporating survey data and registry-based measures such as 9th-grade exam scores and enrolment in science-focused education.

Observations and interviews with students and teachers collected as part of the impact evaluation suggest that some teachers face challenges in implementing its inquiry-based approach (LIFE Fonden, 2024). Exploring whether more direct support for teachers could lead to broader student outcomes is therefore warranted. Such support could improve the program's implementation and potentially enhance teachers' instruction across other science lessons. To address this, a research project is underway to develop teacher support tools that raise awareness of inquiry-based didactics and enable practice of its key elements during the program.

The teaching program exemplifies a scalable approach to science education that combines minimal time investment from teachers with significant improvements in student outcomes. By addressing barriers to participation and achieving broad reach, the program demonstrates the feasibility of providing student access to high-quality educational experiences. This evaluation provides valuable insights into how scalable models can maintain effectiveness while expanding their impact across diverse educational contexts. However, more research is needed to understand what is required to create broader and more lasting effects.

ESERA 2025 Copenhagen

Enhancing Students' Interest In Chemistry Through Authentic Contexts

Elisabeth Dietel and Timm Wilke
Carl von Ossietzky University of Oldenburg, Chemistry Education, Germany

Despite the immense amount of research findings concerning interest and motivation, the successful transfer of these findings into educational practice could be doubted when studies continuously reveal a lack of interest in STEM subjects, especially in chemistry. The authors take the persistent interest deficit as an opportunity to discuss a new way of promoting interest in chemistry based on a combined conceptual framework that draws from various theories connecting interest, authenticity and constructivism. Aiming to create an authentic, context-structured learning environment to enhance situational interest in chemistry, an out-of-school laboratory course for middle school level using authentic medical cases was developed. During the course, students are confronted with an authentic file of a patient after an asthma attack. Drawing on both medical background information and chemical concept knowledge, they conduct different experiments with carbon dioxide and carbonic acid to eventually diagnose the patient with respiratory acidosis. Before the course, individual dispositions and prior situational interest were assessed with a questionnaire. After the course, situational interest was assessed again, as well as the perceived authenticity of the whole course. Analysing the quantitative data of 155 students, indications arose that the relationship between individual interest and situational interest is partially mediated by perceived authenticity. Perceived authenticity is displayed as a crucial factor for potential interest enhancement, especially for learners with low individual interest in chemistry.

Keywords: Interest, Learning Environments, Out-of-School Learning, Authenticity

Introduction

Situational as well as individual interest have been one focus of educational research for over half a century but the transfer of such findings into educational practice could be questioned: Looking at Germany and Austria alone, latest studies show a strongly decreasing gradient from perceived competence, over interest, to the career aspirations in science subjects (SINUS Markt- und Sozialforschung GmbH, 2024). This trend can be found throughout the Western European countries (van Griethuijsen et al., 2015). Chemistry is particularly unpopular. Apart from a shortage of skilled workers in STEM disciplines (Anger et al., 2024), a lack of interest is also problematic for learners who do not aspire a career in science. STEM (here: chemistry) education should therefore not only appeal to future researchers but should also be designed to be attractive to all learners to enable participation in our society and informed everyday decisions (Hüfner et al., 2025). Students often name everyday references and practical knowledge as potentially interesting facets of chemistry (Fleischer et al., 2024; SINUS Markt- und Sozialforschung GmbH, 2024). Yet, these aspects are hardly anchored in (Western European) chemistry curricula, even though various teaching concepts for interest enhancement already exist. Making chemistry more appealing still presents a challenge that needs to be addressed by finding a suitable way to combine approved methods with research findings as well as with the individual learners' views and needs.

Conceptual Framework

Constructivism In Science Lessons

Modern educational systems and educational research are based on the fundamental assumptions of (social) constructivism as the prioritized approach to successful learning. Impactful theories,

such as Situated Cognition, Cognitive Apprenticeship or Anchored Instruction, laid the foundation for our understanding of the conditions for the independent construction of knowledge during learning processes. To enable situated learning and to fight inert knowledge, authentic contexts and activities play a central role (Ghefaili, 2003). It has been well researched that people of all ages tend to neglect the personal relevance of science in their lives (Kantar, 2021). Given that situated learning always relies on creating meaningful learning environments with authentic real-world complexity (Honebein et al., 1993; Ghefaili, 2003), this widespread neglection seems disadvantageous for learning (and liking) science. It has been found that strictly following constructivist design guidelines does not alone make a difference regarding interest in learning situations (Xu et al., 2024; Yeung et al., 2025). It therefore remains to be refined to what extent situated learning, interest and authenticity interact.

Interest And Learning

A stable preference for topics or activities is referred to as individual interest, describing an individual trait. Interest can also show in form of temporary engagement, referred to as situational interest. Individual interest is often seen as the most important predictor of situational interest (Rotgans & Schmidt, 2018), while there is also research describing important "triggers" for situational interest arising from a learning environment (Renninger et al., 2019). The so-called person-object theory of interest (POI) states a bipolar unit of person and situation (Krapp, 1999). Both interest as a personal disposition and interestingness as a feature of learning environments can lead to the psychological state of being interested in something (Krapp et al., 1992). The four-phase model of interest development (FPM) "describes phases of situational and individual interest in terms of both affective and cognitive processes" (Hidi & Renninger, 2006, p. 113), therefore proposing a structured process in which individual interest evolves based on experiencing situational interest. Hidi and Renninger (2006) assume situational interest to be triggered in certain situations with the potential to be maintained through personal relevance of the topics or materials. Both POI and FPM are frequently used as theoretical backgrounds for current research.

Situational interest is composed of an emotional, a value-related, and an epistemic compound, stating that besides experiencing meaningfulness and positive emotions during learning, curiosity and engagement contribute to being interested (Prenzel et al., 1986). Research shows that increased situational interest can lead to more positive affect as well as higher cognitive engagement and therefore contribute to knowledge acquisition through intensifying and maintaining effort (Su, 2020). Research provides scattered results concerning STEM contexts that seem interesting to students (Hoffmann et al., 1998; Sjoberg & Schreiner, 2005) and therefore illustrates that interestingness does not follow universally applicable rules for every individual learner, highlighting the importance of integrating individual perceptions. It is suggested that one context can affect different learners in different ways (Habig et al., 2018; van Vorst & Aydogmus, 2021; Yeung et al., 2025). Some researchers discuss a balance between dispositional and situational (environmental) facets when it comes to enhancing situational interest (Schäfer & Habig, 2024). Such a balance is strongly supported by the constructivist approach that learning equals the behaviour of individuals, bringing their own larger context with them, engaging in a local (learning) environment where tasks are situated (Honebein et al., 1993). Unfortunately, research still provides only limited explanations as to *why* interest develops which way for different learners.

Interest, Authenticity, Contextualization, And Their Link To Constructivism

Chemistry is often perceived difficult or abstract. One reason for low interest in science could be contextualization not fitting highly individual values and preferences. According to the situational

expectancy-value theory (SEVT, Eccles & Wigfield, 2020), low situational interest could be explained by science seeming non-enjoyable and far from useful. As a result, a learning context may be perceived as not compatible with oneself. According to the Person-Environment Fit Theory (PEFT, van Vianen, 2018), only a good alignment between individual characteristics and the (learning) environment leads to engagement and better performance. This fit is therefore directly linked to interest. A similar concept of "fit" is used by Zualkernan (2006). Following this framework for constructivist learning environments, the learner "adapts" to an environment in such a way that she can be "fit" for the tasks in question (Zualkernan, 2006). Especially the "structural fit" seems similar to the PEFT as it describes "how closely the cognitive constraints and learning styles of the learner 'match' to the information present in the environment" (Zualkernan, 2006, p. 200). If complete dissonance occurs, individuals might refuse all information presented in a learning environment. If these models are joined with the concept of authenticity, it could be inferred that a good fit is reflected in a high perception of authenticity before it results in increased (situational) interest.

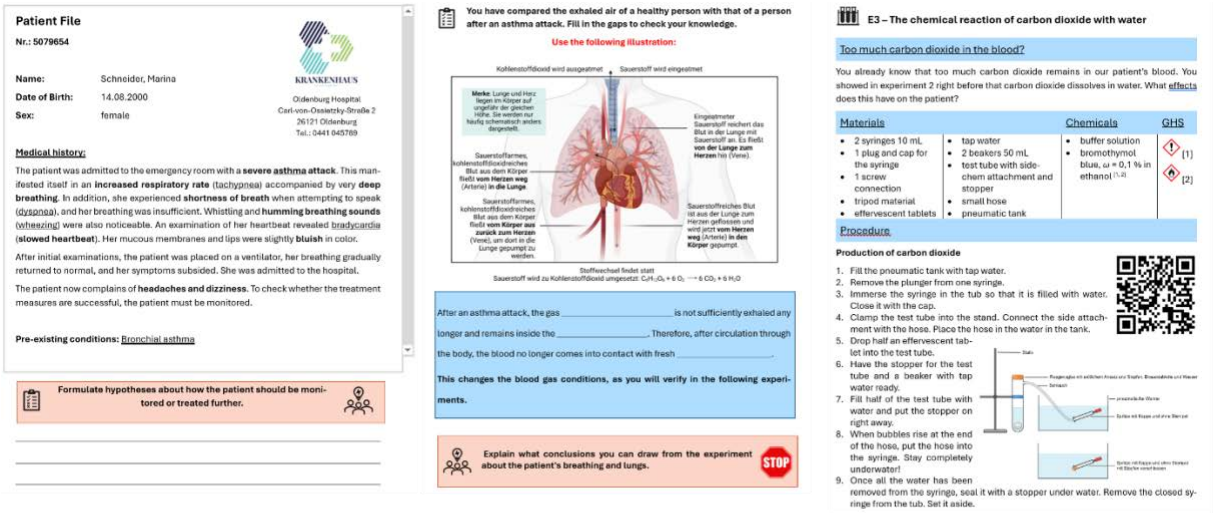
That is, *perceived* authenticity plays a central role in stimulating and maintaining situational interest (Betz et al., 2016). It has been proven that the *intended* level of authenticity neither had effects on perceived authenticity of the students nor on their situational interest, providing us with the necessity to include the learners' personal views. All components connected to the individual feeling of authenticity have been linked within the Model of Authenticity in Teaching and Learning Contexts, stating that the feeling of authenticity manifests as a product of an individual authentication process which is itself influenced by personal dispositions as well as characteristics of the environment (Betz et al., 2016). Aiming to design authentic learning materials means enabling students to make connections of the learning content to real life (Fougt et al., 2019). *Authentic* has been used extensively, but not consistently, to describe learning situations connected to real life. Shaffer & Resnick (1999) state that different kinds of authenticity may overlap to create "thick" authenticity, a strong perception of authenticity. They include criteria like alignment with the outside world, with a specific discipline, or with what learners really want to know (Shaffer & Resnick, 1999). Other authors suggest various design principles for authentic learning environments, e.g. authentic contexts, expert performance, collaboration or scaffolding (Herrington & Oliver, 2000). Real-world problems, inquiry, discourse among the community of learners as well as empowerment of the learners are seen as components of authentic learning (Rule, 2006). A feeling of relevance and usefulness (in these terms: a feeling of "fit") is supposed to arise when students perceive learning environments as authentic (Nachtigall et al., 2018), making authentic contexts a promising approach to effectively use situated learning for interest enhancement. Yet, findings about what really induces perceived authenticity in the individual learner remain ambiguous, e.g. concerning instruction methods and guidance (Hohrath et al., 2024; Nachtigall & Rummel, 2021).

Aims And Research Questions

Although the theoretical foundation suggests that perceived authenticity has a key role in the constructivist view of situated learning processes concerning the development of situational interest, studies often do not integrate *perceived* authenticity in interest assessments of (context-based) learning environments (Nachtigall et al., 2022, 2024). The individual learner's personal perspective is of ultimate value for determining if constructivist pedagogies reach their goal of presenting fitting situated learning environments because "not only is [the learner] entitled to make judgements about what counts as authentic for her but, in the final analysis, it is her authenticity which really matters" (Splitter, 2009, p. 143). One way to examine such a fit is through authenticity (Betz et al., 2016). Learning materials that are perceived as authentic would

enable students to make credible connections between the learning content and real life (Fougt et al., 2019).

This gives rise to the hypothesis that an increased fit and thus an increased perception of authenticity is a positive starting point for the enhancement of situational interest yet depends on the individual learner. Consequently, the following research questions arise:



1. How is the perception of authenticity linked with other interest-determining factors?
2. Does our design of a context-based learning environment seem more authentic, or more interesting, to learners with a special set of dispositions?

Research Design And Methods

Designing An Authentic Context-Based Learning Environment

To examine the connections between situational interest, perceived authenticity and individual dispositions in a context-based learning environment, we decided on conducting a survey in an out-of-school student laboratory. Trying to obtain a high level of *intended* thick authenticity in alignment with Shaffer & Resnick, we searched for a context that connects chemical knowledge with problems from the real world, that is aligned with a specific discipline and with topics learners want to know about. Because various studies confirmed young people's universal interest in medical topics (Hoffmann et al., 1998; Sjoberg & Schreiner, 2005), and because chemical concepts are of essential use for medical cases, we picked a medical context. To align our learning environment with real-world problems, we reconstructed an authentic patient's case in collaboration with experts in medicine from the local clinic. As a result, a learning environment using a patient file as contextual structure was designed (see Figure 1).

Figure 2. Exemplary screenshots from the (translated) learning material.

Task: Formulating hypotheses about how the patient should be treated further.

Task: Explaining how an asthma attack influences the respiratory system.

Task: Explaining how an asthma attack influences the blood gas parameters.

The patient file and the respective diagnosis to be made served as the initial problem the students would encounter. Our patient, a young girl with bronchial asthma, came to the hospital after a severe asthma attack, and was administered oxygen. Now, the causes of her ongoing headaches and dizziness following the treatment should be identified. The students start making suggestions for suitable medical examinations and are supported by additional medical information and scaffolding, concluding that a blood gas analysis should be arranged. In the laboratory, they conduct simple and easy chemical experiments to model the steps of a blood gas analysis. Conducting chemical experiments for the detection and quantification of carbon dioxide as well

as the acidic reaction of carbon dioxide in aqueous solutions, the students are guided towards diagnosing the patient with respiratory acidosis as a condition following the severe asthma attack (Boemke et al., 2012).

Survey Instrument And Methods

The three-hour course was accompanied by a questionnaire in a pre-post format (Dietel & Wilke, 2025). To assess dispositions in the pre-test, five and three items on five-point Likert scales were used to measure individual interest in chemistry (*ind(ch)*) and medicine (*ind(med)*). Situational interest was assessed in both the pre- and post-test using five items on a five-point Likert scale (*sit(pre)* and *sit(post)*). In the post-test, perceived authenticity was also assessed using three items (*auth*). Additionally, the students could deliver a short, written statement on why they felt that way about their authenticity perception. Table 1 shows exemplary items with the original sources and the reliability of the scales.

Table 1. Questionnaire Details.

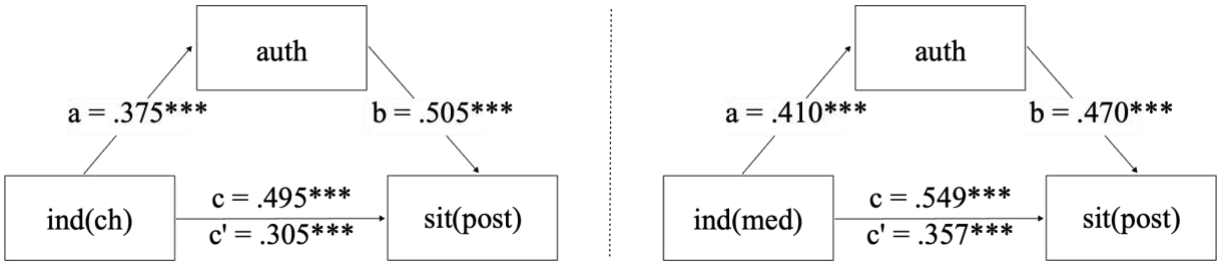
Scale	Exemplary Item (translated)	Source	Cronbach's α
ind(ch) (5 items)	I like working on tasks from chemistry lessons.	Frey et al., 2015; Habig, 2017 (adapted)	.907
ind(med) (3 items)	I enjoy exploring medical topics.	Frey et al., 2015; Habig, 2017 (adapted)	.898
sit(pre) (5 items)	Learning chemistry with this topic will be fun.	Habig, 2017 (adapted)	.863
sit(post) (5 items)	Understanding this topic is important for me.	Habig, 2017 (adapted)	.868
auth (3 items)	I have learned something from everyday life of real people today.	Finger et al., 2022 (adapted)	.792

A correlation analysis was carried out in SPSS. Assumptions concerning mediating effects of different constructs on the development of situational interest were tested using the PROCESS macro by Hayes (Hayes & Little, 2018). Group differences were analysed using ANOVAs.

Findings

The data from 155 students aged 14-16 years were analysed. 79 participants identified as female, 69 as male, and 7 stated another gender. All scales showed good or very good reliability (see Table 1). The participants reported medium-high situational interest in both pre-test (3.61 ± 0.67) and post-test (3.59 ± 0.84) as well as medium-high perceived authenticity after the intervention (3.77 ± 1.06). Individual interest in chemistry (3.05 ± 1.04) was rather low while individual interest in medicine was on a higher level, as expected (3.60 ± 1.11).

To answer the first research question, a correlation analysis as well as mediation analyses were performed. From a correlation analysis (Spearman's rho, see Table 2), it arises that perceived authenticity is correlated with every surveyed construct, and it is especially highly correlated with situational interest in the post-test. Both *ind(ch)* and *ind(med)* are highly correlated with *sit(pre)* as well as with *sit(post)*. Nevertheless, the correlation remains constant (*ind(ch)*) or decreases (*ind(med)*) from pre-test to post-test, while the correlation of *auth* with situational interest increases from pre-test to post-test. This suggests that perceived authenticity became relevant for



situational interest during the intervention while indicating that the dispositions may play a more foundational, rather than dynamic, role in interest development.

Table 2. Correlation Analysis.

	ind(ch)	**ind(med)**	**sit(pre)**	**sit(post)**
ind(med)	ρ = .300 p < .001			
sit(pre)	ρ = .555 p < .001	ρ = .649 p < .001		
sit(post)	ρ = .555 p < .001	ρ = .593 p < .001	ρ = .701 p < .001	
auth	ρ = .380 p < .001	ρ = .430 p < .001	ρ = .424 p < .001	ρ = .714 p < .001

The correlation analysis prompted a further examination of the initial hypothesis: the central role of perceived authenticity for interest enhancement. This is why the effects of different dispositions on the post-test value of situational interest were checked for a mediating influence of perceived authenticity. All relationships were approximately linear, as assessed by visual inspection of the scatterplots after LOESS smoothing. A simple mediation was performed. An effect of *ind(ch)* on *sit(post)* was observed. After entering perceived authenticity into the model, *ind(ch)* predicted this mediator *auth* significantly, which in turn predicted *sit(post)* significantly. We found that this relationship is partly mediated by *auth*. Also, the effect of *ind(med)* on *sit(post)* was significant and got partly mediated by *auth*. The mediation paths are visualized in Figure 2.

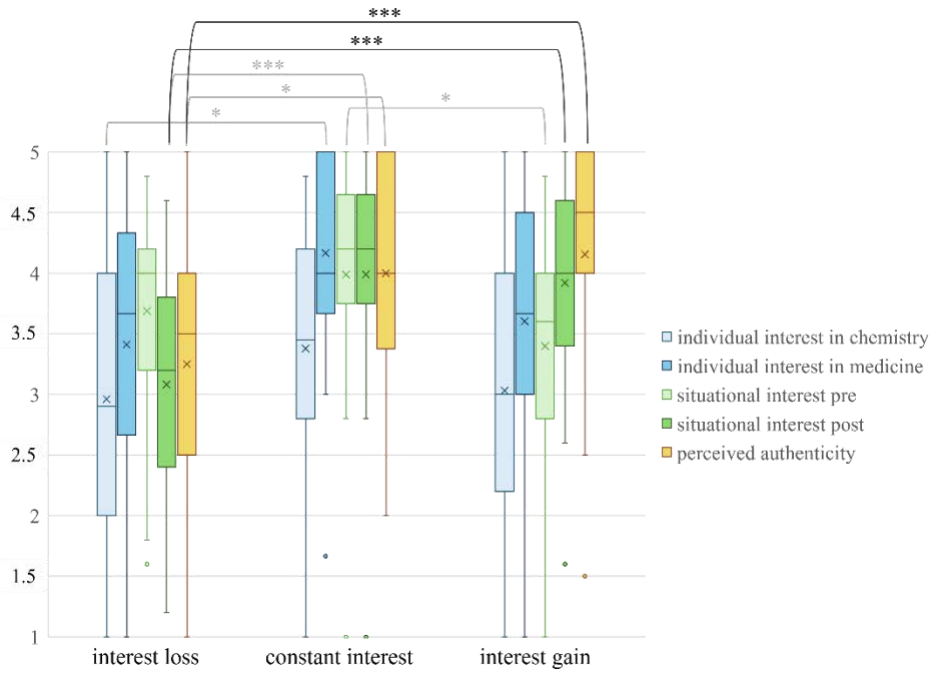


Figure 3. Mediation figures (* - significance p < .001).**

To answer our second research question, we divided the data into three groups according to the development of situational interest from pre-test to post-test. This resulted in the groups "interest gain" (*sit(post)* - *sit(pre)* > 0, N = 71), "interest loss" (*sit(post)* - *sit(pre)* < 0, N = 62), and the group "constant" (*sit(post)* - *sit(pre)* = 0, N = 18). Levene's test revealed equal variance among the groups regarding the constructs *ind(ch)*, *ind(med)*, *sit(pre)* and *sit(post)*. An ANOVA showed significant differences in the areas of *ind(med)*, *sit(pre)* and *sit(post)*. A Tukey test specified that significant differences between the "interest gain"-group and the "interest loss"-group only occurred concerning *sit(post)* ($F(2, 148) = 19.54$, $p < .001$, $\eta^2 = .209$). Other significant differences were found only in comparison to the "constant"-group. For perceived authenticity, variance inequality over the three groups had to be assumed. Here, a Welch-ANOVA followed by a Games-Howell test also revealed significant differences between the "interest gain"-group and the "interest loss"-group ($F(2, 46.25) = 14.42$, $p < .001$, $\eta^2 = .174$). These large effects suggest that, given similar dispositions and similar starting points in terms of situational interest, perceived authenticity is the only factor surveyed here that contributes to divergent interest

development comparing “interest gain” and “interest loss”. Significant differences are visualized in Figure 3.

Figure 4. Boxplots for the group comparison (development of situational interest).

Additionally, data from male and female participants were included to determine gender differences. Levene’s test confirmed the homogeneity of variance between the two groups regarding all constructs. An ANOVA revealed significant differences for *ind(med)* ($F(1, 146) = 12.22$, $p < .001$, $\eta^2 = .077$) well as *auth* ($F(1, 145) = 6.99$, $p = .009$, $\eta^2 = .046$) in favor of girls. For *ind(med)*, the effect ($\eta^2 = .077$) was moderate to large, indicating a practically relevant difference between girls and boys. For *auth*, the effect was moderate ($\eta^2 = .046$), indicating a clear but less pronounced difference. Both results emphasize that gender might be an additional significant factor for the constructs examined.

Discussion

The present study examined the role of perceived authenticity in the development of situational interest during a context-based out-of-school chemistry intervention among early adolescents (aged 14–16). While individual interest in chemistry was relatively low, interest in medicine was notably higher, aligning with the study’s intentional focus on medical contexts.

Correlation analyses revealed that perceived authenticity was strongly associated with all key constructs, particularly suggesting it being increasingly important for interest development over time. Mediation analyses confirmed that perceived authenticity partially mediated the effects of both *ind(ch)* and *ind(med)* on post-test situational interest. This supports the hypothesis that perceived authenticity acts as a key psychological mechanism for interest enhancement.

The ANOVA results underline that the perception of authenticity could play a central role in the development of situational interest during the intervention, as no significant difference between learners from the “interest gain”-group and “interest loss”-group could be found in the other constructs examined. Gender also appears to be related to the perception of authenticity, albeit with smaller effect sizes. It is noteworthy that, despite their significantly higher perception of authenticity compared to boys, girls do not show a generally higher level of situational interest. Here, the hypothesis could be put forward that different learners may require different levels of ”threshold authenticity” to experience an increase in their situational interest, especially if their dispositional starting position already favours an increased perception of authenticity. Partial

mediation was found for both mediation analyses, suggesting that an increased experience of authenticity, in parallel with the existing dispositional situations, promotes an increase in situational interest.

The increasing relevance of authenticity over time may reflect a growing sense of personal relevance and connection to the content. This claim is additionally supported by data from the written statements about the individual authenticity perception. Students from the "interest gain"-group who expressed high perceived authenticity often stated that they had the feeling that the patient file is an example of a phenomenon experienced by a lot of people in daily life. They also often noted that the experiments were only modelling medical procedures but helped them understand important steps towards the diagnosis.

Together, these results suggest that interventions aiming to enhance situational interest should not only focus on content relevance but also on fostering students' perception of authenticity. Future research should explore how authenticity can be intentionally cultivated in classroom settings, particularly through narrative-based, or real-world connected learning experiences.

Conclusion And Outlook

The results of the mediation analysis and group comparisons show that although the perception of authenticity plays a decisive role in the development of interest, the relationship appears to be much more complex than what can be described by a linear relationship or group classification. Accordingly, an increased experience of authenticity could promote an increase in situational interest even if the initial situation in terms of individual interests is not considered favourable per se. At this point, next steps would involve testing the correlations and mediations already identified with a larger sample size in a structural equation model to consider the weighing of the individual items for the distal variables and to be able to draw causal conclusions at the same time. An analysis of possible clusters or profiles also seems promising for identifying gradual developments, as smaller and larger changes in situational interest are currently being considered collectively.

For optimization of our learning environment, it seems highly promising to include steps of guidance for students struggling with drawing the connections between the learning content (the case file) and their own life experiences. To exploit the potential of perceived authenticity as a mediator in the development of situational interest, it seems advisable to keep the contexts linked strongly to authentic relevance in daily life to successfully to mitigate the non-profitable influence of low individual interest. A qualitative follow-up study could provide information on the exact conditions or triggers of the feeling of authenticity to make the findings usable across contexts and disciplines. If authenticity can be used adaptively for learners with different sets of individual dispositions in future learning environments, our approach of authentic contexts seems suitable to make chemistry appealing even for students with lower individual interest.

ESERA 2025 Copenhagen

Using The Four-Quadrant Model To Examine The Character And Value Development Of Pre-Service Primary Teachers About Global Warming

Nejla Atabey[1], Mustafa Sami Topcu[2]
[1] Muş Alparslan University, Faculty of Education, Muş, Türkiye
[2] Yıldız Technical University, Faculty of Education, İstanbul, Türkiye

Due to the alarming consequences of environmental issues, moral dilemmas, and the rapid advancements in science and technology, researchers are now doubting the effectiveness of character and values education. In order to solve current issues and promote a just and peaceful global society, there is an increasing focus on educating people to have an ecological worldview, social and moral compassion, and socio-scientific accountability. Given the significance of the early years in the formation of character and values, the goal of this study was to assess and improve pre-service primary school teachers' character and values holistically using Wilber's four-quadrant model. The study was carried out utilizing a multiple case study methodology and featured two individuals. The pre-service teachers' responses to interview questions both before and after the implementation served as the data sources. Deductive content analysis showed that participants demonstrated enhancement by incorporating more character and value elements in their explanations or by offering more detailed elucidations on these characteristics across all quadrants after the implementation. Therefore, Wilber's four-quadrant model provides a new and effective perspective for assessing and developing the character and values that people of the twenty-first century are supposed to have.

Keywords: pre-service primary teachers, character and value, four quadrant model

Introduction

21st-century character and values include ecological worldview, social and moral compassion, and socio-scientific accountability (Choi et al., 2011). To train individuals who promote social virtue, other people's rights, and the common good (Singh, 2019); behave responsibly on global concerns; and make effective ethical judgments, these characters and values must be fostered.

The ecological worldview addresses interconnectedness and sustainability, as well as being conscious of ecological issues (Lee et al., 2013). Empathy, respect for life, and compassion for the environment and individuals impacted by environmental issues are social and moral compassion. It involves moral and ethical sensitivity, empathy, and perspective-taking (Choi et al., 2011). Socioscientific accountability requires recognition of stakeholder duties (responsibility), the science and society relationship, and action (willing to act) (Choi et al., 2011).

Science education may incorporate character and values through group discussions, argumentation, inquiry, and field excursions (Lee et al., 2012). Many believe character and value development should encompass cognitive, emotional, and behavioural elements in a more holistic way (Khobir & Hasanah, 2021). Comprehensive character education helps students identify their identities and aspirations via social, moral, and environmental links (Khobir & Hasanah, 2021). Wilber's (2000) four-quadrant method develops personalities individually, collectively, internally, and externally in terms of "I (thoughts, emotions, memories)," "We (material body, visible behaviour)," "It (shared value and meanings)," and "Its (systems and government)" perspectives.

This study used Wilber's (2000) model to develop and assess pre-service teachers' character and values by focusing on global warming. Global warming might have dire consequences for the environment, economy, and society (Guterres, 2024). Ecological education, moral and social awareness, and socio-scientific responsibility can prevent global warming. This study intends to develop the character and values of pre-service primary teachers in each quadrant in light of global warming. The guiding question is:

How does the four-quadrant model of global warming help pre-service primary school teachers to develop an ecological worldview, socioscientific accountability, and social and moral compassion?

Method

We employed qualitative multiple case studies with two female pre-service primary teachers studying at a state university in Türkiye. TEAMS and Classroom were used for the lessons in ten weeks after two severe earthquakes hit Türkiye in 2023. Through implementation, the four-quadrant model structured global warming teaching, including activities that support character and values. For instance, sharing information about countries most and least affected by and contributing to climate change was carried out to foster empathy, calculating and discussing individual carbon footprints was realized to foster responsibility, and discussing the consequences of global warming was realized to foster an ecological worldview.

Data Collection And Analysis

The current study adapted Nolan's (2021) perspective-taking questions to collect data. Questions were adapted in four quadrants to represent character and values. Students uploaded their answers in the classroom before and after implementation. The gathered data underwent deductive content analysis. The replies of the participants (Fatma and Leyla) were assessed on the character and value components in each quadrant.

Findings

The findings are presented within the context of each quadrant under the headings of ecological worldview, social and moral compassion, and socio-scientific accountability.

Ecological Worldview

Q1: Fatma presented her ideas in terms of sustainability before implementation. She made explanations regarding sustainability and interconnectedness after implementation.

Initially, Leyla expressed her opinions without considering sustainability or interconnectedness. After implementation, she addressed them.

Q2: Fatma first did not evaluate her behaviours in terms of sustainability and interconnectedness. After implementation, she highlighted that her actions may affect future generations and underprivileged nations (sustainability and interconnectedness).

Leyla originally ignored her behaviour's impact on sustainability and interconnectedness. After the implementation, she said she minimizes her carbon impact for future generations (sustainability).

Q3: Fatma initially lacked sustainability and connectedness explanations for people's shared beliefs. She stated her society recognized global warming and its effects after implementation (interconnectedness).

Leyla never highlighted people's sustainability and connectedness values before or after implementation.

Q4. Fatma said industrialized nations' policies adversely affect non-global warming countries. (interconnectedness). She discussed nations' policies in terms of ecological balance following the implementation (interconnectedness).

Leyla initially explained population growth causes global warming (interconnectedness). Following the implementation, she named various global warming factors and held wealthy nations liable (interconnectedness).

Social And Moral Compassion

Q1. Initially, Fatma expressed her deep concern and sadness about the effects of global warming (emphatic concern). Following implementation, she emphasized that human actions that cause global warming are immoral and unethical, demonstrating her sensitivity to moral and ethical issues.

Initially, Leyla demonstrated empathy for global warming's detrimental repercussions. After the implementation, she made explanations regarding emphatic concern, moral and ethical sensitivity, and perspective taking.

Q2. Fatma explained moral and ethical sensitivity because of her behaviours both initially and after the implementation.

Initially, Leyla did not evaluate her behaviours in terms of social and moral compassion; after implementation, she made explanations regarding moral and ethical sensitivity and emphatic concern by referring to her behaviours.

Q3. Initially, Fatma showed moral and ethical sensitivity because of people's behaviour around her. After implementation, in addition to moral and ethical sensitivity, she stated that people feel sad because of the effects of global warming (emphatic concerns).

Leyla noticed that people don't examine how their activities affect global warming (perspective-taking) and feel awful for those impacted (emphatic concern). After implementation, she only made explanations regarding perspective taking for her society's values.

Q4. Fatma stated that countries do not tackle global warming with moral and ethical sensitivity. After the implementation, she said developed nations felt morally responsible because of their activities contributing to global warming (moral and ethical awareness).

Leyla also said that countries do not act with moral and ethical sensitivity but later stated that they feel ethical and moral sensitivity.

Socioscientific Accountability

Q1. Fatma initially stated her responsibility to care for living things affected by global warming. After implementation, in addition to responsibility, she stated her desire to be willing to act.

In addition to the responsibility stated initially, Leyla expressed a willingness to participate in efforts (willingness to act) after implementation.

Q2. Fatma stated that she wants to join activities that would help her become more conscious of global warming before and after implementation.

In addition to the willingness to act stated initially, Leyla explained her contribution to global warming (responsibility) and desire to change her habits (willingness to act).

Q3. Fatma stated that the people around her are aware of global warming and are willing to act in preventive actions. After implementation, she remarked many around her want to act but don't.

Initially, Leyla stated people around her don't feel responsibility for global warming. After implementation, none of these people has a desire to act, she said.

Q4. Initially, Fatma didn't know what other nations were doing to address global warming. She added, following the implementation, that other countries are taking responsibilities and creating environmental protection measures (willing to act).

Leyla had no idea how other nations viewed global warming. After implementation, she noticed that other countries are planning for climate change (willing to act) and feel responsible.

Discussion

Following implementation, participants discussed their ecological worldview and opinions on global warming, indicating a development. This increase was sometimes observed by addressing more environmental worldview sub-elements and sometimes by providing more explanations for these elements. Information-oriented and reflective activities may have supported the development of participants' ecological worldviews. Participants can develop awareness of their mental state and reflect on their ideas, responses, and emotions surrounding global warming by focusing on the inner world (Esbjörn-Hargens, 2006; Tønnesvang et al., 2015). In addition, the fact that scientific explanations offered are advanced by the information acquired on a subject (Hakyolu & Ogan-Bekiroğlu, 2016) supports this finding.

Other findings of the study are about social and moral compassion. The study reveals that teaching complex scientific issues like global warming enhances students' empathetic concern and moral and ethical sensitivity in accordance with Fowler et al. (2009). Especially, pre-service teachers could discuss additional aspects of social and moral compassion of their behaviours and other countries, possibly due to their moral and ethical assessments of self-behaviours and gathering new information during the study. However, participants' ability to take perspective was lacking. This could be as a result of the present study's increased focus on studying global warming and its reduced number of decision-making-related tasks.

Other findings of the study are about socioscientific accountability. Fatma focused on educating individuals to increase awareness about global warming, while Leyla declared her readiness to take personal action. This suggests that people's approaches to global warming are influenced by their values and character elements. Studies indicate that personal perspectives significantly influence teachers' selection and presentation of information on global warming (Sadler, 2004). Both Fatma and Leyla expressed that society is prepared to combat global warming, but they gave different justifications for this. This may be because people at different educational and socio-economic levels may not be consciously concerned about environmental issues or engage in environmentally friendly behaviours when little is known about the problem or its solutions (Gifford & Nilsson, 2014). They also discussed how nations approach the problem in terms of being willing to act and feeling responsible after implementation. Gaining information about policies and agreements in other countries could have allowed for inferences about countries' socioscientific accountability.

Conclusion And Implications

Participants showed improvement by including more character and value elements in their explanations or by providing more explanations about these elements in all quadrants after the implementation. Therefore, this study's findings offer a new and holistic perspective on developing and assessing character and value elements using a four-quadrant model. Future research might examine the effects of teaching various subjects. Both quantitative and qualitative data may also support these conclusions, and various decision-making exercises may encourage participants to adopt new perspectives.

Technology Blindness: The Loss Of Affinity And Awareness For Technology

Corinna Eußner, Daniel Seebald and Ulf Ahrend
University of Applied Sciences Karlsruhe, Germany

*In recent years, the number of first-year students in STEM subjects, particularly in engineering and technical degree programs, has been declining in Germany. This development is worrying in view of the growing shortage of skilled workers, as falling student numbers can impair Germany's innovative strength and competitiveness in the long term. This paper proposes that this trend can be attributed to a general loss in the perception of technology. This loss is referred to as "technology blindness", an adaptation of the existing term "plant blindness" from biology. One approach to counteracting this is Inspir**ING**®, an elective course at Karlsruhe University of Applied Sciences in which students prepare and carry out a teaching unit for pupils based on an experiment. The didactic methods such as storytelling, didactic reduction and experiments form the foundation of these units. Participants in the conference workshop experienced such a teaching unit live as an example. This workshop aimed to introduce the concept of "technology blindness" and demonstrate to participants how the Inspir**ING**® methodology can reduce it and sharpen awareness of technology.*

Keywords: STEM, engineering, technology blindness, awareness, interest

Note

In order to distinguish between secondary school students and students of engineering subjects at the university, secondary school students are referred to as *pupils* and students at the university as *students*.

Introduction

As one of the world's leading industrial nations, Germany is facing a critical challenge: the number of first-year students studying STEM subjects (science, technology, engineering and mathematics) is falling, particularly in engineering disciplines (Anger et al. 2024). This is an alarming development as it correlates directly with the growing shortage of skilled workers. According to reports, there is already a shortfall of around 140.000 STEM professionals (Plünnecke, 2023). This could permanently weaken Germany's innovative strength and international competitiveness. In the long term, this trend could undermine the country's ability to respond to technological upheaval and maintain its position at the forefront of research and development (Shambaugh et al. 2017; BDI et al. 2024).

This paper proposes that one cause of this problem is a social phenomenon introduced as "technology blindness". Similar to the term "plant blindness" in biology (Wandersee and Schussler, 1999), "technology blindness" describes the growing lack of awareness of and appreciation for the constantly present technology in our modern world. Due to the apparent limitless availability of technology, awareness of its complexity, history, and fundamental contribution to our daily lives and solving global problems is dwindling.

To help address this issue, Karlsruhe University of Applied Sciences developed the elective Inspir**ING**® in 2019. The program takes an innovative didactic approach: engineering students become role models for pupils in eighth grade and above. The students design and lead 45-minute, experiment-based teaching units.

This paper first sets out the theoretical foundation of the concept of technology blindness. Then, the Inspir**ING**® program's didactic trio of storytelling, didactic reduction, and experimentation is explained in detail. Next, the practical implementation of this methodology is demonstrated using the workshop held during the ESERA conference in Copenhagen 2025. Lastly, this approach's implications for STEM education are discussed, and a future research outlook is provided.

Theoretical Framework: Definition Of "Technology Blindness"

The concept of "technology blindness" is a direct adaptation of the term "plant blindness," which was coined by biologists Wandersee and Schussler in 1999. These scientists used the term to describe the human tendency to ignore the plants in our environment, underestimate their importance to the biosphere, and regard them as passive, static backdrops. It is argued that an analogous phenomenon exists in the context of technology. To draw attention to this problem, a clear and precise formulation is necessary.

"Technology blindness" refers to the inability to consciously perceive technology in one's living environment, recognize its importance to society, and appreciate the complexity and ingenuity of technical objects. To define the term precisely, the characteristics that Wandersee and Schussler formulated for "plant blindness" are transferred to the technical context.

The specific characteristics of "plant blindness" are listed in Table 1 in the left-hand column; the transfer to "technology blindness" is listed in the middle column. The third column lists concise examples of technology blindness characteristics. These examples were used in the workshop held during the ESERA conference in Copenhagen 2025.

Table 1. Adapted features and examples.

plant blindness (Wandersee, Schussler, 1999, p. 82)	*technology blindness*	*Everyday example*
"The inability to see or notice the plants in one's environment	The inability to see or perceive technology in one's own environment	"I never consciously realized that even a simple light switch is technology."
the inability to recognize the importance of plants in the biosphere and in human affairs	the inability to perceive technology as an opportunity to solve environmental and human problems	"I have seen solar panels but never realized that they actively contribute to solving environmental problems."
the inability to appreciate the aesthetic and unique biological features of the life forms that belong to the Plant Kingdom	the inability to perceive, understand and appreciate unique features of technical objects in a wider technological context	"I often used GPS without understanding how complex the technology behind it actually is."
the misguided anthropocentric ranking of plants as inferior to animals and thus, as unworthy of consideration"	the perception of technology as self-evident and limitless availability, thus neglecting its true value and impact.	"I only realized how much I take technology for granted in everyday life when my Wi-Fi went down."

These four characteristics of "technology blindness" manifest as a passive consumer attitude toward technology. The smartphone becomes a "black box", electricity just comes out of the socket, and complex infrastructure systems remain invisible as long as they function properly. This lack of awareness results in a diminished basic understanding of technical principles, which ultimately leads to less interest in actively shaping the technological future. This directly impacts the choice of study and career fields.

Elective Program InspirING®

The elective program Inspir**ING**® at Karlsruhe University of Applied Sciences is a possible approach to counteracting technology blindness. Launched in 2019, the program creates practice-

oriented educational units that aim to raise awareness of technology among pupils, as well as stimulate their fascination with it.

A central aspect of the Inspir**ING**® program is its use of peer tutoring, as essential didactic element. Engineering students develop and teach a 45-minute lesson to pupils in the eighth grade and above. This format appeals to two target groups simultaneously, generating double the added value.

First, the program provides pupils with low-threshold access to technical topics by introducing them to young, authentic role models. The small age gap and comparable social status of learners and tutors promote interaction on an equal footing and reduces the hierarchical barriers that exist in traditional teaching and learning situations. In this way, technical content becomes accessible not only cognitively, but also emotionally. Second, students also benefit in several ways from their role as peer tutors. Reducing complex technical content to key principles and communicating it appropriately promotes didactic and communication skills. At the same time, this process deepens their understanding of the subject. Additionally, students reflect on their personal motivations for studying and actively take on the role of ambassadors for their field of study. (Struck, 2023)

The Inspir**ING**® program's overarching goal is to counteract technological blindness by providing positive, self-effective learning experiences that spark long-term interest in STEM education and careers.

Didactic Methodology

The efficacy of Inspir**ING**® is predicated on the synergistic interaction of the three didactic elements storytelling, didactic reduction, and an experiment (see Figure 1). These methods are closely intertwined, mutually dependent and form an inspiring and sustainable learning experience. The individual methods are described in more detail below.

Storytelling

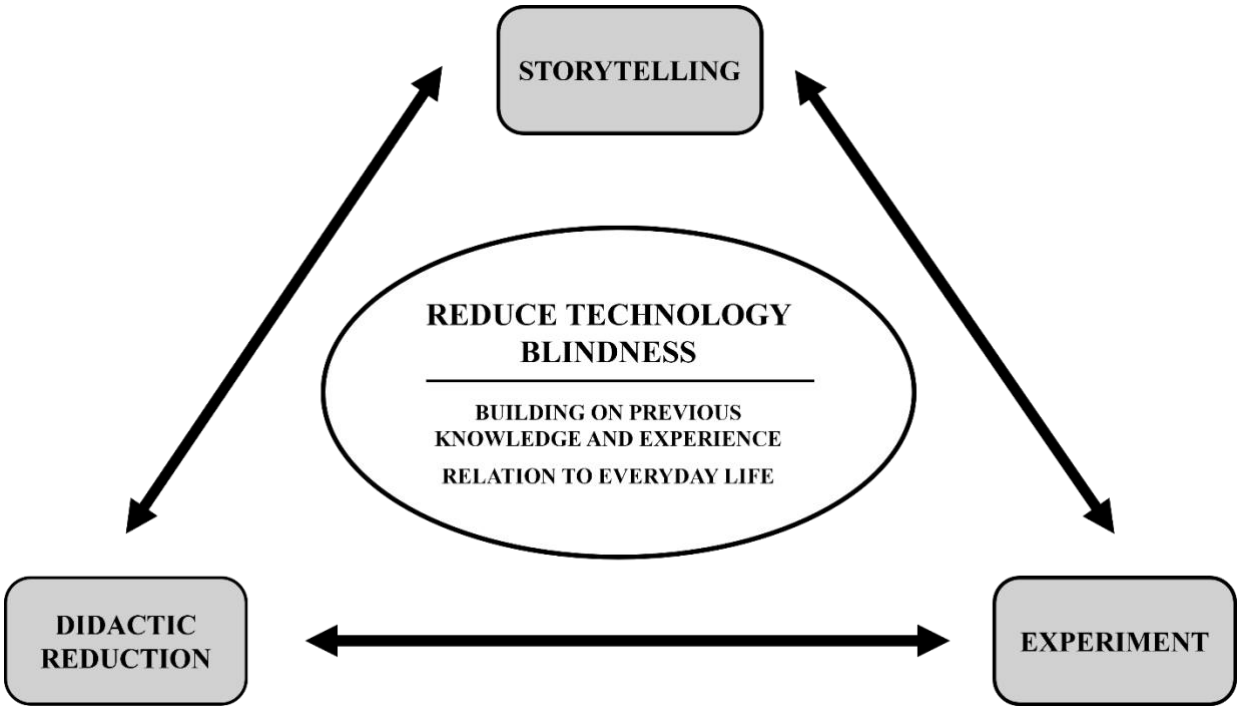
Storytelling is known to establish an emotional and narrative framework. This can give teaching units a vibrant and exciting structure that appeals to pupils emotionally, arouses their curiosity and thus mesmerizes them. (Heering, 2016; Hadzigeorgiou et al. 2011) The program uses this to effectively capture the viewer's attention and to successfully embed the seemingly arid scientific subjects in meaningful contexts. The intention is to spark a greater interest in technology among pupils, not least as an incentive for a future career in science and engineering (Blum & Heering, 2014). Within the framework of Inspir**ING**®, storytelling is employed on two distinct levels:

1. Narrative framing: The scientific topic is embedded in a narrative that is designed to spark curiosity and interest among pupils. Rather than initiating the lesson with formulaic explanations, students begin the lessons with a challenge, an analogy, or a captivating observation, to name a few possible options.

2. Personal stories (peer learning): Students share their own enthusiasm and career paths. The incorporation of personal narratives into the educational experience serves to render abstract concepts and professional disciplines more accessible and relatable to pupils. These authentic narratives about motivation, challenges, and fascination act as a powerful incentive, break down barriers and establish an emotional connection with the pupils.

Didactic Reduction

Didactic reduction functions as a link, ensuring the experiment´s complexity and the underlying theory becomes understandable, manageable, and applicable to the target group. Complex technical and scientific topics are often inaccessible to pupils. The concept of didactic reduction



can be defined as the art of simplifying complex subjects without compromising technical accuracy. According to Lehner (2024), this process entails the selection of essential content, an emphasis on the core principle, and the simplification of the presentation. For students, this necessitates the process of distilling the theoretical framework of their experiment to a comprehensible level, suitable for pupils in grade 8 and above, without requiring any prior knowledge. This process also benefits students, as it requires a deep understanding of the topic in order to reduce it to its essential elements.

Experiment

Knowledge and insights are best gained by linking theory and empiricism helping students to understand technical phenomena better (Pusch et al. 2024; Pfangert-Becker, 2010). Thus, the experiment is the central element of the lesson. Active participation and self-directed discovery have been shown to result in a deeper and more lasting understanding than traditional frontal teaching methods. By establishing the experiment, conducting the tests, and ultimately completing the project independently, pupils can achieve a sense of self-efficacy and enthusiasm, often accompanied by a moment of profound realization. This shift enables them to transition from a passive stance as listeners to an active role as creators.

The common goal of these three approaches is to reduce technology blindness and raise pupils' awareness of technology. Also linking the content to familiar contexts, such as specific references to everyday life, and taking into account the target group's level of experience in order to build on existing knowledge are essential for a successful integration in long term memory (Hadzigeorgiou et al. 2011).

Figure 1. Interdependence of methods with the aim of reducing "technology blindness", own illustration.

Workshop At The ESERA Conference

A workshop called "Technology blindness – The loss of affinity with technology and how to counteract it" was held at the ESERA conference in Copenhagen 2025. The workshop demonstrated the practical application of Inspir**ING**® using an experiment with electromagnetism as an example to explain the idea of technology blindness and to sensitize participants to this

particular technology. The subsequent section delineates the workshop's structure and methodology in detail, as it was implemented as a constituent element of the conference program.

Background

> Any sufficiently advanced technology is indistinguishable from magic. (Clarke, 1973, p. 21)

The phenomena of electromagnetism largely elude our senses. Apart from the small fraction visible to the human eye, it is imperceptible to us. Yet the effects caused by electromagnetism are omnipresent. They range from experiences in our daily lives to enable technologies such as wireless communication, electric drives and navigation systems.

The fact that the cause of these effects is not observable, but quasi “invisible”, can give reason for a certain fascination. What at first sounds a little magic has been commonplace in the natural sciences for centuries: observing things and processes that remain hidden from the eye (Kube, 2019).

This is where the workshop comes in, using a storytelling approach to convey the topic. For example, magnetism becomes visible in everyday life when magnets attach notes or pictures to some metallic surfaces. A compass that is aligned with the earth's magnetic field makes the natural magnetic field directly tangible. By comparing it to magic and the analogy to invisible forces that work like magic, an emotional connection is created, curiosity is aroused and access to the topic is made easier (Heering, 2016; Hadzigeorgiou et al. 2011).

To demonstrate this, magnets are provided at the beginning of the workshop so that participants can experience the phenomenon of magnetism by themselves.

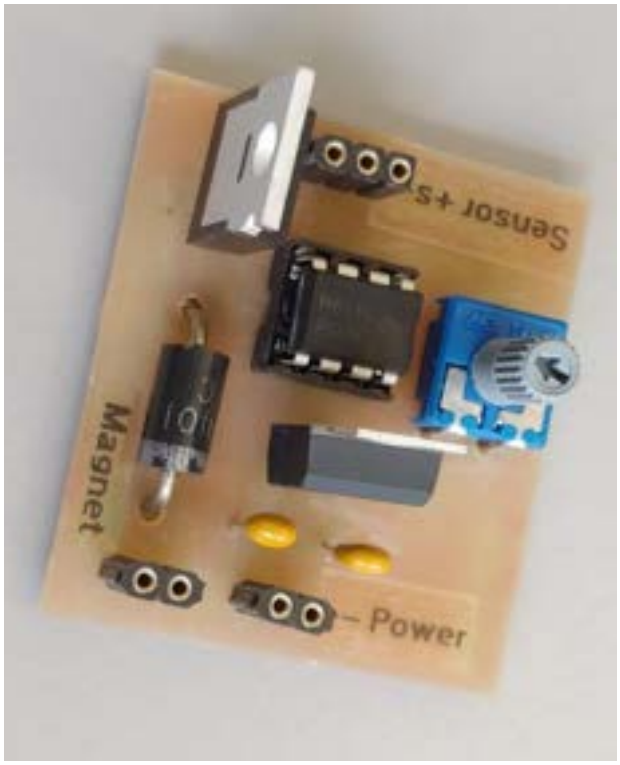
During the workshop, participants are engaged with the didactic methodology of Inspir**ING**®.The invisible force of magnetism is presented as a form of "modern magic" that can be understood through science. The personal narrative of a former Inspir**ING**® student and employee, from his dream of becoming an inventor to studying engineering and technology entrepreneurship, makes the engineering profession tangible and human. This use of storytelling aims to make people curious and excited to learn.

The following section describes the setup and underlying principle of the workshop experiment. The point of the experiment was to keep a permanent magnet suspended in mid-air using an electromagnet (see Figure 2). This requires an active control system to maintain the unstable balance between magnetic attraction and gravity. The setup has four main parts:

1. Permanent magnet: The object that is made to levitate.

2. Electromagnet: A coil that is used to create a magnetic field. The strength of the magnetic field depends on the electric current flowing through the coil.

3. Magnetic sensor (Hall sensor): It measures the strength of the magnetic field and thus indirectly the distance between the permanent magnet and the electromagnet.



4. Control circuit (see Figure 3): An electronic circuit that processes the signal from the sensor and switches the electromagnet on when the distance becomes too great (the magnet threatens to fall) and off when the distance becomes too small (the magnet threatens to jump onto the electromagnet).

The task of the participants was to calibrate the switching threshold on a potentiometer on the circuit board so that the magnet is held in a stable levitation.

Figure 2. Floating ball magnet, own photography.

Figure 3. Control circuit, own photography.

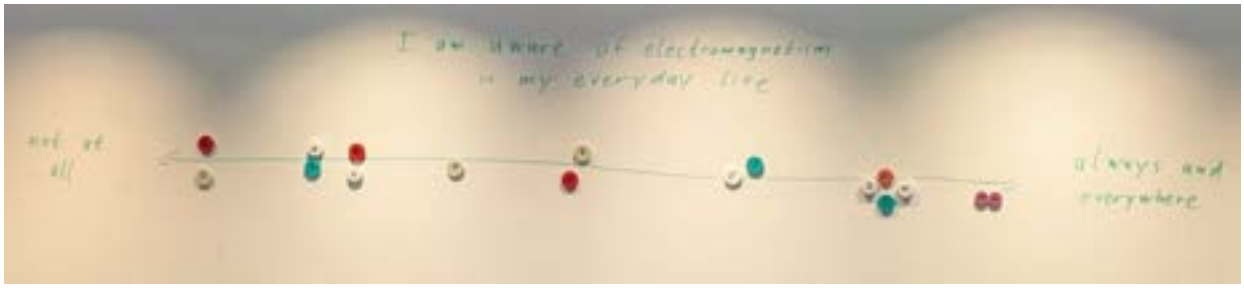
Schedule And Implementation

The workshop followed a clear structure that integrates didactic principles:

1. Awareness check (beginning): At the beginning, participants are asked to rate their own perception of electromagnetism in everyday life on a scale (see Figure 4). This serves as a baseline measurement and makes the phenomenon of technology blindness directly tangible.

2. Introduction and story: The moderators introduce themselves (personal story), introduce the topic using the "magic" narrative and briefly explain the fundamental principles of the experiment.

3. Experiment phase: Participants receive boxes with components and instructions. They set up the experiment, connect the components, and begin the crucial calibration process. This phase requires patience and dexterity and promotes problem-solving skills.



4. Levitation (moment of success): The success of the experiment (the floating magnet) is the highlight and creates a strong sense of self-efficacy.

5. Transfer to everyday life: Working in pairs or groups, participants collect examples of how electromagnets are used in everyday life. Examples such as electric motors, loudspeakers, scrapyard magnets, and magnetic levitation trains are then presented to illustrate the relevance of the principle learned.

6. Awareness check (end): Participants reevaluate their perception of electromagnetism. The

expected increase in awareness serves as evidence of the success of the intervention and as a basis for discussion.

Figure 4. Awareness scale, own photography.

Outlook

The workshop described, which incorporates the Inspir**ING**® program, offers valuable ideas for STEM education and shows a possible way to increase interest in STEM subjects.

It also showed that it is possible to raise awareness of complex technical phenomena in a short period of time. The before-and-after comparison of self-assessment in the workshop serves as a simple but effective indicator of a shift in perception away from technological blindness and toward a more sensitive perception. The program thus addresses a previously little-noticed but plausible cause of the current shortage of young talent in the engineering sciences.

The pedagogical triad of storytelling, reduction, and experimentation proffers a substantial and adaptable template for the design of inspiring STEM learning units. The paradigm shift from pure knowledge transfer to the creation of meaningful and motivating experiences is evident in the impressive demonstration of the floating magnet, which transforms abstract physical principles into tangible and fascinating learning experiences.

A more thorough examination of the long-term effectiveness of such brief interventions on study and career choices is necessary, and this can be best accomplished through longitudinal studies. However, the preliminary outcomes in terms of interest and perception indicate that initiatives such as Inspir**ING**® can serve as a pivotal foundation for cultivating the next generation of engineers, researchers, and technically proficient citizens. It is therefore imperative to deliberately address technological blindness to ensure the future of STEM talent and fortify Germany as a hub for innovation.

ESERA 2025 Copenhagen

Species Portraits As A Means Of Crossing Boundaries To Other Life Forms

Mette Hesselholt Henne Hansen[1], Katrine Bergkvist Borch[2] and Henrik Levinsen[3]
[1]VIA University College, Denmark,
[2] University of Southern Denmark, [3] University College of Copenhagen

The aim of this study is to identify aspects of nature connectedness in the personal experiences of participants while engaging with the natural world. In this contribution we will introduce the concept of aesthetic species portraits as a method for facilitating an experienced personal connection between human and non-human life forms in their natural environment. We report qualitative fieldwork in the form of interviews, video recordings, photographs and creative work from a summer school held at a rewilding project area in Denmark. During a four-day intervention pre-service science teachers and science educators participated in co-creation of art-based artifacts using aesthetic methods of representation of species encountered in the area. We employed four young passionate experts to introduce the pre-service science teachers to the high diversity environment focusing on its natural inhabitants. This introduction created an immersive engagement with place. During the next days we chose subjects among the encountered species and created portraits. We identified the key themes in our data using an abductive thematic analysis with intercoder reliability checks. We discuss empirical findings from our intervention in the light of the concept of nature connectedness. We found that the process of co-creation, the immersive nature of the intervention and the personal encounters with species had transformative effects on the participant's perception of nature.

Keywords: Affective dimensions, Field experience, Pre-service teacher education

Introduction

> Doing science with awe and humility is a powerful act of reciprocity with the more than human world. I've never met an ecologist who came to the field for the love of data or for the wonder of a p-value. These are just ways we have of crossing the species boundary, of slipping off our human skin and wearing fins or feathers or foliage, trying to know others as fully as we can. (*Kimmerer 2020, p. 252*)

Science education focuses increasingly on aesthetic learning processes, particularly in relation to education for sustainable development (Heras et al. 2017). The concept of nature connectedness has been proposed by psychological research as a prerequisite of environmental engagement. In these contexts, aesthetics often enters the science teaching discourse as part of STEAM pedagogy, introducing aesthetics as concept from the humanities aimed at increasing participation and engagement (Peppler and Wohlwend 2018).

Nature connectedness is regarded as an emotional driver and has been suggested to be independent of the cognitive dimensions of science (Lumber et al. 2017). However, both aesthetics and the concept of nature connectedness have deep historical roots within the field of biology.

The natural historians who inspired Darwin and seeded the development of modern biology as a scientific field had a deep aesthetic involvement in their fields of research: In 1805, Alexander von Humboldt published his groundbreaking work on the relation between climate, elevation and botany under the title "Naturgemälde" – painting of nature – and in 1899 Ernst Häckel

meticulously described numerous species new to science in his book “Kunstformen der Natur” – artforms of nature.

The concept of nature connectedness can be traced back to the ecologist E. O. Wilson’s book “Biophilia” from 1984, in which he argues that biology, as a field of science, offers an approach to understanding the living world that aligns with our innate tendency to affiliate with other organisms. Wilson invites the naturalist approach, field biology, as a formula to reengage with the natural world: “To the extent that each person can feel like a naturalist, the old excitement of the untrammelled world will be regained” (Wilson 1984, p. 147). The perspective offered by biology allows observation of other life forms as subjects formed by the same natural processes as the observer themselves: A subject-to-subject encounter, so to speak, since humans are, biologically, one species among many, with our capacities of logic and reflection being one adaptive outcome among all the adaptations outlining the various species of our biosphere.

We explore species portraits as a way of engaging with other life forms, in which aesthetic representation of a species is interwoven with the aim of understanding the life forms we encountered. The aim was to identify aspects of nature connectedness in the personal experiences of participants while engaging with the natural world.

RQ: How do the facilitated species encounters help direct the focus of participants towards knowing a species as a non-human subject?

We will explore this research question through empirical data from a summer school held in the summer of 2024 at an unmanaged natural area in Denmark.

Method

We obtained our data from a four-day intervention during a summer school with the title: “Species, experiences and aesthetics”. The course enlisted 12 pre-service biology teachers, two early career in-service biology teachers, and three teacher educators (with a disciplinary background in biology) participating in designing species portrait activities. We took inspiration for co-creation and co-design from Sanders and Stappers (2008).

We collected qualitative data in the form of interviews, photographs, video recordings and creative artifacts produced during the summer school. At the end of the second and third day of the course, we presented portraits at a “vernissage” event where participants introduced their exhibited portrait, described meeting their species, how they chose their creative media, and the process of constructing the portrait.

In this contribution we report an analysis of a 55-minute video sequence recorded while co-creating a definition outlining the concept ’species portrait’ (video 1), as well as two group interviews with participants at the end of the course, lasting 23 minutes (interview 1) and 40 minutes (interview 2). Interviews were semi-structured, following a simple interview guide based on the course title: Respondents were invited to reflect on species they had encountered and portrayed, experiences they had encountered and their view on the aesthetic processes they had engaged in.

While co-creating the concept definition, one of the authors of this contribution wrote keywords from the dialogue on a flip-over, creating an open coding of points emerging from the conversation. A picture of the flip-over is shown in figure 1. From these codes the authors employed a thematic analysis and developed a coding scheme (Braun and Clarke 2006). Using these themes and codes from the flip-over to code, sequentially, video 1, interview 1 and interview 2, we broke down and reassembled our code structure through an abductive analysis

(Brinkmann 2014), which allowed us to recognize and include patterns emerging throughout the coding process.

Figure 1. A photo of the outcome of co-creating a definition of "species portraits" with course participants. English translations of the concepts emerging from the dialogue are superimposed on the photo.

Findings

Throughout the dialogue in the videos, the motif of sensory experiences emerged as a recurrent and dominant theme when describing species encounters: Respondents reported having engaged their senses in new ways, and they referred to the sensory experience of their particular species. Reports of the encountered species were highly affective, using a vocabulary of deeply personal connections, in several cases in relation to species encountered for the first time.

When asked about their experiences during the course, time and immersion became recurrent elements: Respondents reported a wide range of situations of solitude, absorption, increased awareness and meticulous studies of their chosen species. Many of the experiences reported were intimately related to place, indicating immersive engagement.

Discussion And Conclusion

We were able to mediate species encounters in a particularly rich natural environment, facilitated by young enthusiastic species specialists, and our participants were able to let these initial impressions grow and mature through a generous, curriculum free and immersive aesthetic engagement with their surroundings. But while this intervention does not reflect a common school reality, it did allow us to explore the potential offered by what Wilson called “the naturalist approach” (Wilson 1984). Our participants did not arrive with a deep knowledge of field biology,

but the saturated experience of an inhabited environment, and their aesthetic engagement with particular species initiated transformative processes.

Table 1. This table outlines main themes emerging through our abductive analysis of the interviews, exemplified through selected participant quotes.

	Selected quotes
Sensory engagement	Vanessa:*"Well, I thought it was a bit crazy, that the bees had actual scents […] they smelled like onions or… lemon. And then how you were able to get up that close. I think it was crazy, getting that close to a tiny little animal, such a tiny little bee"*
Time, place, immersion	Erica: *"Well, this is connected to the dung. So, well, the scarabs. I simply find them cute. I didn't know a thing about them. It's not that I am that knowledgeable now, but this, to sit and paint them. I ended up – because I was sketching, I think I drew the same one five times or so. And then you become… it's a really good way to learn to identify the species"*
Affective species descriptions	Birk: "*I think it has resulted in a much more personal affection for specifically the species you went after. You have really been chasing them for a reason, and personally I really want to learn more about them, and I think it is super interesting to capture them in a creative, an aesthetic fashion, making it more, I don't know, personal. That is cool".*
Transformative experiences	Bjørn: *"O told me about sundew, so I thought […] I will go hunting for this one. And I couldn't find my way, and I got lost, and I was alone, and it was sort of magic to come down there and see how, well, like, the bog was there, the quaking bog was there and you had to go out there, and you could feel how it was, like, suspended, and it was embraced by the forest. And there were these tiny sundews, and I was all alone, and I nearly shed a tear, actually."*

Bjørn, a participant describing his own science teacher identity as "sort of a molecular biologist and physiologist by nature, so I never really delved into the species thing" ended up being so affected by an encounter with sundew, that he "nearly shed a tear", while Erica described going from "not knowing a thing" about scarabs to spending a whole day with repeated sketching of one scarab, and concluding that she "just found them cute" (full quotes in table 1).

In spite of their self-declared low initial level of knowledge about field biology or species, and the lack of any assessment of knowledge or specified requirements of biological facts in the aesthetic products, participants embedded many perspectives of biological knowledge in their portrayals of species, from morphological details through life cycles and habitat requirements to effects of the species on ecosystem dynamics. In the interviews, several participants expressed enthusiasm not just for the species itself, but also for the knowledge gained while working on the portrayal. The cognitive side of learning about the species emerged as interwoven with the affective connection, the aesthetics of the creative process and the awareness of the subject of the portrait as a life form in its own right. In the words of Birk: "I really want to learn more about them, and I think it is super interesting to capture them in a creative, an aesthetic fashion, making it more, I don't know, personal. That is cool" (full quote in table 1)

A professional field biologist could be considered to be engaging in, as our opening quote from Kimmerer (2020) reads, "crossing species boundaries" by finding significant patterns in scientific

data describing other species. This level of insight is not readily available in a school science setting, or even in the educational setting of a teacher training program. Our species portraits can be considered short-cuts for creating this transcendent experience of a personal bond to a non-human life form in its natural environment.

Aesthetics has an inherently transcendental aspect in that it communicates affect and emotion from one human to another. The natural sciences, on the other hand, allow us to attempt understanding non-human life forms as subjects in their own right, thus representing another type of transcendence. Bringing the two together adds depth to the concept of nature connectedness by qualifying emotional attachment with curiosity and a desire for knowledge: Science can help us understand who they are, and aesthetics can help us feel that understanding is important.

We see indications of this transformative process in our participants' perception of nature, as reflected through the interviews.

Acknowledgement

We would like to acknowledge the staff at the Molslaboratoriet field station for allowing us to situate our field course in a truly inspiring natural setting, and our colleague, Therese Malene Nielsen for bringing new perspectives on time into our discussions.

Detect, Define And Visualize Epistemic Emotions For Science Education

Francesca Riccioni and Olivia Levrini
Department of Physics and Astronomy "A. Righi", University of Bologna, Italy

Learning science is not solely a cognitive endeavour. The affective dimension has increasingly become a focus of science education research. Within this domain, growing attention is being given to constructs such as epistemic emotions and to novel methodologies used to investigate them. This contribution focused on an NLP (Natural Language Processing) analysis aimed at detecting epistemic emotions in the context of the discovery of the Theory of Special Relativity. The study was conducted by analysing a special text based on historical interviews with Albert Einstein, carried out by Gestalt psychologist Max Wertheimer in 1916, and published in 1945. From this analysis, the following results emerged: an operational definition of the construct of epistemic emotions, developed through three markers that can be applied to analyse other texts or interviews; the creation of a list of epistemic emotions, designed to facilitate their consistent classification and detection in future researches; a dynamic mapping and visualization of the epistemic emotions involved in the cognitive processes associated with the key phases of the genesis of the Theory of Special Relativity, using James Russell's circumplex model of affect. These findings offer tools to bring out and visualize the emotional dimension of problem-solving and scientific research activities. These tools can be both diagnostic and teaching resources, aimed at unpacking affective dynamics in educational contexts.

Keywords: Epistemic Emotions, Physics Education Research, Interdisciplinarity

Introduction

Recent special issues and handbooks have highlighted and formalized the relationship between affect and cognition in science education (Jaber et al., 2023; Vea & Jaber, 2026). Major cognitive theories — such as conceptual change theory (Posner et al., 1982) — have progressively emphasized the multi-layer landscape that has been progressively built to unpack the multiple dimensions and types of knowledge involved in conceptual change. The current research on conceptual change offers a landscape, that is grounded in the foundational work on the nature of concepts and conceptual change, and articulates in further four layers: the role of representations (such as language, visual representations and simulations, equations, and gesture) in concept representation and learning; the interplay between the epistemological practices of explaining, modelling and arguing and conceptual change; the relationship between conceptual change, metacognition, and student's epistemologies; the relation between identity development and conceptual learning in disciplinary domains (Amin et al., 2023). The last two layers point out the need to enrich the research on conceptual change with affective and emotional dimensions (Pintrich, 1993).

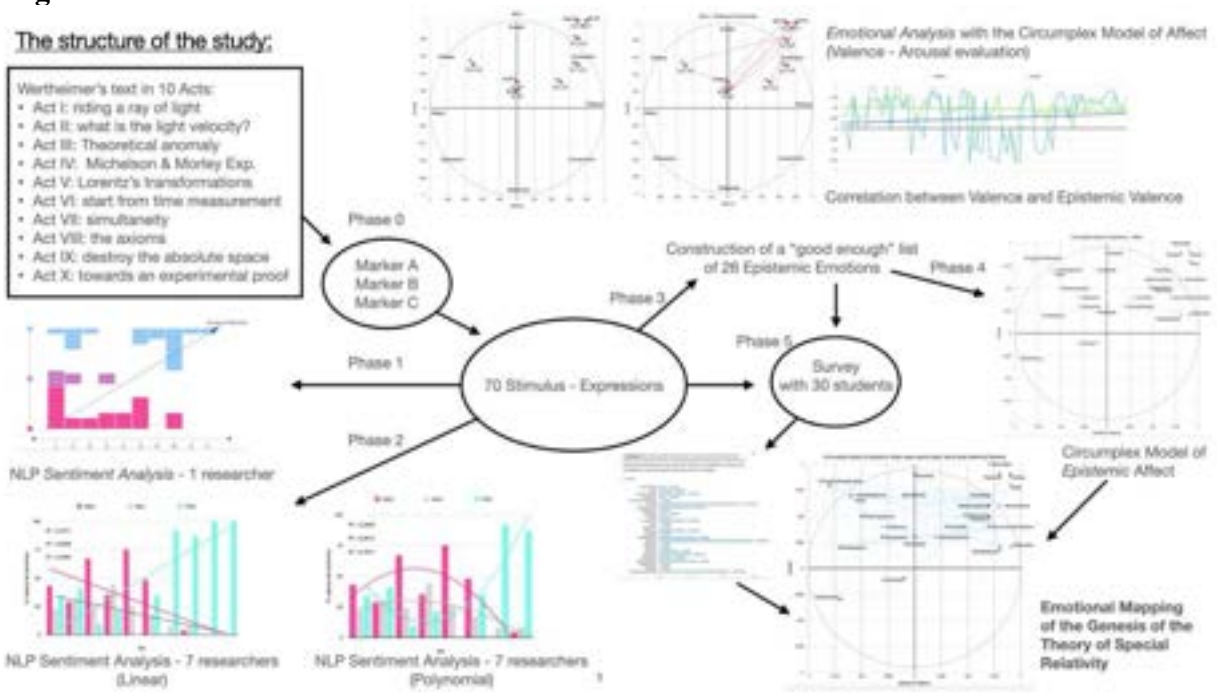
In this context, one of the ways of developing the affective dimension is focused on the epistemic emotions, namely the emotions engaged in the cognitive dynamics of learning (Jaber et al., 2023). These studies on epistemic emotions are shedding light on novel theoretical and methodological challenges.

As for the theoretical issues, the emotional dimension challenges the pure rational assumptions that stay behind the earlier theories of conceptual change (Amin et al., 2023) based, more or less explicitly, on a strict separation between the apparatus of rationality and that of biological regulation (Damasio, 1994).

As for the methodological issues, the debate is still very open and lively, being the emotional dimension particularly subtle and implicit. The wide variety of methods and approaches currently employed to "capture" epistemic emotions has led Jaber and colleagues to refer to a "generative non-convergence" typical of an expanding field of research. In fact, the state of the art shows a great effort to search for new creative methodological approaches aimed to keep a high level of rigour (Jaber et al., 2023). Video-interviews are a typical explored method for multi-modal analyses aimed to investigate the degree of connection between the emotion and the identified cognitive event. For instance, Jaber and Hammer use video interviews to uncover "entangled" emotions that characterize a general attitude toward engaging in science among very young subjects (Jaber & Hammer, 2016), while Gupta and colleagues examine video interviews to capture moment-by-moment epistemic emotions, focusing on short timescale local coherences in high school students (Gupta et al., 2018). More generally, it is recognized that text and natural language are primary vehicles for emotions, emphasizing the need for methods capable of analysing such datasets.

This study has been carried out to explore a pilot methodological approach for detecting and visualizing epistemic emotions, drawing on machine learning techniques for text processing and analysis. The method was tested using a historical text that examines the emotional dimension in the development of a scientific theory. Our goal is to refine and adapt this approach for use in classroom settings as well.

This pilot study was guided by the general research questions of how Epistemic Emotions can be recognized and operationally defined, and how they can be represented and visualized, including which models may be used; these questions were explored through the specific case study described below.



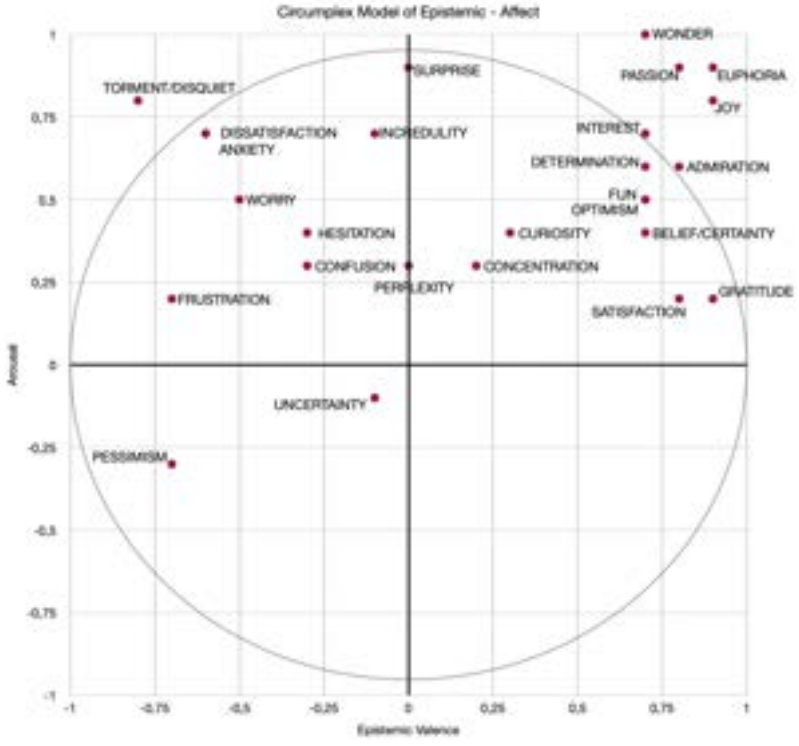
The Source Of Data On Epistemic Emotions

For the pilot study, the textual source of data we chose is the seventh chapter Einstein: The thought that led to the theory of relativity of the book Productive Thinking (Wertheimer, 1945, 2020; Miller, 1975). Max Wertheimer's text collects conversations with Albert Einstein on the genesis of Special Relativity. The conversations refer to a series of meetings that Max Wertheimer, exponent of Gestalt, had with Albert Einstein in Berlin since 1916. This chapter appeared as a suitable text for the analysis for three main reasons. The first reason is that the scientist also describes difficulties and emotional impulses in the genesis of a new scientific theory. The second reason concerns the text structure, organized into ten acts that delineate the pivotal phases of this specific research process. This format allowed the identification of moment-by-moment epistemic emotions (Gupta et al., 2018) and, owing to the open and conversational nature of the interview (Pussetti, 2010), also captured entangled emotional nuances (Jaber et al., 2023) that influenced the direction of inquiry (Jaber & Hammer, 2016). The third reason concerns the topic per se of the conversations: Special Relativity (SR). In fact, SR has been already widely investigated in its historical and philosophical dimensions (e.g. Pais, 1982) in the research on conceptual change (Posner et al, 1982; Hewson, 1982; Villani & Arruda, 1998; Levrini & diSessa, 2008; Levrini, 2013) and, more in general, in physics education (Sherr et al., 2001, 2002; Alstein et al., 2021; Miani, 2022). This constellation of studies, together with Einstein's metacognitive reflections, offers the possibility to triangulate the results obtained by a novel methodological approach to investigate epistemic emotions, that integrates psychological, conceptual, and epistemological dimensions.

Methods And Results

From a methodological point of view, the study was inspired by natural language processing (NLP) techniques (Das & Singh, 2023) to process Wertheimer's text. Through an initial exploration — individually conducted —, 70 specific linguistic expressions linked to emotions and associated with the phases of scientific research were detected. Examples of linguistic expressions highlighted are: "to trouble him", "intensely concerned", "Puzzling to think"... These expressions, termed stimulus-expressions, were identified to elicit and associate specific epistemic emotions. This preparatory phase also included the extraction of three markers — concise indicators designed to systematically detect stimulus-expressions within the text — essential for distinguishing, conceptualizing, and objectifying epistemic emotions linguistically. These markers through which epistemic emotions can be recognized and operationally defined are: A. emotional sound; B. epistemic sense and connection to a specific phase of the construction of the theory; C. liquid lexical structure (Figure 1 Phase 0).

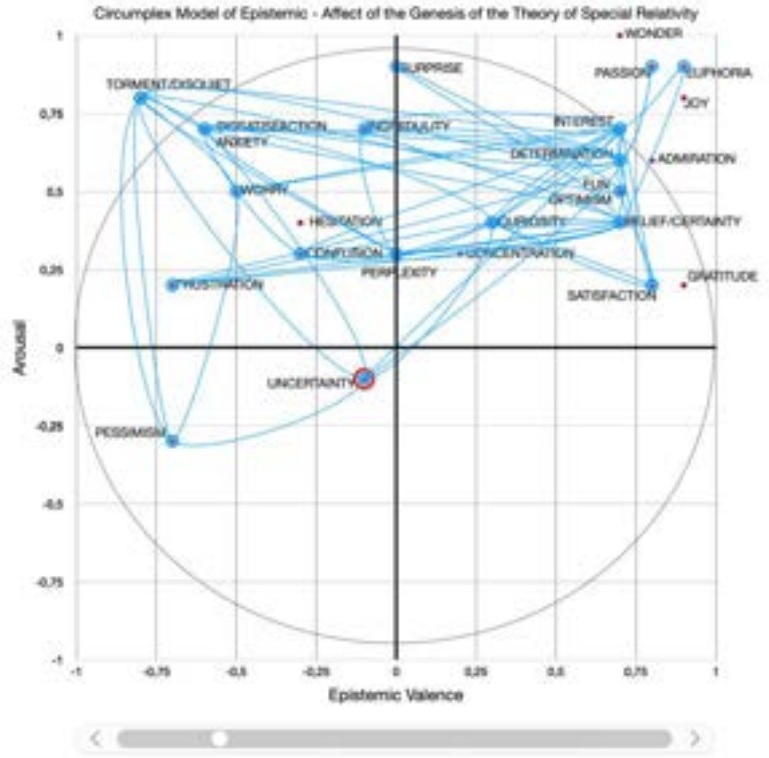
Figure 1. Design and structure of the study. Phase 0: construction of the three markers for operationally defining epistemic emotions within the text. Phase 1 and 2: Visualization of Einstein's "feeling of direction" through an NLP-sentiment-analysis. Phase 3 and 4: Construction of the Circumplex Model of Epistemic Affect. Phase 5: emotional mapping of the genesis of SR.



Thus a primary action was to extrapolate the visualization of Einstein's "feeling of direction" through an NLP-sentiment-analysis (positive-negative-neutral), which took place by processing 70 stimulus-linguistic-expressions extracted from the text, first of all individually and then — to make the result more robust — with the collaboration of 7 researchers in Physics Education, who evaluated again the stimulus-expressions through the three connotations (Figure 1 Phases 1 and 2).

It was found, using linear interpolation, that positive sentiment has an increasing trend while negative and neutral sentiment decreases as the theory develops. We also found the correlation between the positive sentiment and the solving phases of the research path. Using polynomial interpolation, it was surprisingly found that positive sentiment has a trend similar to that relating to the Denning-Kruger Effect (Dunning, 2011) as skills increase.

The preliminary results obtained in phases 0, 1, and 2 have corroborated the plausibility of the hypothesis that the text is rich in epistemic emotions and that these emotions can be detected. The following research phases led us to achieve the main findings.



Going on in "dialoguing" with the text, considering the previous scientific literature on the topic of epistemic emotions and using a strong knowledge of Albert Einstein's work, a list of 26 epistemic emotions linked to problem-solving was created to refine the connotation of the 70 stimulus-expressions. This list is not supposed to be exhaustive, but it represents our first original finding: a novel plug-in that widens and extends the original functions of Russell's Circumplex Model of Affect (Russel, 1980). This model is used in disciplinary fields such as psychology and emotional robotics engineering and represents each emotion with a pair of coordinates — ranging from -1 to 1 — called Valence (from sadness to happiness) and Arousal (degree of activation, from sleepiness to excitement). Each epistemic emotion of the list has been positioned in the Circumplex Model of Affect (Figure 1 Phase 3 and 4; Figure 2), by assigning the values of Valence and Arousal. The assignment has been supported by AI as a stimulus and/or a check of the researchers' qualitative hypothesis. The process led us to turn the Circumplex Model of Affect into our second original finding: a draft of a Circumplex Model of Epistemic Affect (Figure 1 Phase 3 and 4; Figure 2).

Figure 2. Circumplex Model of Epistemic Affect.

Finally, through statistics on a sample of 30 students of a Physics Education university course, a correspondence was constructed between the 26 epistemic emotions in the list with the 70 stimulus-expressions in the text. Going into more detail, the survey took place by administering to the 30 students a format that highlighted each stimulus-expression and asked the subjects to associate every specific stimulus-expression with one or more epistemic emotions of the list. This allowed us to select the epistemic emotion that best characterized every specific stimulus-expression, and to insert all the 70 stimulus-expressions into the Circumplex Model of Epistemic Affect to arrive at the final emotional mapping of the genesis of the theory of SR, with a visualization and an animation on the circumplex showing its dynamics (Figure 1 Phase 5; Figure 3).

Figure 3. Emotional dynamics of the genesis of Special Relativity Theory built in the Circumplex Model of Epistemic Affect.

Conclusions

This research has corroborated the feasibility of constructing an increasingly specific definition of epistemic emotion through the analysis of a text with interviews with scientists. A novel methodology highlights the potential of an interdisciplinary research approach, which brings to light the affective dimension within scientific research processes. The Circumplex Model of Epistemic Affect (CMEA), born from the synergy between the circumplex model of affect and the development of a reference list of epistemic emotions, emerges as a novel tool designed to detect, define, and visualize epistemic emotions, offering a structured approach to assess the affective dimensions of scientific research and learning processes. Further studies will test and revise both the list and the Circumplex. We expect that the evaluation of Valence and Arousal of the single emotions can be made more and more robust. However, by leveraging the CMEA, researchers and educators can systematically identify and categorize these emotions, thereby making them more accessible and actionable within both research and classroom dynamics. The CMEA can operate as both a pedagogical and diagnostic tool and it could represent a significant step forward in integrating affective and cognitive dimensions into educational research and practices. From a pedagogical perspective, the visualization of Albert Einstein's scientific theorizing suggests that emotional trajectories in scientific inquiry are not linear or progressively cumulative, as often implicitly assumed, but rather characterized by fluctuations and reversals. Making such alternating emotional dynamics visible within a classroom pathopoietic process may be particularly illuminating for students, as it foregrounds the affective complexity inherent in authentic scientific problem solving. To check its diagnostic potential, the tool has been used to emotionally evaluate different phases of a classroom problem-solving process to elicit and make visible the affect dynamics associated with an experimental kinematics activity in a second-year upper secondary school class (Rimediotti, 2025). The results show the tool's effectiveness in unveiling students' emotional development throughout their learning processes.

Acknowledgement

This work builds on the Master's thesis of the first author, Francesca Riccioni, supervised by Professor Olivia Levrini, and has been developed within her PhD research thisis in Physics Education at the Department of Physics and Astronomy "A. Righi". It is co-funded by the IDENTITIES Project.

The contributions to the 2025 ESERA conference in this chapter present several research themes related to the focus of the strand. One dominant theme that emerges from the papers is the critical examination of Inquiry-Based Learning (IBL). This covers everything from the theoretical underpinnings of IBL and the systemic determinants of its adoption to its practical implementation in diverse classrooms. The contributions primarily focus on fostering student agency and scientific literacy by engaging learners in authentic scientific practices such as hypothesising, modelling and evidence-based argumentation. Another significant theme is the integration of cognitive and neuroscientific frameworks into pedagogical design. The five studies in this chapter utilise models such as the Five Pillars of the Mind (symbols, patterns, order, categories, and relationships) and the Model of Educational Reconstruction (MER) to align science instruction with the brain's natural learning processes. This cognitive focus also extends to developing specific 21st-century skills, often referred to as the *4Cs* (critical thinking, creativity, collaboration, and communication) framework, which are considered essential outcomes of modern science curricula. Other relevant trends that emerge from the synthesis of these works concern methodological innovation and teachers' professional development. In terms of methodology, the papers focus on gamifying and diversifying the learning environment. Examples include the use of educational escape rooms to promote collaboration and the implementation of learning workshops to support open inquiry in inclusive settings. With regard to professional development, the papers in this chapter emphasise that innovations such as inquiry-based Teaching-Learning Sequences (TLSs) require substantial support for teachers to be effective. Therefore, these contributions are at the forefront of science education research, as they bridge the gap between theoretical constructs and classroom reality. For example, by focusing on the nature of scientific enquiry and the role of domain-specific networks, such as symbols in physics, the studies move beyond simple content delivery towards fostering a deeper understanding of the epistemic practices of science. This aligns the contributions of Strand 3 with the global educational goal of producing scientifically literate citizens who are capable of dealing with the complexities of the present day.

Finally, in terms of their relationship with the conference themes, the contributions focus on digital advances in science education and sustainability. Specifically, the papers explore the digital transformation of education, particularly the development of digital tools designed to reduce barriers to inquiry and the integration of Artificial Intelligence (AI) into experiments and instructional design. Here, digital platforms are presented not just as tools, but as transformative agents that reshape cognitive processes such as metacognition and problem solving. Although less explicitly present, sustainability is integrated into the contributions through real-world scenarios designed to promote environmental awareness. Furthermore, open inquiry formats often utilise topics such as 'habitats and environments' to engage students with their local and global surroundings, thereby fostering the agency required to address future environmental challenges.

What Factors Influence The Adoption Of Inquiry-Based Learning? A Comparative Study Between Chile, Spain, And Portugal

Iraya Yánez-Pérez and Radu Bogdan Toma
Department of Specific Didactics, Area of Science Education, University of Burgos, Spain

Scientific inquiry is an effective strategy for improving students' scientific literacy. However, it is rarely used by teachers. This study aims to identify the variables that predict the use of scientific inquiry by Primary Education teachers in Chile, Spain, and Portugal. A multiple regression analysis of TIMSS 2019 data reveals that its enactment depends on several factors such as teacher training, school climate, and job satisfaction. These variables vary by country. Therefore, educational policies and professional development programs tailored to each context are necessary to promote inquiry in these Ibero-American science education.

Keywords: inquiry, TIMSS, job satisfaction

Introduction

For decades, research in science education has advocated for the use of scientific inquiry to enhance students' scientific literacy. Many studies support a shift toward inquiry-based methods in teaching and learning (García-Carmona, 2020). Despite this, studies (Cañal et al., 2016; Romero-Ariza et al., 2019) show that teachers rarely use inquiry. Instead, they favor traditional methods, such as lectures, reliance on textbooks, and rote memorization. Hence, teachers' practices are far from the recommendations made by science education research (de Jong et al., 2024). This gap between educational policy and classroom reality is not unique to inquiry-based learning; similar discrepancies have been observed in the integration of Information and Communication Technologies (ICT) in science teaching, where reforms like the LOE and LOMCE in Spain have had limited impact on actual pedagogical practices (Yánez-Pérez et al., 2024a).

The limited adoption of inquiry is concerning, especially given its potential to foster deeper conceptual understanding, motivation, and scientific competencies (Lazonder & Harmsen, 2016; Aguilera & Perales-Palacios, 2020). Recent efforts to design digital tools, such as IndagApp, aim to lower the barriers to implementing inquiry by providing structured, curriculum-aligned resources that guide both teachers and students through the inquiry cycle (Yánez-Pérez et al., 2024b). However, the effectiveness of such tools depends on broader contextual factors that influence teachers' willingness and ability to change their practices. Therefore, this study seeks to identify the factors influencing the adoption of scientific inquiry in Primary Education across three Ibero-American contexts. The research question guiding this study is:

- What are the determinants of the adoption of inquiry by Primary Education teachers in Chile, Spain, and Portugal?

Theoretical Underpinnings

Inquiry is commonly defined as a teaching strategy where students generate and evaluate scientific explanations of the natural world while engaging in scientific practices and discussions. It involves analysing data and using evidence and logic to understand phenomena (Crawford,

2014; Schwartz et al., 2023). By adopting this approach, students learn science by mimicking the practices of real scientists. Based on the level of teacher support, four types of inquiry are identified in the literature (Vorholzer & von Aufschnaiter, 2019). At the lowest level, a confirmatory inquiry is one where the teacher provides the research question, procedure, and expected results. At the next level, students engage in structured inquiry, where the research question is unknown, but the teacher determines the question and procedure. Guided inquiry involves greater autonomy for students, who are only given the research question by the teacher. Finally, open inquiry allows students to select a phenomenon, formulate a research question, design an experimental procedure, and draw conclusions based on their findings.

These inquiry types align with the pedagogical cycle proposed by Pedaste et al. (2015), which includes phases such as orientation, conceptualization, investigation, conclusion, and discussion. Digital tools like IndagApp operationalize this cycle, offering scaffolded experiences that can help teachers transition from confirmatory to more open forms of inquiry (Yánez-Pérez et al., 2024b). However, the adoption of such innovative methodologies is often hindered by systemic barriers, including inadequate resources, limited professional development, and contextual school factors—issues also highlighted in studies on ICT integration in science education (Yánez-Pérez et al., 2024a).

Methodology

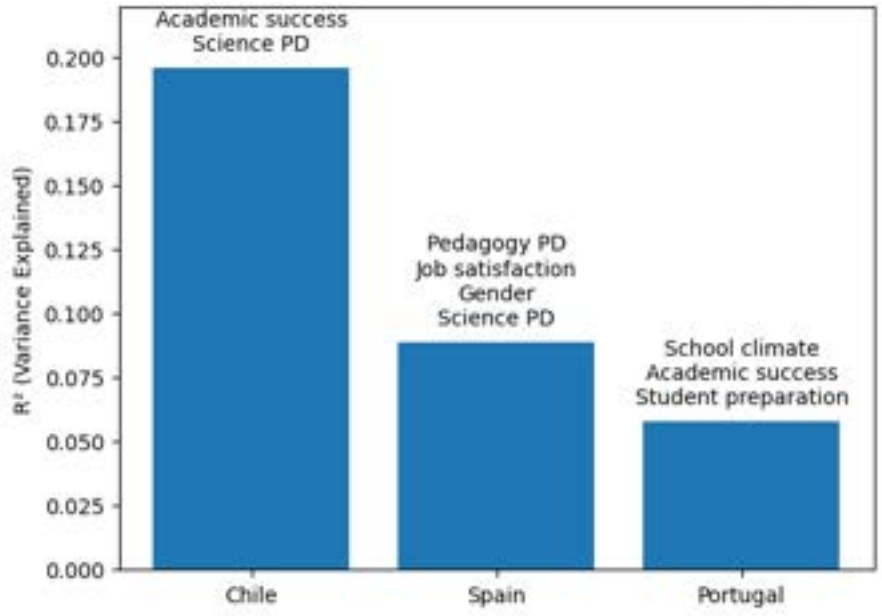
Participants

This study uses data from TIMSS 2019, which includes science teachers in 4th grade. Data were collected from three Ibero-American countries: Chile, Spain, and Portugal. TIMSS 2019 employed a stratified two-stage sampling method. In the first stage, schools were selected based on key variables: in Chile, by school type (public, subsidized private, private) and location (rural, urban); in Spain, by school type (public, semi-private, private) and bilingual status; and in Portugal, by school type (public, private), region, and size. In the second stage, intact classes within the selected schools were chosen. The study involved 169 schools in Chile (236 teachers), 181 in Portugal (314 teachers), and 501 in Spain (743 teachers).

Data Collection Instrument

The teacher questionnaire covered several constructs. This study focuses on the following: first, teacher professional development, measured by 4 items. Second, student preparation, which was assessed by asking teachers how eight factors limited their teaching of science. Examples include: “Students lacking prior knowledge or skills,” “Disruptive students,” and “Uninterested students.” Third, school climate and context, measured by 8 items such as "This school is located in a safe neighborhood" and "Students respect the school infrastructure." Fourth, the school’s emphasis on academic success, with items addressing teachers’ ability to inspire students and teachers’ expectations for student performance. Fifth, job satisfaction, measured by five items such as "I am enthusiastic about my work." Finally, the emphasis on inquiry-based science teaching, where teachers were asked how often they asked students to engage in eight inquiry-based practices.

We performed confirmatory factor analysis to assess the construct validity of the scales (results not shown), confirming their unidimensionality. Additionally, McDonald's Omega was calculated, showing that all scales demonstrated adequate internal consistency reliability ($\omega > 0.77$).



Data Analysis Procedure

Regression analysis was used to identify which factors collected in TIMSS 2019 were associated with teachers’ emphasis on inquiry-based science teaching.

Findings

The determinants of adopting scientific inquiry varied across countries (Figure 1).

Figure 1. Determinants per country

Note: Bars represent the total variance explained (R2) by the most predictive model in each country; text above each bar lists the key predictors included in that country's model, ordered conceptually.

In Chile, the most predictive model included two variables, with an $R^2 = .196$, $F(2, 135) = 16.17$, $p < .01$. The emphasis on academic success explained 13.6% of the variability in inquiry use, while professional development in the science curriculum explained an additional 6%. T-tests showed that teachers in schools with a strong emphasis on academic success adopted inquiry more ($M = 10.99$) than those in schools with less emphasis ($M = 9.75$), $t(143) = 3.74$, $p < .01$, with a large effect size ($d = 1.63$). Teachers who received training in the science curriculum ($M = 11.57$) also adopted more inquiry than those who did not ($M = 9.99$), $t(140) = 3.52$, $p < .01$, with a moderate effect size ($d = .76$).

In Spain, the most predictive model included four variables, with $R^2 = .089$, $F(4, 463) = 11.20$, $p < .01$. Professional development in pedagogy/instruction explained 4.7% of the variability, job satisfaction 2%, gender 1.2%, and professional development in the science curriculum 1.1%. T-tests revealed that teachers with training in pedagogy/instruction ($M = 9.91$) adopted more inquiry than those without training ($M = 9.04$), $t(486) = 4.52$, $p < .01$, with a moderate effect size ($d = .45$). Teachers with high job satisfaction ($M = 9.53$) also adopted more inquiry than those with low satisfaction ($M = 9.07$), $t(489) = 2.60$, $p = .01$, with a small effect size ($d = .24$). Men ($M = 9.59$) adopted more inquiry than women ($M = 9.17$), $t(488) = 2.10$, $p = .04$, with a small effect size ($d = .22$). Teachers with training in the science curriculum ($M = 10.03$) adopted more inquiry than those without it ($M = 9.13$), $t(483) = 3.95$, $p < .01$, with a moderate effect size ($d = .47$).

In Portugal, the most predictive model included three variables, with $R^2 = .058$, $F(3, 290) = 5.84$, $p < .01$. School climate explained 2.3% of the variability, academic success emphasis 2.1%, and student preparation 1.4%. T-tests showed a trend, though not significant, that teachers in schools with a safe school climate ($M = 9.54$) adopted less inquiry than those in less safe schools ($M = 10.14$), $t(304) = 2$, $p = .05$. No significant differences were found between teachers in schools with high or low emphasis on academic success or between those who perceived limitations due to student preparation.

Discussion

Research in science education and curriculum reforms advocates for the early adoption of inquiry-based methods (Crawford, 2014; de Jong et al., 2024; García-Carmona, 2020). However, few teachers implement this strategy (Romero-Ariza et al., 2019). This study identifies the factors influencing the adoption of inquiry in Chile, Spain, and Portugal, showing that these factors vary by country. In Chile, academic success emphasis and teacher training in the science curriculum are key. In Spain, pedagogical and curricular training, gender, and job satisfaction influence adoption. In Portugal, school climate, academic success emphasis, and student preparation are important, though not conclusive.

These findings align with previous research highlighting the contextual nature of educational innovations. For instance, Yánez-Pérez et al. (2024a) found that the integration of ICT in Spanish science classrooms under the LOE and LOMCE reforms was limited, and that teacher participation in continuous professional development was a significant predictor of ICT use. Findings also suggest that the availability of educational resources for inquiry teaching (e.g., Yánez-Pérez et al., 2024b) might be not enough, and specific measures should be developed to reduce logistical and pedagogical barriers to inquiry. Hence, as our results show, the effectiveness of such tools may be mediated by broader systemic factors such as school climate, job satisfaction, and institutional support.

These findings have significant implications for education. Interventions must be tailored to the specific needs of each country. In Chile, promoting academic success and enhancing teachers' knowledge of the science curriculum is essential. In Spain, more pedagogical and curricular training is needed, along with improving working conditions to increase job satisfaction. In Portugal, improving school climate, student preparation, and academic success emphasis are key. Though challenging, these measures are crucial to promoting the adoption of inquiry in science teaching. Future research should explore how digital tools like IndagApp can be embedded within supportive professional development programs that address the specific contextual variables identified in each country.

Several Reasons To Develop Symbols In Physics Education

Daša Červeňová and Peter Demkanin
Comenius University Bratislava, Faculty of Mathematics, Physics and Informatics, Slovakia

Despite extensive research on conceptual change in physics education, comparatively less attention has been paid to the role of domain-specific networks underlying learning. This paper contributes to this area by applying the Theory of the Five Pillars of the Mind, which conceptualises learning as supported by five interconnected domain-specific networks: symbols, patterns, order, categories, and relationships, to physics education. In this study, we approach physics education through a Pillars framework, used both for the design of learning materials and for analysing pupils' learning outcomes with emphasis on symbols in physics education. Based on the literature and initial results, we identify several reasons to support the development of symbols in physics education. A novel approach was used to qualitatively analyse pupils' written responses, interpreted through the Pillars of the Mind framework, which indicates differences in representational use and conceptual reasoning. These results highlight the importance of analysing learning beyond performance scores and the central importance of symbols in physics education.

Keywords: symbols in physics education, error pattern analysis, pillars framework

Introduction

The theories of physics education investigate, among other topics, the cognitive processes involved in learning physics, including how pupils acquire and apply knowledge, for example, when learning Newton's second law. In a well-designed educational environment, pupils, as members of peer groups, are continuously exposed to numerous stimuli that their brains must process in real time. Sensory information is selectively filtered through prior knowledge and experience, with certain elements undergoing deeper cognitive processing. In teaching, specific learning situations are deliberately designed to serve as stimuli capable of resonating with pupils' current understanding.

Research on domain-specific networks remains relatively underexplored in physics education compared to the extensive literature on conceptual change. This paper addresses this gap by drawing on the Theory of the Five Pillars of the Mind (Tokuhama-Espinosa, 2019), which conceptualises learning as supported by five domain-specific networks: symbols, patterns, order, categories, and relationships. These networks are proposed as foundational for learning across domains and are grounded in cognitive neuroscience. To our knowledge, no studies explicitly apply this theory to physics education, although some elements can be found implicitly in textbooks, such as those from the International Baccalaureate (IB) Middle Years Programme (MYP).

This project aims to make these implicit structures explicit by designing learning materials that foster their development. Rather than focusing on content selection, we explore the learning activities and cognitive processes that promote understanding, and how this knowledge can optimise physics instruction. We applied the Pillars framework to design a fluid mechanics course for 15-year-old pupils. This contribution presents evidence for the importance of symbols in physics education through a review of the literature, an analysis of traditional learning materials, and an examination of pupils' incorrect responses in a written summative assessment, all of which we interpret within the proposed framework.

Theoretical Background

The design of learning materials used in everyday classrooms is highly influenced by many variables and can significantly impact pupils' ability to master the selected topic. Pupils' initial interests should be captured (Morkel, & Singh, 2024) to master the topic. Moreover, the arrangement of activities significantly influences pupils' learning, and it may differ across groups of pupils. In our research, we use the theory of the Five Pillars of the Mind (Tokuhama-Espinosa, 2019) as a theoretical framework to examine pupils' learning of selected physics topics. Sands (2021) adopted a similar approach, using sensemaking to formulate a theory of modelling in physics education. In this contribution, we focus on the role of symbols in physics education, which arises from the application of a framework supported by neuroscientific studies.

Benefits resulting from applications of relevant outputs of cognitive neuroscience or neuroscience in general have already been proven. Our research is grounded in the findings of Fynes-Clinton et al. (2022), Bowers (2016), Donoghue and Horvath (2016), Clement and Lovat (2012), Gkintoni and Dimakos (2022), and Immordino-Yang (2011). Some researchers focus on pupils with special needs and gifted pupils and offer interesting insights applicable also to every pupil, e.g., Sirois et al. (2008). The transformative role of neuroscience in school education is extensively discussed by Carew and Magsamen (2010), who highlight the potential of applying neuroscience knowledge to the development of teaching and learning methods and curriculum design. Some authors go further and examine teaching-learning methods and strategies, such as Elouafi, Lotfi, and Talbi (2021) and Owens and Tanner (2017).

Neuroconstructivism

The well-known concept from the learning sciences – constructivism – is closely linked to neuroscience. Westermann et al. (2007) introduced the term neuroconstructivism, which builds on earlier versions of constructivism and explains its key features based on insights into brain function. This term is further evolved by Renouard and Mazabraud (2018), Tokuhama-Espinosa and Borja (2023), and Mason, Schumacher, and Just (2021).

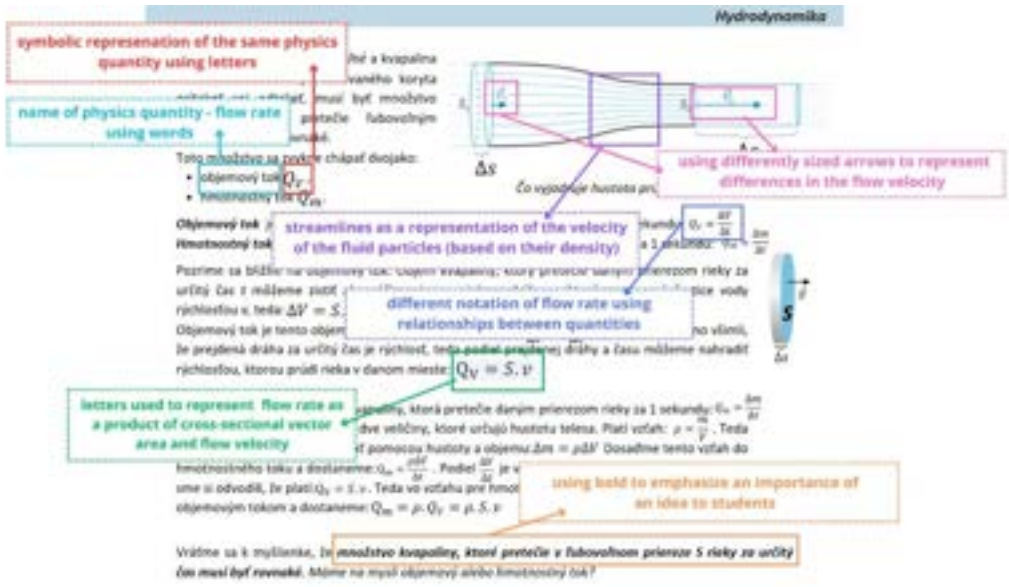
The constructivist part of the radical neuroconstructivist framework implies that 'to construct new learning, people build on previous knowledge using the foundation of the core notions' (Solis-Stovall, 2020) and when combined with "neuro- "approach, it views learning as 'the physical scaffolding of core notions and conceptual change that influence the emergence of mental representations in postnatal development' (Tokuhama-Espinosa, & Borja, 2023). Core concepts serve as prerequisite knowledge at every stage of learning, with each successive level of understanding building on those established at earlier stages. (Sporns, 2022) Therefore, as Tokuhama-Espinosa and Borja state, neuroconstructivism posits that foundational concepts must be acquired before more complex ideas can be developed, with learning progressing in a neurophysiological way, in which primary neural networks are established first, providing a scaffold for secondary networks to build upon. While radical constructivism suggests that context influences one's ability to learn, the radical aspect of the radical neuroconstructivist framework incorporates meaning-making, which is highly influenced by the learner's individuality. The Theory of Five Pillars of the Mind is grounded in radical neuroconstructivism.

The Pillars Framework

A research team led by Tokuhama-Espinosa reviewed approximately 1,000 neuroscientific studies investigating brain processes underlying learning mathematics and language. They aimed to categorise these processes based on the brain regions activated during these activities. This

effort resulted in the Theory of Five Pillars of the Mind, which identifies five fundamental domain-specific networks: symbols, patterns, order, categories, and relationships. These domain-specific networks overlap significantly between math and language (Caravolas et al., 2012). Even though learning maths and languages involves domain-specific networks, learning depends on general cognitive abilities, including attention, memory, and executive function (especially inhibitory control, cognitive flexibility, and working memory). Tokuhama-Espinosa and Borja (2023) further analyse math learning pathways using a radical neuroconstructivist approach, meaning they identify the core notions that are essentially pathways of domain-specific networks.

Each of these domain-specific network groups, called a pillar, has subpillars. We have already been researching the application of this theory to physics education in several domains. Some of the most important results of this research have been published in the *Journal of Baltic Science Education* (Demkanin, Červeňová, & Sands, 2025), *Digital* (Červeňová, & Demkanin, 2025a), and *Girep-Epec conference proceedings* (Červeňová, & Demkanin, 2025b). We have identified significant overlaps between this theory and established theories of physics education, analysed selected physics learning materials, and designed learning materials on fluid mechanics using this framework. Designed learning materials were implemented in the everyday classroom, and their effectiveness was evaluated in a quasi-experimental design and proven valid for everyday use, with significant changes in conceptual understanding of Fluid Mechanics compared to the control group.



Symbols

In this contribution, we focus specifically on pillar symbols. Symbols are defined by Tokuhama-Espinosa (2019) as 'characters used in place of conventional representations to signify meanings, functions, processes, feelings, or objects, including words. A symbol can be a simple mark or letter, but it can also be an emoji or ideogram; anything that stands for something else, including emblems, street signals, company logos, and other visible signs.' (Tokuhama-Espinosa, 2019) Symbols can also be abstract concepts. Symbols further divide into forms, shapes, and representations.

Given the aim of this research, Figure 1 presents an example of an analysis of physics learning material, focusing on identifying symbols in a short section of the material. This learning material has been designed using the Pillars theory as a framework. This section is about flow rate and the continuity equation. The language of this short part is Slovak, but most people can understand the highlighted symbols, since physics uses a unified symbolic language despite small variations in symbols; for example, the function tangent is noted as tg(x) in Slovakia, whereas in other countries tan(x) is commonly used.

Symbols, as mentioned above, are used to represent a concept or a physics quantity. For example, one can use letters (Q_V), words ('objemový tok'), and relationships to represent the same quantity – flow rate. Symbols contain information about the quantity they represent, e.g., using different-sized arrows to illustrate the difference in the magnitude of flow velocity in the different places of a pipe. Streamlines are a symbolic representation of a flow that conveys information about the velocity of fluid particles, based on the density of streamlines at each point in the flow. On the other hand, symbols can be used to communicate between the author of the learning material and the pupils. Authors of learning materials often use bold to emphasise the importance of an idea to pupils.

Figure 1. Examples of symbols in the learning materials – flow rate.

Symbols in theories of physics education and cognitive science

The development of symbols in physics education can be supported by findings from cognitive neuroscience showing partial overlaps between neural systems involved in language and mathematical symbol processing, e.g., (Dehaene, 2011), or (Dehaene, & Cohen, 2010). Behavioral studies of literacy development further demonstrate that learning symbols relies on robust domain-general cognitive predictors across languages (Caravolas et al., 2012). We consider the evidence of overlapping brain areas corresponding to symbolic representations of language and math (Dehaene, 2007; 2009; Dehaene et al., 2015) to strongly support the 'why' of the development of symbols in physics education. Based on the studies mentioned, we presume that the development of symbols in physics supports the learner's ability to process, understand, and manipulate symbols across different subjects.

Strategic development of symbols in everyday physics classrooms can help reduce the cognitive load pupils experience daily when solving physics problems. Pass and Merriënboer (2020) discuss effective methods for managing working memory load in the learning of complex tasks. Some of the methods involve structuring complex information, guiding learners, and strategically integrating visual and symbolic representations to reduce cognitive load.

Multiple representations are connected to a property of the nervous system called redundancy, which means that different configurations of cellular and synaptic components enable the same neural circuit functions. (Mizusaki, & O'Donnell, 2021). This property of the nervous system contributes to the robustness of brain functions by enabling alternative neural pathways to compensate when a particular pathway is damaged or disrupted. Neural representations and their associations are formed through learning. Each object is represented by distributed networks of neurons, in which neural activity is also distributed. This is referred to as distributed representation (Rybár, Beňušková, & Kvasnička, 2002). In other words, the brain stores multiple representations of the same concept across different neural networks as a result of learning. When distributed representations of a given physics concept are established, forgetting tends to occur gradually. When multiple representations are also coherent, conceptual change could be facilitated by linking new and prior knowledge. Symbols are also essential for dual coding (Clark & Paivio, 1991), in which visual and written representations are paired, and they promote the development of correct models when the representations are correct.

Methodology

In this contribution, we primarily present reasons for supporting the development of symbols in physics education. Some of these reasons are grounded in existing literature and are mentioned in the theoretical background, while others emerge from the presented research. In the methodology, we will describe parts of the research relevant to the topic of this contribution. The main goal of our research concerning physics learning material was to identify the extent to which the Pillars are developed in physics education. We identified intermediate objectives, which were:

- to identify the extent to which the Pillars are developed in physics learning materials concerning the inclined plane and fluid mechanics;
- to apply the Pillars framework for the analysis of pupils' errors in the physics summative exam.

Research Sample

Research Sample For Pupils' Error Analysis

In this contribution, we focused mostly on the analysis of pupils' errors in a summative test using the Pillars framework. We conducted a quasi-experiment with a research sample of 26 pupils aged 15-16 and a control group of 27 pupils aged 15-16. The researcher taught the pupils in the research group, while those in the control group were taught by a teacher with over 30 years of experience teaching physics. Assignment to groups was not random. Both research and control groups were assigned a summative assessment concerning three physics topics: fluid mechanics (research topic), gravitational field, and rigid body. The difference between the research and the control group was in the learning materials on fluid mechanics used in the classroom. Pupils in the research group were given designed learning materials using the Pillars framework that aimed to foster the development of the Pillars more uniformly than identified in the existing learning materials. In contrast, pupils in the control group used traditional learning materials. The design and initial implementation of the designed learning materials were published in GIREP-EPEC 23 proceedings (Červeňová, & Demkanin, 2025b).

Research Sample For Analysis Of The Learning Materials

For the initial analysis of the learning materials using the Pillars framework, we selected several physics textbooks to identify the key concepts developed in them. For each concept, a pillar was allocated based on the context in the analysed textbooks. We defined selection criteria for textbook analysis as follows:

- alignment with national requirements for higher education physics graduates;
- market usage of textbooks;
- similarity of pedagogical approach.

Selected textbooks Duncan and Kennett (2014), Morris (2015), Reynolds (2013), Koubek et al. (2009), and Lapitková et al. (2012) all discuss prerequisites and selected topics. They were chosen because they align with the Slovak national requirements. Koubek et al. (2009) and Lapitková et al. (2012) are widely used in Slovakia and approved by the Ministry of Education. Duncan and Kennett (2014), Morris (2015), and Reynolds (2013) are widely used in general and within selected topics, aligning with national requirements. Parts of these textbooks discussing either inclined plane or fluid mechanics constituted our dataset.

Methods Used

Pupils' Error Analysis

In this contribution, we do not focus on overall results comparing the research and control group using different metrics (pre-test, post-test, follow-up test, and summative assessments), but rather on the analysis of errors pupils made in the summative written assessment using the Pillars framework. We believe such analysis will provide insights not only into how Pillars support learning (along with analysis of the learning materials), but also into how the underdevelopment of each domain-specific network influences learning outcomes. In our broader research, we have employed several measurement tools, including recordings of classes, open-ended questions aimed at pupils' initial ideas in a questionnaire, repeated measurements (pre-test, post-test, and follow-up test), and a summative written final assignment. We view pupils as holons, but due to the page limits of this contribution, we will discuss only the results of the qualitative analysis of pupils' mistakes in a summative written assignment.

This assignment consists of two parts: multiple-choice questions aimed at both theory and application, and open-ended theoretical and computational questions. The first part of the written exam is assigned to pupils for 30 minutes and is immediately followed by the second open-ended question part, which is planned for up to 90 minutes. Pupils in the research and control groups were given the same assignment simultaneously. Their answers were then analysed by the researcher and the teacher of the control group using the same marking scheme, followed by analysis of the pupils' answers with a success rate below 50%. For each error, we identified where a pupil could have failed when trying to answer the question by using the Pillars framework.

Analysis Of The Learning Materials

The analysis of the learning materials and the identification of the Pillars were conducted individually by two researchers using MAXQDA24, who coded selected parts of the textbooks. Our coding scheme comprised the Pillars themselves, and the specific code for each pillar was used to code the parts of the textbooks that potentially fostered the development of that pillar. The agreement rate among researchers was 86%, and the final dataset reflected the agreed-upon content in the discussion. Analysing four series of physics textbooks led to the identification of examples for each pillar across physics topics and several observations.

Findings

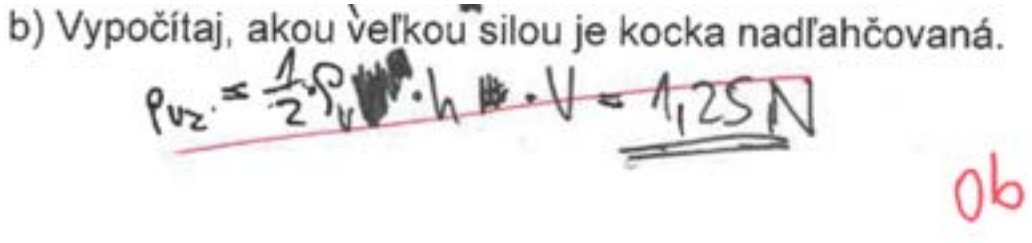
Table 1. Results of initial analysis of the learning materials using the Pillars framework.

Pillar	Discussed topic	N (%)
Symbols	Inclined plane	**7 (50%)**
	Fluid mechanics	**6 (54.5%)**
Patterns	Inclined plane	4 (28.6%)
	Fluid mechanics	3 (27.3%)
Order	Inclined plane	4 (28.6%)
	Fluid mechanics	2 (18.2%)
Categories	Inclined plane	4 (28.6%)
	Fluid mechanics	1 (9.1%)
Relationships	Inclined plane	**8 (57%)**
	Fluid mechanics	**8 (72.3%)**

This contribution is focused on the reasons for developing symbols in physics education. Along with the reasons identified in the literature, we further identified evidence from data collected in pupils' everyday classroom settings. Firstly, we present results of initial analysis of the learning materials using the Pillars framework, followed by the results of analysing pupils' mistakes in the summative written exam.

Table 1 shows the results of the initial analysis of the learning materials concerning the topics inclined plane and fluid mechanics. Results indicate that the most frequently emphasised Pillars in the existing physics learning materials on these topics are symbols and relationships. Although this phenomenon requires further examination in a larger dataset, it aligns epistemologically with existing theories of physics education, which emphasise remembering, understanding, and manipulating symbols as important aims of physics education, along with the relationships between symbols. In existing theories, relationships are viewed as expressing how quantities are related to predict outcomes in response to changes in variables or to understand an observed phenomenon. However, in the Pillars framework, relationships are domain-specific networks that cover not only calculative core notions, but also core notions responsible for measurements, or science process skills. Symbols are also domain-specific networks responsible for several core notions, not only for remembering symbolic representations of physics quantities, but also, for example, different representations of relationships, such as graphs.

Outcomes Of The Analysis Of The Pupils' Mistakes In The Written Summative Exam



Data obtained from the summative written exam administered to both the control and research groups were analysed statistically, and the results were presented at the GIREP-EPEC 2025 conference. In this contribution, we focused on the qualitative analysis of pupils' answers with emphasis on the errors they made. We analysed the answers with errors and a success rate lower than 50%.

Figure 2. An example of pupils' errors in a written summative exam – flow rate.

Figure 2 and Figure 3 show examples of errors pupils made in the written summative exam taken at the end of a semester. Both of these examples are concerning the topic of Fluid mechanics, while Figure 2 shows a task where a pupil should determine the flow rate from given fluid velocity and surface of the pipe, Figure 3 shows a task requiring a calculation of a buoyant force acting on a granite cube, when given the side length of this cube and density of the water it has been inserted in. An error depicted in Figure 2 is identified by researchers as a failure to apply the correct relationship for the flow rate and to understand the symbols used in that relationship, as in Bernoulli's equation, where velocity (v) is present. A pupil probably could not even identify which variables (their symbolic representations) are given in the task or how to use the information to solve it. Figure 3 shows that the pupil did not know the symbolic representation of buoyant force (F_{vz}) and did not know the relationship for the buoyant force. The relationship this pupil wrote was likely a mix of Bernoulli's equation, a hydrostatic pressure relationship, and a buoyant force relationship.

Figure 3. An example of pupils' errors in a written summative exam – buoyant force.

The qualitative analysis of data using the Pillars framework has resulted in several observations:

O1. Pupils mostly failed in the domains of relationships, symbols, or patterns.

O2. When pupils failed in the relationships domain, it was mostly because they did not remember the dependency between variables or were unable to apply it correctly.

O3. When failing in the patterns domain, they could not proceed with the task correctly.

O4. Errors associated with the inability to proceed with the task in the symbols domain were most often assigned a success rate 0%.

O5. Manipulation with symbols does not require understanding of those symbols.

During data analysis, several responses contained no written work and therefore could not be analysed further due to insufficient data. The observations reported above are based solely on responses that included pupils' written notes and expressed ideas. Observation O1 is consistent with the results of the analysis of the selected learning materials and aligns with theories in physics education, which emphasize the central role of symbols and relationships. Nevertheless, pupils continue to experience difficulties in these domains, highlighting their critical importance in physics education. Interestingly, deficiencies were also identified in the domain of patterns, which appeared underdeveloped and contributed to the observed errors. This may be attributed to a lack of explicit and intentional focus on pattern development in physics instruction.

Errors identified by the researchers as belonging to the symbols domain were primarily due to a lack of coherent understanding of both the written formulation of the task and its visual representation. Pupils frequently recalled symbols commonly used in fluid mechanics; however, they often did not demonstrate an understanding of their meanings. Although the relationships domain was identified most frequently, the symbols domain was most strongly associated with a 0% success rate. The analysis across responses further showed that pupils often manipulated symbols without a demonstrated understanding of what those symbols represented.

Conclusions And Discussion

This study aimed to provide converging evidence on the importance of symbols in physics education, drawing on both literature and research. We examined pupils' errors in the written summative physics exam alongside selected learning materials using the Pillars framework. The analysis of pupils' responses showed that symbols were frequently recalled and used, yet often without demonstrated understanding of their meaning. Errors associated with the symbols domain were most consistently linked to unsuccessful problem solving, with a 0% success rate. These findings suggest that difficulties with symbols are not primarily related to a lack of exposure, but rather to insufficient development of meaningful symbolic understanding. These results are epistemologically aligned with existing theories in physics education, which emphasise remembering, understanding, and manipulating symbols—and the relationships between them—as key aims of physics education. The textbook analysis further supports this alignment, as

symbols and relationships were identified as the most strongly fostered domains in the analysed learning materials.

From the perspective of cognitive neuroscience, the importance of symbols in physics learning is further supported by findings indicating partial overlap between neural systems involved in language symbol processing and mathematical symbol processing. On this basis, it can be presumed that the development of symbols in physics may support learners' ability to process, understand, and manipulate symbols across different subject domains. Strategic and explicit development of symbols in everyday physics classrooms may therefore help reduce the cognitive load pupils experience when solving physics problems.

The role of symbols is also closely connected to the use of multiple representations, which correspond to redundancy. When distributed representations of a physics concept are established, forgetting tends to occur more gradually. Furthermore, when multiple representations are coherent, conceptual change may be facilitated by linking new knowledge with prior knowledge. In this context, symbols play an important role. In addition, symbols are essential for dual coding, which has been shown to support the construction of mental models when the representations involved are conceptually accurate and mutually consistent. The prevalence of symbol-related errors identified in this study, therefore, highlights the risk that poorly understood or weakly integrated symbols may contribute to the development of inadequate mental models.

Taken together, the findings from pupils' error analysis, textbook analysis, and existing literature suggest that symbols are not merely formal tools for calculation, but central cognitive and epistemic components in physics learning. These results underscore the need for instructional approaches that explicitly and intentionally develop symbols as a core objective of physics education. Future research may build on these findings by investigating instructional interventions that systematically target the development of symbols domain and by examining how this development interacts with learning across different physics topics and educational levels.

Several limitations of the presented study should be acknowledged and addressed in future research. One limitation concerns the limited interpretability of pupils' responses to multiple-choice questions, as their reasoning may be influenced or constrained by the provided answer options, particularly when incorrect responses are selected with no other notes of the pupils' thinking. While open-ended questions were included in the study, they did not directly elaborate on the corresponding multiple-choice items and, therefore, offered limited insights into the underlying reasoning processes associated with those responses. In addition, pupils' written answers represent observable outcomes of learning that are shaped by numerous, largely uncontrollable variables inherent to everyday classroom contexts. As a result, these responses may not fully reflect pupils' true conceptual understanding.

ESERA 2025 Copenhagen

A Structured Framework For Designing Syllabus-Focused Educational Escape Rooms (EERs) That Promote The Development Of Students' 4C Skills.

Georgios Villias[1,2] and Mark Winterbottom[2]
[1]Anaxagoreio High school of Nea Erythraia, Greece
[2]University of Cambridge, United Kingdom

Educational Escape Rooms (EERs) have gained recognition as an innovative pedagogical approach that enhances student engagement and learning by integrating game-based elements, collaborative problem-solving, and even inquiry-driven activities. By leveraging immersive narratives, puzzles, and teamwork, EERs provide a dynamic environment that fosters both subject knowledge acquisition and essential 21st-century skills, particularly the 4Cs - Critical Thinking, Creativity, Collaboration, and Communication.

This study introduces a structured framework for designing syllabus-aligned EERs that effectively integrate learning objectives with engaging, interactive experiences. Grounded in the Learning Environment, Learning Processes, and Learning Outcomes (LEPO) framework, the proposed model emphasizes key design principles, including real-world relevance, active learning strategies, and scaffolded challenges. The framework highlights how well-designed EERs can enhance cognitive, affective, and psychomotor learning outcomes while promoting autonomy, motivation, and deeper conceptual understanding.

By offering a research-based and adaptable design strategy, this study provides educators with practical guidance on developing effective EER activities across diverse educational settings. This work contributes to the broader discourse on game-based learning and curriculum innovation, equipping educators with tools to create engaging and meaningful learning experiences that cultivate both disciplinary knowledge and essential future-ready skills.

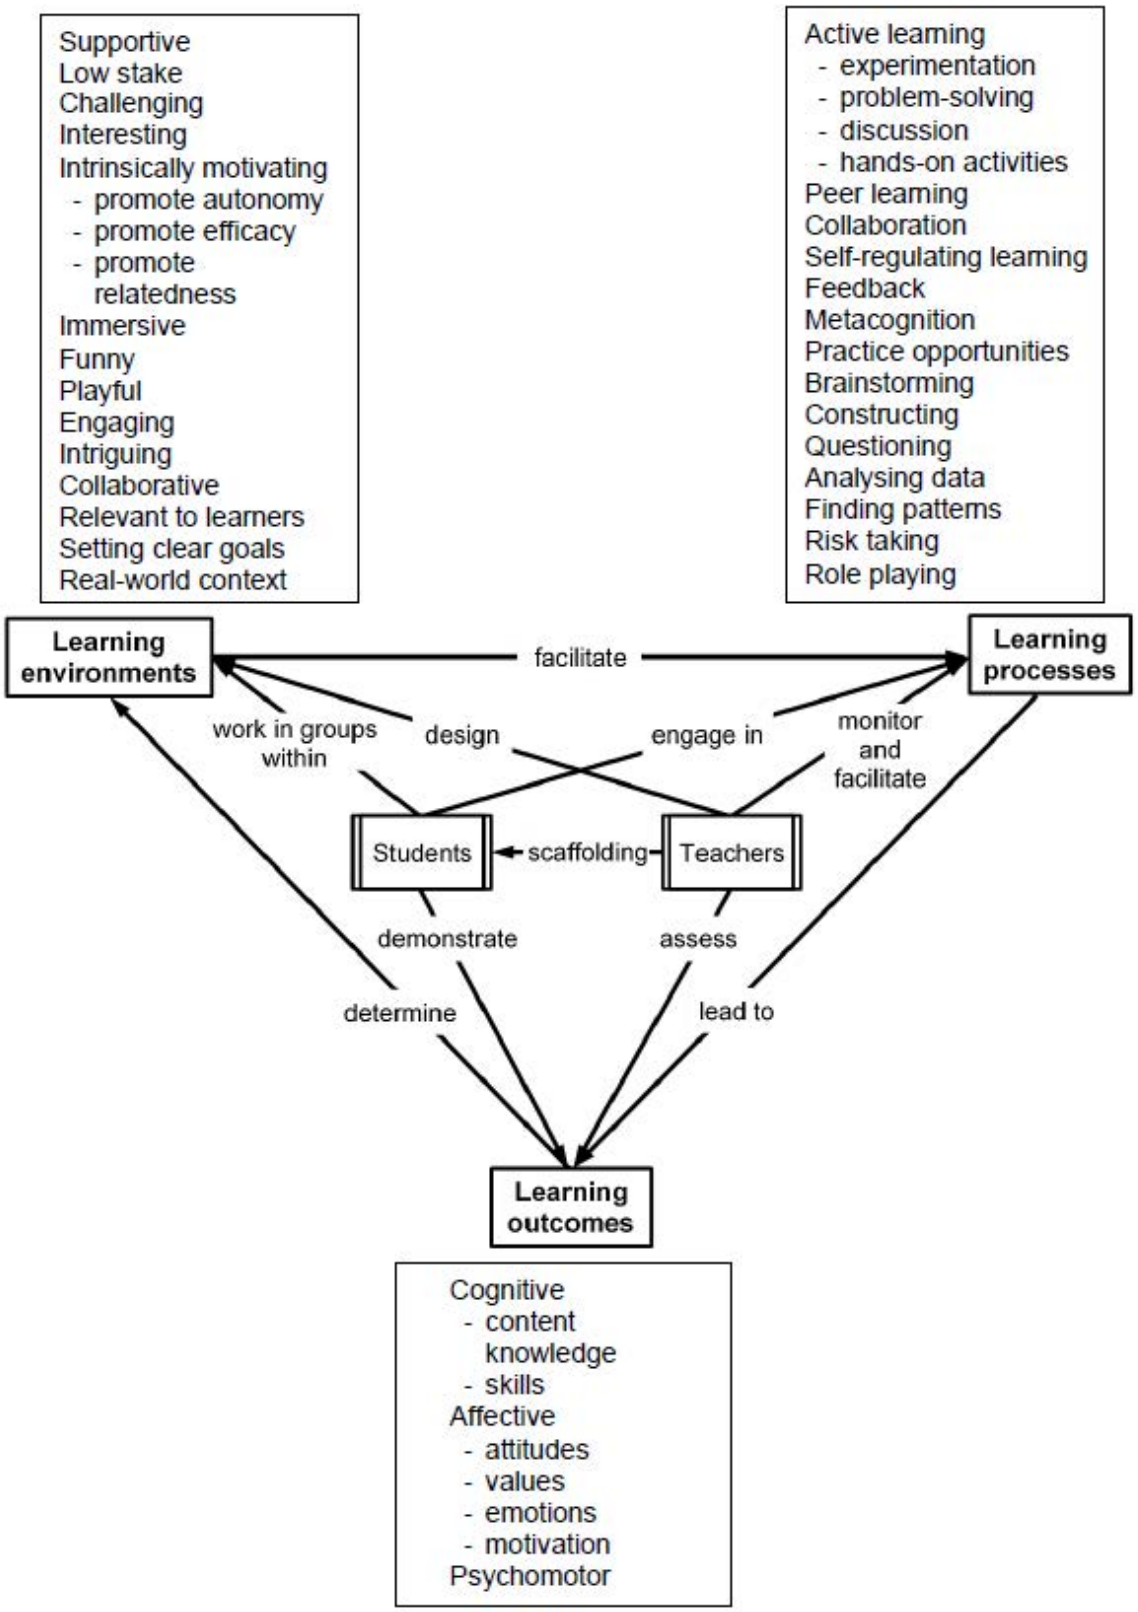
Keywords: Classroom practices, Collaborative learning, Instructional design

Introduction And Theoretical Background

Educational Escape Rooms (EERs)

Educational Escape Rooms (EERs) can be defined as a game-based learning approach that uses problem-based techniques that push students to think critically and creatively while incorporating game features (theme-story, puzzles, and activities to advance). EERs have become a viable substitute for traditional methods of promoting students' conceptual and skill-based learning (Nicholson, 2018). These emerging educational tools exhibit inherent design versatility and are capable of integrating diverse elements of effective learning (e.g., collaborative learning space, challenging tasks, real-world context, supportive environment, hands-on activities). Moreover, they are compatible with several theoretical frameworks (e.g., self-determination and self-efficacy motivational theories, experiential and inquiry-based learning approaches), each offering unique insights into their design and implementation to enhance specific learning processes (see Table 1). Focusing on their ability to promote the practice and development of 21st century skills, like the 4Cs (Villias & Winterbottom, 2024), along with content knowledge, this study attempts to develop an appropriate design framework for this cause.

Table 1. Theoretical underpinnings' connection to EER activities' learning mechanism



Theoretical frameworks	Elements of effective learning
Motivational theories • Self-Determination theory • Self-efficacy theory • Goal-setting theory	Players in control (autonomous) Adapted challenge (competence) Peer collaboration (relatedness) Relevant to learners' interests (intrinsic motivation) Escalating difficulty (mastery experience) Observing others (vicarious experience) Facilitator's and peers' encouragement (verbal persuasion) Relaxed, risk-free environment (physical/emotional state) Setting clear goals Providing direct feedback
Game-based learning	Playful environment (fun) Interesting (curiosity) Intriguing (discovery) Adapted challenge (competence) Setting clear goals Players in control Collaborative (social interaction) Providing direct feedback Low-stake failure Engaging Immersive (flow-like experience)
Experiential learning	Learning by doing (active learning) Hands-on activities Experimentation Problem-solving Discussion Real-world context Collaborative and social environment Reflection (debriefing)
Problem-based learning	Real-world context Collaborative environment Discussion (conversation space) Questioning Brainstorming Metacognition Peer learning Scaffolding
Inquiry-based learning	Interesting (curiosity) Collaborative social environment Discussion Problem-solving Scaffolding Experimentation Questioning

Materials And Methods

A Conceptual Framework of Learning with EERs

Adopting a generalised conceptual and integrated framework of learning, the LEPO framework (Phillips, McNaught, & Kennedy, 2010), and adapting it appropriately to showcase the unique characteristics that EER activities encapsulate, I present below a model that reveals the interrelationships between its basic components (see Figure 1).

Figure 1. Model of the conceptual framework of learning with EERs (adapted from Phillips, McNaught, & Kennedy, 2010, p. 2498).

Dependent on the learning processes being facilitated within EERs' learning environment, different learning outcomes can be produced. For example, debriefing sessions contribute to content learning (Veldkamp, 2022), while problem-solving improves learners' critical thinking skills (Kek & Huijser, 2011). Therefore, when designing an EER learning activity all these components must be considered: the learning environment where students work in, the learning processes they engage in, and the desired learning outcomes they are expected to demonstrate. Key attributes of these components, as informed by the theoretical underpinnings of EERs, are provided in adjacent boxes (see Figure 1). The first box summarises the features of an effective learning environment. The second box lists various learning processes that can be facilitated during the implementation of an EER activity. Lastly, the third box categorises expected learning outcomes based on Bloom's taxonomy across three domains: cognitive, affective, and psychomotor.

Placing a different level of emphasis on these properties while designing an EER should align with the intended learning outcomes of the intervention. For example:

a) *Prioritising the development of social skills* can be supported through the inclusion of collaborative learning activities.

b) *Enhancing science learning among disengaged or low-performing students* may involve tailoring the EER's theme to their interests while cultivating a supportive and playful learning environment.

c) *Developing learners' psychomotor (laboratory) skills* can be facilitated by providing structured practice opportunities and timely, direct feedback during experiments and other hands-on activities that require precision and coordination.

d) *Promoting environmental awareness and the adoption of sustainability values* can be strengthened by linking the EER's theme and narrative to real-world environmental challenges and situating learning within an immersive environment.

e) *Supporting conceptual understanding* may be achieved by integrating scaffolding mechanisms, such as guided prompts, visualisations, and adaptive hints that respond to learners' progress.

f) *Fostering motivation and engagement* can be enhanced through the use of meaningful challenges, clear progression pathways, and reward systems that acknowledge effort as well as achievement.

g) *Encouraging self-regulated learning* may involve incorporating goal-setting tools, reflective prompts, and opportunities for learners to monitor and adjust their own learning strategies.

h) *Developing critical thinking and problem-solving skills* can be supported by presenting open-ended tasks, ill-structured problems, and scenarios that require learners to evaluate evidence and make informed decisions.

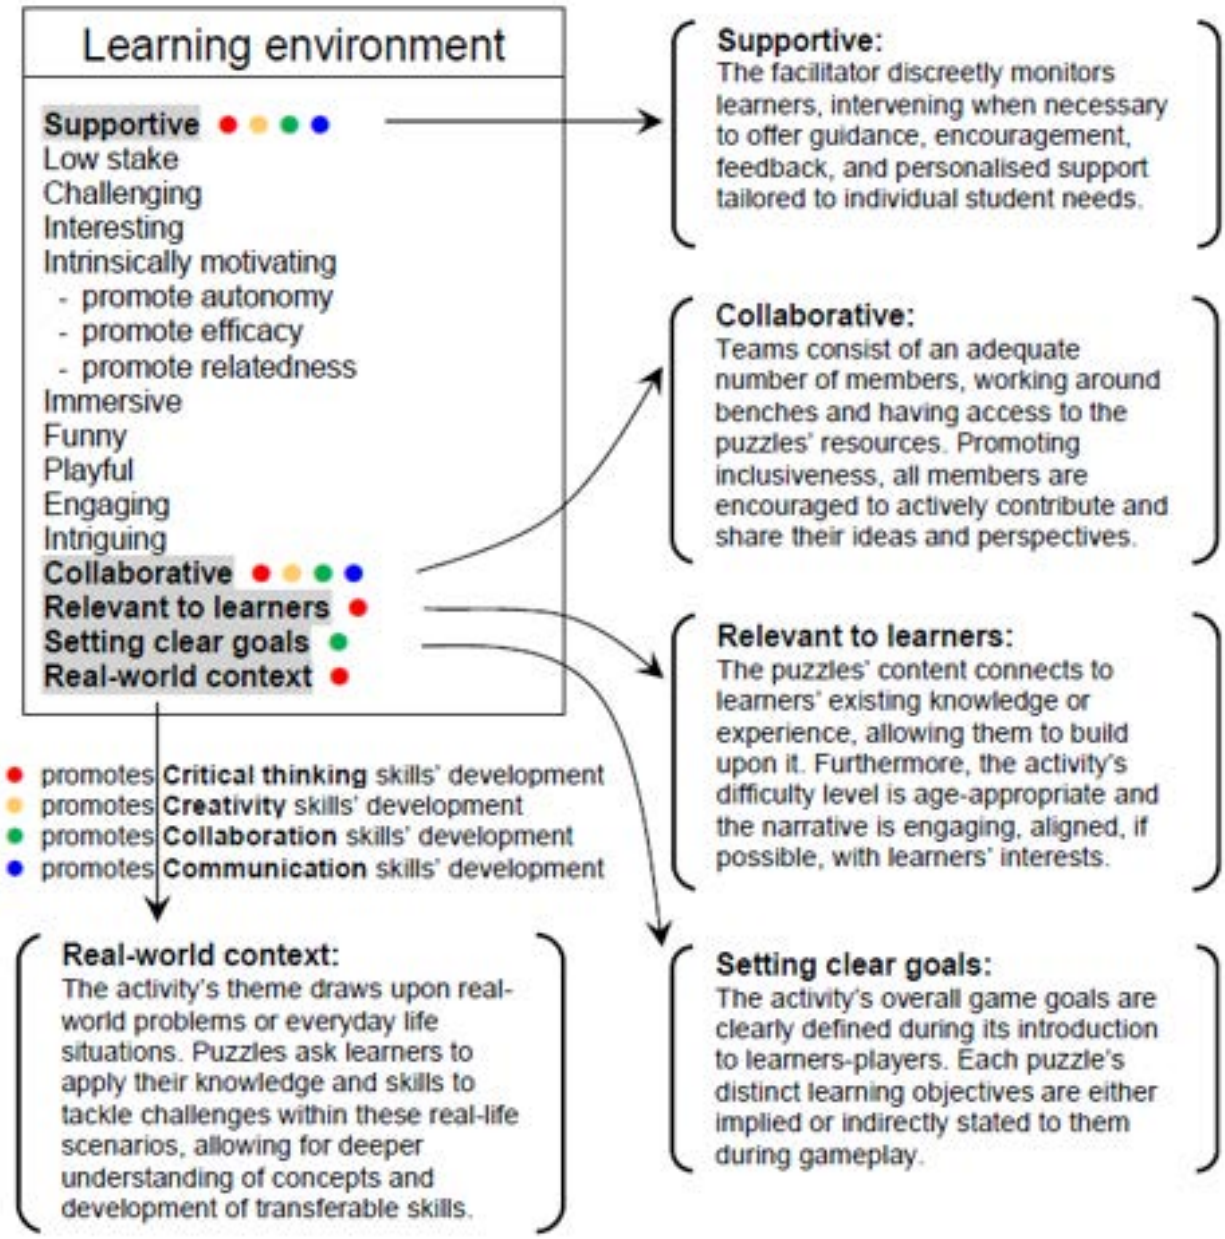
Analyses And Findings

The Design Framework

Using this model as a reference point and concentrating on its particular components that, according to the available literature, are recognized to foster the advancement of the 4C's, I devised a dedicated design framework to guide the structuring of the EER activities in this study (see Figures 2a, 2b). Although the presented framework can serve as a foundation for the design of EER activities, each design should not solely adhere to the highlighted components of the

framework. Instead, additional elements can be incorporated to align each activity with its chosen learning objectives, theme, and content most effectively.

Figure 2a. Design framework for EERs that promote the 4C skills' development. Learning environment component.



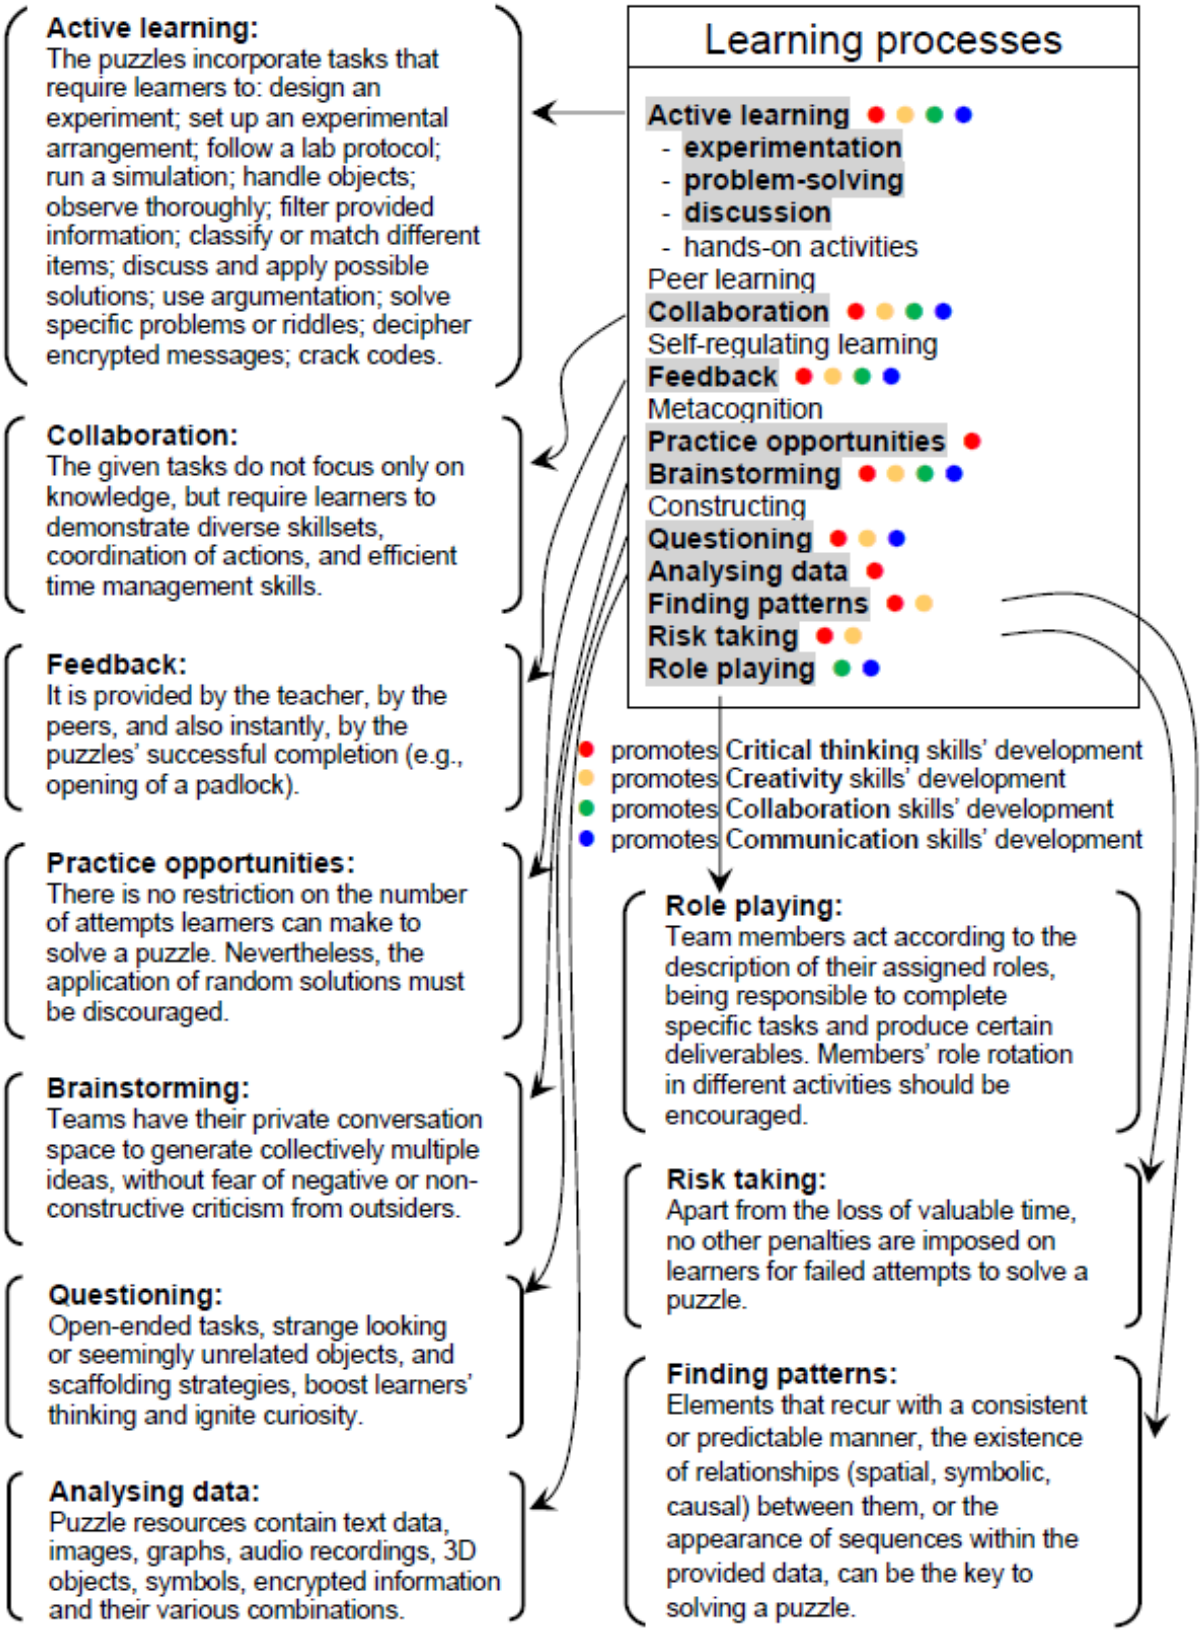


Figure 2b. Design framework for EERs that promote the 4C skills' development. Learning processes component.

Discussion

The presented conceptual and design framework of EERs can be used as a guide to prepare engaging learning activities that are capable of transforming the classroom's learning environment and promote students' active learning, advancing the theoretical grounding of EERs and offering practical advice to practitioners.

ESERA 2025 Copenhagen

A Teaching-Learning Sequence For Heat Transfer And Nature Of Scientific Inquiry At Primary Education

Eleni-Maria Valkanou and Anastasios Zoupidis
Democritus University of Thrace, Greece

The purpose of the present study was to describe and evaluate the pilot implementation of a Teaching–Learning Sequence (TLS) on the modes of heat transfer (conduction, convection, and radiation) and the Nature of Scientific Inquiry (NOSI) for primary school students. The description and evaluation, presented in this paper, focus on part of the taught knowledge, that is, students' understanding of heat transfer by conduction in metals (conceptual knowledge), selected aspects of the Control-of-Variables Strategy (procedural knowledge), and selected aspects of NOSI (epistemological knowledge). Data were collected through a written questionnaire administered before, during, and after instruction and were analysed using a mixed-methods approach. The results indicate a modest and gradual improvement across all three aspects of knowledge. The instructional design of the TLS supported the development of scientifically consistent conceptual understanding, informed procedural reasoning, and improved epistemological views related to scientific inquiry.

Keywords: heat transfer, nature of scientific inquiry, teaching-learning sequence

Introduction

Teaching–Learning Sequences (TLSs) refer to medium-scale curricula that are considered innovative research products. In a TLS, theories and approaches to teaching and learning are systematically integrated, enabling the design and implementation of theoretically informed and empirically grounded teaching–learning activities based on students' reasoning (Méheut & Psillos, 2004). The Model of Educational Reconstruction (MER) is a widely adopted methodological framework for the design and analysis of TLSs. Within the MER framework, the interaction between the results of empirical research on students' conceptions and learning processes and the didactic construction of scientific content is explicitly addressed (Duit et al., 2012).

The development of scientific literacy extends beyond the acquisition of scientific content knowledge and engagement with scientific practices, as it also involves understanding key aspects of the Nature of Science (NOS), with an emphasis on science as a distinct way of thinking and acting (Lederman et al., 2019). Within this framework, several researchers argue that science teaching should adopt a holistic approach, integrating conceptual, procedural, and epistemological learning objectives (Capps & Crawford, 2013). Moreover, fostering students' understanding of issues related to NOS is widely acknowledged as a central goal of science curricula worldwide (AAAS, 2011; NRC, 2011). Lederman et al. (2019) distinguish between NOS, which refers to the characteristics of scientific knowledge, and the Nature of Scientific Inquiry (NOSI), which refers to the characteristics of scientific practices, namely the processes through which scientific knowledge is generated. Although related, these two constructs are conceptually distinct. This distinction is considered pedagogically useful, as students' views of NOSI are generally more amenable to change than those of NOS (Kampourakis, 2016). Table 1 presents the eight aspects of NOSI proposed by Lederman et al. (2019) as instructional learning objectives.

Inquiry-based teaching is widely regarded as a suitable pedagogical framework for foregrounding and explicitly addressing aspects of NOSI (McComas et al., 2020). The purposeful integration of this approach into classroom practice enables students to engage with both scientific concepts and scientific inquiry processes, thereby supporting the development of a more informed understanding of NOSI-related issues (Lederman et al., 2019). At the same time, research indicates that improvements in students' conceptions of NOSI are associated with a deeper understanding of scientific concepts (Bächtold, 2024). Moreover, several inquiry practices have been identified as particularly effective in making NOSI aspects explicit during instruction, including: (a) identifying problems and formulating research questions, (b) managing and controlling variables, (c) constructing, using, and evaluating models, and (d) engaging in interaction and evidence-based argumentation around research findings (Bächtold, 2024).

Table 1. General aspects of NOSI (Lederman et al., 2019)

Aspect	Content
1	Scientific investigations all begin with a question, but do not necessarily test a hypothesis
2	There is no single set or sequence of steps followed in all investigations
3	Inquiry procedures are guided by the question asked
4	All scientists performing the same procedures may not get the same results
5	Inquiry procedures can influence results
6	Scientific data are not the same as scientific evidence
7	Research conclusions must be consistent with the data collected
8	Explanations are developed from a combination of collected data and what is already known

However, it should be noted that the mere implementation of inquiry-based teaching does not necessarily lead to the development of students' understanding of NOSI aspects (Concannon et al., 2020; Morell et al., 2024). Rather, research suggests that an explicit and reflective approach to the processes underlying inquiry-based instruction is required in order to foreground the relevant NOSI aspects embedded within these processes (Witucki et al., 2023). Akerson et al. (2019), synthesising the relevant literature on effective teaching and learning through reflective practices, identify the following as particularly important: (a) students' collaborative group work, (b) the use of teacher-posed reflective questions and subsequent whole-class discussion, (c) scaffolding students' thinking about NOSI, (d) students' engagement in hands-on activities, and (e) a gradual shift from structured to open inquiry.

At the primary education level, the teaching of heat transfer usually remains at a phenomenological level, without systematically confronting alternative ideas that hinder students' conceptual understanding of the phenomenon. In this context, a heat-flow model is often employed; although this model supports students' conceptualisation of abstract thermal concepts, it may simultaneously reinforce the alternative conception that heat has material properties (de Berg, 2006). At the same time, the literature emphasises the need to teach the three modes of heat transfer as conceptually distinct, as students often conflate them, particularly when distinguishing between conduction in metals and heat transfer in fluids (Çoruhlu, 2017). In parallel, it is essential for instruction to explicitly confront the alternative conception of heat as a substance, since this substance-based view negatively affects students' understanding of the modes of heat transfer. Within this broader instructional goal, targeted instruction on conduction, convection, and radiative heat transfer can further support the gradual conceptual change away from this alternative conception.

Methodology

The purpose of the present paper was to describe and evaluate the pilot implementation of a TLS on the modes of heat transfer (conduction, convection, and radiation) designed for primary school students, with a specific focus on selected aspects of the content and practices addressed, as justified below. The TLS integrates inquiry practices, specifically modelling and the Control-of-Variables Strategy (CVS), aiming to support students' understanding of the scientific content, the development of inquiry skills, and the conceptualisation of selected aspects of NOSI (Valkanou & Zoupidis, 2025). It is assumed that the integration of inquiry practices with the explicit and reflective teaching of the NOSI aspects highlighted through these practices enhances students' perceptions of these aspects, as well as their understanding of the scientific content intended to be taught.

The TLS was designed following the MER framework (Duit et al., 2012) and consisted of six instructional units, each with a duration of 90 minutes. The central instructional goals of the sequence were to support a clear distinction between the three modes of heat transfer (conduction, convection, and radiation) and the confrontation of students' alternative conception that heat has material properties (Valkanou et al., 2024b). Table 2 presents an overview of the thematic focus of each unit of the TLS, the inquiry practice integrated into each unit, and the NOSI aspects that were explicitly addressed through these practices.

Table 2. Units of the TLS, the inquiry practices integrated and NOSI aspects highlighted

Unit	Inquiry practice	NOSI aspect(s)
1: Measurements errors in experimental process	-	5^{th}
2: Explicit teaching of CVS	-	5^{th}
3: Heat conduction in metals	CVS	3^{rd}, 5^{th} & 7^{th}
4: Heat conduction in solid materials	CVS	3^{rd}, 5^{th} & 7^{th}
5: Heat convection	Modelling	3^{rd}, 7^{th} & 8^{th}
6: Heat transfer by radiation	CVS	3^{rd}, 5^{th}, 7^{th} & 8^{th}

Note: NOSI aspects are numbered according to Lederman et al. (2019): (3) Inquiry procedures are guided by the question asked; (5) Inquiry procedures can influence results; (7) Research conclusions must be consistent with the data collected; (8) Explanations are developed from a combination of collected data and what is already known.

In the present paper, we focus on the students' understanding of (a) heat transfer by conduction in metals (conceptual knowledge), (b) selected aspects of CVS reasoning (procedural knowledge), and (c) selected aspects of NOSI (epistemological knowledge), as a result of the TLS implementation. Specifically, the research question guiding this study was the following:

"To what extent did students' understanding of (a) heat transfer by conduction in metals, (b) the aspect of CVS reasoning related to distinguishing between valid and invalid experiments, and (c) the third aspect of NOSI namely that inquiry procedures are guided by the research question, improve following the TLS implementation?"

The Structure Of The First Three Units Of The TLS

In the present subsection, the focus is on the design of the first three units of the TLS, since the evaluation of the conceptual, procedural, and epistemological aspects presented in this paper is

primarily contingent upon students' engagement with these units. The first two units of the sequence functioned as introductory lessons prior to the core teaching, while the third unit constituted part of the main teaching and was designed based on the 5E instructional model (Ruiz-Martín & Bybee, 2022).

First unit

The aim of the first unit was the explicit instruction of students, regarding the management of measurement errors in experimental procedures. Previous research has shown that measurement errors and inconsistencies, observed during experimentation, significantly influence students' formulation of conclusions in instructional settings (Valkanou et al., 2024b). Moreover, primary school students are capable of recognising measurement uncertainty, and it is particularly beneficial for them to engage in activities involving multiple measurements for data collection and subsequent analysis (Munier et al., 2013).

Within this framework, this unit followed an uncertainty-oriented approach, aiming to raise students' awareness of these aspects of experimental practice. Specifically, students worked in groups and were asked to measure the length of an object using different measuring instruments. The goal was for them to realise that measurements are not identical, either among groups using the same measuring instruments or among groups using different ones. Subsequently, the teacher explicitly introduced the concept of the mean value, explaining that one way to reduce measurement error is to perform multiple measurements and calculate their average. Through these activities, students were expected to recognise that data collection methods can influence the conclusions that can be drawn. Therefore, this unit was considered appropriate for addressing the fifth aspect of NOSI, namely that inquiry procedures can influence results.

Second unit

The aim of the second unit was the explicit instruction of the CVS. The literature indicates that for the effective use of CVS, explicit teaching is required prior to its application by students (Lorch et al., 2010). In particular, it is important for students to be asked to distinguish between valid and invalid experiments and to justify the validity of appropriately designed experimental setups. Additionally, exposing students to invalid experiments has been shown to be especially effective (Schwichow et al., 2022). Awareness of common design errors that should be avoided during experimentation can support the development of students' metacognitive skills related to CVS and contribute to their conceptual understanding of the phenomenon under investigation (Schwichow et al., 2022).

In this context, the unit employed hypothetical scenarios through which students engaged in activities involving the identification of valid and invalid experiments, the interpretation of valid experimental designs, and the recognition of inconsistencies in invalid ones. This lesson also aimed to explicitly address the fifth aspect of NOSI, as it provided opportunities to discuss how the design of an experiment can affect the results it produces.

Third unit

The third unit focused on teaching the mechanism of heat transfer by conduction. A primary instructional goal was to confront students' alternative conception that heat has material properties, as this idea is considered an obstacle to the conceptual understanding of the phenomenon (Kesidou & Duit, 1993). In addition, the unit aimed to utilise CVS both for understanding the scientific content and for highlighting selected aspects of NOSI. The approach adopted for addressing these aspects was explicit and reflective. The teacher's reflective questions during the lesson, as well as during the concluding discussion, supported the scaffolding of students' thinking about NOSI. Table 3 presents the structure of the third unit.

As mentioned earlier, the design of this unit was based on the 5E instructional model. During the *Engage phase*, students were presented with a hypothetical scenario in which they were described as explorers encountering two adjacent locked doors inside an ancient structure. The doors were secured by a metal rod placed diagonally in front of them, with heat-sensitive locking mechanisms located at the upper and lower ends of the rod, each corresponding to one door. A heat source was positioned directly beneath the centre of the rod, and students were asked to predict whether heating the rod would result in the simultaneous unlocking of both doors or whether one door would unlock before the other, and to justify their reasoning. This scenario served to elicit students' alternative ideas and to identify the variables affecting heat transfer. Through engagement with the scenario, students were guided to formulate the research question: "*How does height difference from the heating source affect how quickly heat spreads above and below it?"* In this way, students recognised the direct relationship between the question posed and the inquiry procedures that would follow. At this stage, the third aspect of NOSI was highlighted, namely that inquiry procedures are guided by the question asked. During the *Explore phase*, students conducted experiments involving the heating of metals (Table 3) and recorded the data obtained. Subsequently, in the *Explain phase*, they were asked to interpret their experimental observations. At this stage, students answered the research question by relying on the data they had collected. Therefore, this phase was considered appropriate for addressing the seventh aspect of NOSI, according to which research conclusions must be consistent with the data collected. In the *Elaborate phase*, students were presented with a simulation illustrating the microscopic motion of particles in a solid during heating and were asked to explain their experimental observations using elements from the microscopic level. Finally, in the *Evaluate phase*, students' understanding of the scientific content was assessed through a relevant activity, and an overall reflective discussion was conducted using targeted questions aimed at highlighting and discussing the NOSI aspects addressed throughout the unit.

Table 3. Description of the 3rd unit of the TLS

Inquiry Practice (IP) & Aspect of NOSI	**Main expected learning outcomes** *(Students will:)*	**Main teaching activities** *(Activities:)*
IP: CVS NOSI3: Inquiry procedures are guided by the question asked NOSI5: Inquiry procedures can influence results NOSI7: Research conclusions must be consistent with the data collected	**Conceptual knowledge:** recognise that heat spreads at the same rate in all directions within metal rods, positioned with a slight inclination relative to the horizontal plane, regardless of the height difference from the heating point above and below **Procedural knowledge:** understanding aspects of CVS, e.g., the ability to distinguish between valid and invalid experiments **Epistemological knowledge:** recognising that every piece of research is linked and guided by a central research question, that inquiry procedures can influence results and that research conclusions must be consistent with the data collected	activities involving heating metal rods, positioned with a slight inclination relative to the horizontal plane and observing their marks, which bear a small amount of wax and have the same height difference from the heating point above and below (Valkanou et al., 2024a)

Note: NOSI3, NOSI5, and NOSI7 refer to the corresponding aspects of NOSI in Table 1.

Participants

The TLS was implemented in a fifth-grade class in a public primary school in Greece. The class consisted of 18 students (9 boys and 9 girls). During the implementation of the TLS, students worked in groups of three or four, across all phases of the instruction.

Data Collection And Analysis

Data were collected through multiple sources: (1) a written questionnaire consisting of seventeen tasks (seven targeting scientific content, three addressing the CVS, three focusing on modelling, and four addressing aspects of NOSI), which was administered before, during (after the fourth

unit), and after the implementation of the sequence; (2) video and audio recordings of all lessons; and (3) post-instruction group interviews conducted in focus groups.

In the present paper, the analysis focuses on the evaluation of students' understanding of (a) heat transfer by conduction in metals (conceptual knowledge), (b) the aspect of CVS reasoning related to distinguishing between valid and invalid experiments (procedural knowledge), and (c) the third aspect of NOSI namely that inquiry procedures are guided by the research question (epistemological knowledge), using data derived from a subset of the written questionnaire. Specifically, the evaluation of the aforementioned aspects of knowledge, presented in this study, was based on eight tasks, namely two tasks addressing scientific content, three tasks targeting the CVS, and three tasks focusing on aspects of NOSI.

The data obtained from the written questionnaire were analysed using a mixed-methods approach, combining qualitative and quantitative methods (Clark et al., 2021). Category construction was informed by a combined top-down and bottom-up analysis (Bryant & Charmaz, 2007). In the top-down analysis, students' answers were compared with the expected learning outcomes defined in the TLS, as well as with relevant categories reported in the literature. In parallel, a bottom-up analysis involved the iterative comparison of students' responses, allowing for the refinement of existing categories and the emergence of new ones. To enhance the trustworthiness of the analysis, two additional researchers independently categorised the responses, and discrepancies were discussed until agreement was achieved. Finally, descriptive statistics were used to quantify and summarise the categorised data.

Results

The results are presented in relation to the three learning areas addressed in the research question. The questionnaire comprised eight tasks assessing the knowledge aspects examined in this study. For reasons of brevity, this section reports indicative findings from three tasks of the written questionnaire, each corresponding to a different learning area (conceptual, procedural, and epistemological knowledge). The findings from the remaining tasks were consistent with those reported here; thus, the results reported are representative and sufficient to support the evaluation of the TLS aspects under investigation.

Task 1 investigated students' understanding of heat transfer by conduction in metals. Students were presented with a sketch depicting two identical metal rods, positioned with the same inclination relative to the horizontal plane. One rod was heated at its upper end, while the other was heated at its lower end. Students were asked to state and justify their views on whether they would feel heat when touching the end of each rod opposite to the heated one.

A representative scientifically accepted response (Category 3) was: *"In both cases, we would feel the same amount of heat, because in heat transfer by conduction, heat spreads equally in all directions"* (Table 4). Respectively, a representative response in Category 2 was: *"In both cases, we would feel heat, because heat goes everywhere",* in Category 1: *"I think we would feel more heat in B, because fire can go down more easily",* and in Category 0: *"No, because the rods are heated in the same way".*

As demonstrated in Table 4, a gradual shift in students' responses across the three tests is evident. In the Pre-test, the majority of responses were classified as alternative ideas, while no responses fell into the scientifically accepted or partially scientifically accepted categories. In the Middle-test, there was a substantial increase in the frequency of responses that were scientifically accepted or partially scientifically accepted. This was accompanied by a marked decrease in the frequency of alternative ideas. This trend continued in the Post-test, with a further increase in

scientifically accepted responses and the elimination of irrelevant or non-responsive answers. This pattern indicates an overall improvement in students' conceptual understanding.

Table 4. Students' answers at Task 1

Categories	Pre	Middle	Post
3: Scientifically accepted	-	5	6
2: Partially scientifically accepted	-	7	8
1: Alternative ideas	14	5	4
0: Irrelevant or No answer	4	1	-
TOTAL	18	18	18

Task 2 examined students' ability to identify a valid and appropriate experiment to investigate a specific scientific question. Students were provided with a table presenting four experiments (each consisting of two trials) investigating whether the colour of crayons affects their rate of melting. The first experiment was valid but not appropriate, as the only variable that changes is not the controlled variable. The second and third experiments were invalid, since although the controlled variable changes from one trial to the other, more than one variable is modified in each case. The fourth experiment was both valid and appropriate, as only one variable changes, namely the controlled variable. Students were asked to select and justify which experiment would lead to a sound conclusion.

A representative scientifically accepted response (Category 3) was: *"The fourth experiment, because only the colour changes. In the others, either more than one thing changes or the colour does not change"* (Table 5). Respectively, a representative response in Category 2 was: *"I believe that experiment 4 would lead to a safe conclusion, because in experiment 4 only one variable changes and the steps of the CVS method are followed correctly",* in Category 1: *"Experiment 3, because it has different colour, size, and time"*, and in Category 0: *"Yes, with a different colour it will be better".*

As demonstrated in Table 5, a gradual shift in students' responses is evident across the three tests. Initially, in the Pre-test, no student provided a correct description of the CVS, while most responses were partially correct or incorrect. In the Middle-test, there was a substantial increase in the frequency of correct responses, accompanied by a decrease in incorrect responses. This improvement was sustained in the Post-test, with the number of accurate responses remaining consistent and a further decline in incorrect descriptions. The distribution of responses indicates a gradual improvement in students' understanding of the CVS.

Table 5. Students' answers at Task 2

Categories	Pre	Middle	Post
3: Correct description of CVS strategy	-	5	5
2: Partially correct description of CVS strategy	7	4	7
1: Incorrect description of CVS strategy	10	8	6
0: Irrelevant or No answer	1	1	-
TOTAL	18	18	18

Task 3 examined students' understanding of the third aspect of NOSI, namely: *"Inquiry procedures are guided by the question asked".* Students were presented with a scenario involving two groups of scientists who were investigating whether certain tyre brands are more prone to damage. The first group tested multiple tyre brands on the same type of road, whereas the second

group tested a single brand on different types of roads. Students were asked to explain why the procedures followed by one of the two groups were better than those followed by the other.

A representative scientifically accepted response (Category 3) was: *"I agree with Group A, because the question is whether some tyre brands can burst more easily than others, so there must be many tyre brands"* (Table 6). Respectively, a representative response in Category 2 was: *"Group A followed the correct steps, because it used many tyre brands",* in Category 1: *"Group B followed the steps better, because there are many types of roads and a tyre has to withstand all of them",* and in Category 0: *"The steps followed by Group A were better".*

As demonstrated in Table 6, a progressive shift in students' responses was observed across the three tests. In the Pre-test, the majority of responses were classified as either mixed or naïve views, with only a small number reflecting informed views. In the Middle-test, there was an increase in the frequency of informed views, accompanied by a reduction in naïve and irrelevant responses. This tendency became more evident in the Post-test, with informed responses demonstrating a substantial increase and naïve or irrelevant answers being eliminated, thus indicating an overall enhancement in students' comprehension of the examined aspect of NOSI.

Table 6. Students' answers at Task 3

1: Naïve views	5	2	-
0: Irrelevant or No answer	3	2	-
TOTAL	18	18	18

Discussion And Conclusions

The present study investigated the extent to which students' understanding of (a) heat transfer by conduction in metals (conceptual knowledge), (b) the aspect of CVS reasoning related to distinguishing between valid and invalid experiments (procedural knowledge), and (c) the third aspect of NOSI namely that inquiry procedures are guided by the research question (epistemological knowledge), improved following the TLS implementation.

Overall, the results suggest a modest positive improvement in understanding across the three aspects of knowledge addressed in this paper. Regarding conceptual knowledge, students demonstrated a progressively more scientifically consistent understanding of heat conduction. In particular, they gradually moved away from viewing heat as a material substance within the context of heat conduction phenomena, and provided interpretations aligned with the scientific view. The observation that, during the heating of metal objects, heat propagates at the same rate in all directions, regardless of the vertical distance from the heating point (above and below it), appeared to have strong instructional value. This observation helped students distance themselves from their initial material conception of heat, in line with findings from a previous implementation of the experimental activities employed in the present TLS (Valkanou et al., 2024b). Moreover, students' understanding of heat conduction in metals further improved following their engagement with subsequent units explicitly addressing the other two modes of heat transfer (convection and radiation). This finding reinforces the need to teach the three modes of heat transfer as conceptually distinct, as documented in the literature (Çoruhlu, 2017). It suggests that such an instructional approach not only enhances students' understanding of each mode but also contributes to the remediation of the alternative idea of heat as a material entity, which constitutes a major obstacle to the conceptualisation of heat transfer (Kesidou & Duit, 1993). With respect to procedural knowledge, the findings show an improvement in students'

understanding of aspects of the CVS, especially in identifying valid experimental designs and justifying their choices. Although some students continued to exhibit partial or mixed understandings, the overall trend seems to be consistent with the literature, which indicates that explicit instruction combined with exposure to both valid and invalid experiments contributed to the development of more informed procedural reasoning (Schwichow et al., 2022). Concerning epistemological knowledge, students showed notable progress in their understanding of the idea that inquiry procedures are guided by the research question. The increase in informed responses suggests that the explicit and reflective approach adopted in the TLS, supported by targeted teacher questioning and whole-class discussion, was effective in fostering students' epistemological understanding, as also reported in the literature (Witucki et al., 2023). Taken together, these findings are consistent with the arguments presented in the introduction, namely that the integration of inquiry practices with explicit and reflective instruction can support students' understanding of both scientific content and aspects of NOSI (Bächtold, 2024).

In the next phase of the research, further statistical analysis of the data would be valuable to explore potential correlations between conceptual, procedural and epistemological knowledge, thus providing deeper insights into the relationships between these learning areas within the TLS framework. In addition, following these analytical procedures, it would be meaningful to refine and further improve the TLS based on the identified findings and to re-implement it, in order to further examine its effectiveness.

ESERA 2025 Copenhagen

"We Had A Lot Of Freedom." Learning Of Students With High Diversity In An Open Inquiry "Lernwerkstatt" Setting

Sandra Puddu and Claudia Ovrutcki
University College of Teacher Education Vienna, Austria

According to the OECD learning compass, effective learning environments are needed to foster student agency. Inquiry-based learning which is increasingly present in Austrian curricula for primary and lower secondary school has the potential to foster student agency. Unfortunately, it is still only partially present in school lessons, the asking of scientifically answerable questions is particularly underrepresented. Lernwerkstatt, which could be translated into learning workshop, is an open inquiry learning format for students where they can ask their own questions, which are stimulated by learning landscapes. In a learning landscape the students find different objects, pictures, tools or other things, which spark their interests and trigger a research question. After finding their question the students have time to develop a research design and finally answer the question. The students are responsible for the whole inquiry and are closely scaffolded throughout the process. The research project "Learning-researching – Lernwerkstatt along different diversity dimensions" follows two primary and two lower secondary school classes. The research diaries of the students were collected and analysed via qualitative content analysis. After the Lernwerkstatt a students' questionnaire concerning the learning format and the perceived scaffolding were conducted. In this paper a Lernwerkstatt regarding the topic "Habitats and environments" is introduced, the students' research questions and their perceptions of the learning format is presented.

Keywords: Inquiry-Based Learning, Learning Environments, Qualitative Research

Introduction

According to the OECD learning compass student agency should be fostered by effective learning environments. There, students have the possibility to decide what and how they want to learn in order to achieve the long-term goal of "learning how to learn" (OECD, 2019, p. 33). Inquiry-based learning is a way to foster scientific thinking, which leads to scientific literate students (AAAS, 2012). Lernwerkstatt (Puddu et al., 2012) which possibly could be translated into learning workshop is an open inquiry-based learning format (Blanchard et al., 2010) where the students are responsible for the whole inquiry process. At level three of the levels of inquiry (see Table 1) they pose a question, decide which inquiry method is suitable for the research, and finally they answer their own research question.

Table 1. Levels of Inquiry (Blanchard et al., 2010, p. 581)

	Source of the Question	Data collection Methods	Interpretation of Results
Level 0: Verification	Given by teacher	Given by teacher	Given by teacher
Level 1: Structured	Given by teacher	Given by teacher	Open to student
Level 2: Guided	Given by teacher	Open to student	Open to student
Level 3: Open	**Open to student**	**Open to student**	**Open to student**

As learning workshop is not considered an adequate translation, the term Lernwerkstatt is used further. The Lernwerkstatt at the University College of Teacher Education Vienna is a room, which is nicely furnished and contains many interesting objects, books, materials for experimentation and consumables (Ovrutcki et al., 2024; Puddu & Ovrutcki, 2025). Additionally,

a learning landscape on a special topic is created. The learning landscape within this research project is about habitats and environments, so the students find many objects, books and models matching the topic like models of animals living in the rainforest, a globe, a model of diverse students where one is using a wheelchair, minerals and garbage cans.

Lernwerkstatt as an open inquiry-based learning format is inherently inclusive. Every learner can pose their own questions and do their own research according to their interests, competencies and skills.

A very important part of inquiry-based learning is the scaffolding (Hofer, 2020). The students need to learn, for example, how to frame a question, how to gather and handle data, how to use available information either in books or on websites. Scaffolding of the language is also necessary, on the one hand because of technical terms, and on the other because the language of instruction is often not the first language of the students (Gabler et al., 2020). The individual scaffolding, as is done in the Lernwerkstatt, meets the needs of the students.

Procedure Of A Lernwerkstatt

In the Lernwerkstatt, the students have three mornings to do research. On the first day, the rules for working in the Lernwerkstatt and possible research methods are discussed, which include e.g. interviews, observations, research from books and encyclopaedias, but also experiments. After that the students discover the topic of the Lernwerkstatt through a puzzle, through pictures that are put together or through colouring dictations. There are many ways to get started here, but it is important that the introduction already arouses curiosity about the topic. After this initial introduction, they visit the learning landscape to find interesting things and subsequently create research questions. The first walk through the learning landscape is first and foremost for making observations, which they can already note down in the research diary they received earlier. The observations are then discussed and the second walk through the learning landscape follows. Initial questions are noted in small pieces of paper. Students with similar research questions can work together and form a group. Then the research begins. At the end of the first morning the teachers and the students meet in a seating circle and discuss the progress of the research and if additional materials or information are needed which can be organized in the afternoon. On the second morning the research process can be continued. The third morning is dedicated to the presentation of the research process and the results.

Research Design

In the research project “Learning – researching. Lernwerkstatt along the diversity dimensions”, a design based research study (Obczovsky et al., 2024), which started in 2024, lies the focus on learning with very diverse students. The main goal is to establish Lernwerkstatt in the affiliated inclusive schools and to encourage teachers to implement inquiry-based learning in their classrooms. To achieve this goal, we wanted to generate enthusiasm among the teachers. Four urban school classes, two primary school classes (grade 4) and two secondary school classes (a multi-grade class with the grades 5 to 8 and a class with grade 5), a total of 89 students, attended Lernwerkstatt between September 2024 and June 2025. The students in these classes show a high diversity. Many children have a first language other than the language of instruction, some have refugee experience or disabilities.

In the case of the middle school classes, the teachers were part of the project and supported the data collection. They were also involved in the scaffolding. In the first class (middle school, multi-grade class) the teacher recruited teacher students for additional scaffolding.

In the case of primary school, teacher students came with their class they practiced in. The teachers of the class accompanied the teacher students and took over groups to scaffold. Sometimes assistant teachers additionally supported the scaffolding.

The research questions are: “What questions do students frame within the topic of habitats and environments?” How do students with high diversity perceive open inquiry-based learning format Lernwerkstatt? How do the students assess their own research? The answers to the research questions provide information for the further development process.

The students write or draw in their research diary during their inquiry. Guiding questions and scaffolding helps the students to write down their questions, what they need for their research, what methods they use and the answer they find to their questions. Additionally, they describe their presentations of the findings to the class. The research diaries were analysed via qualitative content analysis (Kuckartz & Rädiker, 2022).

For the second and the third research question concerning the perception of the open inquiry-based learning format Lernwerkstatt a questionnaire was used with closed items like “I felt comfortable in the Lernwerkstatt” “I am satisfied with my work in the Lernwerkstatt” or “The teacher was there when I needed something” The response scale had four levels, + +, +, - and - - (see Table 1).

At the end of the questionnaire, we posed four open questions about what the students like best and least, what they could do differently the next time and what else they like to say about Lernwerkstatt.

Of the 89 students who attended the Lernwerkstatt 82 students competed the questionnaire.

The closed items of the questionnaire were analysed using descriptive statistics. Therefore, the mean value and standard deviation were calculated. For the calculation the scale was converted, the highest value was four (++), the lowest value was one (--). The open items were analysed using qualitative content analysis (Kuckartz & Rädiker, 2022).

Additionally we took field notes (Thierbach & Petschick, 2022) to document our observations and enrich the analysis.

Findings And Conclusions

The data of this paper stems from four school classes. Two primary school classes (grade 4) with 18 and 17 students respectively and two middle school classes, one multi-grade class with 30 students and one 5th grade class with 24 students visited the Lernwerkstatt.

The students frame very different questions. The questions of the 5th to 8th grade ranged from “How many underground stations are there?” to “How many art styles are there and how do they look like?” Some students asked about specific countries or cities, their structure and how people live there. Other questions were about the difference of the water in a pond, lake and sea. The primary school students asked about the first instrument, about pharaohs, Europe, planets or crystals. So, while the questions are not very different, the research process differs according to the grade and the skills.

In answer to the research questions “How do students with high diversity perceive open inquiry-based learning format Lernwerkstatt? How do the students assess their own research?” the analysis of the questionnaire (see Table 2) showed that the students felt quite comfortable in the Lernwerkstatt ($\bar{x}$=3.390) and were satisfied with their work ($\bar{x}$=3.439) The students also recognized the scaffolding. The item “The teacher was there when I needed something” showed a mean value of 3.622. The item “I learned a lot in the Lernwerkstatt” showed a mean value of

3.463. There may be various reasons for this result. One possible explanation is that the students learn more implicitly, or they don't recognize the learning because the students choose the content.

Table 2. Evaluation of the Lernwerkstatt (n=82).

	Mean value [$\bar{x}$]	Standard deviation [σ]
I felt very comfortable in the Lernwerkstatt	3.390	0,676
I am very satisfied with my work in the Lernwerkstatt	3,439	0,717
I was able to work on the questions that interest me	3,476	0,784
The teacher is interested in my opinion	3,317	0,714
The teacher was there when I needed something	3,622	0,618
I learned a lot in the Lernwerkstatt	3,463	0,752
I made an effort to document accurately	3,439	0,627
I was very satisfied with my/our presentation	3,451	0,751
I liked the other presentations very much	3,512	0,703

The responses of the students to the open-ended question "The best of Lernwerkstatt was…" were analysed via qualitative content analysis using inductive categories. Four categories were found as shown in Table 3. In response to this open question about what the students liked best, the most common category in the winter term was "student agency" with 19 out of 42 answers. It was important for the students to be allowed to choose, to choose the topic, to choose the people they learn with, to have the freedom to experiment. The Lernwerkstatt therefore fulfills the OECD's requirement to offer learning environments that promote student agency. The second most common response is related to elements of the work in a Lernwerkstatt like the learning environment, the learning landscape or the presentation at the end of the Lernwerkstatt. The category 'scaffolding' was only mentioned once, the category "mentioning of specific objects" was found six times when the students wrote how proud they were of the models built by them.

Table 3. Mentionings of students in open question: "What did you like best?"

	Winter term		Summer term		
Categories/classes	1 (middle school, multi-grade, n=30)	2 (primary school, 4th grade, n=18)	3 (middle school, 5th grade, n=24)	4 (primary school, 4th grade, n=17)	Sum
Student agency	10	9	2	3	24
Elements of "Lernwerkstatt"	11	5	10	10	36
Scaffolding	1	0	1	0	2
Mentioning of specific objects made	3	3	1	2	9

The summer term was different. There were only five answers categorized as "student agency" and 20 answers as "elements of Lernwerkstatt". The answers in the categories "scaffolding" and "mentioning of specific objects made" were comparable to the winter term as there were less students in the classroom. To get to the bottom of the difference, field notes, which we wrote down to reflect the days of Lernwerkstatt, were analysed. There we found a few clues. The third class, which was a 5th grade middle school class, was used to work on projects and on their own

questions. Even if the system and the surroundings were different, the type of learning was familiar. That is why we assume that they regarded independence as a matter of course and therefore did not specifically mention it in the open question. The fourth class we analysed, a 4th grade primary school class, was different. The teachers of the class, who did the scaffolding, visited the Lernwerkstatt for the first time and had so much fun, maybe too much fun, that they took over the inquiry for some groups. They led instead of supporting the groups. Therefore, the students still enjoyed learning but were missing out on the Lernwerkstatt experience, which is shown in the answers where we categorized ten answers in “elements of Lernwerkstatt” category and only three in “student agency”.

The most criticized aspect (What did you like least?) was the insufficient number of breaks. This way of learning is strenuous, so it is important to implement more breaks than usual in a school day.

The last question was about what else they want to say about Lernwerkstatt. The students wrote that they liked Lernwerkstatt, said thank you to the heads of Lernwerkstatt, and that they would like to repeat the experience.

Discussion

For teachers, Lernwerkstatt means having confidence in the students' abilities and opening up the space for open inquiry-based learning. This freedom in learning, which is demanded on the one hand by the OECD in the learning compass and on the other hand by the students themselves, is made possible in the Lernwerkstatt. But there are pitfalls.

Because we worked in real classroom situations, the authors had to deal with varying teachers and sick leaves. So, we didn’t always know who would provide scaffolding for the class in addition to the authors who led the Lernwerkstatt. These circumstances led to the situation that we couldn’t convey the challenges of scaffolding and open inquiry-based learning to the teachers in a meaningful way.

Based on the small sample, we would like to make few suggestions. Teachers should be familiar with open inquiry-based learning and ideally have experience in research which aligns with the literature (Capps & Crawford, 2013). Teachers should be familiar with scaffolding of students. As a consequence, the authors plan to offer a Lernwerkstatt for teachers to experience the learning process for themselves beforehand. There we can make the inquiry process and the nature of science explicit and reflect so they feel equipped to work with their students accordingly.

Acknowledgement

We would like to thank the participating teachers and teacher students for their interest in Lernwerkstatt and their support.

Artificial Intelligence In Experimentation: A Bibliometric Approach

Konstantinos Karampelas
University of the Aegean, Greece

This study explores the integration of Artificial Intelligence (AI) in experimentation within science education through a bibliometric lens. Although AI has gained increasing traction in educational research, its role in supporting or transforming experimental science learning has received limited attention. Using data from 2,455 publications indexed in Scopus, this study investigates three key areas: the evolution of publication rates over time; the most active disciplines, countries, and institutions; and the emerging thematic clusters. Descriptive statistics and keyword co-occurrence mapping via VOSviewer were used to analyse publication trends and research directions. Findings indicate a sharp increase in relevant publications after 2020, with notable contributions from computer science and engineering, as well as from institutions in China, the United States, and Europe. Seven thematic clusters were identified, reflecting diverse interests across pedagogy, AI techniques, infrastructure, cognitive processes, and interdisciplinary applications. The study underscores a growing intersection between AI and inquiry-based experimental teaching, highlighting opportunities for cognitive development, teacher support, and accessibility. It also reveals gaps in pedagogical integration and equity of access. These findings offer valuable insights for educators, policymakers, and edtech developers seeking to integrate AI meaningfully into science experimentation.

Keywords: Artificial Intelligence, experimentation, bibliometrics

Introduction

The integration of Artificial Intelligence (AI) into education is reforming teaching and learning institutions worldwide. This transformation is primarily driven by AI's innovative capabilities, including personalized feedback, intelligent tutoring systems, learning analytics, and curriculum adaptation. In science education, which relies on inquiry, problem-solving, and experimentation, AI can promote student engagement with complex phenomena through modeling, testing, and sense-making (Akhmadieva et al., 2023; Almasri, 2024; Dai, 2023; Park et al., 2023). Specifically, experimentation—a core element of science teaching involving hypothesis formulation, data collection, and variable manipulation for knowledge construction—can benefit from AI in several ways. Virtual labs, simulations, adaptive systems, and data processing tools can help teachers overcome barriers such as equipment shortages, safety issues, and time constraints (Cheung et al., 2024; Paul et al., 2016; Tang et al., 2024).

Despite the expanding use of AI in science instruction, a limited number of studies focus specifically on its role in experimentation. These studies suggest that AI serves not only as a tool for effective experimentation but also as a force that transforms cognitive and pedagogical aspects, such as metacognition and scientific thinking (OECD, 2024; Ng et al., 2024). A bibliometric study can reinforce these findings by offering insights into research trends, key contributors, and emerging themes in the literature. This study aims to provide significant outcomes regarding the evolving relationship between AI and experimentation in science teaching, which can be useful for educators, policymakers, and education experts (Akhmadieva et al., 2023; Donthu et al., 2021; Marzi et al., 2024; Öztürk et al., 2024).

Literature Review

Experimentation In Science Teaching

Scientific experiments offer students opportunities to observe scientific phenomena as they unfold in real time, rather than merely reading about them or watching demonstrations. This direct engagement bridges the gap between abstract theoretical concepts and tangible experiences, enhancing conceptual understanding, curiosity, and retention. When learners witness cause-and-effect relationships, such as chemical reactions, forces in motion, or energy transfers, they are more likely to internalize key scientific ideas (Lee et al., 2023; Paul et al., 2016).

Experimentation is, therefore, fundamental to teaching science. It is a systematic process of investigating scientific questions that involves hypothesizing, observation, data collection, and analysis. It plays a multidimensional role by fostering scientific literacy. Through experimentation, learners can control variables such as mass, volume, light, temperature, voltage, and distance, allowing them to witness how concepts relate to one another. Learners can then participate in evidence-based explanations, exchange ideas, and engage in argumentation. This process enables them to actively construct knowledge within inquiry-based learning activities (Paul et al., 2016; Tang et al., 2024). Learners develop skills such as reasoning, critical thinking, scientific thinking, modeling, and metacognition, which lead to cognitive development, a better understanding of scientific content, and an appreciation of the nature of science and epistemic practices. Hence, national curricula and frameworks present experimentation as a core practice in science teaching (Lee et al., 2023; OECD, 2024).

There is considerable interest in the role and influence of information and communication technologies, such as AI, in experimentation. This integration can streamline the process, offering several advantages and disadvantages (Tang et al., 2024).

AI In Science Teaching:

The use of AI in science teaching presents both opportunities and challenges. On one hand, AI can enhance instruction through intelligent tutoring systems, adaptive learning tools, virtual laboratories, and generative applications, leading to more effective lesson plan design and improved learning outcomes (Ng et al., 2024; Ivanova et al., 2024). For example, with AI, teachers can quickly adapt session content and pace to meet individual learners' needs, providing timely feedback and fostering critical thinking (Almasri, 2024; Park et al., 2023). Moreover, applications such as virtual labs provide avenues for experimentation, especially in scenarios that are dangerous, complex, or inaccessible in traditional classroom settings (Tang et al., 2024; Park et al., 2023). Simultaneously, inquiry-based learning, a dominant teaching approach in contemporary literature, can be supported by AI, as it can enhance hypothesizing, experimental design, scientific thinking, collaboration, cooperation, creativity, and other fundamental components of inquiry (Lee et al., 2023).

AI is also associated with cross-curricular teaching subjects such as Science, Technology, Engineering, Arts, and Mathematics (STEAM), which are linked to contemporary science teaching paradigms. It can facilitate feedback and data collection from activities such as inquiry-oriented tasks and experiments, aiding analysis, decision-making, and knowledge construction (Cheung et al., 2024; Darayseh, 2023). Furthermore, teachers can use AI to monitor learners' progress and performance development, identify barriers, and map innovative learning paths (Ng et al., 2024; Ivanova et al., 2024). Through these interactive and adaptive features, AI can foster

stronger motivation among learners to actively participate in science sessions and develop a positive attitude toward the subjects and inquiry (Almasri, 2024; Park et al., 2023).

On the other hand, challenges arise with the use of AI. A major concern is linked to ethical, epistemological, and pedagogical issues, primarily due to data validity, privacy, algorithm accuracy, and overdependence on technology, which can assist but also undermine scientific thinking and other essential skills (Tang et al., 2024). Additionally, effective AI integration requires professional development and competencies from educators, who may not always feel confident or prepared to integrate these technologies into their work (Genc & Kocak, 2024; Cooper, 2023).

This challenge is compounded by the need for AI to align with curricula, syllabi, lesson plans, and education policies. In other words, attention must be paid to how AI is used in science teaching to ensure effective learning outcomes and to identify or develop AI tools that are compatible with teaching processes and contexts (Lee et al., 2023; Ivanova et al., 2024). Finally, inequalities in AI usage among countries and regions persist, as technologically advanced countries are more familiar with AI and the development of appropriate policies, which cannot be easily implemented in less advanced regions (Dai, 2023; Akhmadieva et al., 2023).

Bibliometric Analysis Of Trends Regarding AI In Science Teaching

Several bibliometric studies have examined the integration of AI into science teaching. These studies report a growing rate of relevant publications, with notable acceleration after 2020. This aligns with the general trend in digitalization and its impact on educational settings. A global interest exists around this topic, as publications originate from many countries, although the greatest number comes from the United States, China, and several European countries such as the United Kingdom, Germany, and Spain (Jia et al., 2023). The most prolific authors or researchers publishing in this area come from technical fields, such as computer science, with a limited number from education studies or social sciences. Consequently, emphasis is placed on engineering, computer-oriented issues, and content delivery, while less attention is given to pedagogical and education-oriented issues, such as experimentation in science teaching or inquiry-based instruction (Genc & Kocak, 2024; Ng et al., 2023). Correspondingly, the clusters drawn from these studies focus on topics such as educational robotics, STEAM, automation, prediction, ethical issues, and personalized learning and adaptivity. The number of studies examining pedagogical matters or teaching practices remains limited (Jia et al., 2023; Genc & Kocak, 2024).

Intersections Between AI And Experimentation

When it comes to the integration of AI in experimentation, as with science teaching in general, potential advantages and disadvantages can emerge. On one hand, AI can assist in planning experimental activities and learning scenarios that incorporate them. Thanks to AI-based virtual laboratories, it is possible for a session to include experimental activities that would otherwise be unfeasible due to safety, cost, or equipment shortages. Such simulations and virtual labs can also aid learners in tasks of hypothesizing, variable control, data collection, and analysis. This support fosters positive attitudes toward experimentation along with inquiry-based learning (Cheung et al., 2024; Cooper, 2023; Ivanova et al., 2024; Lee et al., 2023).

However, the use of AI in experimentation may oversimplify tasks and limit students' engagement in processes such as using materials, handling sensors, and measuring, which are basic components of experimentation. It may also deter them from learning other essential characteristics, such as argumentation, trial-and-error, and dealing with ambiguous data. Additionally, processes such as auto-grading and auto-generated outputs may undermine

learners' ability to judge, draw conclusions, and actively construct knowledge (Almasri, 2024; Paul et al., 2016; Tang et al., 2024).

In short, integrating AI into experimental tasks in science sessions can facilitate inquiry-based learning and familiarity with experiments through actions that ease their implementation. However, this approach can also impede the development of experimentation and inquiry skills and competencies that learners are expected to acquire. Teachers and education policymakers must thus be prepared to promote the appropriate use of AI in experimentation (Almasri, 2024; Darayseh, 2023).

Methodology

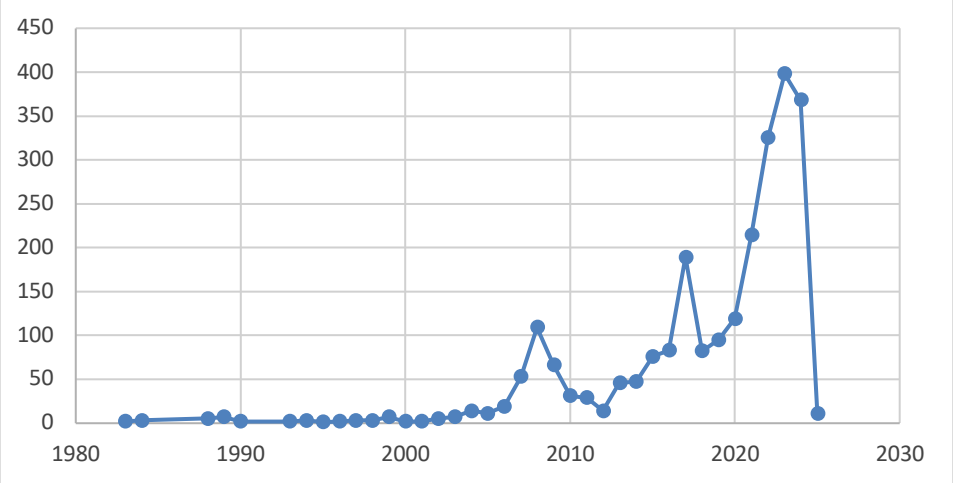
An examination of contemporary research trends regarding the intersection between AI and science teaching reveals a growing interest and recognition of AI's potential (Jia et al., 2023; Ng et al., 2024). However, there is a shortage of studies examining trends at the intersection of AI and experimentation in science teaching. A more focused bibliometric study is needed to outline the basic findings of research productivity around this topic and point out disciplinary and conceptual emphases (Genc & Kocak, 2024; Tang et al., 2024).

This study aims to address this gap with a bibliometric approach, which can unveil the desired trends by providing insights into publication rates, authors' research areas, regions, countries, affiliations with the most contributions, and thematic clusters. The research questions are formulated as follows:

- What are the publication rates for integrating AI and experimentation in science teaching?
- Which disciplines, countries, and institutions are most active in this area?
- What key topics and thematic clusters are identified in the research? (Donthu et al., 2021; Marzi et al., 2024; Öztürk et al., 2024)

The Scopus database was selected as the most appropriate data collection tool for such a study because it can gather publications, such as articles, books, or papers, around a specific topic. This is accomplished by executing a search query composed of terms relevant to this topic or its subthemes. Apart from gathering data, it provides functions that assist in analysing these publications concerning the three research questions. (Scopus, 2025).

A search was conducted on Scopus by executing the following command:



TITLE-ABS-KEY (experimentation OR experiment OR science AND education AND experiments) AND TITLE-ABS-KEY (artificial AND intelligence)

The search returned 2,453 publications. The data needed to answer the first two questions were obtained through the relevant analysis functions provided by the Scopus platform. The data were gathered and downloaded in sets of Microsoft Excel files that included the number of publications per year, along with research areas, countries, regions, and affiliations of the most authors or contributors. These data were analysed using descriptive statistics. To address the third research question specifically, the keyword co-occurrences of publications were gathered through Scopus, but the clusters were designed and visualized with VOSviewer, which assists in precisely identifying clusters of publications that can clearly reflect research trends and patterns. The analysis, therefore, included a combination of quantitative bibliometric mapping and qualitative cluster interpretation. This approach provides a clear and comprehensive picture of research, examining the role of AI in experimentation in science teaching. This is a common approach in bibliometric studies (Donthu et al., 2021; Scopus, 2025; Van Eck & Waltman, 2010).

Findings

Regarding the first research question about publication rates per year, the findings reveal that the earliest publications can be traced back to 1983. This indicates a long-standing interest, although initially limited, as several years had only five or seven publications, and in 1995, there was only one. This volatility persisted until the 2010s, with specific years, such as 2008 and 2017, showing significantly more publications than the preceding or following years. Nevertheless, a remarkable acceleration was noticeable after 2020, when the number of publications exceeded one hundred, and in 2023 and 2024, it even reached three hundred (Scopus, 2025).

Figure 1. Publications per year (Scopus, 2025).

Regarding the second research question, most authors who publish on this topic work in computer science, accounting for a large portion of the publications. Other contributing science-oriented disciplines include engineering, mathematics, physics and astronomy, and materials sciences. Several publications also come from social sciences and health areas, as shown in Figure 2. The countries with the most contributions include China and the United States, followed by the United Kingdom, Germany, Spain, Japan, Canada, Taiwan, India, Australia, and South Korea, as illustrated in Figure 3. Finally, the affiliations with the most contributions include the Chinese Academy of Sciences as the most prolific single institution, followed by the Ministry of Education of China and Carnegie Mellon University. Other notable institutions include Tsinghua University, Stanford University, and MIT, suggesting a strong emphasis on AI tool development over experimentation in science pedagogy from universities and governmental bodies (Jia et al., 2023; Genc & Kocak, 2024).

Finally, regarding the third research question, keyword analysis led to the identification of seven thematic clusters using VOSviewer software, as displayed in Figure 4. The first cluster, which is the largest, focuses on pedagogy and contains keywords such as teaching practices, learning, achievement, professional development, engagement, and science instruction. The second cluster pertains to AI techniques and includes keywords such as deep learning, machine learning, chatbots, and intelligent systems. The third cluster centres on human-centred learning and contains keywords such as motivation, attitudes, satisfaction, creativity, and learning preferences. The fourth cluster focuses on data analytics and modelling, containing keywords such as prediction, classification, data mining, and decision-making. The fifth cluster addresses technological infrastructure and includes keywords such as flipped classroom, e-learning, mobile learning, simulations, and digital platforms. The sixth cluster pertains to cognitive aspects and includes keywords such as cognitive load, metacognition, conceptual understanding, and problem-solving. The seventh cluster addresses cross-disciplinary applications and contains keywords such as interdisciplinary, health sciences, and engineering labs. Each cluster reflects a

conceptual domain in the integration of AI and experimentation in science teaching (Almasri, 2024; Darayseh, 2023; Van Eck & Waltman, 2025).

Figure 2. Subject areas (Scopus, 2025).

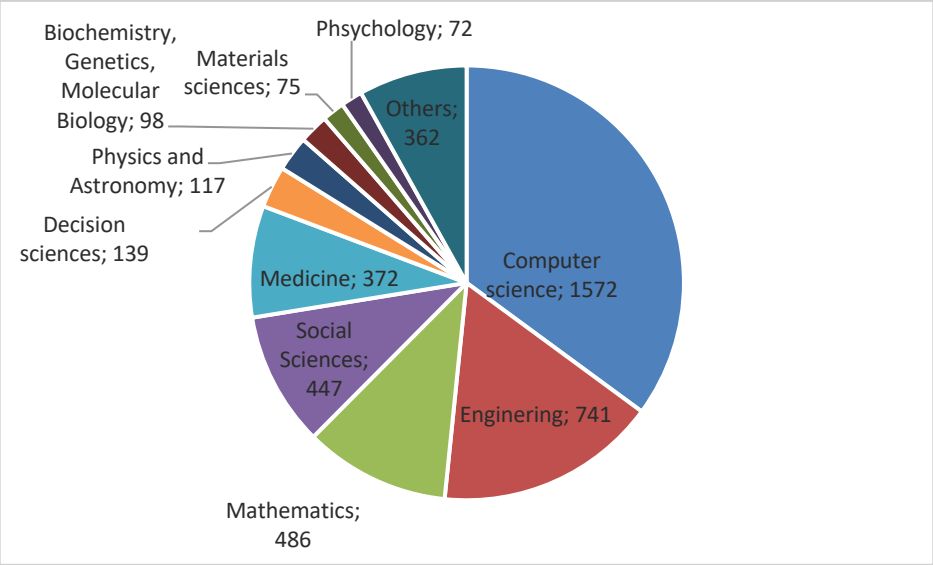


Figure 3. Countries with the most contributions (Scopus, 2025).

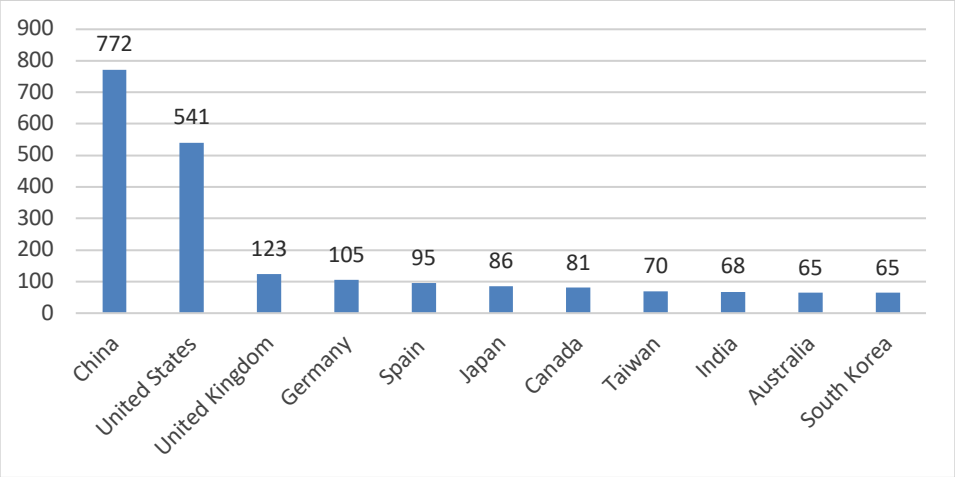

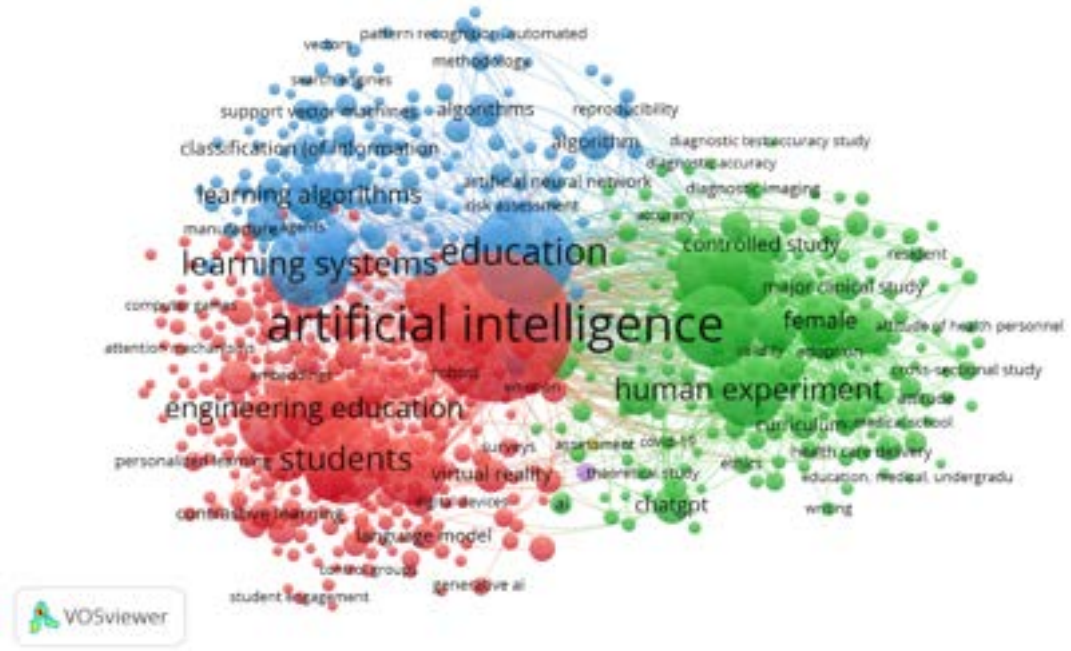

Figure 4. Clusters (Van Eck & Waltman, 2025).

Discussion

An analysis of the rate of publications per year indicates a sustained and growing interest in the role of AI in experimental science teaching over the last few decades. The non-linear growth pattern, with periods of declining publications, especially until the mid-2010s, is typical of fields undergoing conceptual formation (Donthu et al., 2021). This fluctuation can be explained by early pilot implementations of AI, without a specific focus. This changed drastically after 2018 and was not disrupted by challenging periods such as the COVID-19 pandemic, likely due to the significant development of AI tools (Marzi et al., 2024; Öztürk et al., 2024), which were subsequently introduced into educational practices and settings (Jia et al., 2023; Ng et al., 2024).

Although the publication rates appear to taper slightly after 2023, indicating a possible saturation of the field, the number of publications remains high, indicating a vibrant area of research (Donthu et al., 2021). This may be related to interest in technological advances such as virtual labs or AI-oriented learning platforms, which provide opportunities for teaching innovation, especially in experiments and inquiry-based approaches. Moreover, it may reflect educational researchers' interest in topics such as ethics and critical pedagogy (Genc & Kocak, 2024; Ng et al., 2023; Paul et al., 2016; Tang et al., 2024).

Regarding the second research question, the dominance of computer science publications reinforces the notion that technological advances drive innovation and research. The parallel presence of publications from social sciences suggests an interest in the implementation and use of AI in experiment-driven science instruction, either as a tool for experimental teaching activities or as a means to reshape students' attitudes toward science, scientific knowledge, and inquiry (Akhmadieva et al., 2023; Almasri, 2024; Genc & Kocak, 2024).

The strong presence of universities and governmental institutions in publications from various countries indicates a global interest, which may reveal funding and infrastructure in institutions to support AI use in experimental science teaching. However, the predominance of publications from technological disciplines raises concerns about the focus of research on social aspects such as pedagogy and ethical issues, although these areas are not entirely neglected. Additionally, the concentration of publications in specific countries, particularly English-speaking ones, may highlight inequalities in interest and access to AI tools for pedagogical purposes. Despite these concerns, evidence exists regarding cross-disciplinary and international collaborations between AI experts and education specialists (Almasri, 2024; Park et al., 2023). This reflects a recognition of AI's potential in experimental science teaching (Ng et al., 2024; Ivanova et al., 2024).

As for the third research question, the prominence of pedagogy can be associated with interest in dominant paradigms of experiment-oriented science teaching, such as learner-centered and inquiry-based approaches. This, combined with the clusters that emphasize AI techniques and human-centered learning, aligns with general findings that AI is reshaping pedagogy and can be associated with instructional methods that respond to learners' experiences and needs, particularly those that utilize experiments. The emphasis on professional development and learning effectiveness underscores the importance of teacher preparation (Akhmadieva et al., 2023; Almasri, 2024; Dai, 2023; Park et al., 2023).

The clusters focusing on technological infrastructure and functions, such as analytics, can be associated with AI's potential for promoting instruction where experiment implementation, based on context-rich learning experiences, is combined with virtual labs, simulations, or other practices that enhance digital awareness, feedback innovation, assessment, and knowledge construction within STEAM-oriented activities. This further justifies that AI can enhance experimentation by facilitating the execution of related activities in real-time and beyond classroom constraints (Park

et al., 2023; Zhang, 2021). The final clusters prove that cognitive scaffolding can be achieved through the use of AI in experiments, as it can assist not only in their execution but also in the development of scientific skills, such as hypothesizing, reasoning, metacognition, and problem-solving. As implied by the clusters, this can be applied in cross-disciplinary contexts, such as health sciences, robotics, and environmental projects. In fact, these clusters also provide evidence that AI can be utilized in designing experimental activities in such subjects or topics, leading to improved learning outcomes (Cheung et al., 2024; Ng et al., 2024; Paul et al., 2016; Park et al., 2023; Tang et al., 2024).

Conclusions

This study concludes that research trends reflect a general interest in the integration of AI in experimentation in science teaching, signifying reforms in the field of education. AI is redefining the role of experiments in developing scientific literacy. Its functions and possibilities can enhance elements such as inquiry, modelling, and hypothesis testing, which are foundational in experiment implementation and science subjects. Simultaneously, it provides opportunities for innovation through novel teaching practices and activities oriented towards student-centred learning, inclusion, equity, metacognition, and STEAM literacy (Cheung et al., 2024; Donthu et al., 2021; Jia et al., 2023; Öztürk et al., 2024; Park et al., 2023; Tang et al., 2024).

These trends are shaped by publications predominantly originating from specific countries and particularly from computer science research centres, institutions, or faculties. While educational institutions and departments contribute to this domain, their output is less frequent. This raises concerns regarding the actual implementation of AI in educational settings (Akhmadieva et al., 2023; Genc & Kocak, 2024; Ng et al., 2024; Zhang, 2021). A more focused, strategic alignment of education policy may be required with the integration of AI in experimentation for science teaching, achievable through professional development, training, appropriate curricula, supportive environments, and funding (Akhmadieva et al., 2023; Almasri, 2024; Öztürk et al., 2024).

Before generalizing these conclusions, it is essential to acknowledge the limitations of this study, which employs a bibliometric approach and focuses on research trends. Future research should triangulate this data with formal education documents or the opinions of policymakers, educators, and stakeholders. Nevertheless, this study affirms that AI's influence on experimentation in science teaching is undeniable and complex, as evidenced by the trends (Cohen et al., 2017; Donthu et al., 2021).

Acknowledgment

This research was made possible through the support of the University of the Aegean and access to the Scopus database. Permission to use and present data retrieved from Scopus in the form of custom graphs and visualizations was granted via direct email correspondence with the Scopus support team.

Technologies In Dialogue Across Sections

This collection brings together 22 articles that explore the growing presence of digital technologies in science education research and practice. Although the studies differ in terms of educational level, disciplinary focus, methodological approach, and technological tools, they collectively reflect an ongoing effort to understand how digital technologies are shaping learning experiences, student engagement, and teacher education in science-related fields. Across the collection, technologies such as generative artificial intelligence, virtual and augmented reality, digital games, simulations, multimodal resources, and online instructional platforms appear as elements that reorganise classroom interactions, pedagogical practices, and forms of participation in science learning.

The recurring presence of artificial intelligence immediately stands out. In just a few years, AI-based tools have moved from technological curiosity to a dominant topic in conferences and journals in the field. Several papers here follow this movement by investigating the use of customised chatbots, ChatGPT, and generative AI for lesson planning and the preparation of future teachers. Still, perhaps the most interesting aspect of the collection is that the papers do not adopt a homogeneous stance toward these technologies. Rather than announcing radical transformations or replacing pedagogical discussions with technological enthusiasm, the studies seek to observe how teachers and students use these tools in teaching situations. In this sense, the papers help compose a picture of the field of experimentation, seeking to understand both the possibilities and the limitations of these new digital mediations. The collection can therefore be read through three broad thematic axes that cut across the different contributions.

Artificial Intelligence, Teacher Education, And Pedagogical Mediation

The first group brings together studies focused on the use of generative artificial intelligence in teaching and teacher education contexts. This includes investigations into customised chatbots in Mathematics and Physics education, inquiry-based activities mediated by ChatGPT in Biology classes, lesson planning with generative AI, teacher preparation, and discussions surrounding AI literacy. Despite the diversity of contexts, the papers converge in several ways. First, AI appears as a tool to support, reorganise, or expand certain pedagogical practices. The most interesting results emerge when there is some form of intentional teacher mediation, creating opportunities for students to move beyond rapid, instrumental uses of these tools toward more elaborated, exploratory forms of questioning once they receive guidance on how to interact with the technology.

Another recurring aspect concerns teacher education amid the rapid spread of these tools. Some studies suggest that future teachers express interest in and openness to AI use, while also expressing uncertainty about ethical issues, authorship, information reliability, and institutional boundaries surrounding its use. The papers reveal how AI reopens longstanding educational

discussions related to teacher autonomy, the role of pedagogical mediation, and the broader meanings of school learning.

Immersion, Engagement, And Affective Dimensions Of Learning

A second axis groups papers that explore immersive technologies and multimodal languages to enhance student engagement. This includes studies on 360° videos for teacher education, virtual reality, augmented reality, hybrid games, and digital curation in socio-scientific issues. What these studies share is a focus on students' experiences during the learning process. Their interest extends beyond conceptual gains to encompass motivation, stress, participation, immersion, and emotional involvement. The study on comics, for example, suggests that narrative and visual formats may help create less stressful learning environments for students. Meanwhile, studies on virtual reality and hybrid games investigate how more interactive, embodied experiences can bring students and teachers closer to inquiry-based STEM practices.

At the same time, the papers show that incorporating these technologies also entails concrete limitations and tensions. Participants report physical discomfort during immersive experiences, while other studies highlight the need for careful planning to prevent technology from becoming merely a source of distraction or spectacle. What emerges from this group of papers is an attempt to understand the conditions under which these tools may contribute to more meaningful learning experiences.

Digital Materials Design And The Organisation Of Teaching Practices

The third axis brings together studies focused on the design of digital materials, activities, and environments for science education. These include research on digital laboratory reports, STEM teaching sequences developed on digital platforms, physics simulations, digital learning objects, and digital teacher guides. These studies are connected by a shared concern with the organisation of pedagogical practices and the ways in which different digital formats influence learning. Some investigate issues related to cognitive load and visual design, while others analyse how pre-service teachers structure inquiry activities within digital environments.

Interestingly, several of these studies point to a recurring tendency: even in technologically innovative contexts, highly guided, linear approaches still predominate. Convergent activities, structured sequences, and more controlled forms of inquiry appear frequently in participants' materials. This does not diminish the relevance of these proposals, but it suggests that technological changes are not always accompanied by equivalent shifts in pedagogical conceptions.

Looking Ahead With Open Questions For Technology And Science Education

The papers in this collection portray a field undergoing rapid transformation while still marked by important continuities. Questions related to student engagement, teacher education, the organisation of school scientific inquiry, and pedagogical mediation remain central, even as new technologies increasingly occupy a visible place in research. Perhaps for this reason, the main contribution of this collection lies in documenting how researchers and teachers are attempting to negotiate the possibilities and limitations of these technologies in real teaching contexts.

At the same time, the collection also makes visible a series of open questions that may guide future research. Many studies demonstrate how digital technologies can support engagement, participation, immersion, or instructional design, but less attention is given to the broader institutional, political, and economic conditions shaping the adoption of these technologies in schools and teacher education programs. As digital platforms, generative AI systems, and data-

driven educational tools become increasingly embedded in educational systems worldwide, questions about dependence on private technological infrastructure, data governance, platformization, and commercial interests become difficult to ignore.

A more explicitly critical perspective on technology and science education still has significant room to develop within the field (Garcia-Romano et al., 2021). Future studies may increasingly need to ask whose interests are served by particular technological agendas, which forms of knowledge and participation become privileged, and which educational practices risk becoming marginalised. These questions become especially relevant in the context of the ongoing neoliberalization of education across different parts of the world, where efficiency, personalisation, scalability, and performativity often shape educational innovation agendas.

As schools and universities continue to incorporate AI systems, immersive environments, and digital learning platforms into everyday practices, science education research may benefit from approaches that also examine how technology reshapes relationships between teachers, students, institutions, knowledge production, and educational policy (Azevedo and Santos, 2025). In this sense, the studies gathered here may also be read as part of a larger conversation about the future of science education itself: a future in which technological change is likely to remain central, but where pedagogical, ethical, and political questions will continue to demand careful and critical attention.

Examining The Generalisability Of Trained Computer Vision Models For Instructional Support In Science Experiments

Edwin Chng[1] and Bertrand Schneider[2]
[1]National Institute of Education, Nanyang Technological University, Singapore
[2]Harvard Graduate School of Education, Harvard University,
United States of America

When science teachers facilitate conduct of student experiments, they face challenges in monitoring students' procedural steps due to presence of multiple students and limited cognitive bandwidth. Yet, without adequate teacher supervision, students' procedural missteps, incorrect experimental techniques, and safety violations become missed teacher observations that can result in the formation of undesirable student practices. To address this, computer vision can be deployed in science laboratories to continuously monitor students' procedural steps and highlight relevant student information for teachers to intervene. However, the generalisability of trained computer vision models for instructional support in science experiments is untested. To this end, we examined the performance of a trained computer vision model (SlowFast) on YouTube videos. The SlowFast model was trained on videos collected from 140 middle school students (which is of a specific population and context), and the gathered YouTube videos consists of 77 individuals from a wide variety of populations and contexts. Results indicate that model generalisability depends on choice of pretrained model and size of training dataset, together with recording conditions and data consistency of the new context. More specifically, precaution ought to be taken to ensure that collected training data contains at least hundreds of training instances, and that camera setup in all contexts are of similar viewpoints and zoom factors. Furthermore, variations in training instances should imitate expected variations in different contexts. Overall, this work attained preliminary evidence of the general feasibility of deploying trained computer vision models for instructional support in science experiments.

Keywords: Artificial Intelligence, Laboratory Instruction, Science Education

Introduction

When science teachers facilitate the conduct of student science experiments, they face challenges in monitoring students' procedural steps. This is because in a typical science laboratory setting, science teachers are tasked with attending to the learning needs of several students, and as humans, they experience natural cognitive limits in being able to pay sufficient attention to every action taken by each student (Sherin & Star, 2011). Yet, awareness of students' procedural steps is critical for science teachers to be able to provide students with suitable formative feedback on their experimental work (Stiggins, 2006). Without adequate teacher awareness, students' procedural missteps, incorrect experimental techniques, and safety violations become missed teacher observations that can result in the formation of undesirable student practices.

In this case, there exists a teacher observation gap that can be fulfilled with the use of artificial intelligence (AI). Specifically speaking, computer vision models can be deployed in science laboratories to continuously monitor students' procedural steps and highlight relevant student information for teachers to intervene (Chng, 2024). However, training of computer vision models is sensitive to data inputs (Gudivada et al., 2017) and the generalisability of trained computer vision models for instructional support in science experiments is untested. In particular, it is unknown if a computer vision model that is trained with a specific set of student data can perform well in the observation of another population in another context. With this in mind, this research

work seeks to examine the generalisability of trained computer vision models so as to establish the general feasibility of deploying AI for instructional support in science experiments.

Methods

Our research question asks, "What is the generalisability of a trained computer vision model in conducting student observations from another population and context?" As detecting students' procedural steps is the primary concern for teachers during science experiments, we focus on the generalisability of action recognition models in this research.

Our chosen action recognition model is that of SlowFast (Feichtenhofer et al., 2019). In terms of model performance, SlowFast belongs to the latest generation of models that have demonstrated state-of-the-art capabilities for action recognition (Fan et al., 2021). In terms of model architecture, SlowFast is "partially inspired by biological studies on the retinal ganglion cells in the primate visual system" (Feichtenhofer et al., 2019, p. 6203) and mimics the way in which visual information is processed by humans. With these advantages in mind, we target SlowFast as the intended computer vision model for our generalisability test. A SlowFast model that was pretrained with the Kinetics400 dataset (Kay et al., 2017) was downloaded from the PyTorchVideo library (Fan et al., 2021). The motivation for using a pretrained model is due to the fact that such models contain primitive understandings of lower-level action features (Sharif Razavian et al., 2014), which renders them easier to train and adapt for our purposes (Tajbakhsh et al., 2016).

Table 1. **Statistics of video clips in our video datasets**.

Action ID	Student Action	Number of Student Video Clips	Number of YouTube Video Clips	Action Category
1	close air hole	117	55	Light Bunsen burner
2	close gas tap	166	74	
3	ignite Bunsen burner	367	84	
4	open air hole	253	60	
5	open gas tap	220	72	

Our target set of student actions is related to the lighting of a Bunsen burner (see Table 1 for detailed list of actions). This set of student actions was chosen because lighting Bunsen burner is a common procedure in science experiments. To prepare our downloaded SlowFast model for test of generalisability, we first train it with videos collected from 140 middle school students as they light a Bunsen burner. With the trained model, we then evaluate its performance on YouTube videos of 77 individuals lighting a Bunsen burner. YouTube was selected as a source for our generalisability test since it contains videos of individuals from a wide variety of populations and contexts. In other words, we can address our research question by examining the YouTube performance of a SlowFast model that was trained on data collected from a middle school (which is of a specific population and context, as compared with YouTube videos which is of a wide variety of populations and contexts). Findings from this investigation will ultimately apprise us

of the need to retrain action recognition models for use in other science experiments and provide us with an appreciation of the general feasibility of deploying AI for instructional support in science experiments.

Table 1 shows the statistics of video clips in each of our video datasets (i.e., student dataset and YouTube dataset). Each video clip represents an uninterrupted instance of a particular action taken by the student/individual within the video. Since each action can possibly be taken by the student/individual more than once or none at all, the number of video clips obtained for each action deviates from the total number of videos collected in each dataset.

Results

Table 2 shows the class prediction accuracies of our trained SlowFast model on YouTube videos. Surveying Table 2, our model's class prediction accuracies are consistently above 70% and has an overall accuracy of 76.81%. Compared with Slowfast's reported state-of-the-art accuracy of 76.94% (Fan et al., 2021), our model's performance on the unseen YouTube dataset with different populations and contexts is respectable. This is possibly because our trained SlowFast model reaped the performance benefits of being pretrained with the Kinetics400 dataset to learn lower-level action features and being further trained with a sizeable student dataset to learn our target set of student actions. It is noteworthy here that the reported state-of-the art accuracy was attained with a dataset that contains at least 400 video clips for each action class (Fan et al., 2021). By contrast, our smallest action class (i.e., "ID 1 close air hole") only possessed 117 video clips and our largest action class (i.e., "ID 3 ignite Bunsen burner") contains no more than 400 video clips. Yet, our trained model is able to perform on unseen data with a class prediction accuracy of 80.00% for our smallest action class and achieve an overall model accuracy of 76.81%. This signals the importance of transfer learning for AI models and hints at the general feasibility of deploying trained AI models for use in other science experiments. On balance, our test on data from the wild (i.e., YouTube videos) demonstrates the generalisability of trained computer vision models as long as the choice of pretrained model is appropriate and the size of training dataset is sufficient.

Table 2: Class prediction accuracies of our trained SlowFast model on YouTube videos.

Action ID	Student Action	Class prediction accuracies
1	close air hole	80.00%
2	close gas tap	78.38%
3	ignite Bunsen burner	83.33%
4	open air hole	70.00%
5	open gas tap	70.83%
-	Overall	76.81%

In an effort to better understand model generalisability, I further investigated examples of incorrect model predictions qualitatively. In this respect, two inherent sources of model confusion were discovered. First, even though the camera viewpoint and zoom factor of our collected student videos is fixed, those of YouTube videos can be changing. For instance, some YouTube videos provide a shifting perspective as the Bunsen burner is being lit (e.g., from front to side). Otherwise, some YouTube videos zoomed in on the gas tap when it is being opened or closed and later zoomed out to reobtain a full view. By contrast, all of our student videos adopted an all-

encompassing frontal viewpoint with unvarying zoom. Second, the apparatus used in school science laboratories may differ from that of YouTube videos. For example, gas lighters appeared in all our student videos, but certain YouTube videos featured spark lighters. Altogether, these differences in recording conditions and apparatus used resulted in more incorrect model predictions when contexts are switched, which serves to remind us that model generalisability is dependent on recording conditions and data consistency as well.

Discussion

In contemplating the widespread deployment of trained AI models, we think about the implications of our investigation findings and deliberate on the integration of computer vision models for instructional support in science experiments. From our model investigation, it became evident that model generalisability depends on the choice of pretrained model and the size of training dataset, together with the recording conditions and data consistency of the new context. Consequently, we should take precaution to ensure that collected training data contains at least hundreds of training instances for each action class, and that camera setup in all contexts are of similar viewpoints and zoom factors. Furthermore, as with common machine learning approaches, variations in training instances should imitate expected variations in different contexts. For example, if both spark and gas lighters are expected to be found within deployment contexts, then gathered training instances ought to contain ignition of Bunsen burner with both spark and gas lighters. In this way, widespread deployment of AI models in general science experiments can be achieved without concerns for reduced performance in new contexts.

As for the integration of computer vision models for instructional support in science experiments, we note that teachers face severe time constraints in schools and would not possess sufficient bandwidth to go through model outputs for every student (Chng, 2024). Under these circumstances, the delivery of instructional support should include added processing steps to consolidate pertinent information for teachers. More specifically, we can apply auxiliary algorithms to extract needed student information from detected student actions. For instance, if teachers wish to track the order of procedural steps taken by students for formative feedback, then we can rely on sequence analysis (Mannila et al., 1997) to ascertain order of student actions and highlight to teachers whenever students deviate from expected sequences. In essence, the integration of computer vision models for instructional support should take into consideration the realities of teacher circumstances and pedagogical concerns so as to promote widespread deployment of AI models in general science experiments.

Finally, although we have attained preliminary evidence of model generalisability in this investigation, more testing is required to establish the parameters and boundaries of general applicability. Specifically, more research work is needed to uncover the nuanced performance of trained AI models across different experiments, for diverse students, and in varied environments.

Partners In Science Lesson Planning: GenAI-Driven Design With Human-In-The-Loop Validation

Kalliopi Meli[1], Yaron Lehavi[2], Ioanna Taouki[3] and Dimitrios Pantazatos[4]
1University of Patras, Greece
2David Yellin Academic College of Education, Israel
3100mentors, Greece
2National Technological University of Athens, Greece

Generative Artificial Intelligence (GenAI) has emerged as a disruptive technology with vast potential in education. A workshop that took place during the ESERA 2025 conference explored the intersection of GenAI and science education, focusing on how educators utilize GenAI tools to develop lesson plans that consider students' common alternative frameworks. We investigated the awareness and adoption levels of GenAI among science educators, explored how researchers and practitioners use GenAI to construct science lessons, and assessed how collaboration with other experts in science education and research can validate and enhance instructional design developed with GenAI. During the workshop, participants engaged in hands-on activities using a customized GenAI tool, allowing them to design instructional material tailored to their specific educational needs. This session emphasized the importance of integrating scientific accuracy and pedagogical principles in exercise design, and discussions centred on best practices for leveraging GenAI in educational contexts while addressing potential concerns and limitations. The workshop equipped participants with a comprehensive understanding of GenAI's potential in science education and served as a stepping stone towards developing more effective, personalized, and engaging teaching environments.

Keywords: Generative Artificial Intelligence; Human-in-the-loop; Students' alternative frameworks

Introduction

Generative Artificial Intelligence (GenAI) has emerged as a disruptive technology with vast applications across various domains, including education. GenAI offers opportunities to create more engaging, personalized, and effective learning environments (Meli et al., 2024). From the educator's perspective, integrating GenAI streamlines instructional material development, reduces instructor workload, and enhances material quality (Dickey & Bejarano, 2024).

GenAI can potentially assist educators in generating instructional materials and supplementary resources tailored to the curriculum and individual student needs (Bonde, 2024). While previous research has explored various applications of GenAI in educational settings, there remains a need for further investigation into its potential for supporting instructional design in a structured and efficient manner (Karpouzis et al., 2024). The integration of GenAI into science education may present a significant opportunity to transform lesson planning, not only by enhancing its feasibility and robustness for educators but also by increasing educators' awareness of students' learning requirements within the context of the scientific content they must acquire (Almasri, 2024).

While educators may acknowledge that GenAI potentially facilitates and enhances their work, concerns persist regarding the limitations of this emerging technology, particularly in disciplines where the model's training data are insufficient. To mitigate these risks, it is crucial to maintain a "human-in-the-loop" approach, which generally refers to the need for human interaction, intervention, and judgment to control or change the outcome of a process (Meng, 2023, p.1). This

ensures that critical decisions are not left solely to automated systems and allows for the detection and correction of potential mistakes or unintended consequences and the improvement of the overall outcome quality (Chen et al., 2023).

Addressing these multifaceted opportunities and challenges, the workshop held during the ESERA 2025 conference aimed to transcend individual trials and provide structured guidance and support to assist educators in enhancing their awareness of GenAI capabilities (Bonde, 2024). Specifically, it sought to facilitate the utilization of GenAI for context-specific needs, particularly for developing lesson plans that incorporate relevant pedagogical aspects. Additionally, the workshop intended to expose participants to the "human-in-the-loop" methodology, where the human is an expert in teaching a specific scientific topic, to validate and enhance the results they co-created with GenAI.

Theoretical framework

Addressing students' alternative frameworks is essential for designing effective science education. Educators are expected to engage students in activities that challenge their ideas and promote conceptual change toward a scientifically accurate understanding of the world (Vosniadou, 2011). This aligns with the emphasis on integrating science practices and developing sophisticated teaching methods to support student learning (Arias et al., 2016).

However, traditional textbooks and guidelines often focus more on scientific content, rather than on the alternative frameworks students may employ in their interpretations (Zourmpakis et al., 2023). Consequently, embracing more progressive pedagogical approaches challenges science educators at an individual level as they frequently encounter diverse content and varying levels of complexity that are often related to a broad spectrum of alternative frameworks (Johsua & Dupin, 1991).

In this respect, GenAI shows the potential to accelerate educators' lifelong learning progression and effectively support them in implementing their day-to-day educational duties (Pantazatos et al., 2024). GenAI tools introduce new methodologies for effective teaching and learning, addressing traditional educational challenges. This technology can empower educators to develop dynamic teaching materials, fostering innovation in educational practices and facilitating ongoing learning and skill development. Adopting GenAI in education can transform instructional design by analysing and expanding subject-specific content and creating learning pathways informed by educational research (Meli et al., 2024).

Integrating GenAI into science education presents a promising avenue for enhancing teaching methodologies and addressing students' alternative frameworks. GenAI can simulate complex physical phenomena and provide visual and interactive learning experiences, which are often challenging to replicate in traditional classroom settings. By leveraging GenAI, educators can personalize their teaching by streamlining their workflow, creating more efficient lesson plans, generating diverse problem sets, and developing tailored explanations for complex concepts. This technology can assist in identifying and targeting common areas of alternative conceptions among students, allowing for more effective instruction (Cooper, 2023). In teaching planning, GenAI can direct educators to consider established knowledge in the discipline they teach and in the discipline of teaching it. This can enhance their awareness of using their own PCK in planning and conducting their teaching.

Concurrently, implementing GenAI in educational contexts presents several significant challenges (Alier et al., 2024). The efficacy of the models underlying GenAI depends heavily on the quality of user-provided prompts. The caliber of responses can exhibit considerable variability

based on the application domain, potentially resulting in inconsistent or inadequate information in certain areas. The underlying models can generate content that appears authoritative but may be entirely fabricated or irrelevant to the query, which can be misleading in educational settings. The responses may perpetuate biases and reinforce stereotypes present in the training data. Finally, from a personal development aspect, there exists a risk of diminished creativity and critical thinking among users due to excessive reliance on the outputs that GenAI can readily produce. While the respective tools can assist, they cannot supplant the value of human interaction, crucial for users' development.

Mitigating the risks of GenAI in education requires a multifaceted approach that addresses ethical, pedagogical, and technological concerns. Developing critical GenAI literacy among educators is crucial for responsible innovation and informed use of GenAI (Rudolph et al., 2024). This involves fostering an environment where stakeholders can understand and critically evaluate GenAI-generated content. Maintaining human oversight is essential to address potential privacy, bias, and accuracy issues in GenAI tools (Noroozi et al., 2024). Human-in-the-loop approaches, informed by experts' input, can solve problems related to data scarcity, feedback accuracy, annotation costs, and decision-making reliability in educational material development. Combining human expertise with artificial intelligence capabilities offers promising solutions for creating more effective and efficient educational tools and experiences (Chen et al., 2023).

To complement these theoretical considerations, further inquiry is needed into how researchers or practitioners and institutions can critically and productively integrate GenAI into science instruction. Several open questions emerge as particularly relevant to ongoing research and practice:

1. What would effective integration of GenAI tools into teaching planning and delivery look like, and what improvements might it bring to instructional quality and educator workload?
2. How can GenAI be leveraged to identify and address students' alternative frameworks, or other considerations embedded in science education, in supporting deeper conceptual understanding?
3. What strategies can be employed to combine human expertise and GenAI to ensure that instructional materials are both pedagogically sound and scientifically accurate?
4. How might additional human input—through peer collaboration, student feedback, or expert review—be used to maintain the quality and integrity of GenAI-generated content in educational contexts?

These questions not only reflect the pedagogical tensions and opportunities surrounding GenAI but also help frame future empirical studies and practical design considerations in science education.

Method

To explore and exemplify a means to address the questions above, we organized a workshop as part of the ESERA 2025 conference. The workshop engaged the participants with GenAI tools for lesson planning, while emphasizing educator agency, peer collaboration, and reflection. In essence, the workshop served as a pilot implementation of an educator-centred GenAI approach in science education.

Participants And Context

The workshop brought together higher education science researchers and practitioners (*N*=25) from diverse backgrounds, most of whom were curious about using GenAI but had limited prior experience. An initial poll confirmed that less than half had experimented with tools like ChatGPT, roughly mirroring the split found in larger surveys (e.g., Pantazatos et al., 2024) on GenAI adoption. This mix provided a rich environment for peer learning. The focus on science education (as opposed to general teaching) allowed us to tailor scenarios to common science topics and students' alternative frameworks, making the experience directly relevant to participants' real-life contexts.

Workshop Design

We structured the 45-minute session into four interactive phases aligned with the human-in-the-loop design: orienting and framing GenAI use, hands-on experimentation, collaborative expert review, and reflective synthesis.

Orientation And Critical Framing

The workshop began with a brief introduction to GenAI's capabilities and limitations, using current research and classroom examples to provoke reflection. We demonstrated GenAI's potential to simulate scientific phenomena and its tendency to state confidently scientific errors. Framing was informed by literature highlighting GenAI's epistemic risks (e.g., Cooper, 2023; Rudolph et al., 2024), setting a tone of curiosity paired with critical literacy. Participants shared their hopes and concerns in an open dialogue: many were enthusiastic about reducing lesson-planning load, while others voiced concerns about delegating too much conceptual work to GenAI or inadvertently circulating misconceptions. This ideas exchange helped establish the workshop's central tension: how to meaningfully integrate GenAI without surrendering pedagogical judgment.

Hands-On GenAI Tool Use

Participants then logged into a fine-tuned GenAI tool interface developed by our team. The tool was inspired by prompt-engineering systems like that of Karpouzis et al. (2024), and invited users to input topics, student level, known alternative frameworks, and teaching preferences. Based on this, the tool generated a structured lesson plan, typically including: (1) learning objectives, (2) an introductory warm-up targeting a common alternative framework, (3) an interactive activity, and (4) an assessment item. To scaffold engagement, we pre-loaded one editable prompt that served as a model:

> Design a 60-minute lesson plan for first-year university students focusing on the First Law of Thermodynamics, particularly energy change and energy conservation.
>
> Address common alternative frameworks such as the idea that energy is 'used up' or disappears during a process. The lesson should support students in developing a correct understanding of energy conservation through both conceptual and quantitative reasoning.
>
> Include: (1) a context-rich example involving heat and work (e.g., gas expansion, heating a metal block), (2) a guided problem-solving activity, and (3) a checkpoint for discussion where students compare their initial ideas with formal thermodynamic reasoning.
>
> Conclude with a summary that reinforces the conservation principle across system boundaries.

Participants worked in pairs to simulate collaborative use, actively revised outputs, applying their pedagogical knowledge to fill in gaps or correct inaccuracies, demonstrating the central role of

educator judgment in human-in-the-loop design. As they interacted with the tool, facilitators supported prompt refinement (e.g., adding context, specifying alternative frameworks). Participants were reminded that GenAI outputs were first drafts to be evaluated critically. Educators noted several emergent patterns: some plans were praised for creative analogies (e.g., comparing chlorophyll to a "solar panel"), while others lacked experimental rigor (e.g., omitting control variables in suggested investigations).

Human-in-the-Loop Validation Exercise

Following initial design work, groups submitted a selected lesson plan for live review by a science education researcher (co-facilitator), modelling expert oversight. The reviewer projected excerpts from a participant-generated plan and engaged in a public "think-aloud," identifying both strengths and areas of concern. For instance, a proposed analogy about current flow was deemed accessible but conceptually imprecise; the expert revised the phrasing on the spot. Positive design features were also highlighted, such as an GenAI-suggested student role-play where learners acted as parts of a circuit. This segment gave participants a concrete example of what human-GenAI co-design might look like in situ, reinforcing the necessity of content validation. Feedback from attendees suggested this was one of the most impactful workshop moments, providing a mental model for how educators might vet GenAI-generated materials in their own practice.

Outcomes

This workshop provided participants with a structured, immersive experience at the intersection of GenAI and science education. By engaging in hands-on activities, collaborative design, and guided expert review, participants explored how GenAI can support lesson planning—particularly in addressing students' alternative conceptions. The implementation foregrounded human agency and critical engagement with GenAI, aiming not merely to showcase technological capabilities but to situate them within authentic pedagogical challenges (Zourmpakis et al., 2023; Chen et al., 2023).

By the end of the session, participants reported feeling more confident in experimenting with GenAI tools for educational purposes. Many articulated a shift in mindset, from skepticism or apprehension to a more empowered and strategic view of GenAI use. As one participant remarked, "I was worried AI would take over, but now I see it's up to me to direct it. It's like a super-smart apprentice – helpful, but it still needs supervision." This comment reflects a broader theme that emerged across reflections: GenAI, when used thoughtfully, can extend educator capacity without displacing professional judgment.

Participants left the workshop with concrete lesson plan drafts (customized to their classroom context and structured using the GenAI tool) that could be further refined for actual use. Several noted that the tool had helped them generate ideas they might not have considered otherwise, affirming literature on GenAI's role in ideation support and workload reduction (e.g., Pantazatos et al., 2024). Yet this creative potential was matched by a shared recognition of GenAI's limitations. All participants identified at least one factual error, omission, or pedagogical mismatch in the GenAI output, reinforcing the necessity of educator oversight. This outcome was viewed positively: the experience functioned as a form of inoculation against uncritical use of GenAI, strengthening participants' critical GenAI literacy.

The workshop also illuminated the dynamics of educator agency and collaboration. Educators who initially expressed low confidence in using GenAI tools showed greater enthusiasm and initiative when paired with peers. This suggests that co-use scenarios not only improve outcomes but also reduce intimidation, highlighting peer collaboration as a key factor in building collective

confidence and competence. Furthermore, the visible role of the invited science education researcher (as a constructive and approachable "critical friend") helped normalize the idea that integrating GenAI into practice is a shared, iterative process. Participants responded positively to this modelling of expert feedback, indicating openness to seeking similar validation mechanisms in their own contexts.

In sum, the workshop outcomes support the viability of a teacher-centred, human-in-the-loop approach to GenAI in science education. Participants valued the time-saving and creative affordances of GenAI, while also deepening their appreciation for the irreplaceable role of human judgment. These insights not only confirm existing hypotheses in the literature but also offer direction for future implementations, particularly the need to scaffold peer collaboration, embed expert review, and foster critical literacy as core components of any GenAI-supported instructional design process.

Discussion

The findings of this workshop-based study offer valuable insights into the evolving role of GenAI in science education, particularly when implemented through a human-in-the-loop, teacher-centred design. As the results illustrate, educators engaged with GenAI not merely as consumers of pre-generated content but as critical co-designers, actively shaping and refining outputs in response to pedagogical needs. This aligns with existing calls for educators to retain epistemic authority in the classroom, even in the presence of increasingly sophisticated AI tools (Cooper, 2023).

The varied responses to GenAI-generated lesson plans underscore a central theme in the literature: that while GenAI offers substantial affordances (such as idea generation, time efficiency, and personalized content creation) it also demands rigorous human oversight to mitigate the risks of inaccuracy, superficiality, and bias (Alier et al., 2024; Noroozi et al., 2024). Participants' recognition of these risks and their capacity to critique and improve the GenAI outputs reflect the growing importance of critical GenAI literacy in educator professional development (Rudolph et al., 2024). Rather than viewing GenAI as a threat to educator autonomy, many participants reframed it as a tool requiring pedagogical steering—consistent with the "super-smart apprentice" metaphor voiced during the session.

Notably, the workshop demonstrated how GenAI might be harnessed to better address students' alternative frameworks in science. By prompting the GenAI to design warm-ups and activities that target known alternative frameworks, participants practiced a generative form of lesson planning aligned with constructivist goals and conceptual change theory (Vosniadou, 2011; Arias et al., 2016). This suggests that when GenAI is guided by well-crafted prompts and supported by expert or peer knowledge, it can serve not only to expedite instructional design but also to embed more responsive and diagnostic pedagogical strategies.

In this regard, the findings also validate the theoretical potential of GenAI as a tool for accelerating educators' professional growth (Pantazatos et al., 2024; Meli et al., 2024). Participants' experiences echo research suggesting that GenAI-powered platforms can scaffold educators' reflection and creativity, provided they are used in contexts that value human interpretation over automation. The design of the workshop—emphasizing peer collaboration and expert validation—resonates with broader literature advocating for multi-layered human input in educational GenAI systems (Chen et al., 2023). The observed benefits of pair work among less confident participants further emphasize the need to structure GenAI training within socially

supported collaborative environments that promote collective educator agency.

At the same time, the workshop exposed important design tensions. For instance, the variability of GenAI outputs highlighted the ongoing challenge of prompt precision (Alier et al., 2024), and participants' mixed trust in GenAI-generated facts mirrored broader concerns about misinformation and fabricated content. This reinforces the notion that GenAI's value lies not in its autonomy but in its ability to extend human thinking, provided researchers and practitioners are equipped to filter, contextualize, and critique its suggestions.

Ultimately, this study contributes to a growing body of evidence indicating that successful integration of GenAI in education requires more than access to tools—it requires frameworks for thoughtful, ethical, and collaborative use. As such, it affirms that teacher-centred, critically reflective approaches are not only compatible with GenAI but essential for its responsible and pedagogically sound implementation.

Conclusions

This study contributes to the emerging landscape of GenAI in science education by demonstrating how teacher-centred, human-in-the-loop approaches can enable thoughtful integration of AI into lesson planning. The workshop highlighted that while GenAI offers clear benefits, such as efficiency, idea generation, and flexible adaptation, it must be embedded within pedagogical frameworks that prioritize human judgment, contextual relevance, and critical oversight.

Participants' experiences affirmed that educators are eager to explore GenAI, but they require structured opportunities to build confidence, develop prompt literacy, and collaboratively review outputs. These findings support a vision of GenAI not as a replacement for researcher or practitioner expertise, but as a partner in pedagogical design; one that, when properly guided, can enhance science instruction and help address persistent challenges such as student alternative frameworks.

Looking ahead, future work should explore longitudinal implementations of teacher-GenAI co-design, particularly across varied school contexts and subject areas. Developing professional development models that promote peer collaboration, expert feedback, and iterative refinement of GenAI-generated content will be key. Additionally, more research is needed into how GenAI can support formative assessment, differentiation, and inclusive pedagogy. As GenAI tools continue to evolve, the education community must remain committed to evaluating their impacts, not only on efficiency and design quality, but also on educator identity, student understanding, and the broader ethics of AI-enhanced teaching.

Acknowledgement

The authors would like to thank all the participants of the ESERA 2025 workshop for their enthusiastic engagement and thoughtful contributions.

ESERA 2025 Copenhagen

Game-Based Learning In Computer Science Lectures – A Study In Higher Education

Melissa Gruber
University of Education Karlsruhe, Germany

In higher education, incentivizing approaches are shifting from traditional teaching to constructivist, self-determined learning methods. The latter allow students to study at their own pace and focus on individual needs. One such approach is game-based learning, which is understood as the use of games for educational purposes. Based on predetermined learning objectives, such serious games are specifically designed to foster learning by playing educational games. Considering digital transformation of learning materials, serious games are often realized as digital games. These are considered particularly suitable for students with prevalent engagement with computers and high understanding of digital tools, such as computer science students. Within the scope of an elective subject at the faculty for Business Informatics at the University of Applied Sciences Karlsruhe, Germany, digital serious games were introduced as an integral part of the lectures. Over the course of 3 semesters, these educational games were evaluated by students. In total, n=87 higher education computer science students participated in the study. Results shed light on students generally expressing enthusiasm as well as appreciation for educational games. Students respond positively to the adoption of innovative game-based teaching methodologies. There is a notable appreciation for the replacement of traditional unidirectional teaching methods. In addition to providing positive feedback, students offer suggestions for the enhancement of digital serious games regarding their utilization, incorporation into lectures, and game design. Students indicate that digital serious games are enjoyable and anticipate their incorporation into future curricula. This article delves into the survey results and provides recommendations for further application of game-based learning in higher education.
Keywords: Constructivism, Digital Learning, Student Engagement

Introduction

In the contemporary era, a decline in the attention span of students has been observed. This leads to educators seeking innovative methods to gain students' attention and interest in lectures. The integration of incentivizing approaches into higher education lectures has gained significant traction as to enhance student engagement, motivation, and attention (Gruber, 2025). Hence, game-based learning has evolved as a popular method for interactive learning (Bencsik et al., 2021).

Game-based learning is an established approach in higher education, especially in science, technology, engineering and mathematics (STEM) disciplines (Semmler et al., 2024). The problem-solving approach that is taught and applied in STEM disciplines can be aligned with solving problems in educational games (Ishak et al., 2021; Manzano-León, Camacho-Lazarraga, Guerrero, et al., 2021). Platforms like genially and Kahoot! have emerged as popular tools for educational games, offering interactive experiences that can transform traditional educational paradigms (Martinez et al., 2023).

Even though there are many studies on the effect of digital serious games on student motivation (Bröker et al., 2021; Ehrlich et al., 2020; O'Brien & Pitera, 2019), computer science students' perception of quiz-based digital games have yet to be investigated. Therefore, this study showcases computer science students' perception of digital educational games based on the

aforementioned platforms in higher education settings, drawing insights from survey-based studies and evidence-based research.

Background

Constructivist learning theory focusses on learners actively constructing their own understanding and knowledge of the world through experiences and reflection (Kergel & Heidkamp-Kergel, 2020). Rooted in the work of theorists like Jean Piaget and Lev Vygotsky, this theory posits that learning is a process of meaning-making rather than passive absorption of information. In other words, constructivist learning theory favours active learning and refrains from the concept of teaching. Constructivism advocates for learner-centred approaches, where students engage in problem-solving, exploration, and critical thinking, often through collaborative activities. This approach highlights the importance of prior knowledge, social interaction, and contextual learning in shaping new understandings (Vygotsky et al., 1980). Teachers act as facilitators, guiding learners to build connections between new and existing knowledge, fostering deeper comprehension and skill development (Franco & DeLuca, 2019).

Following the idea of students constructing their own knowledge and taking an active part in the learning process, constructivist learning environments focus on presenting information. The information is based on the learning objective and part of the learning content. Students process the information provided individually and reconstruct their own knowledge. In the next step, students show a certain behaviour applying their knowledge. Teachers take a supporting role in diagnosing competences as well as potential weaknesses. Monitoring students' behaviour and success, teachers modify the information and learning support offered. At this stage, the cycle of constructivist learning environment closes at the stage of information presentation (Kerres, 2024).

In accordance with the theory of constructivism, constructivist learning environments enable students to self-regulate their learning process. Working on complex and lifelike problems with minimal intervention by teachers is key (Gräsel & Gniewosz, 2011). This approach is particularly well suited to digital learning methods. As they offer students the advantage of being able to work through and access digital learning resources at their own individual pace, they support constructivist learning (van Ackeren et al., 2017). Among many digital learning methods, digital learning games are evolving as popular constructivist learning approach.

Digital game-based learning refers to the use of digital games to facilitate learning. This approach makes use of entire games, specifically designed for educational purposes addressing learning objectives. These games are referred to as serious games (Weselek, 2022). In contrast to game-based learning and serious games, gamification is defined as the use of single game elements (Deterding et al., 2011). Gamification elements and serious games can be used in a physical and in a digital environment (Gruber & Faßbender, 2025).

Regarding the conceptualization of serious games, it is of importance to consider the target group. In higher education, students often face difficulties concentrating on lecture materials (Bencsik et al., 2021). This necessitates a comprehensive understanding of the students' existing knowledge and skills. Especially the learning process needs to be considered. As digital serious games operate based on different stimuli, the internal learning process and attention span can differ from learning in traditional settings (Frey & Uemminghaus, 2021). Selective perception can cause the differentiation of how students perceive digital settings (Gagné, 1980). Therefore, it is important to communicate expectations and the purpose of digital serious games to the students.

In higher education contexts, digital serious games aim to create immersive and interactive environments that promote active learning, addressing individual learning paths by means of constructivist learning environments (Frey & Uemminghaus, 2021). The constructivist framework is particularly relevant in digital serious games, as interactive games create helpful environments for experimentation, feedback, and active learning (Kerres, 2024). Digital serious games are particularly promising for students with a high affinity for gaming in their leisure time. It is evident that this is the case for STEM programs (Fleuren, 2016; Ishak et al., 2021; Manzano-León, Camacho-Lazarraga, Guerrero, et al., 2021). Indications in the literature suggest that students' perception of and their satisfaction with the lecture can be affected by digital serious games (Priesto et al., 2021). In general, previous studies show that STEM audiences are suitable for the use of digital serious games (Buchner et al., 2022; Makri et al., 2021; Taraldsen et al., 2022).

Prominent examples for digital serious games in the context of digital game-based learning are escape games, simulations and quizzes (Gruber & Faßbender, 2025). Quizzes are tests including numerous questions as well as related pre-formulated answer sets. In a quiz, questions can be phrased either single or multiple choice (Georg, 2022). Tools for the development of quizzes utilized in higher education are g*enially* and *Kahoot!*:

- *genially* is a web-based tool offering features for creative content creation. The portfolio includes presentations, infographics and game-based learning like quizzes (Genially Web, 2023). Moreover, the platform allows for the incorporation of multimedia elements and interactive scenarios, making learning more engaging and dynamic. *Genially* has been evaluated for its pedagogical quality and is noted for increasing student engagement through gamified quizzes (Martinez et al., 2023; Sanchez & Plumettaz-Sieber, 2019).

- *Kahoot!* is a game-based learning web platform that allows educators to create quizzes and interactive lectures (Kahoot!, 2024). It is evident that the use of *Kahoot!* for educational purposes enhances constructivist learning, as the digital environment encourages learners to actively engage and construct knowledge and concepts. This allows for self-determined learning and developing students' problem-solving competences (Allegra et al., 2019).

In summary, genially and Kahoot! can contribute positively to constructivist learning in higher education. Considering the aptitude of digital serious games for STEM students, it is imperative to examine quizzes on these two platforms within the context of this study. The following section describes the research interest in more detail.

Objectives

The main objective of this project is to conduct a study on the use of digital quizzes as serious games in STEM higher education lectures. In addressing the issue of poor student engagement in recent lectures, this research is directed towards student motivation and engagement. The subordinate objectives of this project are summarized as follows:

- Creating digital quizzes based on predefined learning objectives for investigation.

- Evaluating engagement and motivation to measure the impact of these platforms in the learning process.

- Identifying challenges and limitations associated with implementing digital serious games in STEM higher education settings.

- Developing best practices to establish recommendations for effectively integrating these platforms into higher education teaching.

Based on these objectives, the following research question arises: *How do computer science students perceive digital serious games in STEM higher education?* The underlying research methodology selected for this project is outlined in the following section.

Methodology

Based on the aforementioned objectives, the study examines digital quizzes in STEM higher education lectures. For this purpose, 8 digital quizzes in *genially* as well as 2 *Kahoot!* quizzes were created based on lecture materials for computer science students at the University of Applied Sciences Karlsruhe, Germany. The *genially* quizzes are designed as single player games, whereas the *Kahoot!* quizzes are to be played in pairs against each other in plenary sessions. These 10 games were incorporated into the curriculum over the course of 3 semesters. On average, one to two games were used per lecture.

To accompany the use of the games in teaching, an anonymous evaluation was carried out at the end of each semester. This approach is chosen to evaluate the digital quizzes in the computer science lectures in STEM higher education, allowing students to share their opinions and give feedback. The anonymous questionnaire allows students to reply honestly and openly in the feedback process without fearing judgement on their opinions. Therefore, questionnaires are suitable to gather data on perceptions, experiences, motivation, and attitudes towards these platforms (Manzano-León, Camacho-Lazarraga, Guerrero, et al., 2021). The use of surveys allows the participants to work through the questions at their own pace. Digital surveys underscore the advantage of self-determination and anonymity and is therefore often applied to educational settings (Reinders et al., 2022).

The questionnaire was designed based on the standard lecture evaluation at the University of Applied Sciences Karlsruhe, Germany. The survey included questions on students perception of digital serious games, based on relevant literature on game-based learning (Manzano-León, Camacho-Lazarraga, Guerrero-Puerta, et al., 2021). Ethical considerations, including informed consent and anonymity, were addressed to protect participants' rights and privacy. As the questionnaire was anonymous, no conclusions can be drawn about individual participants. A total of n=87 higher education computer science students participated in the study.

The survey comprised open-text fields, and the respective entries in the open-text fields were assessed employed qualitative content analysis according to Philipp Mayring (2015). Qualitative content analysis is applied to explore meanings and patterns in qualitative data (Mayring, 2015). A systematic approach with predefined rules ensures that the analysis is both reproducible and transparent, addressing scientific quality criteria. The main objective is the development of categories, following deduction or induction: Deduction is the application of pre-defined, theory-based category to the material, whereas induction is defined as observing patterns in the data without pre-defined categories (Reinders et al., 2022). Regardless of the chosen approach, qualitative content analysis can be conducted in three different ways: (1) summarizing the qualitative data by shortening the text; (2) explicating the data by enriching the text with more

data sources; or (3) structuring the material by units of meaning (Mayring, 2015).

In this study, the structured qualitative content analysis was employed. Following this approach, the participants' entries were analysed using thematic coding, providing a comprehensive understanding of the research subject. The findings are outlined in the following section.

Findings

The qualitative content analysis results in four main categories: *Pleasant atmosphere*, *Positive perception of digital serious games*, *Interactivity and engagement*, *and Diversification of lectures by using digital serious games*. The categories and the respective absolute as well as relative frequencies are displayed in the following Table 1.

Table 1. Qualitative Content Analysis Categories.

Category	Absolute frequencies	Relative frequencies
Pleasant atmosphere	3	3,6%
Positive perception of digital serious games	48	57,8%
Interactivity and engagement	25	30,2%
Diversification of lectures by using digital serious games	7	8,4%

Table 1 shows that most of the student responses can be categorized as positive properties of digital serious games. The majority of all entries can be classified under Positive perception of digital serious games. Student responses show that students generally favour digital game-based learning. Enthusiasm for educational games and positive responses to the adoption of novel teaching methodologies was captured. There is a notable appreciation for the replacement of conventional teaching methods.

In particular, students appreciate being incentivized to actively participate in lectures. This is represented by the category *Interactivity and engagement*, which accounts for 30% of the survey responses. The students value their active participation in the quizzes. Students emphasized that studying with digital serious games like quizzes helps them testing their knowledge. The digital serious games are appreciated for their student-centred design and intuitive usability.

The platforms *genially* and *Kahoot!* were assessed suitable for digital game-based learning by the students. Students enjoyed the digital learning games, especially the quiz characteristics were mentioned to be helpful for consolidating lecture content. The *Diversification of lectures by using digital games* comprises 8,4% of all survey entries. Students appreciate the incorporation of digital serious games, which is partly attributable to their computer science affinity. Consequently, it is not surprising that students did not have any issues with the game usability or navigation. Following, 3,4% of entries show that participants value the *Pleasant atmosphere* created by using digital serious games. Participants value the competitiveness of the quizzes in *Kahoot!* and mentioned positive effects on group dynamics when working in pairs. The integration of both genially and Kahoot! incentivized students to participate and actively engage in the learning activity. Traditional unidirectional teaching by the lecturer in which students are

passive shifted to the students actively by playing the games, adopting an active role in the learning process.

In addition to providing feedback, the participants suggested possible enhancements of digital serious games regarding their utilization, frequency, and design. The following recommendations for higher education lecturers are derived from this study:

- The education of digital educational games into higher education is recommended once or twice per lecture to consolidate previously acquired knowledge. The incorporation of gamified elements is imperative in the creation of competitive and motivating characteristics within the game.

- The challenge of digital games lies in the necessity to learn how to utilize the tools and invest time in creating and maintaining them. However, it should be noted that the functionality of these devices may be constrained when employed within the specific context of a given didactic application.

- Digital games have the capacity to stimulate learners' motivation by achieving an equilibrium between playful elements, competition, and enjoyment. Group competitions, in which all learners competed against each other, were found to be particularly appealing.

- It is important that these digital learning games are aligned with the learning objectives. These should be communicated transparently in advance, allowing students to allocate the digital serious game in their learning process.

Evaluating these findings, it can be stated that the game design needs to be student-centred and intuitive to minimize barriers and maximize student engagement. In addition, the content created on genially and the quizzes designed on Kahoot! is to be closely aligned with the learning objectives to minimize barriers for students to engage with the material, maximizing the educational impact.

Discussion

This study sheds light on how computer science students perceive digital serious games in a quiz-based format during lectures. Based on the underlying research question *How do computer science students perceive digital serious games in STEM higher education?*, this study shows that the participants are generally in favour of digital serious games. In brief, the participating students have indicated that the learning games were enjoyable and anticipate their incorporation into future curricula. Digital game-based learning platforms like *genially* and *Kahoot!* foster student engagement by addressing students' interest in playing games. Student motivation is addressed by the playfulness of the game, having a positive impact on student engagement and activation.

In addition to the positive experience with digital learning games, minor technical issues were observed within the scope of this study, such as network instability, which affected students experience with *Kahoot!*. These technical issues had a disruptive effect on the learning experience. Ensuring reliable internet connectivity is crucial for the seamless implementation of these platforms.

Moreover, it is worth mentioning that the time required to create interactive content on *genially*

and design quizzes on *Kahoot!* can be a challenge for educators, especially those with limited technological proficiency. Designing quiz-based digital serious games requires more resources than designing traditional unidirectional teaching materials. This aspect needs to be considered when deciding for game-based learning.

The qualitative analysis of participant feedback allowed to deeply examine the data. Nevertheless, it is recommended to further assess students' perception of digital serious games. It may be of interest to the research community to investigate which game design elements are particularly beneficial and which are rather harmful to learning environments. Targeting the challenge of students being easily distracted while learning, immersive game design elements could incentivize students to be more involved in digital serious games, therefore leading to less distraction. Therefore, immersive game design elements are recommended to be investigated in future research.

ESERA 2025 Copenhagen

Activating Epistemic Emotions To Enhance Student Engagement In Socio-Scientific Issues Through Digital Curation

Remah Haj and Dina Tsybulsky
Technion Israel Institute of Technology, Israel

Learning through socio-scientific issues (SSI) confronts students with uncertainty, competing knowledge claims, and the need to justify positions in the absence of clear-cut answers. Such epistemically demanding learning situations are likely to evoke a range of emotions that are closely tied to students' processes of sense-making and participation in learning, yet these emotional dynamics remain underexplored, particularly in digitally mediated SSI contexts. Addressing this gap, the present study examined the potential of Digital Curation (DC) as a learning pathway for integrating SSI learning with intentional activation of epistemic emotions. The study employed a qualitative bounded case design in a tenth-grade biology classroom in Israel (n=42). Students participated in four structured units on animal welfare (food choices, environmental conservation, animal experimentation, and legislation). Data were collected through reflective written reports, semi-structured interviews, and video recordings of classroom discussions. A combined deductive–inductive content analysis was employed to investigate the interplay between epistemic emotions and dimensions of student engagement. The findings revealed that the SSI-DC learning pathway initially elicited negative epistemic emotions such as confusion, frustration, and anxiety, which gradually transformed into curiosity, enjoyment, and surprise as students progressed through the learning process. This emotional trajectory supported sustained engagement across cognitive, behavioural, emotional, social, and agentic dimensions. These findings underscore the importance of designing emotionally responsive digital learning environments that intentionally leverage epistemic emotions to enhance student engagement and foster a sense of ownership in learning.

Keywords: Socio-scientific issues, digital curation, epistemic emotions, student engagement

Introduction

In recent years, science education has shifted towards actively involving students in socio-scientific issues (SSIs) that directly connect to their everyday lives, rather than solely imparting scientific knowledge. This shift supports students' understanding of scientific concepts while encouraging critical examination, informed decision-making, and the construction of scientific arguments in response to ill-structured social dilemmas (Sadler et al., 2016). However, sustaining student engagement with SSIs remains challenging, particularly in digitally mediated learning environments (Klosterman et al., 2012; Solli, 2021).

Integrating Digital Curation (DC) into SSI teaching has recently attracted considerable attention due to its potential to enhance student engagement (Dayan & Tsybulsky, 2024). DC involves selecting, organizing, and preserving digital content to create coherent collections of relevant and reliable information (Tsybulsky, 2020) and has been shown to foster critical thinking and media literacy practices needed to navigate complex online information (Gadot & Tsybulsky, 2023; 2025; Forkosh et al., 2021).

Beyond its documented contribution to student engagement, integrating DC into SSI learning also places students in epistemically demanding situations that require them to search for information, evaluate the credibility of sources, negotiate conflicting claims, and justify knowledge-based positions. These features position DC not only as a pedagogical tool, but as a learning

environment that foregrounds processes of sensemaking under conditions of uncertainty.

Building on this perspective, our research group proposed the SSI-DC instructional pathway as a learning pathway within the SSI teaching and learning framework, integrating the social and scientific dimensions of SSI learning through digital curation (Dayan & Tsybulsky, 2024). In our prior SSI-DC work (Haj & Tsybulsky, under review), students frequently expressed confusion, curiosity, frustration, and surprise, suggesting that epistemic emotions - knowledge-focused emotions arising during information processing and sensemaking - may function as mechanisms that shape engagement (Brun et al., 2008; Pekrun & Stephens, 2012; Muis et al., 2018). Yet, research has rarely examined how epistemic emotions are activated in digitally mediated SSI contexts and how they contribute to multidimensional engagement (Fredricks et al., 2004; Sinatra et al., 2015). Accordingly, this study demonstrates how a designed SSI-DC pathway can transform negative epistemic emotions (confusion, frustration, anxiety) into positive ones (curiosity, enjoyment, surprise) and thereby strengthen cognitive, behavioural, emotional, social, and agentic engagement. The guiding research question was: How are epistemic emotions activated during the SSI-DC learning pathway, and how do they shape students' multidimensional engagement (cognitive, behavioural, emotional, social, and agentic)?

Method

Research Setting And Participants

This qualitative bounded case study was conducted in a secondary school in Israel and focused on a single tenth-grade biology classroom (n = 42). The classroom was selected as a bounded case (Yin, 2003), enabling an in-depth exploration of how the SSI-DC pathway influenced students' epistemic emotions and multidimensional engagement within their authentic instructional environment. The students were enrolled in an advanced science track and had prior exposure to SSI. Throughout the learning pathway, students participated in four structured SSI-DC units related to animal welfare (food choices, environmental conservation, animal experimentation, and legislation). Each unit spanned approximately 8 hours and required students to collaboratively research, curate, and reflect on digital content using Wakelet. Each unit began with an open-ended, provocative question, followed by whole-class discussion and peer dialogue in self-selected groups, and concluded with group presentations and whole-class evaluation of competing positions. All activities were conducted during regular classroom hours; units were required but ungraded. Ethical approvals were obtained from the Ministry of Education and the Institutional Review Board (IRB). Informed consent was obtained from all participating students and their parents, including permission for classroom video recordings. Confidentiality was ensured, and pseudonyms were used in all transcripts and reports.

Data Collection

Data were collected from three sources: (A) guided reflective written reports completed after each animal welfare lesson, focusing on students' emotional responses, engagement, and participation in the SSI-DC process; (B) face-to-face semi-structured student interviews conducted after completing the SSI-DC unit, including 14 open-ended questions examining students' emotions and perceptions of learning and engagement. Each interview lasted about 50 minutes, was recorded and transcribed, and remained flexible to follow participants' responses while prompting students to reconstruct the steps of creating their digital collections; and (C) video documentation of selected classroom sessions capturing group discussions, affective expressions, and collaborative reasoning, enabling analysis of verbal and non-verbal interaction and how epistemic emotions emerged and evolved in real time within the SSI-DC environment.

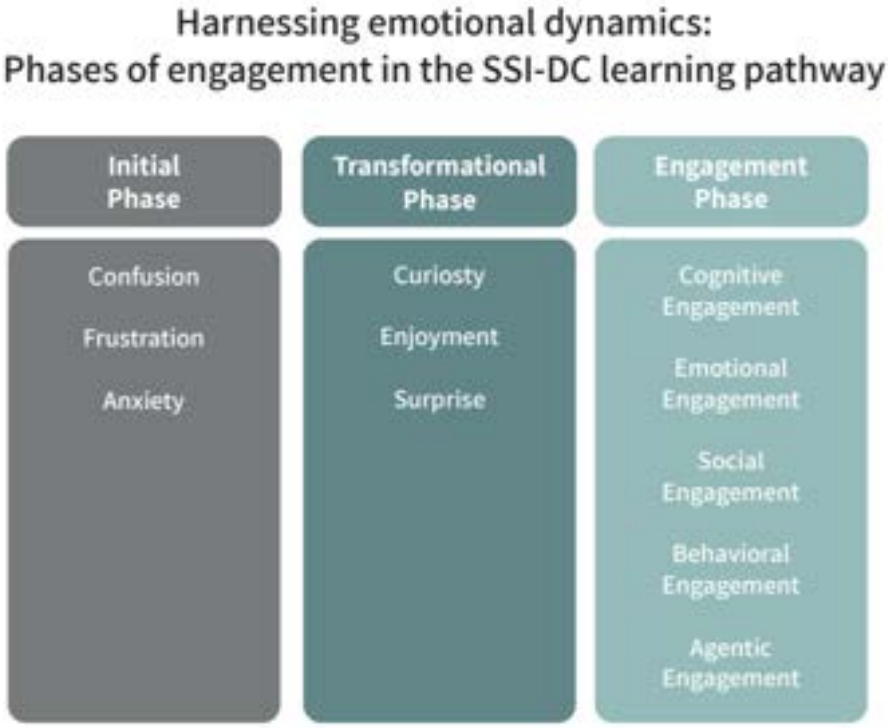
Data Analysis

We analysed the data using a combined deductive–inductive qualitative content analysis (Schreier, 2012; Kuckartz, 2016). Deductive coding was guided by established frameworks of student engagement (Fredricks et al., 2018; Sinatra et al., 2015) and epistemic emotions (Pekrun et al., 2016), while inductive coding enabled the identification of emergent patterns not captured by the predefined categories (Elo & Kyngäs, 2008). First, reflective reports, interview transcripts, and selected classroom video recordings were reviewed to familiarize ourselves with the data. Epistemic emotions were then coded using a theory-informed codebook developed based on Pekrun's conceptualization of epistemic emotions (Pekrun et al., 2016) and related empirical work on knowledge-related emotions in learning contexts. This codebook included definitions of each epistemic emotion (e.g., confusion, frustration, anxiety, curiosity, enjoyment, and surprise), their key features, and the cognitive conditions and triggers through which they typically emerge (e.g., contradictory information, uncertainty, difficulty verifying sources). In parallel, student engagement was coded using a multidimensional codebook grounded in established engagement models (Fredricks et al., 2018; Sinatra et al., 2015). This engagement codebook operationalized five dimensions—cognitive, behavioural, emotional, social, and agentic engagement—by specifying definitional characteristics and indicative manifestations in students' written reflections, interview responses, and classroom discourse. The data were subsequently revisited to examine how epistemic emotions co-occurred with, and shaped, students' engagement throughout the SSI-DC pathway, and themes were refined through iterative research team discussions.

Trustworthiness

To ensure trustworthiness, we applied triangulation across data sources—student reflections, interviews, and classroom observations—to enhance credibility (Lincoln & Guba, 1985). Multiple researchers independently coded the data and resolved discrepancies through discussion. The analytic process was systematically documented, and key interpretations were supported with direct excerpts from the data. Rich contextual information about the setting and participants was included to support transferability, while transparency in coding and decision-making strengthened confirmability (Shenton, 2004).

Findings



The findings presented in this section are organized into the Initial Phase, Transformational Phase, and Engagement Phase (see Figure 1). Each phase represents a different stage in the learning process and shows the dynamic interplay between the dimensions of engagement and the evolution of epistemic emotions in the SSI-DC learning pathway, thereby helping account for how engagement and epistemic emotions interact throughout the learning experience.

Initial Phase: Pre-SSI-DC Learning Epistemic Emotions

The initial phase reflects students' baseline epistemic emotions prior to engaging in SSI-DC. This stage was dominated by confusion, frustration, and anxiety, stemming from uncertainty about the unfamiliar learning method and the complexity of SSI tasks. Although these emotions were strongest at the outset, they occasionally reappeared later, especially when students confronted contradictory evidence or were required to justify their claims publicly. Positive emotions were limited during this phase and became more salient only in later stages.

A. Confusion: Introducing SSI-DC initially generated confusion, mainly due to unfamiliarity with the digital curation process and uncertainty about how to approach complex dilemmas.

Figure 1. The three phases highlight the dynamic interplay between the engagement dimensions and the evolving epistemic emotions in the SSI-DC learning pathway.

B. Frustration: Emerged when students struggled with information overload, unreliable sources, and disagreement within groups. In many cases, frustration also pushed students toward deeper searching and verification.

C. Anxiety: Was common as students worried about succeeding in an unfamiliar task and meeting expectations, especially under time pressure or peer comparison.

Table 1. Students' quotes illustrating epistemic emotions in the Initial Phase.

Emotion	**Students quotes**
Confusion	"At the start, I couldn't settle on a clear position, so I kept going back and forth and hesitated to speak." (DF10, interview) "I didn't understand how to approach the topic at first, and that uncertainty made me feel lost." (NF10, interview)
Frustration	"It frustrated me when others' views didn't align with mine, and it pushed me to search more intensely for supporting information." (DF10, interview) "There were so many sources, and many didn't seem reliable, which made the task feel overwhelming." (DF10, reflective report)
Anxiety	"At the beginning, I was worried and hesitant because the process was new and I wasn't sure I could handle it." (FF10, interview) "I felt anxious about not finding strong materials and not meeting expectations." (LF10, reflective report)

Transformational Phase: Transformation Of Emotions During SSI-DC

As students progressed through SSI-DC, the early negative emotions gradually decreased and were replaced by curiosity, enjoyment, and surprise. Although confusion and frustration occasionally resurfaced, they became less central. Positive epistemic emotions increasingly supported deeper inquiry, stronger collaboration, and more meaningful engagement.

A. Curiosity: Became a key driver of exploration and persistence, encouraging students to investigate multiple perspectives and verify information.

B. Enjoyment: Increased once students became comfortable with the platform and experienced successful collaboration and progress.

C. Surprise: Often appeared when students encountered unexpected insights or new arguments, prompting them to reconsider ideas and deepen reasoning.

Table 2. Students' quotes illustrating epistemic emotions in the Transformational Phase.

Emotion	Students quotes
Curiosity	"Exploring different sources and perspectives kept me engaged and made me want to continue investigating." (AF10, interview) "When I found evidence that challenged what I believed, I became more curious and checked additional sources to understand better." (JF10, classroom discussion)
Enjoyment	"Once I started working with different materials like videos, images, and articles, I felt increasingly excited." (FF10, reflective report) "I enjoyed building the digital collection and discussing it with the class—it made the learning feel engaging." (NF10, interview)
Surprise	"I was surprised by how much I learned and by how engaging the whole process turned out to be." (DF10, reflective report) "When another group presented evidence we hadn't considered, it surprised me and made us rethink our position." (HF10, classroom discussion)

Table 3. Students' quotes illustrating the five dimensions of engagement.

Engagement	Students quotes
Cognitive engagement	"Following the structured steps and building the group collection helped me understand the topic in a deeper way." (FF10, interview) "When classmates challenged my source, I rechecked it and justified it, which pushed me to analyse more carefully." (JF10, classroom discussion)
Emotional engagement	"As I learned more, the process became more enjoyable and broke the routine—it felt energizing." (KF10, interview) "Presenting our collection made me feel proud, especially because my contribution really mattered." (TF10, classroom discussion)
Social engagement	"Class discussions exposed me to ideas and information I hadn't encountered before." (DF10, reflective report) "Working together on the collection helped me understand more and made the learning experience more enjoyable." (KF10, interview)
Behavioural engagement	"I stayed highly involved and organized, completed all the steps, and even went beyond them because I wanted to keep researching." (DF10, interview) "Even when the group disagreed, I kept searching for evidence because I didn't want to give up." (LF10, classroom discussion)
Agentic engagement	"This approach made me feel like an independent researcher, responsible for building my understanding." (DF10, interview) "I suggested reorganizing our collection so it would be clearer, and once the group agreed, I felt my voice had real impact." (JF10, classroom discussion)

Engagement Phase: During SSI-DC Learning

In the engagement phase, curiosity, enjoyment, and surprise translated into sustained engagement across all five dimensions. Negative emotions appeared rarely and no longer shaped the overall

experience. Instead, positive epistemic emotions were the main drivers of students' effort, persistence, collaboration, and agency.

A. Cognitive Engagement: Students demonstrated deeper processing, synthesis, and critical evaluation of information as they built and defended their curated arguments.

B. Emotional Engagement: Was reflected in interest, enthusiasm, pride, and a growing sense of belonging during collaborative work and presentations.

C. Social Engagement: Peer dialogue and teamwork supported richer reasoning, exposure to new perspectives, and stronger learning relationships.

D. Behavioural Engagement: Students showed persistence, high effort, and increased time investment, even when facing disagreements or difficulties.

E. Agentic Engagement: Students increasingly shaped their learning by initiating ideas, personalizing tasks, and influencing group decisions.

Discussion and Conclusion

This study examined how epistemic emotions function as a mechanism for enhancing student engagement within the SSI-DC instructional pathway. Across the three phases (Initial, Transformational, Engagement), students shifted from negative epistemic emotions (confusion, frustration, anxiety) to positive ones (curiosity, enjoyment, surprise), and this trajectory supported sustained engagement across cognitive, behavioural, emotional, social, and agentic dimensions. These patterns align with research positioning SSI learning as engagement with ill-structured dilemmas that require learners to evaluate evidence, negotiate values, and construct arguments through discourse (Sadler, 2004; Zeidler, 2014; Sadler et al., 2017). They also reinforce the view that student engagement is multidimensional and dynamically shaped by instructional context (Fredricks et al., 2004; Sinatra et al., 2015). These phase-based patterns were identified through the theory-informed codebooks used in the analysis, which operationalized epistemic emotions and the five engagement dimensions across students' reflections, interviews, and classroom discourse (Pekrun et al., 2016; Fredricks et al., 2018; Sinatra et al., 2015).

The observed emotional transitions are consistent with theoretical accounts suggesting that epistemic emotions emerge when learners encounter uncertainty, contradiction, or cognitive incongruity in knowledge-rich tasks (Pekrun & Stephens, 2012; Muis et al., 2018; D'Mello & Graesser, 2012). Specifically, confusion and frustration appeared when students faced competing claims or struggled to verify sources, reflecting findings that epistemic emotions can be triggered by unresolved conflict and information overload in complex learning situations (Di Leo et al., 2019; D'Mello et al., 2014). Over time, these emotions shifted toward curiosity, enjoyment, and surprise—emotions that have been linked to sustained information exploration, deeper processing, and more productive engagement with knowledge-building tasks (Litman, 2008; Loewenstein, 1994; Brun et al., 2008). This progression supports Pekrun's control-value theory, which highlights how both negative and positive emotions can shape learning outcomes, but positive activating emotions are especially relevant for maintaining attention, persistence, and meaningful participation (Pekrun, 2006, 2016).

From a design perspective, three features of SSI-DC appear central to this transformation: (1) posing open-ended, controversial questions that create productive uncertainty and invite position-taking; (2) guiding students through iterative digital curation practices (locating, evaluating, organizing, and synthesizing resources) that surface contradictions and require justification; and (3) structuring collaborative dialogue and public sharing that prompts peer critique and refinement of claims. These design features resonate with research on technology-supported SSI

learning emphasizing digital practices such as evaluating sources, media literacy, and participation in discourse as core components of contemporary SSI pedagogy (Vlachopoulos & Makri, 2017; Solli, 2021; Soomro et al., 2020). They also align with digital curation literature positioning curation as an active knowledge-construction process that supports critical thinking, authenticity, and learner agency (Deschaine & Sharma, 2005; Pasek & Hargittai, 2015; Antonio & Tuffley, 2015).

The findings further showed that cognitive and emotional engagement were especially prominent, supporting prior work highlighting the interdependence of engagement dimensions and the central role of emotion in sustaining meaningful learning (Fredricks et al., 2016; Wang & Sui, 2020). Emotional engagement through curiosity and enjoyment appeared to stabilize students' persistence and investment in complex tasks, consistent with evidence linking positive affective experiences to academic engagement and success (Ucar & Sungur, 2017; Fredricks et al., 2016). At the same time, the collaborative structure supported social and agentic engagement, reflecting research emphasizing that peer dialogue and shared reasoning contribute to deeper engagement in SSI contexts (Sadler et al., 2017) and that agentic contributions are strengthened when students are positioned as active participants who shape their learning environment (Sinatra et al., 2015; Fredricks et al., 2018). Together, the phased model proposed here extends prior SSI-DC work by foregrounding epistemic emotions not only as outcomes of learning but as mechanisms that can be intentionally leveraged to strengthen multidimensional engagement in digitally mediated SSI instruction.

Acknowledgement

We thank the participating students and their science teacher for their engagement and commitment throughout the SSI-DC units. We also acknowledge the contributions of the research team for their support in data collection, analysis, and ongoing discussion throughout the study. We are grateful to the ESERA Proceedings Editors for their careful editorial work and guidance, and to the ESERA Conference and Doctoral School organizers for providing a supportive and inspiring scholarly community.

A New Paradigm For Science Lesson Planning: Adaptive Expertise And Generative AI Integration

YeJun Bae[1] and Ercin Sahin[2]
[1]Appalachian State University, USA
[2]Ministry of National Education, Turkey

This study examines pre-service teachers' reflections on using ChatGPT for lesson planning. As AI-integrated learning environments gain prominence in schools, preparing teachers for their future roles in science education is increasingly important. Building on Davis et al.'s (2024) emphasis on integrating AI tools in teacher preparation, we argue that using such tools is a critical practice for developing pre-service teachers' adaptive expertise. The data comprises 116 quotes from the reflexive writing of elementary pre-service teachers enrolled in science teaching methods courses during two semesters. Participants used ChatGPT as part of classroom activities to design 5E lesson plans. A coding scheme was developed based on two key dimensions of adaptive expertise—efficiency and innovation—and an additional category, collaboration, identified through open coding. Findings revealed that ChatGPT enhanced pre-service teachers' efficiency by streamlining the brainstorming process and generating lesson plan ideas quickly. It also supported their innovation by encouraging critical reflection and adaptation of ChatGPT's outputs to align with classroom contexts and student learning needs. Additionally, integrity emerged as an essential component of adaptive expertise in AI-integrated learning environments, highlighting the need for ethical awareness and critical evaluation of ChatGPT's relevance and accuracy. The study underscores the importance of repeated practice in using ChatGPT effectively and fostering critical thinking to ensure the appropriate adoption of AI tools in lesson planning. These findings offer valuable insights for practitioners and researchers aiming to prepare teachers for the challenges of 21st-century classrooms.
Keywords: AI literacy, Preservice teacher education, Qualitative research

Background

The use of AI tools, particularly ChatGPT, has grown substantially in education, with notable applications in teacher education programs. Goodman et al. (2024) highlighted the critical need to enhance pre-service science teachers' competence in effectively integrating ChatGPT to improve teaching practices and streamline lesson preparation. Furthermore, there is a growing demand for establishing ethical guidelines to ensure the responsible use of generative AI tools in teacher education, addressing concerns such as plagiarism and biases (University of South California, 2024, October 14). Despite these calls, clear strategies for supporting pre-service teachers in developing the competencies needed for lesson planning with generative AI tools remain lacking. Adaptive expertise, as emphasized by Hess et al. (2023), offers a comprehensive framework to address these challenges, balancing timesaving and creating a new idea. This framework not only helps preservice teachers to well prepare for the use of generative AI tools but also ensures that they critically evaluate AI outputs and adapt their practices to diverse and evolving educational contexts.

Adaptive expertise is the ability to flexibly navigate between routine efficiency and creative modification to solve problems (Opre, 2015; Schwartz et al., 2005). This competency is essential for managing the complexities of routine teaching tasks (Hess et al., 2023). Davis et al. (2024) highlight adaptive expertise as a foundational component in establishing teacher competencies for integrating generative AI tools into instructional development. Two key dimensions of adaptive expertise—efficiency (streamlining routine processes) and innovation (generating novel ideas)—are particularly relevant for effectively utilizing generative AI tools to create inclusive

science learning environments. For example, a 5th-grade science teacher might use ChatGPT to quickly generate ideas for inclusive activities related to a life science topic. The teacher can then critically reflect on these suggestions, assessing their understanding of inclusivity and adapting them to better meet students' needs. This iterative process of leveraging AI tools while engaging in reflective practice exemplifies the dynamic interplay between efficiency and innovation.

Building on the vital role of adaptive expertise in teaching, generative AI tools like ChatGPT significantly support teachers in exercising this competency, particularly in lesson planning. These tools enhance efficiency by enabling teachers to quickly access familiar information, such as the components of the 5E learning cycle (Engage, Explore, Explain, Elaborate, Evaluate), through simple prompts. In addition to this ability, teachers also need to be able to apply judgment and adapt AI-generated content to student needs, ensuring ethical use and addressing biases.

Theoretical Framework

Our framework emphasizes the interplay between adaptive expertise and the integration of AI tools in preservice teacher education, specifically within the context of science lesson planning. We identify three critical components essential for effectively leveraging adaptive expertise when utilizing generative AI tools in this context: efficiency, innovation, and integrity. Efficiency and Innovation represent the core dimensions of adaptive expertise**,** streamlining routine processes and fostering novel ideas. Building on this foundation, we introduce Integrity as an additional essential component. Integrity encompasses the ethical and reflexive application of AI tools, ensuring that their use aligns with educational goals and values while fostering trust in the learning process.

Efficiency refers to the ability to apply knowledge or generate solutions based on established routines quickly. According to De Arment et al. (2013), experienced teachers often exhibit high levels of efficiency in routine practices such as classroom management and lesson documentation. However, preservice teachers typically require additional support to develop efficiency, as they lack extensive experience in classroom teaching and interacting with students who have diverse needs.

Innovation, the second key component, is closely linked to flexibility—the ability to adjust context-specific decisions based on various students' learning needs. Unlike efficiency, which is rooted in routine and time-saving behaviours, innovation requires teachers to draw on their knowledge and skills to adapt prior experiences and make decisions that optimize student learning (De Arment et al., 2020). It involves grappling with complexity and finding ways to navigate and understand it within diverse classroom contexts.

The third component, Integrity, is particularly relevant in the context of generative AI tools. While efficiency and innovation enable effective decision-making, the integration of AI tools introduces the need for critical reflection on digital resources. Davis et al. (2024) emphasize that evaluating AI-generated content's reliability, bias, and ethical implications is a key competency in an AI-integrated educational landscape.

Balancing these three components**,** efficiency, innovation, and Integrity**,** is vital for leveraging generative AI tools effectively. Despite their importance, few studies have explored how adaptive expertise intersects with the use of generative AI tools in lesson planning. Our study aims to fill this gap by examining how these aspects contribute to teacher competency in AI-integrated environments.

Purpose of Study

The purpose of this study is to investigate how preservice teachers potentially demonstrate three key competencies—efficiency, innovation, and integrity—when using ChatGPT in science lesson

planning. Specifically, our research seeks to address the following questions:

1. To what extent do preservice teachers exhibit the three key competencies, efficiency, innovation, and integrity, when integrating ChatGPT into science lesson planning?
2. What common patterns emerge from preservice teachers' lived experiences with ChatGPT in the context of science lesson planning?

Method

Data was collected over two semesters, including the Spring and Fall semesters of 2024. Participants consisted of preservice elementary education students enrolled in elementary science teaching methods courses. As part of their coursework, students were required to design a 5E lesson plan to implement during their internships. To support this process, students were encouraged to use ChatGPT for brainstorming ideas, enhancing their ability to support diverse learners, and creating more inclusive learning environments.

Following the classroom activity, students submitted reflections as part of an exit task. These reflections were collected via a Google Form that included questions about the frequency of their ChatGPT usage, their preferences for using ChatGPT, and open-ended prompts about their overall experiences with the tool in lesson planning.

The data were analysed using a deductive qualitative analysis approach (Pandey, 2019). A coding scheme was developed based on the three key competencies for integrating generative AI tools in lesson planning, as outlined in the theoretical framework section (Table 1). Within these three broad categories, we developed specific codes by reviewing the data through several rounds of review.

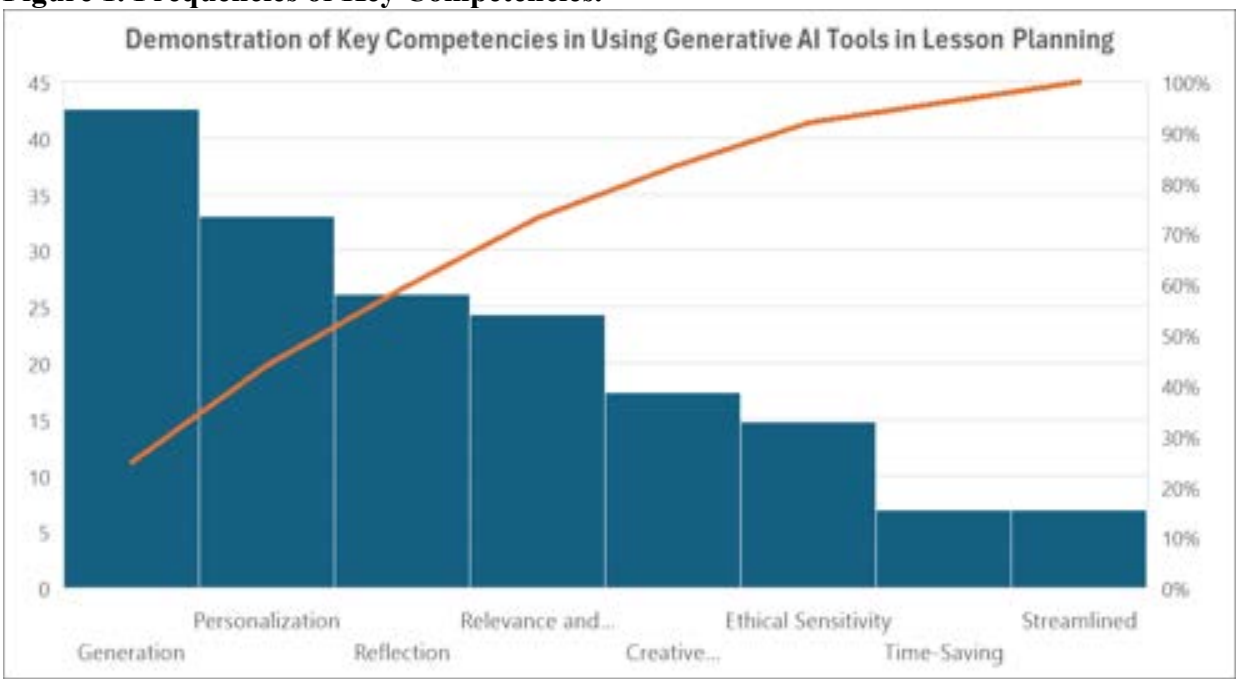

Table 1. Coding Scheme.

Category	Code	Explanation
Efficiency	Timesaving	AI reduces the time needed for lesson planning
	Streamlined Process	Preservice teachers easily adapt AI ideas to specific classroom needs.
	Facilitated Reflection	AI prompts deeper familiar tasks connecting new ideas with prior knowledge.
Innovation	Idea Generation	AI sparks strategies and ideas for science teaching as a brainstorming tool
	Creative Adaptation	Preservice teachers use AI outputs to develop various novel lesson plan ideas that suit their classrooms.
	Personalization for Equity	Preservice teachers recognize the necessity of tailoring AI suggestions to better meet diverse student needs and learning contexts.
Integrity	Relevance and Accuracy	Preservice teachers ensure AI outputs are relevant, accurate, and culturally sensitive.
	Ethical Sensitivity	Preservice teachers remain mindful of ethical concerns, including bias, and over-reliance on AI.

Findings

The data analysis allowed us to find answers to two research questions. First, we identified the competencies that participating preservice teachers demonstrated most frequently. Based on the analysis, participants showed a strong tendency toward idea generation, a component of the innovation category (Figure 1). Specifically, participants appreciated using generative AI tools to generate initial ideas for lesson design. This finding underscores a critical area for supporting preservice teachers in science lesson planning. De Arment et al. (2013) emphasized that unlike experienced in-service teachers, preservice teachers often require additional scaffolding to bridge their theoretical understanding from teacher education courses to practical applications in real classroom environments. Our study highlights the importance of fostering innovation through generative AI tools, demonstrating their potential to enhance preservice teacher education.

Figure 1. Frequencies of Key Competencies.

Additionally, the findings revealed that participants exhibited a high sensitivity to the integrity aspect. While they found generative AI tools helpful for creative brainstorming and starting lesson plans, they also expressed awareness of ethical considerations and potential biases inherent in using such tools. This aligns with Davis et al. (2024), who stress that integrity is a critical competency in the emerging era of generative AI in education.

Additionally, the findings revealed that participants exhibited a high sensitivity to the integrity aspect. While they found generative AI tools helpful for creative brainstorming and starting lesson plans, they also expressed awareness of ethical considerations and potential biases inherent in using such tools. This aligns with Davis et al. (2024), who stress that integrity is a critical competency in the emerging era of generative AI in education.

Our findings are consistent with existing literature that emphasizes the importance of integrating AI tools into science teacher education. However, this study advances the conversation by focusing on three critical competencies, efficiency, innovation, and integrity, necessary for the effective and responsible use of generative AI tools. These findings have important implications for science teacher educators, suggesting the need for the intentional incorporation of generative AI tools into teacher preparation programs to foster adaptive expertise while addressing both opportunities and challenges.

Conclusion

This study demonstrates how ChatGPT into science lesson planning is not merely about AI proficiency but about fostering adaptive expertise. Our findings highlight a critical shift in teacher preparation: while ChatGPT significantly enhances efficiency by streamlining the brainstorming process for science lesson planning, its true value lies in its role as a catalyst for innovation and integrity. By engaging in interactive prompting, pre-service teachers moved beyond passive adoption of AI generated content. Instead, they practiced critical reflection, adjusting AI suggestions to better cater to diverse learning needs and promote effective science learning environments. This process of innovative planning with AI underscores the necessity of high-level teacher agency. While AI helps brainstorm, the pre-service teachers develop their lesson plan ideas based on the context of classroom learning environments.

Young people's contact with nature has been decreasing, leading to negative consequences for their physical and psychological well-being. Additionally, education faces the challenge of including all students in the learning process, regardless of their functional, social, linguistic, or cultural characteristics. This project aimed to address these issues and involved 36 primary pre-service teachers in the development of inclusive educational resources focused on areas rich in biodiversity and geodiversity, while also integrating mother tongue content. The participants received scientific and didactic training to design more inclusive digital resources. The evaluation of these resources was based on indicators aligned with recommended principles. On a positive note, the pre-service teachers managed to explore biodiversity, geodiversity, and mother tongue learning in an integrated manner. However, they faced challenges in formulating coherent questions—both closed and open—and in simplifying scientific concepts. The resources were deemed adequate in aspects such as font type, size, and spacing, but the choice of colours often failed to follow inclusive criteria, being more driven by aesthetic preferences. Although the resources included audio texts, the diction was sometimes unsuitable for students with Portuguese as a non-native language. As a result, characteristics such as flexibility, simplicity, and equitable use were only partially achieved. The most promising resources will be tested with state school students later this school year, allowing for further adjustments before being made openly available on the website of the institution responsible for the project.

Keywords: Inclusive Learning, Digital Resources, Biodiversity and Geodiversity.

Introduction

The contact of young people with nature has been declining over recent decades (Freeman & Quigg, 2009; Woolley & Griffin, 2015; Almeida, Rato, & Dabaja, 2023). The consequences of this decline are significant, as such contact contributes to children's mental and physical health, stimulates the development of their cognitive, social, and emotional skills (Frost, Wortham, & Reifel, 2012). Furthermore, this lack of contact appears to reduce knowledge about native biodiversity, affecting not only children but also teachers in training (Almeida, García Fernández, & Strecht-Ribeiro, 2019). Louv (2010) even states that we are experiencing a deficit in nature contact and that the widespread use of the internet and electronic devices has also contributed to this situation.

Nevertheless, technologies are increasingly present in people's daily lives. Their utility and necessity in various contexts have grown, making it impossible for schools to ignore them. Technologies offer an ever-expanding range of applications, and many educational resources are in digital format. As Almenara and Ruiz-Palmero (2018) quote, Information and Communication Technologies (ICT) are one of the key variables in the knowledge society. Whether we are for or against it, the world in which we operate is increasingly technological and will continue to be so,

making their inclusion in schools, and consequently in teaching and learning processes, inevitable.

Education is also currently faced with the challenge of including all students in the learning process, regardless of their functional, social, linguistic, or cultural characteristics. In Portugal, the legal framework for inclusive education (Decreto-Lei n.º 54/2018) assumes that all students have the right to fully participate in a common educational project and to benefit from support that meets their needs, potential, and expectations. So, students from diverse social backgrounds, and a growing number of children from countries where the Portuguese language is not the official language, highlighting the multicultural reality of regular schools nowadays. The decree embodies a vision of inclusive education aligned with Universal Design for Learning (UDL) principles, which provide a framework that can be used to proactively design inclusive, flexible, and welcoming learning environments, considering the variability of all students (Rose & Meyer, 2006). The UDL stands at the forefront of contemporary efforts to create universal access to educational curricula for all students, including those with disabilities. Thus, the need to design more inclusive resources using digital tools aligns with UNESCO's (2009) recommendation of "education for all," as well-designed digital resources can better reach students with diverse characteristics.

The European Agency for Special Needs and Inclusive Education (2015) also emphasizes the fundamental role of inclusive practices in promoting equitable educational opportunities. Similarly, the Sustainable Development Goals (SDGs), specifically Goal 4 (Quality Education) and Goal 10 (Reduced Inequalities), underline the importance of these practices. However, such practices still lack the necessary prominence (Stinken-Rösner et al., 2020), with these authors pointing to a significant gap in research and practice in this critical area.

In this context, the present project aims to contribute to addressing the identified gap and fostering inclusive educational practices.

The Project

The present project, with the acronym GreenLink, aimed to address the various challenges outlined earlier. On one hand, it seeks to promote contact with biodiversity and geodiversity, thereby increasing knowledge and interest in nature. On the other hand, it aims to foster this contact through inclusive digital resources, supporting the inclusion of students from diverse backgrounds.

The project is focused on enhancing the training of pre-service teachers by deepening their scientific knowledge of biodiversity and geodiversity, as well as their pedagogical knowledge for designing inclusive digital resources for primary education. This involved applying knowledge acquired through outdoor activities.

At this stage of the project, during which the resources were designed, the goal is to highlight the challenges faced by the pre-service teachers in creating these resources after their training. Based on this evaluation, the resources have since been improved, and their testing with primary school children is scheduled to take place during the current academic year. The goal is to make these resources available on the institution's website, which offers a range of open-access digital resources for teachers.

Figure 1. The webpage of Lisbon School of Education where the resources will be available.

Methodology

The project involved 36 (35 females) primary pre-service teachers enrolled in two master's courses, with a mean age of 23 (SD=2.013), and four higher education professors. The project was developed across two curricular units: one scientific, Earth Science, focused on biodiversity and geodiversity knowledge, which included outdoor activities in nature; and another didactic unit called Integration Projects: Mother Tongue-Science. The latter explored integrative themes between language and science, emphasizing different text types, metaphorical and analogical language, argumentation on socioscientific topics, and children's literature. Additionally, it highlighted principles to follow in constructing assessment items and designing more inclusive digital resources, elements that were evaluated in the resources created. Pre-service teachers were tasked with designing an interdisciplinary inclusive resource for children, focused on the educational exploration of natural sites visited during the Earth Science curricular unit.

In preparing the pre-service teachers, emphasis was placed on the seven principles defined by Santos and Fernandes (2017) for designing inclusive resources: (i) equitable use, which refers to the resource being usable by everyone, regardless of their skills; (ii) design flexibility, which ensures accommodation of diverse user preferences and individual capabilities; (iii) simple and intuitive use, which highlights the resource's functional aspects; (iv) perceptible information, adapted to users' sensory needs, whether visual, auditory, or linguistic; (v) error tolerance, addressing potential negative consequences resulting from unintentional actions during use; (vi) low physical effort, ensuring the resource does not cause user fatigue; (vii) size and space for approach and use, designed to meet accessibility and manipulation requirements, considering factors such as posture, height, or mobility.

The pre-service teachers' training also incorporated principles outlined by the Centre on Inclusive Software for Learning (CISL, n.d.), such as line and letter spacing, font size, and type. It is widely agreed that greater spacing facilitates reading, especially for children and individuals with dyslexia. Additionally, larger font sizes improve comprehension and reading fluency for individuals with dyslexia and benefit those with visual impairments. Optimal font sizes vary across studies, ranging between 18 and 26, while simpler fonts like Arial or Verdana are considered more effective.

The choice of colours for resources also requires careful consideration to combine background and text/image colours that are complementary. These contrast patterns result in more efficient and comfortable visual performance, particularly for individuals with visual impairments or dyslexia.

Eight resources were developed in groups using Genially software. Group working was supported through tutorials, which allowed for iterative improvements to the resources. After their conclusion, each project was graded as part of the assessment of the curricular unit with didactic content. The marks given were based on an analysis grid, which included indicators reflecting the principles of inclusive digital resource design. Both positive aspects and persistent shortcomings were noted, even after the tutorials. Testing with primary school students, planned for the current academic year, will further evaluate and refine each resource.

Results

The resources were focused on several of the sites visited during the outdoor activities, with three being the most frequently chosen. This preference may be attributed to their potential for linking geodiversity and biodiversity and the presence of legends associated with two of them. These legends were seen by the pre-service teachers as a great possibility to integrate mother tongue and science, leading them to explore the natural features of these sites alongside the legends they inspired.

Other language-related contents incorporated into the resources included various text types (informative, narrative), word families, and derivation through prefixation and suffixation, integrated with multiple scientific concepts.

The construction of resource items, despite improvements during the tutorial sessions, posed challenges on several levels. Due to their lack of professional experience, pre-service teachers struggled to use simple language when defining scientific concepts. Difficulties were also identified in the formulation of open questions, which were often overly complex. In other resources, common errors in multiple-choice items included options with significantly unequal lengths and inconsistent grammatical constructions.

The selection of images was a positive aspect, as pre-service teachers had taken many photos and created short videos during the outdoor activities. Additionally, the use of artificial intelligence-generated imagery as a complement to their photos was a common practice among most groups and proved to be successful.

Regarding the seven principles to be considered in the development of digital resources, equitable use, flexibility of use, and simple and intuitive use were partially achieved. In fact, linguistic complexity, the failure to include audio instructions in several cases, poor diction in reading some texts, and the lack of instructions on how to approach certain tasks were evident in almost all resources, although in most cases these problems were found in only parts of the resources. Consequently, the information was not always easily presented for those with auditory or linguistic difficulties.

On a more positive note, the resources ensured that only a few negative consequences occurred to the users when moving forward in a resource, and the instructions, when present, did not require extra effort from the user.

Among other positive aspects, the font type and size chosen in most cases were effective. However, the selection of colours was somewhat neglected in terms of ensuring sufficient contrast, which is crucial for inclusivity. The pre-service teachers seemed to prioritize aesthetic preferences over the needs of all users.

Discussion and Conclusions

From the analysis conducted, it can be concluded that the design of inclusive digital resources is not an easy task and that the possibility of reaching all students is a difficult goal to achieve.

Nevertheless, the training provided allowed pre-service teachers to consider aspects that made the resources more inclusive, although others were overlooked. The attempt to reach students whose first language is not Portuguese proved to be partially successful, as better diction in reading contents revealed a need for improvement. The tendency to approach scientific concepts in a more complex manner also resulted, in part, from the scientific preparation that the pre-service teachers had been undergoing and their difficulty in finding simpler ways to explore these same concepts now for a younger audience. The exploration of biodiversity and geodiversity in an articulated manner proved to be more successful, perhaps because the course they had been attending sought this same articulation. The connection between science content and mother tongue content was also generally successful, with pre-service teachers showing some creativity in the selected articulations. As mentioned, the resources will only be freely accessible after being tested with students from state schools with diverse characteristics. However, the option to access the resources via provided links or QR codes already allows for an initial assessment of their potential and limitations.

Moreover, the process highlighted the importance of ongoing reflection and feedback when designing inclusive resources, emphasizing that initial attempts often need substantial refinement. Observing how different students interact with the materials will provide critical insights into the adaptability and accessibility of the resources. Future revisions are likely to benefit from closer collaboration with experts in language acquisition and special education, helping to address any remaining gaps more effectively. Ultimately, this experience underscores that inclusivity in educational resource design is an iterative process, requiring patience, continuous learning, and a willingness to adjust strategies based on real-world classroom experiences.

Bridging Digital And Physical Worlds: Leveraging AR And AI For Personalized Science Education In Geography And Astronomy

Anastasia Georgiou, Athina Karatza and Apostolia Galani
National and Kapodistrian University of Athens, Greece

This article presents a Preliminary Design Report (PDR) of the prototype of the educational game AcademIa of ARistarchus, which integrates Augmented Reality (AR) and Artificial Intelligence (AI) to revolutionize science education. By addressing persistent challenges such as student misconceptions, the game focuses on enhancing the understanding of complex concepts in geography and astronomy. In an era of rapid technological advancement and increasing environmental concerns, this game aims to prepare students for future challenges. AR allows students to interact with and visualize abstract scientific phenomena, including the greenhouse effect and planetary atmospheres, while AI provides personalized learning experiences by offering real-time feedback. Guided by established learning theories, the game intends to promote critical thinking, problem-solving, and collaboration among students. By providing a technology-enhanced model for science education, AcademIa of ARistarchus lays the foundation for future innovations in educational technology.

Keywords: Augmented Reality, Artificial Intelligence, Science Education

Introduction

The integration of technology into education is vital in today's rapidly evolving digital landscape. Emerging technologies such as AR and AI have shown immense potential for transforming how students engage with complex scientific concepts. In response to the conference theme of transitions and transformations in education, this research explores the design of *AcademIa of ARistarchus*, a prototype that aims to enhance student comprehension of geography and astronomy through innovative digital tools.

A detailed literature review of AR and AI-based educational applications revealed a gap in integrated solutions for these disciplines (Georgiou et al., 2024; Georgiou et al., 2025). While AR enhances understanding by visualizing abstract concepts (Yen et al., 2013), AI provides personalized learning pathways through adaptive feedback (Ayeni et al., 2024). Despite their potential, few initiatives effectively combine these technologies to create immersive educational tools. Addressing this gap is essential for making science education accessible and engaging.

The design of the prototype AcademIa of ARistarchus aims to fill this gap by engaging students in immersive scenarios that explore the greenhouse effect on Earth, Mars and Venus, the planets' atmospheres and the role of human activities in Earth's greenhouse effect. The final purpose is to develop an educational game to address research questions, such as whether it enhances students' knowledge about geography and astronomy topics such as the greenhouse effect and planetary atmospheres.

Prototype Design Framework

Core Idea And Purpose

The core idea of the AcademIa of ARistarchus is to develop an engaging and educational game centred on planetary atmospheres and the greenhouse effect. The game will integrate modern technological tools, such as AR and AI, to enhance the learning experience. Designed for students

aged 10 to 12, it aims to be both educational and enjoyable. Subsequently, the educational aspects of the game as well as the gameplay features are illustrated.

Learning Objectives And Learning Theories Used In The Design

Learning Objectives

The prototype's learning objectives are designed in alignment with Bloom's Taxonomy (Krathwohl, 2002). Additionally, relevant goals from the Greek Geography curriculum have been incorporated. The knowledge objectives of the game, are organized into three thematic units, each with corresponding learning outcomes, as described following:

Thematic_Unit_1: The atmosphere composition of Earth, Mars, and Venus. Students will be able to:

- Define the atmosphere.
- Compare the atmospheres of Earth, Mars, and Venus.

Thematic_Unit_2: The greenhouse effect on these planets and its role in regulating planetary temperatures. Students will be able to:

- Define the greenhouse effect.
- Justify why Venus has higher temperatures compared to Earth and Mars.
- Explain the greenhouse effect and the role of greenhouse gases in increasing planetary temperatures.
- Compare the temperatures of Earth, Mars, and Venus.

Thematic_Unit_3: The impact of human activity on the greenhouse effect. Students will be able to:

- Describe how human activities influence the greenhouse effect.
- Categorize the human activities that intensify the greenhouse effect.
- Propose solutions to mitigate the impact of human activities on the environment.
- Evaluate whether human activities are the primary cause of the increase in Earth's temperature.
- Critically assess which solutions are most effective in reducing CO_2 emissions.

The prototype also aims to develop collaboration and communication skills through teamwork and problem-solving.

Learning Theories

In AcademIa of ARistarchus, several learning theories were integrated into the prototype design to enhance student engagement, described as following:

- Constructivism: Players build knowledge by solving interactive problems, experimenting with scientific scenarios, and utilizing AR/AI features to enhance their understanding of key scientific concepts.
- Behaviourism: Players receive rewards for their actions, promoting motivation and reinforcing positive behaviour in learning.
- Active Learning: The prototype fosters hands-on engagement through problem-solving, requiring players to make decisions.

- Social Learning: Group tasks and teamwork allow players to share strategies and learn collaboratively, enhancing group dynamics.
- Multidimensional Learning: The use of AR/AI offers diverse perspectives and learning styles, enriching the educational experience.

Gameplay Features

Prototype Scenario

The story of AcademIa of ARistarchus takes place in the future, where the effects of rising temperatures are still undeniable. The players take on the role of aspiring scientists tasked with developing strategies to protect the planet's future. To accomplish this, they have to explore the greenhouse effects and planetary atmospheres of Mars and Venus and participate in activities to propose solutions to mitigate the impact of human activities on Earth's atmosphere. The players' objective is to answer questions accurately and successfully complete activities, earning stamps for their pAsspoRt and collecting tokens as they progress. The winner is the player who has collected all the stamps in the pAsspoRt and has gathered the most tokens.

Gameplay Mechanics

Drawing from principles of immersive learning and serious gaming (Bopp, 2008; Wang & Huang, 2021), the design of the prototype combines clear educational objectives, real-world challenges, compelling storytelling, interactive gameplay, and effective reward systems to create a meaningful and engaging experience for players. More specifically, the gameplay mechanics implemented are the following:

- Starting Point: Players embark on their journey from the island of Samos, Greece, equipped with a grant of tokens from the Cosmos Exploration Institute. They are supported by Aristarchus, an AI assistant tutor, which will help them overcome challenges along the way. Movement across the game board is determined by a micro:bit dice roll, allowing players to advance 0 to 3 steps. This adds an element of excitement to the journey.
- Interactive Challenges:

(a) The Cosmos Library offers three types of cards: Action_Cards, Exploration_Cards, and AR_Cards. As players progress, they draw cards, each presenting unique, time-bound challenges designed to test their knowledge and critical thinking skills. Action_Cards present collaborative challenges where players have to team up to solve critical questions and activities. Exploration_Cards focus on key scientific topics like the greenhouse effect and human impact on the environment, offering both knowledge-based and thought-provoking challenges. AR_Cards introduce interactive experiences through QR codes. For example, players will have to adjust greenhouse gas levels and observe how these changes alter global temperatures and the greenhouse effect. These cards offer an immersive and hands-on learning experience.

(b) Along the way, players must also overcome obstacles like solar storms, which adds complexity to their journey by disrupting their progress.

- Motivational Rewards: These tokens (RFID cards) are crucial for progressing and unlocking additional challenges. There are several parts in the game where players gain tokens. Firstly, they earn tokens from the Cosmos Exploration Institute for successfully completing missions. In addition, Action_Cards reward players when collaborating effectively in solving critical questions and activities. Moreover, the Exploration_Cards'

varying difficulty levels provide corresponding tokens. The token-based reward system motivates players to engage deeply with the content, encouraging both learning and progress throughout the game.

- Checkpoints: Key locations on Earth, such as the Arctic, which are highly connected to impacts of human activities, serve as checkpoints where players interact with AR_cards to explore the atmosphere, the greenhouse effect, and the impacts of human activities on these phenomena. Each checkpoint visit is marked with a stamp in the player's pAsspoRt.
- Equipment for Space Missions: layers who invest in higher-tier equipment will gain a strategic advantage in completing challenges and activities, allowing them to solve questions and tasks more thoroughly.
- Winner: Upon completing all tasks, players return back to Samos. The player who successfully finishes the journey and collects every stamp in the pAsspoRt will be ranked on the leaderboard according to the number of tokens earned. Subsequently, the top player will be crowned the winner.

Design Model Of The Prototype

- The game board features an illustrated Global Map of the Earth at its centre with Mars and Venus positioned on opposite sides, symbolizing interplanetary exploration. Players traverse paths across Earth's diverse regions, leading to the other planets for space missions.

The design of the prototype follows a hybrid approach, combining the waterfall model (Ruparelia, 2010) for the initial requirements specification and prototype design, with the agile methodology, as outlined by Al-Azawi et al. (2014), for iterative development and continuous refinement. The initial phase involved specifying the requirements and designing the prototype to ensure alignment with the learning objectives described in the previous section. Subsequently, iterative development cycles were applied, incorporating expert review and theoretical refinement at each stage. This approach, consistent with Agile principles, allows continuous refinement and improvement of the prototype's design.

Methodology for Future Work

The future work for AcademIa of ARistarchus involves several key steps: iterative development cycles were applied, incorporating expert review and theoretical refinement at each stage. This report serves as the Preliminary Design Report of the project. Final development will integrate feedback to refine and expand the game, ensuring it meets quality standards before full-scale implementation.

The evaluation process will involve a mixed-methods approach to collect both quantitative and qualitative data. A sample of 120 students aged 10-12 from different schools will participate in the study. The game's effectiveness will be measured using pre- and post-tests to assess knowledge acquisition, Likert-scale questionnaires to gauge engagement and enjoyment, and semi-structured interviews to gain deeper insights into student experiences. A triangulation approach will enhance validity and reliability by cross-referencing questionnaires, observations, and interviews. Quantitative data will be analysed statistically using t-tests to compare mean scores, while qualitative data will be thematically coded to identify recurring patterns and insights.

The study, scheduled for September 2025, aims to evaluate how the AR/AI game enhances students' understanding of the greenhouse effect and planetary atmospheres. Findings will guide

future improvements to optimize the game's learning potential and user experience.

Discussion

Integrating AR and AI in education enhances students' understanding of complex concepts through interactive learning. However, challenges such as technological complexity, accessibility, and equipment requirements must be addressed. Some key questions to consider are as follows: What are the pros and cons of AR/AI in teaching? How can these technologies be optimized for better learning outcomes? What challenges emerge when teaching complex scientific concepts/phenomena? How could the game be adapted to different age groups?

ESERA 2025 Copenhagen

Talking To Or Talking Through Teachers - An Analysis Of A Digital Teacher's Guide

Charlotta Nordlöf[1], Susanne Engström[2] and Pernilla Sundqvist[3]
[1]Linköping university, Sweden
[2] KTH Royal Institute of Technology, Sweden
[3]Mälardalen university, Sweden

Teaching materials not only support students but also support teachers in how they transfer their subject knowledge to teaching. Teacher guides are often digital and can address teachers by talking through or talking to the teacher, thus supporting teachers. In this paper a digital teacher's guide for grades 7-9 is analysed to see how it communicates with the teachers. The teacher's guide in technology education was analysed by content analysis in two steps. Firstly, on whether it talks to the teacher or through the teacher, and secondly the units that talk to the teacher were analysed by using six design principles. The results show that most of the guide (75 %) is text that talks through the teacher, e.g. by giving direct instructions for the teacher on how to carry out the teaching. In the remaining sections of the guide, text that talks to the teacher, there are examples of all six design principles. These sections include the purpose and structure of each chapter, describe key content, highlight challenges, suggest teaching adaptations and provide definitions of important terms and concepts. The analysed guide does not take advantage of the benefits of digitalization. Teacher guides should enable teachers to adapt and expand upon the material. It is important to design teacher guides with more text that speaks to teachers, not just through them.

Keywords: Teaching materials, K-12 Education, STEM education

Introduction

Teaching materials, such as textbooks and teacher guides, play a central role in the way teachers transfer their subject knowledge into teaching. Teaching materials support teachers and influence the choices they make in planning and delivering lessons (Oates, 2014). Teachers with low subject knowledge are particularly dependent on teaching materials. Teacher guides in particular have the potential to support teachers in different ways.

Teacher guides are often digital. The digital format provides the possibility to redesign the material, i.e. to do what was not possible with the analogue format (Puentedura, 2020; Blundell et al., 2022). Remillard (2000) distinguishes between how the teacher guides communicate with teachers. Teacher guides that talk through the teacher and tell the teacher what to do, while teacher guides that talk to the teacher explain the underlying ideas of these suggestions.

In this paper, we analyse a digital teacher's guide for grades 7-9. The purpose is to give an account of the ways in which the examined teacher's guide communicates with the teachers, in terms of talking through and talking to the teacher.

Theoretical perspectives

Educative Curriculum Materials

Remillard (2000) points out that teacher guides commonly talk through teachers but argues that they should be designed to speak to teachers. However, van Steenbrugge and Ryve (2018) emphasise that teacher guides that talk through teachers can also be a support, especially for teachers who feel insecure about the subject or are unaccustomed to teaching situations.

Distinctive for educative curriculum materials (talk to teachers) is that they include educative features specifically designed to support teachers when adapting their teaching, both regarding content and how to conduct teaching. Based on Davis and Kracjik's (2005) guidelines for how and why teacher guides should be designed, and studies where versions of these guidelines were tested (Arias et al., 2016; Davis et al., 2014), Davis et al. (2017) constructed six design principles to characterise teacher guides in science education. These can shortly be described as:

1. Educative features should suggest ways to adapt lessons without losing their purpose.
2. Educative features should explain the reasoning behind pedagogical ideas and support teachers in adopting these ideas through contextualised examples.
3. Educative features should help make important content visible and explain it, showing how it connects across lessons.
4. Educative materials should offer various types of features to meet diverse needs.

Principles 5-6 are excluded since they are not used in this study.

The SAMR-Model

The SAMR-model (Substitution, Augmentation, Modification, Redefinition) is a model for integrating digital technology in education. Puentedura (2009) describes it as a guide for how teachers can design tasks and learning processes when using digital technology in education and states that digital tools can either be used to improve existing analogue teaching practices or to fundamentally transform them to a digital format. He describes four levels of integration:

- Substitution: at this level, the digital format is simply replacing the analogue format and offers no improvement or functional change.
- Augmentation: existing practice is improved by the digital tool.
- Modification: Instead of teaching in the same way and using the same tasks, the digital tool is used to adapt and change the tasks.
- Redefinition: The digital technology allows for and is used to create new tasks, and is transforming learning.

Learning activities categorised as substitution or augmentation are understood to improve or support learning, whereas those categorised as modification or redefinition are considered to fundamentally transform the learning experience (Romrell et al., 2014, with reference to Puentedura).

Since we study teacher's guides as potentially educative for teachers, we find the SAMR-model useful for analysing how the design of the teacher's guide benefits from the digital format in order to enhance teachers' understanding of how to organise and enact the teaching.

Method

The Teacher's Guide

The teacher's guide of a widely used curriculum material for technology education in grades 7-9 in Sweden is analysed (Lovén & Citrohn, 2022). It is a digital resource and can be bought as a complement to the textbook. Its size is equivalent to about 200 pages in book form, consisting of an introduction and six chapters based on the same structure. First, introduction, connections to the curriculum, and assessment. This is followed by sub-chapters corresponding to the textbook, covering the content (facts and theoretical information) and projects (tasks and assignments) contained in the book.

Analysis

To study how the teacher's guide benefits from the digital format, we looked at all the features of the digital guide and categorised them according to the four levels of the SAMR-model.

To examine how the teacher's guide communicates with the teacher, content analysis was performed in two steps. First, we coded each unit (phrase, sentence or paragraph) based on whether it talks *to* the teacher or *through* the teacher (Remillard, 2000). Then, we further coded the units that talk *to* the teacher using an adapted version of the design principles created by Davis and colleagues (2017). We used the original design principles 1-4 but modified 5-6 to fit the technology subject, inspired by Robert's vision I and II: like other researchers in technology education (e.g. Stoor & Popov, 2021).

1. In technology education, students should try, analyse, and evaluate working methods in various technical areas, such as design processes and life cycle analyses. The teacher's guide should provide examples of how work in different technical disciplines is carried out in practice and how this can be part of the teaching.
2. One objective for technology education is to prepare students to become conscious citizens in a society where technology plays a central role. The teacher's guide must support teachers in motivating the importance of technology education for society and everyday life and provide examples that highlight technical knowledge for making decisions at both individual and societal levels.

All three researchers coded the first chapter of the teacher's guide individually and subsequently discussed the coding agreement until consensus. The remaining chapters were divided among the researchers.

Findings

First, we present the findings related to the digital format of the teacher's guide. Second, the findings are summarised based on whether the text talks *through* or talks *to* the teacher.

The Digital Format Of The Teacher's Guide

This teacher's guide is digital, but it resembles a printed version. It does not offer any additional functionality compared to what an analogue guide can do. Thus, it is a substitute for a printed guide and placed at the substitution level in the SAMR-model.

Text That Talks *Through* The Teacher

Approximately 75% of the teacher's guide is text that talks *through* the teacher, where a large part is the answers to the questions in the textbook. Also, there are direct instructions for the teacher on how to perform the teaching. These are clear and explicit: *Let the students read the text on pages 48–55 silently or read the text aloud to them* or *Use the worksheet and have students write a list of various technical solutions*.

Overall, most of the guide talks directly *through* the teacher, who can essentially use it as a script. Alternatively, it can be employed as a practical step-by-step guide: *Distribute the worksheet to the students, then ask them to answer the questions*.

Text That Talks *To* The Teacher

The teacher's guide contains about 25 % text that talks *to* the teacher, mainly in the Introduction sections. These sections outline the purpose and structure of each chapter, describe key content, highlight challenges, suggest teaching adaptations and provide definitions of important terms and concepts. Additionally, the guide connects the content to the syllabus of technology education.

Another part of the teacher's guide where there is text that talks *to* the teacher is in the Assessment sections. These sections include a rubric providing examples of student responses at passing level and at higher grade levels. Findings and examples from each principle are presented in Table 1.

Table 1. Design principles 1 to 6 with examples.

Design principle (DP)	Findings	Example
DP1 – suggestions on how lessons can be adapted in several ways without losing the intended purpose.	Not extensively covered, occurs as suggestions for adjustments based on time, alternative projects, and strategies to address common difficulties students face.	*Students often find it challenging and complicated to create drawings. If they are given sufficient time, they usually manage to produce drawings that show simple objects with two views and measurements after some practice. Allow students extra time for this section.*
DP2 – the reasoning behind, and contextualised concrete examples of, the pedagogical ideas included in the teacher's guide.	Not very present overall. However, it is visible in the assessment section included in each chapter. It is also found in some introductory sections.	*Many students prefer to make drawings on graph paper, which can be a good starting point. However, when adding measurements and drawing lines between the grids, a drawing on graph paper can become unclear. […] Make students aware of this and let them try drawing their sketches and drawings on white paper.*
DP3 – supporting teachers' subject knowledge, making important content visible, and explaining it.	Appears to varying degrees. E.g. in the chapter about technological development work, there is a strong focus on essential subject content. Also found in some introduction sections.	*The circular motion refers to the frequent need to go back and improve technical solutions during development*
DP4 – support teachers' different needs for themselves and their students.	Examples are found when the guide points out content that may be difficult for students.	*Understanding the system boundary can be difficult.* (No support to the teachers on how to teach about this or explain boundaries in different situations.)
DP5 – provide teachers with examples of how work within technical disciplines is carried out in practice and can be part of the teaching.	Links to professions as a way of making lessons meaningful and relevant to the world outside school.	*Students may think that block programming is something you do in school, but block programming is also common in industry, for example, to control industrial robots or manufacturing machines.*
DP6 – support teachers to make the importance of technology for societal and everyday life visible.	Found in the chapter addressing the consequences of technology, also examples of historical perspectives and technological systems.	*Emphasise to students that the best approach is to minimise waste, meaning we should only buy products we truly need.*

Discussion

The analysed guide predominantly speaks *through* the teacher, as teacher guides often do (Remillard, 2000). The structure and content in this guide provide direct instructions that leave little room for adaptation, e.g. for diverse student groups. Fixed structures and specific instructions in guides can limit students' exposure to diverse perspectives and the broadness of the subject, as a previous study found that a textbook does not sufficiently cover a subject and that supplementary materials are needed (Engström et al., 2023). Lack of explicit explanations for methods can hinder teachers' understanding and ability to make informed decisions. Teacher guides can be a support for insecure teachers (van Steenbrugge & Ryve, 2018), but over-reliance on guides can lead to inadequate explanations and support for students. Even though guides should not replace teacher education or professional development, they can be useful for substitutes and as part of professional development if designed educatively.

The teacher's guide in this study is digital, which is a common format of teacher guides within this field. The digital format offers great opportunities and possibilities for redefining the materials (Puentedura, 2020), such as visualisations in the form of images, simulations, and video clips, both when talking *to* and *through* the teacher. However, the current guide does not take advantage of the benefits of digitalisation. Rather, it acts like a substitute for the analogue format (c.f. Puentedura, 2020). It mainly consists of text and images that are copies from the textbook. This is because the structure of the guide is designed to support the teacher by speaking through the teacher and linking directly to the book's pages, tasks, and so on.

Teacher guides should empower teachers to adapt and expand upon the material by speaking *to* teachers, not just *through* them. Teacher education programs should provide opportunities to explore different types of guides, encouraging reflection on their approaches and implications for teaching practice. This fosters flexible and reflective teaching practices.

The Relationship Between Critical Thinking And Generative Artificial Intelligence: A Two-Way Street For Science Education

[3]Jerusalem College of Technology (Machon Lev), Israel

The emergence of Generative Artificial Intelligence (GenAI) has presented new opportunities and challenges for developing critical thinking skills in science education. From the learning perspective, students' critical thinking skills are challenged during content creation (input) and evaluation (output) when interacting with GenAI. This process establishes a continuous loop that implicitly requires critical thinking to achieve desirable outcomes. From a teaching perspective, GenAI can be used as a tool to explicitly develop and assess critical thinking skills. During an exploratory seminar, we invited participants (N=26, working in pairs) to (a) rank science-related questions by the degree of critical thinking they are likely to provoke, (b) evaluate alternative GenAI-generated rankings as 'good', 'weak', or 'random' critical thinking, and (c) reconsider their own rankings after exposure to GenAI outputs and group reflection. We examined how difficult it is to judge critical thinking demands even without GenAI support, and how GenAI suggestions can shift participants' decisions. Descriptively, most participants revised at least one ranking, and a slight majority reported that GenAI influenced their final choices. We discuss these findings, arguing that GenAI can support critical thinking when positioned as an object of critique and a partner for structured reasoning rather than an answer engine.

Keywords: Critical Thinking; Generative Artificial Intelligence; Science Education

Introduction

The importance of critical thinking (CT) in science education is reflected in curriculum standards and educational goals across many countries and jurisdictions, highlighting its perceived value in developing scientifically literate individuals capable of reasoned analysis and decision-making in scientific contexts (Bailin, 2002). While CT is often cited as a key competency, its definition has become too broad to be helpful in science education, which stresses what scientists do: generate, test, and evaluate claims, data, and theories. This can be suggested as a definition of CT in the context of science education (Schmaltz et al. 2017). Such CT skills involve awareness of cognitive biases to avoid them, conducting impartial analyses, and using logical reasoning and evidence to support claims. These skills may enable students to question established social norms, challenge conventional wisdom, and expose societal inequities (O'Reilly et al., 2022; Larson et al., 2024).

Technology provides innovative tools and platforms for developing such CT skills, necessitating new teaching and assessment approaches in digital environments (Saadé et al., 2012). This necessity has become increasingly evident with the emergence of Generative Artificial Intelligence (GenAI) (Verma et al., 2023). CT and GenAI interaction encompasses both the learning and teaching perspectives. During learning, GenAI can challenge students' CT skills in (a) content creation (student input) and (b) content evaluation (GenAI output) (Larson et al., 2024). This continuous loop can extend as far as the student permits. While this interactive process between students and GenAI necessitates engaging students' CT to achieve desirable outcomes, the teaching perspective is also viable in utilizing GenAI specifically and explicitly

for CT skills development and assessment (Noroozi et al., 2024).

Given the relative novelty of this technology, only a limited number of research studies have investigated the impact of GenAI on students' critical thinking abilities (Bahroun et al., 2023), predominantly through indirect means, and even fewer have exploited GenAI as a tool for teaching and evaluating critical thinking. In the pertinent literature, scholars need to extend this research to address these questions and elucidate the potential outcomes that may be derived from the relationship between critical thinking and GenAI (Larson et al., 2024). In the context of science education, such research may yield a profound perspective for the development of future scientists and the advancement of broad scientific literacy.

This paper reports on an ESERA 2025 exploratory seminar that treated GenAI not primarily as a tutor but as a stimulus for reflection on what counts as ‘critical thinking’ in science-related questioning. Participants completed a brief activity sequence: initial ranking of four climate–agriculture related questions by how much critical thinking they provoke, classification of three GenAI-generated rankings as good/weak/random, followed by post-reflection re-ranking and a short survey on whether GenAI influenced their final decisions. We use the seminar outputs to illustrate (a) the intrinsic difficulty of evaluating critical thinking demands and (b) the ways GenAI can reshape judgments even in a meta-level task about critical thinking itself.

Theoretical framework

Critical thinking is a crucial 21st-century skill that enhances scientific understanding, promotes democratic citizenship, and develops higher-order cognitive abilities (Santos, 2017). Together with the above definition of CT skills in science education, it has the potential to humanize sciences and situate them in broader contexts, fostering inquiry and creativity through questioning, critique, and argumentation. It prepares individuals to tackle complex future challenges, supports informed decision-making on socio-scientific issues, and involves complex reasoning and evidence-based argument construction. CT skills are increasingly needed and challenged in an environment progressively influenced by advancing GenAI technologies (Zhai et al., 2024).

Prompting, or prompt engineering, provides a natural-language-based interface for GenAI, facilitating iterative and interactive exchanges between humans and GenAI systems in a collaborative creative process (Oppenlaender et al., 2024). Initial prompts are evaluated, and GenAI responses are assessed against students' intended outcomes. If GenAI's output is inadequate, the prompt is modified and re-evaluated until the desired result is achieved (Cain, 2023). This process implicitly promotes learning by reflecting on students' objectives, GenAI's capabilities and limitations, and language nuances.

While GenAI offers numerous opportunities to enhance education, critical thinking remains crucial to ensuring its effective, ethical, and pedagogically sound implementation in learning environments (Giannakos et al., 2024). The potential for biased or misleading information in GenAI outputs underscores the importance of critical thinking skills in recognizing and addressing these issues. The limitations of GenAI in nuance, context, and common sense necessitate human interpretation and evaluation to ensure meaningful learning experiences. Additionally, there are potential ethical concerns regarding data privacy, security, and intellectual property rights when using GenAI in educational settings that students should learn to address critically.

The overreliance on solutions generated by GenAI, without applying critical thinking skills in input development and output evaluation, may compromise students' capacity for independent

learning and conceptual understanding (Thiga, 2024). Therefore, there is a growing focus on developing effective teaching strategies and assessment methods to foster skills, including critical thinking, across all educational levels, from early childhood to higher education (O'Reilly et al., 2022) and teacher education (Verma et al., 2023). Recent research in the STEM education context demonstrates some attempts to develop frameworks for explicitly cultivating critical thinking utilizing GenAI tools as skill-teaching or assessment assistants (Lee & Low, 2024; Pantazatos et al., 2024; Shanto & Ahmed, 2024; Thiga, 2024).

Shanto & Ahmed (2024) proposed a framework that offers structured guidance for focused inquiry, gathering diverse perspectives, evaluating responses, synthesizing insights, and reflective learning to analyse and build upon GenAI-generated output critically. Lee and Low (2024) demonstrated the application of GenAI tools in parallel workshop activities, utilizing the Paul-Elder framework to foster critical thinking development among students. In concurrence, Thiga (2024) posited that critical thinking skills can be cultivated through GenAI by employing systematic and in-depth interrogation of tools' outputs. Similarly, Pantazatos et al. (2024) investigated the integration of a GenAI-based virtual assistant, with particular emphasis on its influence on students' critical thinking abilities.

Research consistently shows that GenAI can both enhance and inhibit students' critical thinking. Applied within structured educational frameworks, GenAI tools notably improve critical thinking (Lee & Law, 2024; Pantazatos et al., 2024). However, misuse can reduce motivation for independent inquiry and reflection, indicating a need for careful integration into curricula (Thiga, 2024). Research suggests that a deliberate, well-designed framework can significantly elevate critical thinking (Shanto & Ahmed, 2024). These findings highlight the importance of strategically guiding GenAI use to foster critical thinking skills in education.

Research studies on the impact of critical thinking on students' interaction with GenAI (learning perspective) and the utilization of GenAI to develop critical thinking skills (teaching perspective), explicitly call for further investigations to explore this intersection (e.g., Bahroun et al., 2023; Larson et al., 2024). While there have been attempts to identify the role of critical thinking in several STEM education domains, there is a deficiency in addressing the potential and challenges specifically in science education fields, where critical thinking is important (Bailin, 2002; Santos, 2017).

To begin addressing this gap, we designed an exploratory seminar that examines the two-way relationship between critical thinking (CT) and GenAI in science education: first, how participants' CT is mobilised when they evaluate and justify the quality of GenAI-generated reasoning (learning perspective), and second, how GenAI's outputs can shape or steer participants' subsequent judgements about what counts as "critical-thinking demanding" work (teaching perspective). In the context of this exploratory seminar study, we developed two research questions to be used as a principled starting point for future, more tightly operationalised research questions considering the participants' responses, feedback, and concerns.

RQ1 (CT → GenAI evaluation): To what extent can participants discriminate between GenAI-generated rankings that are presented as reflecting different levels of critical thinking, and how consistently do they make these classifications?

RQ2 (GenAI → CT evaluation): How does exposure to GenAI-generated rankings influence participants' subsequent judgements of critical-thinking demand?

Method

Seminar Participants

Participants (*N*=26) were attendees of the ESERA 2025 conference who voluntarily selected this exploratory seminar session. They comprised science education researchers and practitioners of diverse ages and national backgrounds, bringing a range of perspectives to the activity. All participants worked in self-selected pairs to facilitate collaborative discussion and decision-making during the activities.

Description Of The Seminar Activity

The activity was delivered through a structured online form (developed in Typeform) and consisted of five sequential phases. The scenario and the related questions were generated by GenAI to situate the task in a science-education context. An expert-derived rubric, based on the Holistic Critical Thinking Scoring Rubric ((Facione & Facione, 1994; Ramlo, 2019), was used to judge the CT demand of each question on a 1–4 scale (1 = least CT required, 4 = most CT). ChatGPT 5.0 was instructed to assess the CT provoked by these questions using the rubric and the result was calibrated by the researchers. Ultimately, the four questions had increasing CT complexity in the order: Q1 (score 1) < Q3 (2) < Q2 (3) < Q4 (4). This "ground truth" ranking (Q1 → Q3 → Q2 → Q4, from less to more provoking) was later used to generate example AI rankings and to evaluate participant responses.

Phase 1: Scenario and Initial Ranking
Participants first read a brief GenAI-generated scenario on climate change and agriculture, then individually ranked four GenAI-generated questions (Q1–Q4) from 1 (provokes the least critical thinking) to 4 (provokes the most critical thinking). This captured each pair's baseline judgment of which questions demanded more critical thinking.

The scenario text read:

> Uneven shifts in climate and atmospheric CO_2 are altering agricultural conditions. Evidence indicates both potential gains and losses that vary by method, timescale, and context, with cascading effects across production, trade, and food access amid uncertainty. Regional responses differ as growing seasons and crop suitability shift. Inferences about magnitude and direction often depend on data sources (observations versus model projections) and underlying methodological choices.

The four questions were:

> 1. What potential agronomic benefits associated with climate change have been observed or projected, and how can these be empirically evaluated across regions?
>
> 2. What lines of evidence both support and challenge the hypothesis that climate change may improve agricultural conditions in some locales, and how might methodological choices influence these findings?
>
> 3. How might shifts in climatic suitability and growing seasons affect crop selection, global trade flows, and food distribution, and what key uncertainties should be considered?
>
> 4. Which evidence-based decision-making framework could guide policies that both leverage potential local benefits and mitigate risks to food security, and how would trade-offs be justified?

Phase 2: Evaluation of GenAI Rankings

Next, participants reviewed three anonymized GenAI-generated rankings of the same questions, labeled "Ranking A," "Ranking B," and "Ranking C." They were told that one ranking was generated by a "Good Critical Thinker," one by a "Weak Critical Thinker," and one randomly, though the identities were not disclosed. Participants were asked to classify each ranking as *Good*, *Weak*, or *Random*, and identify which one they believed represented the best critical thinking ordering.

Phase 3: Justification

Participants were prompted to justify their choice of the "Good CT" ranking by writing a brief explanation of the criteria they used. This open-ended response captured their reasoning process and CT criteria (e.g., evidence use, synthesis, complexity) in their own words.

Phase 4: Re-Ranking

After completing the evaluation and justification phases, participants returned to their original question ranking and were invited to revise it based on the GenAI examples and their reflections. This phase allowed researchers to observe any shifts in judgement influenced by GenAI exposure.

Phase 5: Reflection On GenAI Influence

Finally, participants answered a Yes/No question on whether the GenAI-generated rankings influenced their revised decisions. If they answered "Yes," they were prompted to elaborate on what factors caused their change in ranking. This phase captured participants' perceived influence of GenAI on their thinking and decisions.

Data Collection and Analysis

The online form recorded all responses, yielding both quantitative and qualitative data. Quantitative measures included each pair's initial and final question rankings (for comparing changes), and their classification of the GenAI rankings (to assess identification accuracy of "Good/Weak/Random" rankings). Qualitative data included the textual justifications for selecting a particular ranking as "Good CT" and the open-ended reflections on GenAI's influence.

For analysis, we calculated simple descriptive statistics: the number of participants who correctly identified the AI's good-vs-poor CT rankings, the proportion who revised their question ordering, and the degree of alignment between participant rankings and the expert rubric before vs. after the GenAI intervention. The open-ended responses were reviewed to extract common themes regarding how participants judged critical thinking and why they did or did not alter their rankings.

Results

Discrimination Of GenAI-Generated Rankings (RQ1)

Overall, participants showed moderate success in distinguishing the quality of the AI-proposed question rankings. As summarized in Table 1, 9 out of 13 pairs (69%) correctly identified the "Good Critical Thinker" ranking generated by GenAI (the sequence aligning with the expert rubric). The remaining 4 pairs misidentified a suboptimal ranking as the "good" one – notably, 3 pairs were confused by the reversed (weak) ranking, labelling it as the best. Participants were most adept at spotting the nonsensical ordering: 11 pairs (85%) recognized the random ranking for what it was. Identification of the weak ranking was more challenging (only 8 pairs, 62%, labeled it correctly), with some of its misinterpretation being mistaken for either a good or random order. In fact, just over half of the groups (54%) managed to classify all three AI-generated rankings correctly. These results indicate that while many participants could discern obviously

poor vs. strong question orderings, a substantial minority struggled, particularly confusing the weakest ranking with the optimal one.

Table 1. Participant accuracy in classifying GenAI-generated rankings (*N*=13 pairs).

GenAI Ranking Type	Correct Identifications (n)	Accuracy (%)
"Good" ranking	9	69%
"Random" ranking	11	85%
"Weak" ranking	8	62%
All three classified correctly	7	54%

Participants' open-ended justifications shed light on the criteria they used to evaluate these rankings. Many participants based their judgments on the depth and complexity of thinking that questions in each ranking would demand. For example, responses frequently mentioned the inclusion of multiple perspectives, evaluation of evidence, and higher-order reasoning as signs of a "good" critical thinking question order. One pair explicitly referenced Bloom's taxonomy levels, noting that questions asking "how" and requiring synthesis or solution planning signaled higher cognition, whereas questions focusing on recall of details indicated lower critical thinking. Others emphasized the importance of evidence-based reasoning: e.g. "Being able to collate data, interpret data, and apply knowledge" was cited as a hallmark of the stronger ranking. In contrast, rankings where questions were simply factual or one-dimensional were seen as reflecting weaker critical thinking. These qualitative insights confirm that participants were attending to meaningful aspects of the questions (such as breadth of analysis, need for justification, and consideration of uncertainties) when judging the AI-generated rankings as strong or weak in CT terms.

Influence Of GenAI On Final Rankings (RQ2)

Exposure to the GenAI-generated examples had a notable impact on many participants' own question rankings. After evaluating the GenAI's rankings and reflecting, a majority of the pairs (8 of 13, ~62%) revised their original ranking of the four questions before final submission. In other words, only five pairs chose to keep their initial ordering unchanged through the activity. To gauge whether these revisions moved participants closer to the expert-defined ranking, we compared the alignment of each pair's ordering with the rubric-based "correct" order pre- and post-activity. Table 2 shows that alignment improved overall. Initially, only 1 out of 13 pairs (8%) had an exact match to the rubric's ideal order (Q1 < Q3 < Q2 < Q4). After the GenAI intervention and re-ranking, this number rose to 5 pairs (38%). Similarly, a simple alignment metric (total rank difference from the rubric, on a 0–8 scale) showed a substantial reduction: before the activity, participants' rankings deviated from the expert order by an average of 3.1 points; after revision, the average deviation dropped to 1.4. This indicates that many participants' final rankings were more in line with the expected difficulty order of the questions, suggesting a positive influence of the GenAI examples on their critical evaluation of the questions' demands.

Table 2. Alignment of participants' rankings with expert rubric (initial vs. final).

Alignment Metric	Initial Ranking	Final Ranking
Mean total difference (0–8)	3.1 ± 1.8	1.4 ± 1.1
Pairs with exact rubric order (n)	1 (8%)	5 (38%)

Qualitative self-reports from the reflection stage help explain how and why GenAI influenced (or did not influence) participants' thinking. Among the 13 pairs, 7 explicitly answered "Yes" – the GenAI rankings influenced their final decisions – while 6 reported no influence. Those who acknowledged influence often said that reviewing the GenAI-generated orderings prompted them to re-evaluate the criteria for critical thinking. For instance, one pair described how the AI

examples made them "think about the characteristics of critical thinking" and led them to consider "the depth of thinking and the amount of analysis" required by each question, even attempting to tie their reasoning to Bloom's taxonomy. Others noted that the contrast between their initial ranking and the GenAI "good" ranking revealed gaps or mistaken assumptions in their original thinking, prompting adjustments for a more evidence-based or multi-faceted approach. In a few cases, participants admitted the GenAI rankings caused confusion or doubt: "The results led me to get confused," one pair wrote, while another even joked that seeing an unexpected ordering made them "panic and question everything [we] knew about critical thinking." Nevertheless, even these instances of surprise or uncertainty often triggered deeper reflection on why a given question might be harder or easier than initially thought.

Conversely, the 6 pairs who reported no influence tended to stick with their initial reasoning despite the GenAI input. Some of them had already ranked the questions in an order close to the rubric's, so the GenAI examples may have simply affirmed their choices. Others indicated scepticism about the GenAI outputs, noting (for example) that the GenAI did not provide a rationale for its rankings, which limited its persuasive power. One pair commented that none of the AI-proposed orders matched exactly what they initially thought, but they did not fully trust those examples enough to overhaul their original ranking. This highlights that while GenAI can introduce new perspectives, participants with strong prior convictions or justified reasoning might resist changing their answers without a clear justification.

In the seminar activity, participants engaged with critical thinking in two distinct but complementary ways. First, they deployed critical thinking when analysing the cognitive demands of the four questions—drawing on reasoning, comparison, and synthesis to judge which required deeper thought. Second, they evaluated critical thinking when interpreting the logic and quality behind GenAI-generated rankings, reflecting on the reasoning implicit in each proposed sequence. This dual engagement allowed participants to not only practice critical thinking skills but also refine their understanding of what constitutes critical thinking in a science education context.

Discussion

This study contributes to a growing body of work examining how GenAI can be harnessed to support the development of critical thinking in science education. As previous research has noted, while CT is a central aim of science learning, its definition and operationalization often remain ambiguous (Bailin, 2002; Schmaltz et al., 2017). The seminar activity addressed this challenge by creating a concrete task in which participants had to weigh the cognitive demand of different questions and assess GenAI's ability to do the same. The difficulty many experienced in making these judgments reinforces the complexity of critical thinking as a construct, aligning with concerns raised by O'Reilly et al. (2022) and Larson et al. (2024) about the need for more precise and context-sensitive tools.

The outcomes also resonate with literature that has framed GenAI as a partner in learning rather than a passive tool (Lee & Low, 2024; Shanto & Ahmed, 2024). Participants who altered their rankings described how the AI examples prompted deeper reflection on what constitutes a high-quality, thinking-oriented question. Rather than adopting AI outputs uncritically, they weighed the underlying reasoning, compared it to their own, and sometimes changed course. This kind of iterative, evaluative engagement reflects the kind of interaction that Oppenlaender et al. (2024) and Giannakos et al. (2024) have highlighted as central to using GenAI to enhance learning.

Still, the variation in responses underscores the need for robust scaffolding and transparency

when incorporating GenAI in critical-thinking tasks. Some participants reported confusion or distrust toward the AI's rankings, particularly in the absence of explanations. This confirms the concerns raised by Thiga (2024) regarding potential misuse or misinterpretation of GenAI outputs and points to the importance of embedding such tools within pedagogically grounded frameworks. Educators must help learners develop both the cognitive and digital literacies required to critically assess GenAI-generated content.

Looking ahead, future studies should explore how this kind of seminar-based approach could be scaled, adapted for student populations, or integrated into pre-service teacher training. Further research might incorporate control conditions, longitudinal designs, or direct assessments of critical thinking before and after engagement with GenAI. In practical terms, educators might adopt similar ranking and justification tasks in classrooms to promote deeper reasoning about what makes a question cognitively demanding and how AI-generated reasoning can be critically assessed.

Ultimately, this work highlights a promising path forward: rather than viewing GenAI as a challenge to critical thinking, we can frame it as a site where critical thinking is activated, tested, and refined. By making GenAI both a partner in reasoning and an object of analysis, science educators can better prepare students (and themselves) for navigating the increasingly complex interplay of knowledge, technology, and judgment in a digital age.

Conclusions

The exploratory seminar provided valuable insights into how science education professionals engage with GenAI-generated content when evaluating and re-evaluating the critical-thinking demand of science-related questions. Participants were moderately accurate in distinguishing between question rankings of varying quality, and their reasoning often drew on meaningful indicators such as depth of analysis, evidence use, and synthesis. Moreover, many participants revised their original rankings after reflecting on the GenAI-generated examples, resulting in greater alignment with expert expectations. These findings suggest that while distinguishing levels of critical thinking remains a nuanced and challenging task, especially when mediated by GenAI, structured activities such as this can foster improved judgment and metacognitive awareness.

Crucially, the results point to the value of positioning GenAI not as an authoritative answer engine but as a prompt for reflection and critique. Participants' engagement with the AI rankings influenced their decisions in ways that highlighted both the potential and the limitations of GenAI in supporting critical thinking. This two-way interaction, where GenAI both elicits and is subject to critical evaluation, offers a promising direction for future teaching and research practices in science education.

Acknowledgement

The authors would like to thank all the participants of the ESERA 2025 exploratory seminar for their enthusiastic engagement and thoughtful contributions.

Exploring The Use Of ChatGPT In Science Lesson Planning

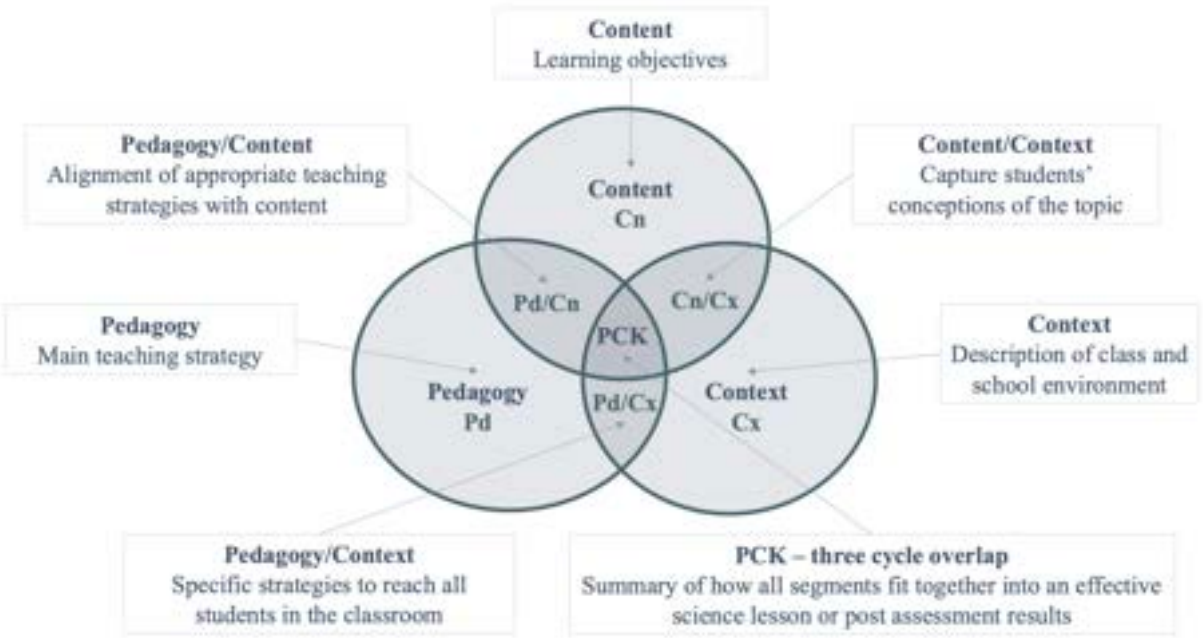
Giorgos Peikos and Dimitris Stavrou
Department of Primary Education, University of Crete, Greece

Generative AI (GenAI) is increasingly recognized for its potential to support teachers in tasks such as lesson planning. However, its limitations, including inaccuracies in generated responses, make it essential for teachers to critically evaluate its outputs. This study explores the use of GenAI in science lesson planning through the lens of Pedagogical Content Knowledge (PCK). The research is structured in two phases. In the first phase, we examined the use of ChatGPT in science lesson planning by engaging with the tool as researchers, focusing on how lesson plan suggestions generated reflect components of PCK. Building on the findings from this phase and insights from related literature, the second phase investigates how primary school teacher students utilize ChatGPT for lesson planning informed by PCK within the context of a university seminar. Findings from the first phase, based on qualitative content analysis, indicate that when ChatGPT is guided by PCK-informed layer prompts and supported by relevant reference texts, it generates more pedagogically appropriate lesson plan suggestions. Results from the second phase show that, after being introduced to PCK and prompt engineering strategies, primary school teacher students increasingly employed layer prompts, particularly Natural Language Instruction and Follow-up prompt types, and incorporated PCK components in more meaningful ways. Overall, the findings support the conceptualization of ChatGPT as a co-designer in science lesson planning, rather than as a substitute for teachers' pedagogical judgement.

Keywords: artificial intelligence, pre-service teacher education, instructional design

Introduction

Generative AI (GenAI) is widely recognized for its generative capabilities in producing human-like text (Chan & Colloton, 2024). In the field of education, GenAI tools such as ChatGPT show potential to support teachers in lesson planning and creating teaching materials (Calvo-Utrilla et al., 2025; Choi, 2025; Cooper, 2023; ElSayary, 2023; ElSayary et al., 2025). However, concerns about inaccuracies, biases, and ethical issues in its outputs (Avraamidou, 2024; Calvo-Utrilla et al., 2025) highlight the importance of critical evaluation and responsible use by educators (Blonder & Feldman-Maggor, 2024; UNESCO, 2023). Prompt engineering has emerged as an essential skill for educators to optimize GenAI outputs, forming a critical part of their Technological Pedagogical Content Knowledge (TPACK) in the age of AI (Blonder & Feldman-Maggor, 2024; UNESCO, 2023). For instance, effective strategies may include instructing GenAI to adopt a specific persona, using step-by-step layer prompts also referred to as chain of thought prompting, and supplying reference texts such as scientific papers to reduce inaccuracies and minimize fabricated responses (Atlas, 2023; Blonder & Feldman-Maggor, 2024; Knoth et al., 2024; Wei et al., 2023). Nevertheless, human oversight remains imperative to address these limitations (UNESCO, 2023).



Research on the use of GenAI in lesson planning demonstrates its ability to create lesson plans for specific science topics based on inquiry-based teaching approaches (Cooper, 2023; Großmann et al., 2025), with evidence showing that its output improves when guided by iterative prompts (Hashem et al., 2024; Peikos & Stavrou, 2025). From the teachers' perspective, GenAI tools such as ChatGPT are valuable for generating innovative ideas, enhancing lesson quality through engaging activities, supporting personalized learning, aligning lessons with real-life scenarios to boost student motivation and saving time. Nevertheless, both researchers and teachers emphasize that GenAI should serve as an assistant rather than a substitute for teachers. They also raise

concerns about the reliability of its outputs, such as potential weaknesses in content accuracy and in the provision of meaningful pedagogical suggestions (Cooper, 2023; ElSayary, 2023; ElSayary et al., 2025; Großmann et al., 2025; Uğraş et al., 2025).

Building on the above literature findings, it is evident that GenAI holds significant potential for assisting with lesson planning, although this potential is interwoven with limitations regarding the accuracy of information. Therefore, it is essential for teachers to critically evaluate GenAI outputs when using it to support lesson planning (UNESCO, 2023), drawing on PCK (Blonder et al., 2025; Feldman-Maggor et al., 2024; Großmann et al., 2025; Peikos & Stavrou, 2025) as a foundational knowledge base to enhance its responsible use.

PCK has been established as a core construct for understanding teaching effectiveness and informing teacher professional development. PCK is "the knowledge of, reasoning behind, and planning for teaching a particular topic in a particular way for a particular purpose to particular students for enhanced student outcomes" (Gess-Newsome, 2015, p. 36). Over more than four decades of PCK research following Shulman's seminal work (Shulman, 1986), several PCK models have been proposed, leading to the formulation of the Refined Consensus Model of PCK (Carlson et al., 2019). Across these models, key PCK components have been consistently identified, including knowledge of students' understanding, instructional strategies, curriculum, assessment, context, content knowledge, pedagogical knowledge, and orientations toward teaching science. These components are intrinsically interconnected in practice, and their integrated enactment constitutes the core of effective science teaching (Carlson et al., 2019; Chan & Hume, 2019; Gess-Newsome, 2015; Magnusson et al., 1999; Park & Oliver, 2008). The Refined Consensus Model (Carlson et al., 2019) conceptualizes PCK across three interrelated realms: collective PCK, referring to shared professional knowledge; personal PCK, representing the knowledge and skills teachers develop through experience; and enacted PCK, referring to the knowledge and skills drawn on when planning, teaching, and reflecting on instruction and student outcomes.

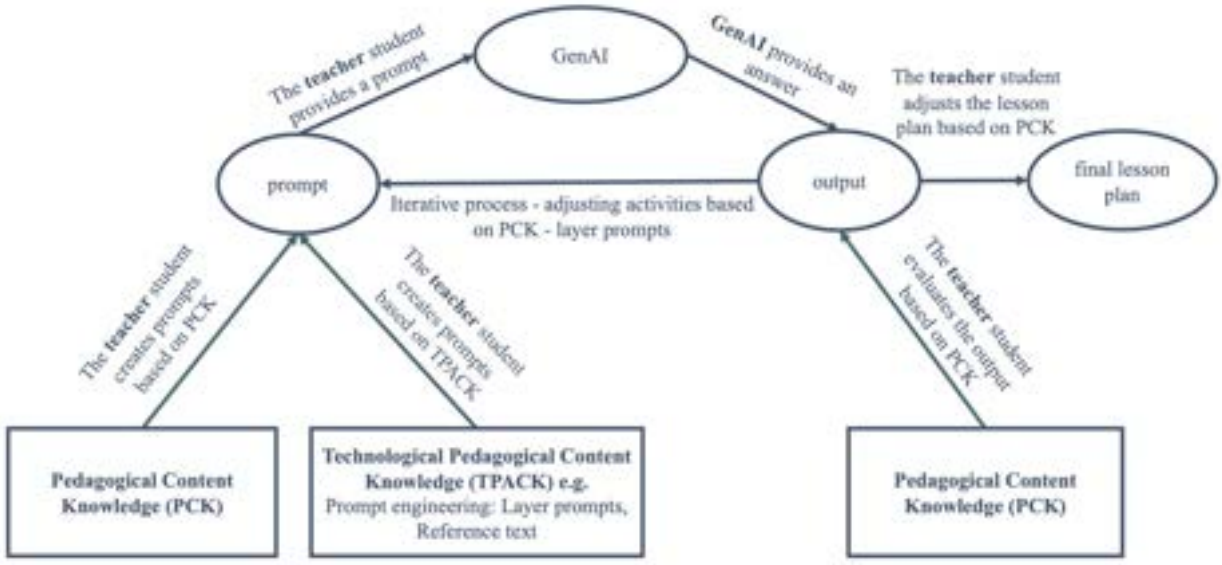
Figure 1. Venn diagram of PCK for science lesson planning, adapted from Otto and Everett (2013).

Focusing more closely on enacted PCK, particularly when teachers plan instruction (Carlson et al., 2019), Otto and Everett (2013) have developed an innovative teaching strategy for introducing PCK concepts to pre-service elementary teachers by utilizing a three-circle Venn diagram for

science lesson planning (Figure 1). The diagram featured overlapping circles representing Pedagogy (e.g., teaching strategies), Content (e.g., learning objectives), and Context (e.g., classroom environment), Pedagogy/Context (e.g., specific strategies to reach all students in the classroom), Pedagogy/Content (e.g., aligning appropriate teaching strategies with content), Content/Context (e.g., capturing students' conceptions of the topic) as well as the PCK overlap summarizing how these components fits together into an effective science lesson (Otto & Everett, 2013).

Lesson planning is a key component of teachers' professional competence, requiring the application of PCK to design and justify pedagogical decisions (Großmann & Krüger, 2024). In the era of GenAI, within the context of a teacher-AI co-design process for lesson planning (UNESCO, 2023), PCK is proposed as a valuable framework for crafting effective prompts and critically evaluating the pedagogical quality of GenAI outputs (Blonder & Feldman-Maggor, 2024; Peikos & Stavrou, 2025). To explore these opportunities and challenges, this research is structured in two phases. In the first phase, we investigate the use of ChatGPT in science lesson planning, with the goal of identifying the characteristics of ChatGPT-generated lesson plan suggestions through the lens of PCK. Building on the findings from the first phase and insights from related literature, in the second phase, we explore how primary school teacher students integrate ChatGPT into their lesson planning process within the framework of PCK. The research is guided by the following research questions (RQs):

- RQ1: What are the characteristics of lesson plan suggestions produced in ChatGPT's outputs during collaboration between researchers and ChatGPT, in terms of PCK?
- RQ2: How do primary school teacher students utilize ChatGPT for lesson planning, focusing on (a) the types of prompts they used and (b) the PCK components incorporated into the prompts?



Methods

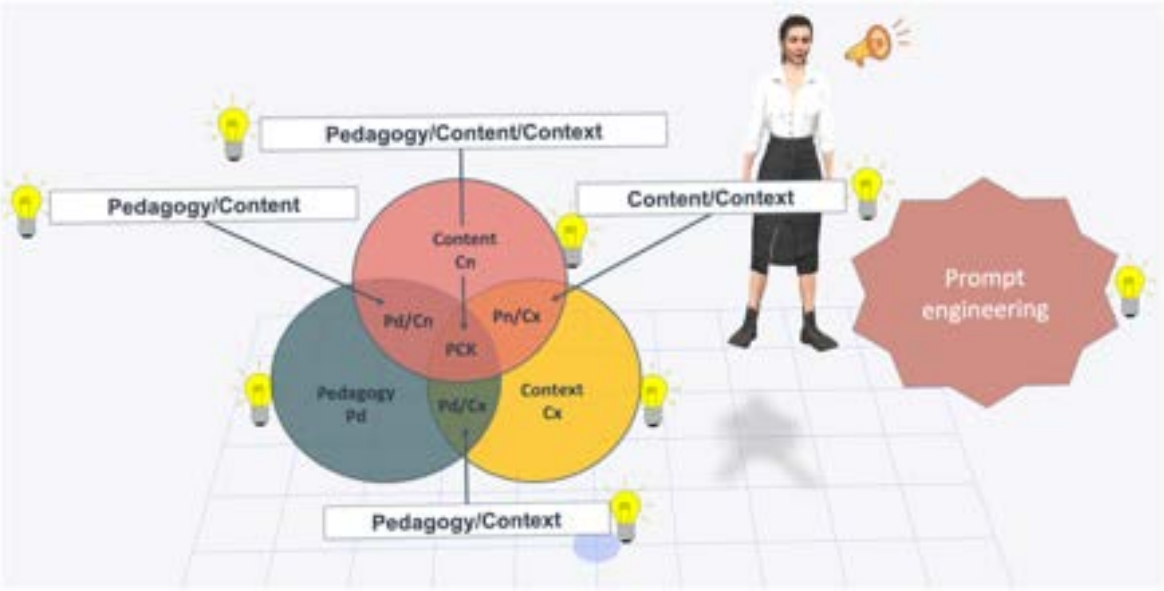
The Context

In the first phase, the researchers examined the use of ChatGPT for science lesson planning through the lens of PCK by using the tool themselves to design lesson plans. To this end, four interactions with ChatGPT were designed to generate lesson plans, each differing in prompt engineering strategies and PCK integration. ChatGPT was instructed to adopt the persona of an expert in science lesson planning for primary schools (Atlas, 2023; Chan & Colloton, 2024). The first interaction used a single prompt to create a lesson plan based on the 5Es instructional model for the topic of floating, sinking, and density, targeting 5th-grade primary school students. The second interaction introduced specific learning goals related to declarative and procedural knowledge. The third and fourth interactions employed layer prompts in a conversational manner to address several PCK aspects. For instance, ChatGPT was asked to describe activities to uncover students' misconceptions about floating and sinking (Content/Context overlap). The fourth interaction differed by providing a reference text i.e., an open-access scientific paper relevant to the topic. This phase resulted in the formulation of guidelines for the use of GenAI as a co-designer of lesson plans (Peikos & Stavrou, 2025) (Figure 2). Briefly, the guidelines indicate that teachers could initiate the process by formulating prompts that integrate components of PCK, including explicit learning goals, instructional strategies, and students' conceptions. Drawing on prompt engineering, a TPACK-related feature, they are encouraged to use layer prompts in a conversational manner, offering clear, step-by-step guidance that embeds PCK elements. In addition, ChatGPT is provided with relevant reference texts, such as scientific papers related to the instructional topic. The resulting output should be critically examined by the teacher through

the lens of their PCK and iteratively refined to address issues such as student misconceptions and grade-level appropriateness. Finally, teachers could select and adapt the proposed activities to their specific instructional context, leading to the development of the final lesson plan (Peikos & Stavrou, 2025).

Figure 2. Guidelines for student teacher–GenAI co-design of lesson plans based on PCK (adapted from Peikos & Stavrou 2025).

In the second phase, within the context of a semester-long university seminar, primary school teacher students were introduced to the use of GenAI for science lesson planning through the free web-based version of ChatGPT (GPT-4o). Based on the guidelines derived from the first phase, activities were designed to support the use of ChatGPT as a co-designer. The participants studied material related to the benefits and challenges of using ChatGPT, prompt engineering, and PCK. In addition, the researchers developed a pedagogical agent, Anna (Figure 3), within an augmented reality environment, which provided primary school teacher students with guidance during the development of lesson plans, particularly with respect to prompt engineering and the PCK diagram proposed by Otto and Everett (2013). For example, by selecting the Content/Context option (Figure 3), participants receive information, both in written and oral form, regarding the meaning of the Content/Context overlap, which focuses on the identification of students' ideas related to the Content, as well as on the elicitation of students' alternative ideas or prior knowledge. Moreover, they are provided with an example of a related prompt, such as: "Describe a structured activity aimed at eliciting students' alternative ideas about [insert the concept/phenomenon]".



Participants

The participants were 18 primary school teacher students in their third and fourth year of study, who attended most of the seminar sessions.

Data Collection And Analysis

For RQ1 (first phase), the data sources comprised texts produced through four interactions between the researchers and ChatGPT during the lesson planning process, with a focus on ChatGPT's outputs.

Figure 3. Augmented reality pedagogical agent Anna.

For RQ2 (second phase) qualitative data were collected through the discussions between primary school teacher students (working in teams of two) and ChatGPT during the lesson planning process. The focus was on the prompts formulated by the teacher students. Data were collected at three time points, as participants were engaged in the creation of three lesson plans: (a) before the introduction to GenAI and PCK, (b) after the introduction to GenAI and PCK, and (c) after the provision of feedback by the instructor on the primary school teacher students–AI co-design lesson planning process.

For RQ1 and RQ2b, the texts were analysed deductively in order to categorize coding units into predefined PCK components (Chaitidou et al., 2018; Otto & Everett, 2013; Peikos & Stavrou, 2025), namely Pedagogy, Content, Context, and their overlaps, with additional subcategories formed inductively from the data (Table 1).

Table 1. Data coding for RQ1 and RQ2b: PCK components, based on Chaitidou et al. (2018), Otto & Everett (2013) and Peikos & Stavrou (2025)

Category	Description	Examples of subcategories
Content	Learning objectives	Declarative knowledge, Procedural knowledge,
Context	Descriptions of class and school environment including resources and time constraints	Grade level, List of resources, Students' characteristics, Time constraints
Pedagogy	Main teaching strategy	5E format
Content/ Context	Capture students' conceptions of the topic	Activity to identify specific students' misconceptions, Activity to identify students' prior knowledge/ideas/common misconceptions
Pedagogy/ Context	Specific strategies to reach all students in the classroom	Activity to address common misconceptions, Activity to address a specific misconception
Pedagogy/	Alignment of appropriate	Activity aligned with specific learning objective,

Content	teaching strategy with content	Activity with specific teaching strategy for the content
PCK	Summary of how all segments fit together/proposed assessments	General assessment activity, Assessment activity based on specific characteristics

For RQ2a, concerning the types of prompts used by primary school teacher students, the texts were analysed deductively based on the prompt types proposed by Şimşek (2025), which distinguishes six types of prompts: (a) Natural Language Instruction (NLI), (b) Question (Q), (c) Follow-up (FU), (d) Extend (E), (e) Search Query (SQ), and (f) Emotive Feedback (EF), as well as combinations of these types such as Natural Language Instruction & Follow-up (Table 2).

Table 2. Data coding for RQ2a: Types of prompts (Şimşek, 2025, p. 11413).

Category	Definition
Natural Language Instruction (NLI)	A prompt formulated as an explicit instruction for a task in natural language.
Question (Q)	A prompt that begins with a question word and is formulated as a direct or indirect interrogative statement.
Follow-up (FU)	A prompt related to the response given by ChatGPT in the previous step.
Extend (E)	A prompt that encourages ChatGPT to extend or continue an input data example.
Search Query (SQ)	A prompt, such as a search query, typed into a search engine to access information.
Emotive Feedback (EF)	A prompt that provides no contribution to the task and offers positive or negative feedback to ChatGPT as if it were human.

Results

In the following paragraphs we present the preliminary findings of this study. Concerning RQ1 “How do lesson plans generated by ChatGPT reflect the components of PCK?” we found that, in relation to the overlap between Content/Context, ChatGPT demonstrated potential to create activities aimed at uncovering students’ prior knowledge and misconceptions. In the absence of detailed prompts, the model often provided generic activities. However, when guided by specific layer prompts, ChatGPT produced more structured and targeted strategies, such as concept mapping. Concerning Pedagogy/Context overlap layer prompts enhanced ChatGPT’s ability to propose strategies for addressing student misconceptions and accommodating learning diversity. In early interactions, the model’s outputs lacked targeted activities to address specific misconceptions. However, after providing related prompts, ChatGPT began generating inquiry-based tasks designed to challenge common misconceptions, such as the belief that “heavier objects always sink”. Furthermore, regarding the Pedagogy/Content overlap in its initial responses, ChatGPT frequently suggested both qualitative and quantitative approaches to

teaching the concepts of floating and sinking. However, when considering the Context, i.e., the grade level of primary school students, literature suggests that qualitative approaches, such as visual representations, are more appropriate than quantitative approaches, such as the formula d=m/v (Zoupidis et al., 2021). With the use of layer prompts and the provision of reference text, ChatGPT's outputs in the fourth interaction became more aligned with students' grade, emphasizing qualitative instructional approaches. A detailed presentation of the results related to RQ1 is provided in Peikos and Stavrou (2025).

Regarding RQ2a, which focuses on the types of prompts used by primary school teacher students, a noticeable shift was observed during the second and third lesson planning processes. In particular, prompts identified as Natural Language Instruction became more prevalent. This suggests that, once introduced to GenAI, primary school teacher students increasingly framed their interaction with ChatGPT through explicit task-oriented instructions expressed in natural language. For example, one team formulated the following prompt:

> Take the role of an expert in science education for the 5th grade science lesson. Help me create a one-hour lesson plan using simple everyday materials, to teach the phenomenon of floating and sinking by explaining it through density, according to the 5E instructional model…

Similarly, Natural Language Instruction combined with Follow-up was observed more frequently during the second and third lesson planning processes. This category refers to prompts formulated as explicit instructions in natural language that build directly on the response provided by ChatGPT in a previous step. For instance, a team of students wrote:

> For the activity in the engagement phase, according to what we said above, I would like it to be in the form of a short story that narrates a problem related to the phenomenon of sinking and floating, so that students' alternative ideas can become evident based on the solutions they will give. Make it in the form of a worksheet that will include an image showing the problem of the story.

Regarding RQ2b "How do primary school teacher students utilize ChatGPT for lesson planning, focusing on the PCK components incorporated into the prompts?" notable changes were observed in the Content category. In the first lesson planning process, teacher students' prompts that explicitly referred to specific learning objectives were limited. Most prompts either addressed the topic in general terms or asked ChatGPT to define the learning goals. For example, a team of students submitted the following prompt to ChatGPT:

> [Create a teaching scenario for the subject of Physics. It is intended for 5th grade primary school students. The topic is floating-sinking and density.] Write the objectives in detail.

In contrast, during the second and third lesson planning processes, teacher students clearly incorporated specific learning objectives into their prompts. These objectives were connected to both declarative and procedural knowledge, indicating a more explicit integration of Content. For instance, a team of students submitted the following prompt to ChatGPT:

> […Help me create a lesson plan on density and its relationship to floating and sinking for 5th-grade students, based on the 5E instructional model ...] The learning objectives are: (a) for students to understand the rule governing whether an object floats or sinks based on its density; (b) for students to state that density is a characteristic property of a material; and (c) for students to be able to apply strategies for controlling variables…

Examining more closely the overlaps among the PCK components, notable patterns were identified. With regard to the Pedagogy/Context overlap, most primary school teacher students'

prompts in the second and third lesson planning processes asked ChatGPT to propose resources to support the planned activities. These resources included, indicatively, videos, simulations, models, illustrations, storytelling, and worksheets. For example, one team of primary school teacher students wrote:

> Propose the use of supportive educational materials such as simulations and models that contribute to the understanding of the concept of heat transfer by conduction in metals.

In addition, during the second and third lesson planning processes, primary school teacher students more frequently asked, through their prompts, for activities that would connect to students' experiences, foster collaboration, and elicit students' interest. Regarding the Content/Context overlap, prompts explicitly related to students' prior knowledge and misconceptions were very limited in the first lesson planning process. In contrast, during the second and third lesson planning processes, primary school teacher students asked ChatGPT to develop activities explicitly aimed at identifying students' prior knowledge and misconceptions. For example, a team of students wrote:

> In the Exploration phase, propose one or more hands-on activities during which students will express their initial conceptions and reveal their misconceptions, focusing on the misconception that the temperature of water rises above 100 degrees Celsius while it is boiling.

Conclusion

In the first phase, the study examined the use of ChatGPT for science lesson planning through the lens of PCK by engaging the tool in a series of lesson planning interactions conducted by the researchers. These interactions varied in both prompt engineering strategies and levels of PCK integration. The findings demonstrate that incorporating PCK elements into prompts, using layer prompts, and providing ChatGPT with reference texts related to the instructional topic may enhance the integration of PCK components in GenAI-generated outputs related to the lesson plans. In this phase, the PCK framework appeared meaningful for supporting responsible interactions with ChatGPT in the context of teacher and GenAI lesson co-design. It provided a coherent knowledge base for both crafting pedagogically informed prompts and critically evaluating ChatGPT's responses in relation to science lesson planning (Peikos & Stavrou, 2025).

Building on these insights, the second phase examined how primary school teacher students utilized ChatGPT for science lesson planning within the context of a university seminar, following their introduction to prompt engineering strategies and the PCK framework. The findings indicate that the students were able to formulate prompts grounded in their PCK, with particular emphasis on overlaps such as Pedagogy/Context, as well as Content/Context. In parallel, they engaged with aspects of TPACK, particularly in relation to prompt engineering. Rather than limiting their interaction to ChatGPT's initial responses, the students engaged in an iterative prompting process guided by their PCK, progressively refining the generated outputs. Through the use of layer prompts, mainly in the form of Natural Language Instruction and Follow-up prompt types, they adapted the proposed activities to better align with pedagogical goals and classroom context.

Grounded in the Refined Consensus Model of PCK (Carlson et al., 2019), the findings indicate that teachers' engagement with GenAI tools for lesson planning, as an activity situated within enacted PCK realm, involves the design, reflection, and justification of lesson plans drawing primarily on their personal PCK, while also being shaped by collective PCK and the particularities of the learning context. Within this process, research-based literature on the

teaching and learning of specific science concepts, as an aspect of collective PCK, may be provided to GenAI tools as reference material, thereby informing lesson plan suggestions and potentially reducing inaccuracies. In parallel, responsibility for critically evaluating GenAI-generated outputs remains with the teacher. Drawing on their personal PCK, teachers are required to evaluate the pedagogical soundness of proposed activities, the accuracy of the scientific content, and their suitability for the specific classroom context. Taken together, these findings support the view that GenAI should be conceptualized as a co-designer in the lesson planning process, rather than as the primary designer of instructional plans.

The results underscore the importance of preparing teachers to engage with GenAI through a strong grounding in PCK, combined with prompt engineering skills. Teacher education and professional development programmes should therefore explicitly address this interplay, as it may support more responsible and pedagogically informed integration of GenAI into science lesson planning. Moreover, GenAI can be positioned not merely as a time-saving assistant, but as a tool for supporting teachers' reflection on their own PCK (Blonder et al., 2025). When used in a critical way and potentially supported by pedagogical agents that scaffold interaction between teachers and GenAI, such engagement may help raise teacher teachers' awareness of their pedagogical reasoning and instructional decision-making in science lesson planning.

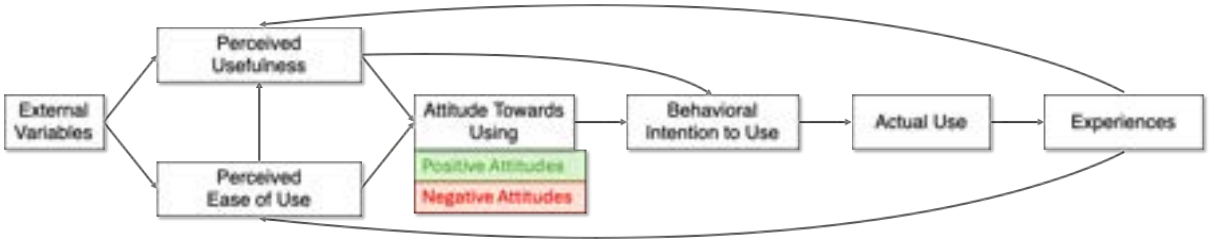
ESERA 2025 Copenhagen

Artificial Intelligence In Teacher Education: Attitudes, Usage, And The Road To AI Literacy

Wolfgang Lutz, Jens Damköhler and Thomas Trefzger
Julius-Maximilians-Universität Würzburg, Germany

The rapid development of artificial intelligence is also having an impact on the education sector and placing new demands on the professionalisation of future teachers. This study examines the extent to which teacher trainees use generative AI in their studies and how they assess their attitudes and skills with regard to this technology. To this end, two cross-sectional surveys were conducted via online questionnaire in April 2024 (n = 221) and April 2025 (n = 204). The results show a significant increase in AI use between 2024 and 2025, especially in the study-related use outside of lectures, while its use in courses remains comparatively low despite the increase. It also shows that higher use is associated with an increase in positive and a decrease in negative attitudes. There is also a positive correlation between usage rates and subjectively perceived AI literacy, AI self-efficacy and AI self-competence. In 2025, positive attitudes and all recorded perceptions of competence increase significantly, while negative attitudes remain largely stable as compared to 2024.

Keywords: AI usage, AI attitudes, AI literacy



Introduction And Theoretical Background

The advancing digitalisation of schools is expanding the possibilities for the didactic and methodological design of lessons. To exploit this potential, it does not suffice to simply replace analogue media with digital media. Rather, teaching and learning processes must be transformed (Puentedura, 2006). These changes keep presenting teachers with new challenges (Eickelmann, 2018; Scheiter, 2017). It is thus not only important to master digital technologies but above all to use them in a didactically reflective manner. The introduction of ChatGPT at the end of 2022 marked the beginning of a rapid and ongoing development of artificial intelligence (AI), which has also triggered changes in the field of education. In this context, current and future teachers bear a great responsibility (Europäische Kommission, 2022) as they are expected to systematically integrate teaching and learning with and about AI into their subject teaching and prepare their students to use this technology competently (Huwer et al., 2024). In a rapidly evolving digital world, the continuous training and further education of teachers appears to keep gaining importance. Teacher trainees are the prospective teachers who must take on these tasks in future. Even though as digital natives they are considered to be tech-savvy, research paints a more differentiated picture: During their studies, teacher trainees often gain too little practical experience with digital technologies (Eickelmann et al., 2019), show competence deficits in the area of digitalisation compared to students of other disciplines (Senkbeil et al., 2020), and rate their digital competences as only mediocre (Drossel & Eickelmann, 2018). The discrepancy between digital requirements and insufficient experience in teacher training programmes highlights an urgent need for action.

Therefore, it seems important that teacher trainees are willing to engage with AI in order to develop AI competences (Huwer et al., 2024). In the Technology Acceptance Model (Figure 1), two factors influencing a person's attitudes and thus their acceptance of a technology can be identified: perceived usefulness and perceived ease of use. These two factors result in positive and negative attitudes which shape a person’s overall attitude. A positive attitude promotes the intention to use the technology, whereas a negative attitude reduces the intention to use. In

addition, the intention to use a technology can also be influenced independently of a person's individual attitudes. This is the case, for example, when the added value or efficiency gains offered by the technology are obvious. The intention to use ultimately determines the actual use of a technology. Through every use of a technology, a personal automatically gains experience which is why this component may be added to the Technology Acceptance Model. The successful application of a technology can also increase its perceived usefulness and have a positive effect on attitudes, as, for example, experienced users recognise more possible applications for a technology and find it more intuitive to use due to their familiarity with it.

Figure 1. Technology acceptance model enhanced by experiences (according to Davis, 1986).

Research Questions And Hypothesis

This article focuses on the use of generative AI in teacher training programmes and the attitudes and perceived competence of students. It also examines changes between 2024 and 2025. The following research questions and hypotheses specify this research interest.

Q1: To what extent do teacher trainees use AI?

New technologies, such as AI, can often only be used in university courses after a delay, especially when licences must first be purchased and data protection issues clarified. Furthermore, the use of AI in higher education has so far been described mainly through isolated best practice examples, while systematic evaluations of teaching concepts are still pending (Huwer et al., 2024). While universities must first clarify formal and legal criteria, students can immediately access free offers and use AI for interactive and adaptive learning, for example, or as a personal learning coach (Baidoo-Anu & Owusu Ansah, 2023; Baig & Yadegaridehkordi, 2024; von Garrel & Mayer, 2025). According to the TAM model (Davis, 1986), the perceived usefulness and low-threshold accessibility of AI tools increases the likelihood of use. This leads to the following hypothesis:

H1.1: Teacher trainees' out-of-courses use of AI tools is higher than their use in courses.

Q2: To what extent are teacher trainees' attitudes and perceived AI competence influenced by their AI use?

Surveys on the use of generative AI show that a large number of students already use this technology for their studies (Gottschling et al., 2024; Lutz et al., 2025; von Garrel & Mayer, 2025). Based on the extended TAM model (Figure 1), it can be assumed that positive attitudes promote the intention to use a technology and thus the actual use, while negative attitudes tend to inhibit both. At the same time, every experience with a technology contributes to a change in perceived usefulness and perceived ease of use, which in turn affects a person's attitudes. While successful applications have a positive effect, unsuccessful application can have a negative impact. In addition, little or no experience with a technology can be associated with increased uncertainty and fear, which inhibits technology acceptance (Dönmez-Turan & Kır, 2019). This leads to following hypothesis:

H2.1: Students with greater AI use rate the chances of AI more positive and the risks less negative.

Competences are not built by the acquisition of cognitive skills and abilities alone, but also by their successful and responsible application in various situations (Weinert, 2001). Competent AI use thus requires active use of the technology. Practical experience also helps to familiarise oneself with the possibilities and limitations of generative AI. This allows the technology to be used in a more targeted, effective, and reflective manner. As a result, the successful application of AI tools becomes more likely. In the study by Süße & Kobert (2023) high correlation effects between the use of generative AI and perceived learning success were found among some students. According to Bandura (1997), perceived successes strengthen one's self-efficacy and thus confidence in one's competence, even in challenging situations. This leads to following hypothesis:

H2.2: Students with a higher usage behaviour rate their AI competences, their AI self-efficacy, and their AI self-competency higher.

Q3: How did usage behaviour, attitudes, and perceived AI skills change between 2024 and 2025?

Generative AI is subject to particularly dynamic technological development, which is accompanied by continuous improvement and increased performance. The further development of new language models means that the up-to-then most recent versions are made available free of charge as previous versions. That way, increasingly better versions are made available free of charge. For students, this means that AI tools with a growing range of functions can be integrated into everyday student life without financial barriers. Better and more powerful systems increase the perceived usefulness, which, according to the TAM model (Davis, 1986), leads to a more positive attitude and more frequent use of the technology. Based on a total of 49 study results on the usage behaviour of generative AI among students, Von Garrel & Mayer (2025) performed a regression analysis that shows an increase in usage behaviour from 2023 to early 2025. Thus, the following hypotheses arise:

H3.1: In 2025, teacher trainees' study-related use of AI is higher than in 2024.

H3.2: In 2025, teacher trainees associate fewer risks and more chances with the study-related use of AI tools than in 2024.

H3.3: In 2025, teacher trainees rate their AI competence, AI self-efficacy, and AI self-competency higher than in 2024.

Study description

Study Design

This study aims to record the usage behaviour, attitudes, and subjectively perceived skills of teacher trainees with regard to generative AI. To this end, cross-sectional surveys were conducted in April 2024 and April 2025 using an online questionnaire. Participation in the surveys was voluntary, and data collection was pseudonymised by creating an acronym from personal queries. This code shows that the overlap between students who participated in both surveys is less than 1 percent. A longitudinal analysis of the data therefore does not appear to be meaningful, so the data collected in 2024 and 2025 are considered statistically independent in the analysis.

Sample

Table 1 provides an overview of the teacher trainees participating in the surveys in 2024 and 2025. The sample sizes of both studies are comparable with n = 221 (2024) and n = 204 (2025). The gender distribution is similar in both years, with a significantly higher proportion of female students There were only a few participants in both surveys who stated that they were non-binary. In Germany, teacher training is organised according to school type and comprises five types of

school, each of which has its own degree programme. The percentage distribution of students across the school types roughly corresponds to the number of students enrolled in each school type. The imbalance is therefore not due to the survey design. In both surveys, most students were in their third to sixth semester. Plausible explanations for this are that the standard time to degree vary between seven and nine semesters depending on the type of school and that the surveys were conducted by lecturers as part of didactic courses. These are typically attended by students in the middle of their studies.

Table 1. Sample composition.

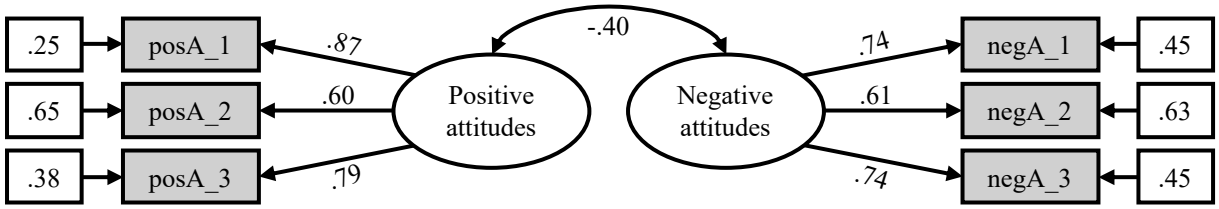
	2.3%	1.4%	1.4%			3.2%	0.5%	0%		

Operationalisation And Test Instruments

The use of generative AI was assessed using two single-item measures, one relating to courses ("Was artificial intelligence used as a tool to support the learning process in courses you attended in previous semesters?") and the other relating to individual study-related out-of-course use ("Do you use AI tools in your studies?"). Both items were rated on a four-point frequency scale (never = 0, rarely = 1, occasionally = 2, regularly = 3).

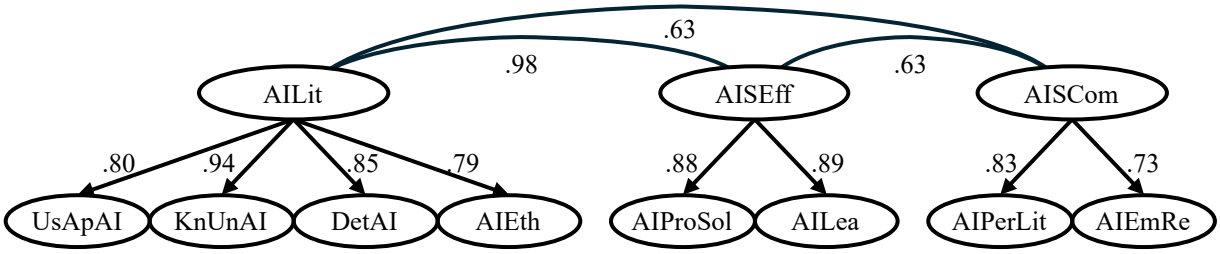
To assess teacher trainees' attitudes towards generative AI, the General Attitudes towards Artificial Intelligence Scale (GAAIS, Schepman & Rodway, 2023) was adapted. The original scale comprises a total of twelve items on positive attitudes and eight items on negative attitudes, each rated on a five-point Likert scale (strongly disagree = 0, disagree = 1, neutral = 2, agree = 3, strongly agree = 4). For the present study, three positive items (e.g., "I am interested in using artificially intelligent systems in my daily life") and three negative items (e.g., "I think artificial intelligence is dangerous") were selected. The reliabilities are in an acceptable to good range, with $\alpha = 0.76$ (positive attitude) and $\alpha = 0.74$ (negative attitude).



The subjectively perceived AI literacy (AILit), AI self-efficacy (AISEff) and AI self-competency (AISCom) of the teacher trainees were assessed using the Meta AI literacy scale (MAILS, Carolus et al., 2023). The 30 items are each rated on an eleven-point rating scale (not at all pronounced 0 – 10 very well pronounced). The scale is multidimensional. The AILit factor is composed of the factors use & apply AI (UsApAI, 6 items, $\alpha = 0.96$), know & understand AI (KnUnAI, 6 items, $\alpha = 0.88$), detect AI (DetAI, 3 items, $\alpha = 0.84$) and AI ethics (AIEth, 3 items, $\alpha = 0.87$). The factor AISEff is formed from the subcategories AI problem solving (3 items, $\alpha = 0.90$) and AI learning (3 items, $\alpha = 0.88$). The AISCom factor is composed of AI persuasion literacy (3 items, $\alpha = 0.73$) and AI emotion regulation (3 items, $\alpha = 0.83$). The reliabilities for each construct are in the acceptable to very good range.

Modelling

According to the multi-component model of attitude (Zanna & Rempel, 2008), a person's attitude is derived from the overall evaluation of cognitive, affective, and behavioural information. Attitudes can be ambivalent, i.e. both positive and negative (Haddock & Maio, 2014). For example, on a cognitive level, a person may perceive a technology as useful and yet at the same



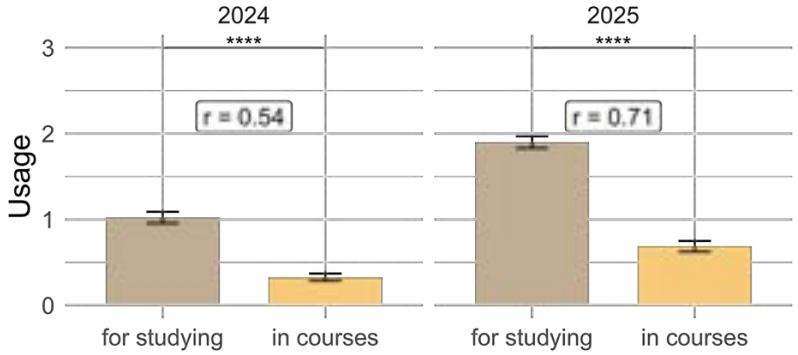
time recognise risks in its use (e.g. data protection). On an affective level, both positive emotions (e.g. joy) and negative emotions (e.g. frustration) can arise when the use of a technology leads to successes but also failures. On a behavioural level, a person may consciously reject the use of a technology in certain situations (e.g. sensitive data) despite an overall high willingness to use it. Against this background, the positive and negative attitudes of teacher trainees were modelled as two separate and mutually influencing factors using confirmatory factor analysis (see Figure 2). Both the fit indices (CFI = 0.998, RMSEA = 0.020, SRMR = 0.025) and the non-significant chi-square test ($\chi^2(8) = 9.325$, p=.316) indicate a very good fit of the model (Hu & Bentler, 1999; MacCallum et al., 1996).

Figure 2. Latent measurement model of positive and negative attitudes.

Based on the multidimensional approach of Carolus et al. (2023), the constructs AILit, AISEff, and AISCom were specified as latent variables using confirmatory factor analysis (Figure 3). Although the chi-square test is significant (χ^2 (381) = 781.309, p<.001), which is often observed in larger samples and complex models, the fit indices (CFI = 0.953, RMSEA = 0.048, SRMR = 0.053) indicate a good model fit (Hu & Bentler, 1999; MacCallum et al., 1996).

Figure 3. Latent measurement model for AILit, AISEff, and AISCom.

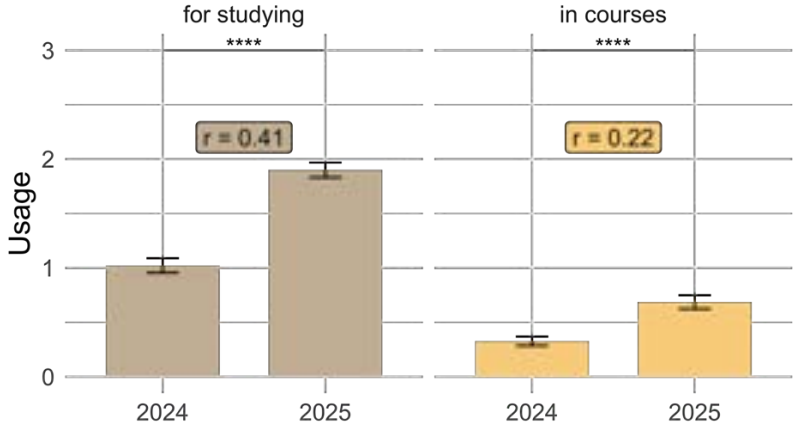
Results



In 2024, the majority of students (74.5%) stated that generative AI is never used in courses. Only a small proportion of respondents answered that they rarely (19.1%), occasionally (5.5%), or regularly (0.9%) used AI. However, the frequency of use increased in 2025. More students stated that AI tools are used rarely (23.9%), occasionally (16.4%), or even regularly (4.0%) in courses. Nonetheless, the majority of respondents still stated that AI is never used in courses (55.7%).

The frequency of study-related out-of-class AI use has also increased. In 2024, most students stated that they never (40.5%) or rarely (23.6%) used AI for study-related matters. However, a significant number of students used AI tools occasionally (29.1%) or even regularly (6.8%). In 2025, only 10.0% of students said that they never used AI tools for their studies. Most respondents indicated they used AI rarely (23.4%), occasionally (33.3%), or even regularly (33.3%) for their studies.

Paired Wilcoxon tests were used to examine the extent to which teacher trainees rated the frequency of use of generative AI for their studies and in courses differently (Figure 4). The students indicated that they used generative AI more frequently outside of class for their studies (2024: $\mu = 1.02$, SE = 0.067, Mdn = 1 | 2025: $\mu = 1.90$, SE = 0.069, Mdn = 2) than in courses (2024: $\mu = 0.33$, SE = 0.042, Mdn = 0 | 2025: $\mu = 0.69$, SE = 0.063, Mdn = 0). According to the



Wilcoxon rank sum test, this difference is significant in both surveys, with a large effect size in each case (2024: V = 7196, p < .001, r = .54 | 2025: V = 11753, p < .001, r = 0.71).

Figure 4. Comparison of frequency of out-of-course use and use in courses.

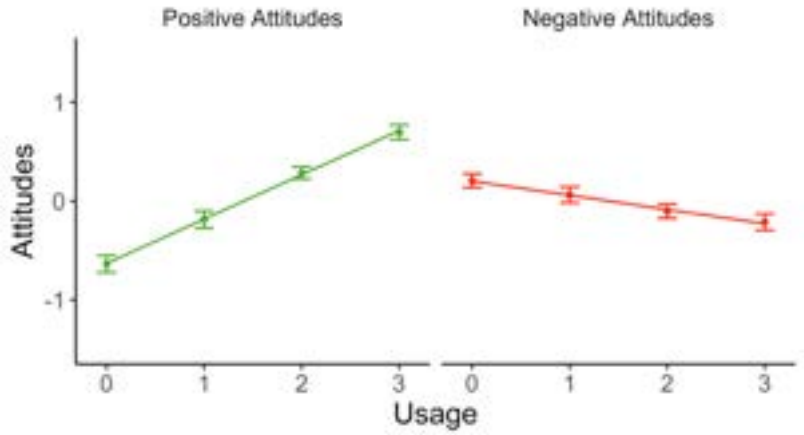
To analyse the changes in frequency of use, unpaired Wilcoxon rank sum tests were calculated based on statistically independent samples. It can be seen that both the study-related out-of-course use of AI (V = 12096, p < .001, r = 0.41) and in courses (V = 17408, p < .001, r = 0.22) increased significantly over time with a medium or small effect size (Figure 5).

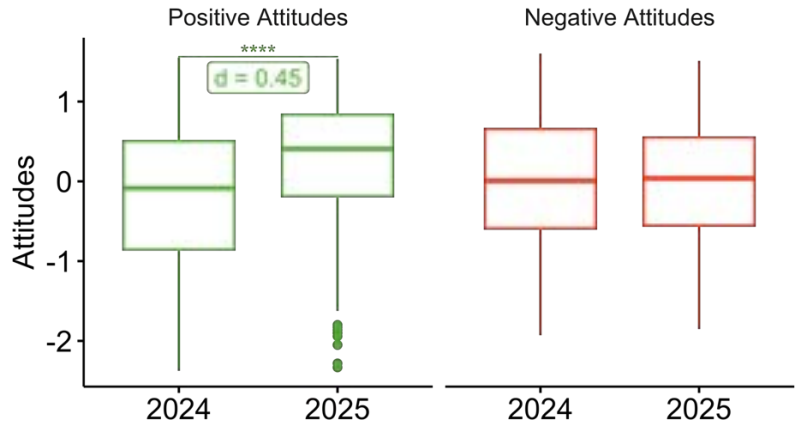
Figure 5. Comparison of the frequency of generative AI use in 2024 and 2025.

To examine the relationship between attitudes and the frequency of use reported by students (Figure 6), linear regressions were calculated based on data from both surveys. There is a significant correlation between positive attitudes and frequency of use (b = 0.45, SE = 0.04, t = 12.58, p < .001), i.e. students who report higher usage tend to have more positive attitudes. Frequency of use explains 27% of the variance in positive attitudes ($R^2 = 0.27$). Negative attitudes also show a significant correlation with frequency of use (b = -0.14, SE = 0.03, t = -4.08, p < .001), i.e. students with higher usage rates have fewer negative attitudes towards the technology. However, the explained variance is significantly lower at $R^2 = 0.04$ compared to positive attitudes.

A multivariate analysis of variance was calculated to compare the attitudes of students in 2024 and 2025 (Figure 7). The attitudes differ significantly with a medium effect size ($\Lambda = .94$, $F(2 , 418) = 13.95$, $p < .001$, $\eta^2 = 0.06$). In the follow-up tests, t-tests with Bonferroni correction were calculated for the positive and negative attitudes. The positive attitudes of the students grew significantly from 2024 ($\mu = -0.177$, SE = 0.061) to 2025 ($\mu = 0.225$, SE = 0.063) with a small to medium effect size (t(419) = -4.57, p < .001, d = -0.45). The negative attitudes towards AI among students did not change significantly between 2024 ($\mu = -0.009$, SE = 0.056) and 2025 ($\mu = -0.002$, SE = 0.053) (t(419) = -0.09, p = .93, d < -0.01).

Figure 6. Mean values of attitudes with standard errors in relation to the frequency of use.





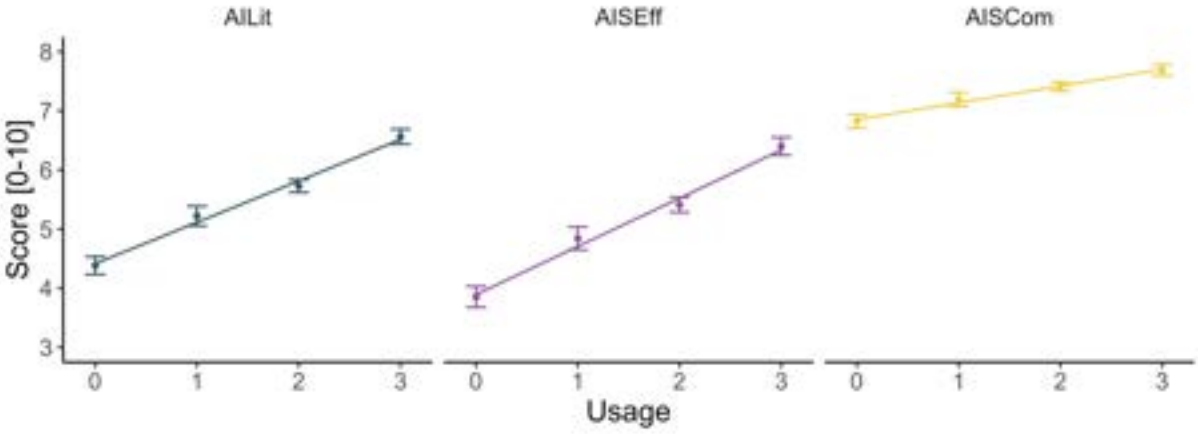


Figure 7. Comparison of attitudes towards generative AI in 2024 and 2025.

As with the attitudes, the correlations between frequency of use and AI literacy, AI self-efficacy and AI self-competence (Figure 8) were examined using linear regression analyses. All data from the surveys were used for this purpose. All factors showed a significant correlation with frequency of use (AILit: $b = 0.70$, $SE = 0.06$, $t = 10.86$, $p < .001$ | AISEff: $b = 0.81$, $SE = 0.08$, $t = 10.77$, $p < .001$ | AISCom: $b = 0.28$, $SE = 0.05$, $t = 5.92$, $p < .001$). The variance explained by usage behaviour is $R^2 = 0.22$ (AILit), $R^2 = 0.21$ (AISEff), and $R^2 = 0.08$ (AISCom).

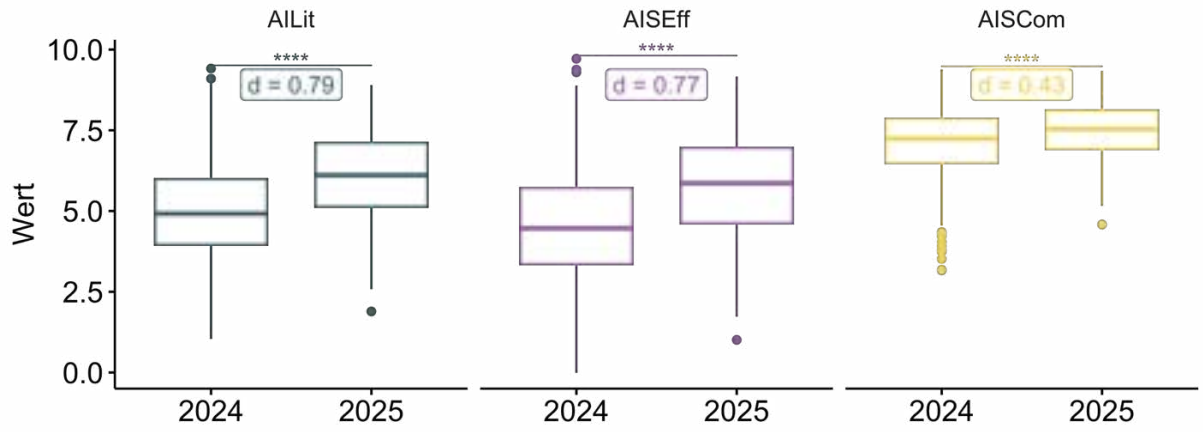

Figure 8. Correlation between the perceived AI competences and the frequency of use.

In a final study, the students' perceived competence in 2024 and 2025 (Figure 9) was compared. For this purpose, a multivariate analysis of variance with Pillai's Trace was calculated, as the significant results of the Levene tests (AILit: $F(1, 419) = 6.63$, $p = .01$ | SCom: $F(1, 419) = 8.43$, $p < 0.01$ | SEff: $F(1, 419) = 6.35$, $p = .01$), showed no variance homogeneity between the groups.

The analysis shows that the students' perceptions of competence differ significantly between years with a large effect size ($V = 0.15$, $F(3, 417) = 24.52$, $p < .001$, $\eta_p^2 = 0.15$). Welch's tests with Bonferroni correction were performed for each variable to analyse this effect in more detail. A comparison of the students' AI literacy ratings reveals a significant difference between the years 2024 ($\mu = 4.86$, $SE = 0.11$) and 2025 ($\mu = 6.04$, $SE = 0.09$) with a medium to large effect size ($t(410) = -8.14$, $p < .001$, $d = 0.79$). A similar picture emerges when comparing the AI self-efficacy ratings, which were lower on average in 2024 ($\mu = 4.42$, $SE = 0.13$) than in 2025 ($\mu = 5.77$, $SE = 0.11$). This difference is significant with a medium to large effect size ($t(412) = -7.97$, $p < .001$, $d = 0.77$). The AI self-competence rating also increased significantly from 2024 ($\mu = 7.04$, $SE = 0.08$) to 2025 ($\mu = 7.50$, $SE = 0.06$) with a small to medium effect size ($t(399) = -4.42$, $p < .001$, $d = 0.43$).

Figure 9. Comparison of perceived AI competences in 2024 and 2025.

Discussion

The results of this study show that the use of generative AI in teacher training has increased and that the majority of students now use this technology occasionally or regularly for their studies. Even though the use of AI tools in courses has increased significantly, this technology is still not used in most courses. The results of the study show that generative AI is used significantly more often outside of courses than within courses. Thus, hypotheses H1.1 and H3.1 can be confirmed.

In the context of this study, increased use of generative AI is associated with more positive attitudes and fewer negative attitudes. Hypothesis H2.1 can thus be confirmed. However, it is striking that the correlation between use and positive attitudes is significantly stronger than the correlation between use and negative attitudes. This suggests that experiences primarily contribute to the perception of potential, while concerns and perceptions of risk only decrease slightly. This effect is also evident when comparing the attitudes of students in 2024 and 2025. With increased usage in 2025, there is also an increase in positive attitudes among students, while negative attitudes remain unchanged. Hypothesis H3.2 can therefore only be accepted to a limited extent for positive attitudes.

There is a positive correlation between frequency of use and the level of AI literacy, AI self-efficacy, and AI self-competence. Hypothesis H2.2 can therefore be confirmed. Students' experience with generative AI leads to greater confidence in their own abilities and the perception that they can use AI in a targeted manner. However, it should be noted that this study deals with subjectively perceived competencies. Frequent use can therefore also lead to a misjudgement of competence, especially if students accept the information generated by AI without systematic verification. This is particularly relevant in the case of generative AI, because the technology produces outputs that are written in a convincing manner but often incorrect in terms of content.

It therefore remains unclear to what extent the increased perceptions of competence are actually accompanied by objective gains in competence. A comparison of students' perceptions of competence between 2024 and 2025 also shows a significant increase in the perception of competence in all categories considered; hypothesis H3.3 can thus be accepted.

Limitations Of The Study

Despite the meaningful results, some limitations must be taken into account. For example, the frequency of use is recording through single-item measurements, which limits the objectivity and differentiation of the measurement. Furthermore, the data is cross-sectional, which reflects differences between the survey dates in 2024 and 2025, but does not allow conclusions to be drawn about individual changes. Finally, the measurement of skills was based exclusively on self-assessments and not on skills tests. The extent to which experience with generative AI influences actual skills development cannot be answered within the scope of this study.

Conclusion

Overall, the results of this study show that the use of generative AI in teacher training has increased significantly within a short period of time. While students are developing more positive attitudes towards the technology and rate their AI literacy, AI self-efficacy, and AI self-competence higher, negative attitudes remain unchanged. In addition, the use of generative AI in courses has been limited so far, with students primarily using AI outside of institutional learning settings. On the one hand, this indicates an increasing normalisation of generative AI in everyday student life, but on the other hand, it also shows that this development has so far been largely self-organised and less supported by universities in a targeted manner. Thus, it becomes clear that although increasing use is an important foundation, it does not automatically lead to pedagogically and didactically reflective application in later careers. In order for teacher trainees to be prepared for the use of generative AI in a school context, more than just user experience is needed. They must develop the skills to use AI responsibly, didactically, and reflectively. At this point, the university has a central responsibility to prepare future teachers for this task. The work of (Damköhler et al., 2024a, 2024b, 2025) or Herz et al. (2025) shows how generative AI can be successfully implemented in teaching.

Augmented Reality For Chemistry Education: Visualizing The Invisible In The Nitrogen Biogeochemical Cycle – A Pilot Study

Luka Ribič, Luka Vinko and Iztok Devetak

University of Ljubljana, Faculty of Education, Ljubljana, Slovenia

Chemistry is a subject that students usually find very complex, also due to the triple nature of chemical concepts. Learners have to bridge, in their working memories, different levels of chemical phenomena explanations in order to adequately understand them. These learning processes can cause difficulties. One way to address these difficulties is through the use of technology. Virtual learning environments, such as augmented reality (AR) can provide important information, enable connections between observable (macroscopic) and unobservable (submicroscopic) processes and thereby might contribute to a better understanding of chemistry. The aim of this pilot study was to gain insight into pre-service primary school teachers' attitudes toward the use of AR technology in the context of environmental chemistry and sustainable development as well as their perceptions of the usability of the AR application. 10 participants completed the Technology Acceptance Model questionnaire and the System Usability Scale. The results showed that the pre-service teachers had positive attitudes toward AR technology, perceived the AR application easy to use, and expressed willingness to participate in additional courses that integrate AR into chemistry teaching and learning. These findings primarily indicate the feasibility and acceptance of AR supported laboratory activities in environmental chemistry. The results provide a foundation for further research examining the effects of AR on conceptual understanding, particularly in relation to supporting connections between macroscopic, submicroscopic and symbolic representations of chemical phenomena.

Keywords: augmented reality, environmental chemistry, pre-service teachers

Introduction

In science education, assessing students' conceptual understanding is essential for enhancing learning outcomes (Halloun & Hestenes, 1985). It is well known that students experience difficulties in constructing and understanding of chemical concepts (Johnstone, 1991). Previous research (Horvat et al., 2023; Tan et al., 2020) has highlighted the importance of conceptual understanding in science education. Therefore, it is crucial for learners to develop deep comprehension of scientific ideas, rather than merely memorizing facts. The learning difficulties students face in different science subjects should be taken into account when planning instructional approaches (Taber, 2008). To identify these difficulties and address them effectively, an understanding of both the discipline and the philosophy of chemistry is required (Kaya & Erduran, 2013). Consequently, chemistry educators need to be familiar with the nature of chemical phenomena, not only with the chemistry content they teach (Erduran, 2007). However, previous studies (Allen et al., 2024; Pavlin et al., 2009; Syahrial et al., 2023) have shown that primary school and chemistry teachers often hold misconceptions about various chemistry topics. These findings suggest that pre-service teachers in particular possess significant gaps in their conceptual chemistry content (Allen et al., 2024).

The major source of complexity in chemistry lies in the nature of chemical concepts, which often extend beyond human senses (Johnstone, 1991). To explain chemical phenomena effectively, learners must be able to bridge different levels of chemical phenomena (Sjöström et al., 2020). Johnstone (1991) proposed a model consisting of three different levels of chemical presentations (microscopic, submicroscopic and symbolic), which is reflecting the triple nature of chemical

phenomena. Integrating all three levels of representations is essential for effective chemistry teaching (Sjöström et al., 2020) and can be supported through laboratory work (Gurung & Gurung, 2023). Due to its inherent complexity, chemistry concepts have been challenging for both learners and educators (Wilsson & Bernie, 1999). Nevertheless these challenges can be mitigated through the use of technology, which can enhance students' motivation and support conceptual understanding by providing meaningful visualizations and information (Mei-Hung et al., 2018). Emerging technology with considerable potential for chemistry education is augmented reality (AR) (Akçayir & Akçayir, 2017). Several studies have investigated the use of AR in chemistry teaching (Coduto et al., 2023; Tarng et al., 2021; Yamtinah et al., 2023). However, no previous studies have examined the use of AR to enhance students' understanding of the triple nature of chemical phenomena within the context of environmental chemistry.

Chemistry Triplet

Students often perceive chemistry as a difficult subject, due to the triple nature of chemical phenomena (Johnstone, 1991). Achieving an adequate understanding of chemical phenomena, requires learners to comprehend chemical concepts across different levels of representation. This implies that educators themselves need a thorough understanding of how chemical phenomena are represented and how the use of visual representations can support chemistry learning (Gilbert & Treagust, 2009). Johnstone (1982) who proposed that chemical phenomena can be understood at three distinct levels:

(1) Descriptive and functional: The level at which phenomena are directly experienced through the senses and can be described.

(2) Representational: The level at which symbols are used to represent entities and processes that cannot directly be observed.

(3) Explanatory: The level at which phenomena are explained using models.

In later work (Johnstone, 1991) clarified these levels as the macroscopic level, referring to observable phenomena, symbolic level which includes chemical equations, formulas and mathematical representations and submicroscopic level, which involves models of particles and interactions. Experts in chemistry are able to operate fluently across all three levels, whereas novice learners tend to function primarily at the macroscopic level and experience difficulties in relating it to the submicroscopic and symbolic levels (Talanquer, 2010). Research has shown the integrating all three levels of representation, particularly through the use of interactive visualization tools can lead to improved conceptual understanding of chemistry content (Ferk Savec et al., 2009). Despite this, chemical educators often emphasizes only one level of representation at a time, most commonly the symbolic level, which can hinder students' ability to construct coherent mental models of chemical phenomena (Sjöström et al. 2020). To bridge this gap, the use of interactive visualization elements is particularly important (Wu et al., 2001). Two-dimensional and three-dimensional visualizations, such as diagrams, molecular models, and animations are commonly used as visualization tools in chemistry education (Atkins et al., 1995; McMurry & McFay, 2001). These representations function as analogue models of chemical phenomena, helping learners to connect abstract concepts with observable effects (Harrison & Treagust, 1998).

The use of emerging technologies has the potential to further address difficulties associated with understanding abstract chemical concepts (Winkellman et al., 2017). In particular, virtual learning environments enable students to explore processes that cannot be observed with the naked eye (De Jong et al., 2013). During learning chemistry, a substantial portion of information is processed through visual channels (Sanders & McCormick, 1987), These channels can be

effectively supported through virtual technologies that provide real-time visualization, three-dimensional representations and opportunities for learners to manipulate and interact with virtual or real objects.

Augmented Reality

Augmented reality (AR) is a virtual learning environment that enables the digital enrichment of learning content through interactive experiences by overlaying the computer-generated elements onto the real world. Unlike virtual reality, which fully immerse users in a simulated environment, AR enhances real world without completely replacing it (Ardiny & Khanmirza, 2018). Azuma (1997) defined AR as technology that fulfils three main criteria: (1) it combines real and virtual environments, (2) it is interactive in real time and (3) it is registered in three-dimensional space. Accordingly, AR represents the continuum between the real and the virtual world (Milgram et al., 1994). In chemistry education, AR technology allows the visualization of abstract chemical phenomena particularly at a submicroscopic level of representation (Mazzuco et al., 2022). AR applications have been developed across all educational levels (Bacca et al., 2019), and studies indicate that AR can enhance students' learning outcomes (Tarng et al., 2022). However, the effectiveness of AR is influenced by multiple factors, including technology acceptance (Liu et al., 2022). Inappropriate use of AR applications may hinder learning. Making it essential to evaluate the usability and suitability of each application within its specific learning context (Peeters, 2022). The effectiveness of an AR application in the learning process can be assessed based on three criteria: (1) effectiveness, that is, whether it enables task completion and the attainment of high-quality outcomes; (2) efficiency, meaning that it requires minimal resources for its use; and whether it provides; and (3) user satisfaction, that is whether it is engaging and motivating for learners (Brooke, 1995). Ribič and Devetak (2024) highlighted in their literature review that no previous studies have investigated the effectiveness of AR in supporting students' understanding of the chemical triplet. Furthermore, AR has not been previously used to linked selected chemical processes demonstrated in a laboratory setting to the context of environmental chemistry. Nonetheless, studies included in this review emphasized that ease of use and acceptance of technology are critical factors influencing the learning experience with AR. The authors also noted the lack of research on the application of AR specifically within the field of environmental chemistry.

Aim of the Research

Despite the potential of AR use to enhance chemistry learning, pre-service primary school teachers often hold misconceptions about both the triple nature of chemical phenomena (Pavlin et al., 2009), and the biogeochemical cycles of the elements, which are fundamental for understanding environmental chemistry (Ribič et al., 2025). Effective chemistry teaching can also be hindered by the lack of appropriate learning models and instructional resources (Timilsena, 2022). Previous studies have shown that AR technology can improve students' understanding of chemical concepts by providing interactive visualizations that support learning at submicroscopic and symbolic levels (Tarng, 2022; Tsai et al., 2021). However, the effectiveness of AR-based learning depends on multiple factors, including learners' acceptance of the technology (Tarng, 2022) and the usability of the application (Peeters et al., 2022). Laboratory work has been shown to further support students' understanding of chemical phenomena by allowing observation of processes at the macroscopic level. Integrating AR with laboratory activities therefore provides an opportunity to bridge the gap between observable phenomena and abstract chemical representations, offering learners information that cannot be directly observed with the naked eye. Based on this rationale, the aim of this pilot study was to evaluate pre-service primary school

teachers' technology acceptance and perceptions of the usability of an AR application designed to enhance learning during laboratory work in environmental chemistry. Specifically, the study addressed the following research questions:

(1) What is the attitude of pre-service primary school teachers towards the use of AR in the implementation of the environmental chemistry learning module?

(2) How do the pre-service primary school teachers perceive usability of the AR application?

Participants

A total of 10 undergraduate second year pre-service primary school teachers (20 years old) from the Faculty of Education at the University of Ljubljana participated in this pilot study.

Instruments

Two paper-based questionnaires were used to collect the data in this study. The System Usability Scale (SUS) by Brooke (1996) was employed to evaluate the usability of the AR application within the environmental chemistry module. The SUS questionnaire is widely used tool for assessing usability, perceived usefulness, user attitude, intention to use and perceived ease of use. Responses were recorded on a 5-point Likert-type scale ranging from 1 (*strongly disagree*) to 5 (*strongly agree*). For positively formulated items responses of 3 or higher were considered positive feedback, whereas for negatively formulated items, responses of 3 or lower were treated as positive feedback (see Table 1).

The Technology Acceptance Questionnaire (TAM) by Holden & Rada (2014) was used to investigate participants' acceptance of the AR system when learning specific chemical phenomena. The questionnaire included 15 items assessing three dimensions: perceived ease of use (PEU), perceived ease of use and usability (PEUU) and perceived usefulness (PU). Responses were recorded on a 7-point Likert-type scale ranging from 0 (strongly disagree) to 6 (strongly agree). In addition, five items using semantic differential scale ranging from 1 (*bad*) to 7 (*good*) were included to assess participants' attitudes toward the use of the technology (AT).

Research Design

This pilot study introduced a new environmental chemistry module on the nitrogen cycle to pre-service primary school teachers. The module included ten different activities, a relatively large number intended to provide participants with broader contextual knowledge of nitrogen cycling across different environmental spheres. Four of these activities were laboratory activities enhanced with AR visualizations: (1) the simulation of the Haber-Bosh process, (2) the dissolving of ammonia in water (the fountain), (3) spectrometry to determine the concentration of ammonium ions in water, and (4) the adsorption of ammonium and nitrate ions on soil particles. These AR visualizations represented processes at the submicroscopic level, providing learners with interactive, otherwise unobservable views of chemical phenomena. Prior to the module, participants attended a 10-minute training session to familiarize themselves with the AR technology and associated hardware. After completing the module, participants fulfilled paper-based questionnaires (SUS and TAM). For reporting purposes, the items measuring perceived ease of use (PEU) and perceived ease of use and usability (PEUU) were combined into a single category (PEU+PEUU). Given the small sample size, a descriptive approach was used to analyse the data.

Findings and Discussion

The multimedia environment was evaluated using two instruments. In this pilot study, the primary aim of the SUS was to assess the usability of the AR app and to determine its suitability for the

implementation in the main study. Overall, participants evaluated the AR application positively, indicating that it was easy to use and supportive of the learning process (*Table 1*).

Table 1. Students' evaluation of the items in the SUS instrument.

Category	No. of items evaluated as good	No. of items evaluated as neutral	No. of items evaluated as poor	Total No. of items
Usability	5	3	0	8
Perceived usefulness	2	0	0	2
Attitude	2	2	0	4
Intension to use	2	1	0	3
Perceived ease of use	2	1	0	3
Total number of items				20

Based on participants' responses across all SUS categories, the AR application demonstrated good overall usability. The students reported positive attitudes toward the use of AR in chemistry learning, expressed willingness to attend additional classes using this technology, and perceived the application easy to use and easy to learn. These findings are consistent with previous studies (Peeters et al., 2022; Akçayir & Akçayir, 2017), which have shown that well-designed AR applications can positively influence students' usability perceptions and learning experiences. From a usability perspective, Brooke (1995) emphasized that effective system should enable task completion, require minimal resources for use and provide satisfying user experience. The results of this study suggest that the developed AR application meets these criteria, as participants found it engaging, motivating and supportive during laboratory work. This is particularly important in chemistry education, where visualization tools are needed to support the integration of macroscopic observations with submicroscopic representations (Gilbert & Treagust, 2009; Johnstone, 1991). However, these findings should be interpreted with caution as this was a pilot study and participants were exposed to AR for the first time. The positive evaluations may be partially influenced by a novelty effect, whereby learners initially respond more favourably to new and unfamiliar technologies (Mazzuco et al., 2022). Consequently, while the current results indicate that the AR application is usable and well accepted, further investigation in a larger scale study is required to evaluate its long-term impact on learning and conceptual understanding.

Results of questions on questionnaire on technology acceptance are presented in *Table 2*.

Table 2. Descriptive results of technology acceptance factors (TAM)

TAM dimension	No. of items	Mean range	Interpretation*
PEU + PEUU (Perceived Ease of Use & Usability)	9	5.3 – 6.6	High
PU (Perceived Usefulness)	5	5.6 – 6.8	High
AT (Attention to Use)	5	3.2 – 6.9	Mainly positive

*Interpretation is based on item mean scores relative to the scale midpoint. Scores above the midpoint are interpreted as positive (Liu et al., 2022).

As shown in *Table 2*, participants responses indicated mainly positive perceptions across all TAM factors. No student reported neutral or negative ratings for any statement related to technology acceptance, suggesting that the AR application did not negatively affect students' engagement

with or understanding of the learning content (Tarng et al., 2022). These results suggest that the AR application was generally well received. The high PEU + PEUU scores indicate that the students found the system easy to use and supportive of learning, while the high PU scores demonstrate that learners recognized its educational value. The AT scores, although slightly lower for one item, indicate that most participants were willing to engage with the AR application in future learning activities. From a theoretical perspective, the positive usability and technology acceptance results suggest that AR has the potential to support learners in bridging the gap between macroscopic observations and submicroscopic or symbolic representations in chemistry, consistent with the chemical triplet framework (Johnstone, 1991; Gilbert & Treagust, 2009). By providing visualizations of the processes such as the Haber-Bosch reaction, ammonia dissolution, and ion adsorption, the AR application may offer learners interactive ways to explore chemical phenomena that are otherwise difficult to observe, which could be particularly valuable in environmental chemistry education.

Conclusions

This pilot study evaluated a newly developed AR application for teaching the nitrogen cycle in an environmental chemistry module to pre-service primary school teachers. Overall, participants reported positive perceptions of usability, perceived usefulness, and attention to use. The System Usability Scale (SUS) indicated that the application was easy to use, engaging, and supportive of learning, while the Technology Acceptance Questionnaire (TAM) demonstrated that students were willing to engage with the application and recognized its educational value.

The findings suggest that the AR application is well received and has the potential to support chemistry learning, particularly in providing interactive visualizations of chemical processes that are difficult to observe directly. However, future research with a larger sample will allow examination of additional variables, such as conceptual understanding, motivation, and learning outcomes, to more fully assess the educational impact of AR in environmental chemistry. As a pilot study, these findings should be interpreted with caution. The small sample size limits generalizability. Future studies are needed to directly assess whether these visualizations improve conceptual understanding and learning outcomes. Also, previous studies on emerging technologies in education highlighted the importance of longitudinal studies to determine whether positive attitudes toward AR are sustained over time. Therefore, larger study is required to evaluate long term impact on attitudes towards AR technology.

Beware The Slider's Range: A Design Lesson From Physics Simulation Development

Jared Arnell, Hillary Swanson, Boyd Edwards, Sadra Jafari Ghalehkohneh, Kaden Hart, and John Edwards
Utah State University, United States

Digital simulations are a critical component of modern education, yet guidance for the many microscopic design decisions that accompany their creation is incredibly rare. During our own development of a physics simulation, our team encountered one such decision regarding the range of the sliders in the simulation. We recount how an initial 'intuitive' choice resulted in significant changes to the simulations' functionality, which ultimately overshadowed rich details of the phenomenon. From this experience, we devised a sequence of design principles for choosing slider boundaries, which includes stating learning goals, identifying necessary inclusions/exclusions, quantifying relationships, and checking maximizing/minimizing cases. Through this explication, we illuminate the utility of small-scale design principles for creating digital simulations for educational applications.

Keywords: Physics, Simulations, Design Principles

Introduction

Digital educational simulations play a key role in modern STEM education and have proved extremely effective at improving students' conceptual understanding (Rutten et al., 2012; Wieman & Perkins, 2005). Today, a wide array of such simulations exists, covering a multitude of domains and topics including physics, chemistry, and mathematics (Banda & Nzabahimana, 2021; Fan & Geelan, 2013; Molina-Toro et al., 2019; Moore et al., 2014; Yuriy et al., 2022). Given their resounding empirical support and wide applicability, developing educational simulation technologies remains a vital goal in educational research.

Although there are countless studies examining the application and effectiveness of digital simulations across disciplines, the literature on how to *create or design* such simulations remains drastically underdeveloped by comparison. There are myriad instructional design methodologies which are (in theory) generalizable, but the unique challenges presented in developing a computer-based technology mean many of these methods lack the specificity or detail to be helpful at a granular level. For example, Becker & Parker (2012) synthesized general principles from instructional and game design frameworks to develop an overarching design process for digital simulations. Their process—which follows a familiar phase-based plan with such recognizable steps as "preparation," "design," and "testing"—may offer a helpful roadmap for large-scale planning, but its limited guidance within these phases leaves designers on their own when facing the deluge of choices and commitments that must be made when building a simulation from the ground up.

Some researchers have sought to look across empirical studies which showcase digital simulations in educational environments in order to construct a sort of "best practices" list of affordances and features employed by effective simulations. Blake & Scanlon (2007) compiled one such list by comparing three simulations—two physics-based and one biology-based—and concluded that effective simulations must a) be based on real-world phenomena, b) use multiple representations like graphs and visualizations, and c) offer appropriate support and scaffolding to guide inquiry. A similar analysis by Podolefsky et al. (2010) presented a detailed case study of

two students using a physics simulation and explored how the simulation's ability to make invisible phenomena observable and provide real-time feedback contributed to the students' learning. These analyses begin to identify design priorities and goals that are specific to simulation development, but their advice still leans towards the birds-eye view—primarily considering the targets of study for simulations and the instructional environment in which they will be situated.

A larger study was performed by Scalise et al. (2011), who reviewed 79 studies of virtual labs and simulations in secondary school science classrooms. From their analysis, they composed three rubrics: one for software/hardware elements, one for the visualizations themselves, and one for the scientific inquiry which the simulation scaffolded. While many elements of their rubrics arrive at the same conclusions of the works mentioned previously (such as showing scale models of large/small phenomena or providing lesson plans), they also unpack several fine-grain components of simulation design, like API compatibility and the inclusion of auditory elements. Such atomized dissections of minute components of simulation design are quite rare and often only mentioned in passing. For instance, Podolefsky et al. (2010) did mention how the affordance of the pause button was useful for one student, but an interrogation of the simulation at that scale was obviously not their main focus.

One examination of simulation design at this grain-size is found in Williams (2003), who drew upon theories from design and learning research to critique the common practice of defaulting to interface choices which seem to be the most intuitive at first glance. Instead, Williams examines the ways in which miniscule trade-offs in modes of interaction—like swapping direct manipulation of an object with typing in a command prompt or delaying the speed at which the simulation updates or responds to user inputs—may have a subtle but significant effect on the learner's cognitive experience. While Williams still devotes substantial time to discuss larger-scale issues (like the designer's "intent"), his considerations on interface design remain one of the few instances of such zoomed-in granularity.

By far, the most detailed guidance on small-scale design choices for digital simulations comes from the Physics Education Technology group (PhET, n.d.), who have published in-depth accounts of both their approach to designing educational simulations (Adams et al., 2008b) as well as implementing them in practical settings (Adams et al., 2008a). These treatises condense results from over 200 clinical interviews of students interacting with digital simulations, and so touch on many of the themes already mentioned: real-world connections, guiding prompts, and scaffolding inquiry. In addition, Adams et al. (2008b) shed much-needed light on a variety of design choices that arise during the piece-by-piece construction of such computer simulations: default/start-up settings, stylization, color choice, distinguishing "control panels" from "play areas," and even the use of backgrounds.

One of the conclusions Adams et al. (2008) draw regarding interface design is that controls which "resemble using the mouse as a simple extension of direct manipulations by hand" (p. 568) are particularly intuitive. This philosophy of prioritizing direct manipulation in simulations has been understood for some time (Shneiderman, 1997), but Adams et al. go a step further to share at length the subtle differences they observed between users' interactions with various types of manipulatable elements, such as click-and-drag objects, radio buttons, and checkboxes. For designers new to the computer simulation landscape, deconstructions like these can prove to be an invaluable asset.

For the last three years, our research team has embarked on just such a maiden voyage into digital simulation design. Our goal has been to develop simulations for upper-division physics curricula

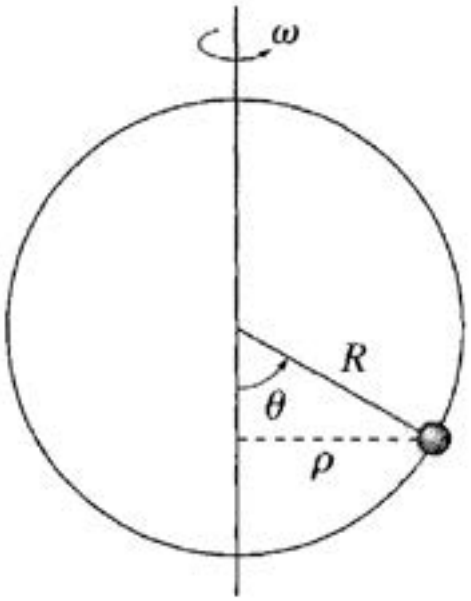
(Jafari Ghalehkohneh et al., 2025), a niche we feel is critically underexplored. In our nascent efforts to learn the tricks and tools of the trade, we inadvertently stumbled into a design oversight which, in hindsight, may provide a useful example for unwrapping a previously undiscussed element of simulation micro-design: the decision of what *range* to use on grabbable sliders. By recounting the factors which led to this hurdle, the turbulence it caused, and the way we corrected it, we hope to contribute to the literature on micro-scale design choices for digital simulations.

In part one of this work, we will relate the development process of our first simulation, the circumstances of our design oversight, and the impact it had on users during our pilot interviews. In part two, we will outline how we used this learning opportunity to construct a sequence of design principles for decision making in this narrow but critical element of simulation design.

Part One: Simulation And Study Context

Our research group has been developing a suite of physics simulations called PhysMath (PhysMath, n.d.), which go beyond traditional visualizations of physics phenomena to incorporate interactive equations as well. These mathematical inclusions aim to address a distressingly common finding in physics education research: students who can successfully perform mathematical tasks in physics contexts often have little to no ability to explain the purpose or meaning of such actions (Arnell, Swanson, Edwards, & Edwards, 2024; Mason & Singh, 2010; Tuminaro & Redish, 2007).

Our development team consists of individuals from three fields: physicists as content experts, computer scientists to build and program the simulations, and learning scientists to base the design in education theories and conduct user testing. Our design process begins with the physicists crafting a detailed explanation of the phenomenon, which is communicated to the computer scientists to develop a basic (functional) simulation. Then, the simulation is presented to the team for feedback to improve its aesthetics and usability. When the team feels the simulation has reached a satisfactory level of polish after several iterative refinements, the learning scientists conduct clinical interviews with volunteer students to observe their behaviour and receive user feedback.



The first simulation we chose to design was the "bead on a spinning wire hoop" problem (Taylor, 2005, p. 261) from Classical Mechanics. We chose this target because it was conceptually and mathematically rich yet nearly impossible to demonstrate physically (Jafari Ghalehkohneh et al., 2025). The design experience we share in this work took place during the earliest versions of this simulation. In the following section, we will cover the necessary background for understanding the phenomenon and how a seemingly innocuous design choice on slider ranges compromised our simulation's instructional utility.

The PhysMath Bead-On-Hoop Simulation

Fortunately, a rigorous mathematical understanding of the Bead-on-Hoop is not required for our purposes in this work; instead, a cursory, qualitative explanation will suffice. For this problem, a bead is threaded onto a wire hoop with radius R, which is then spun around a vertical axis with angular velocity ω, as diagramed in Figure 1. The position of the bead at any moment can be described with a single parameter: the angle θ which the bead makes with the bottom of the hoop.

As the bead is allowed to slide around the hoop, its motion is governed by two forces. The first is gravity (traditionally symbolized by g), which always points downward and has a constant magnitude. The second force is the centrifugal force, which always points horizontally outward away from the axis of rotation and gets larger as the hoop spins faster and as the bead moves further away from the axis of rotation (a distance denoted by ρ in Figure 1).

Figure 1: The bead on a spinning hoop (Taylor, 2005, p. 261)

On its own, the gravitational force would pull the bead to the lowest point on the hoop (at $\theta = 0°$), and this is indeed the primary equilibrium point for the bead when the hoop is not spinning. As the hoop begins to spin (and if the bead is not perfectly at $\theta = 0°$), the centrifugal force will begin to grow. For small values of ω, the centrifugal force will be present but too small to overcome gravity, and the bead will continue to find equilibrium at the bottom of the hoop in spite of the hoop's rotation. But as the hoop spins faster, the centrifugal force can eventually grow strong enough to overcome gravity. When this occurs, the bead will rise away from $\theta = 0°$. As the bead approaches $\theta = \pm 90°$, the centrifugal force—although growing larger due to the increased distance ρ from the rotational axis—will approach an angle normal to the hoop, causing its influence on the bead's motion around the hoop to diminish. At the same time, the gravitational force will approach an angle which is tangential to the hoop and thus become more influential. This shifting balance will result in some 'critical angle' θ_{crit} at which the effects of gravity and the centrifugal force are equivalent, and the bead can remain stationary at this position on the hoop indefinitely; as the hoop rotates faster, the critical angle will approach 90°. Importantly, this critical angle can only exist if the centrifugal force is sufficiently strong, and so there is some 'critical angular velocity' ω_{crit} at which the hoop must spin before the bead can achieve this additional equilibrium point.

This rich bifurcation of behaviour was one of the reasons the bead-on-hoop problem was such a tantalizing target for our simulations. Our hope was that students could use the PhysMath simulation to explore how the parameters of the system—namely, the strength of gravity and the size of the hoop—would affect this critical angular velocity and observe how the motion of the bead is significantly altered as the rotation rate of the hoop crosses this crucial threshold.

As our programmers crafted the earliest versions of the PhysMath Bead-on-Hoop simulation, they followed the well-established practices for physics simulations (Adams et al., 2008b) and included draggable sliders for each of the system's parameters. Unfortunately, our team had not had any explicit discussion about what the minimum and maximum values for each slider should be. As this was the first PhysMath simulation to be built and there was no previous experience to draw upon, the programmers chose values which seemed intuitive: a minimum of 0 (0.1 for the radius slider, which cannot be 0) and a maximum of 100.

While these values may be sensible in other circumstances, they turned out to be quite problematic for the Bead-on-Hoop in particular, especially for the radius slider! The magnitude

of the centrifugal force is dependent on ρ, and thus dependent on R as well. At a radius of only a few meters, a hoop could rotate at an incredibly small rate and still create a substantial centrifugal force. This would mean that the critical angular velocity ω_{crit}—the threshold point around which we wanted our students' explorations to revolve—resides so close to zero that it practically vanishes. With the slider's maximum set at 100, even positions on the slider that would intuitively appear to be quite low (e.g., 5–10% of the slider's total length) would still represent radii that were inappropriately large and would result in an overwhelming centrifugal force.

Unfortunately, the rest of our design team did not recognize the eventual consequences of these slider ranges during our rounds of iterative feedback on the programmer's prototypes. It was only when our learning scientists sat down with students to observe their interactions with the simulation that the impact of the slider ranges was revealed. In the next section, we will share excerpts from the students' interviews to demonstrate how our design oversight hindered their explorations into the simulated phenomenon.

Pilot Study Observations

Eventually, the simulation prototype was ready for user testing. Students who were enrolled in Classical Mechanics at our institution were recruited for clinical interviews (Arnell, Swanson, Edwards, Hart, et al., 2024), in which they shared their understanding of the phenomenon and then explored the PhysMath Bead-on-Hoop simulation. On the whole, the students' experience was positive, and our observations concurred with Adams et al. (2008b) regarding the intuitiveness of controls that mimic physical manipulations. However, during these pilot interviews, we finally noticed the size of the radius slider impeding the students' learning. Here, we will share excerpts from interviews with four students: Alena, Armando, Jake, and Ronan (pseudonyms).

Alena's first act when she began exploring the simulation was to change the radius of the hoop, saying, "what happens if we make [the radius]… like, five?" As the hoop spun, the bead sat relatively stable near 90°, at which Alena commented, "It seems to just hang out right here." She then began increasing and decreasing ω, but without readjusting R to a smaller value. When this had little effect on the bead, Alena changed the bead's starting position before varying ω again. All of Alena's experiments yielded the same result: the bead found its equilibrium near 90°, regardless of any other system parameter. Alena concluded that "if you start it at the halfway mark, it will tend to stay there"—a conclusion which is only true if the hoop is spinning above the critical angular velocity.

Armando was also drawn to the radius slider first, saying "let's increase R, see what that does." He dragged the slider up about a third of the way (34 m). After watching the simulation for a moment, he moved on to other variables without resetting R. Armando played around with the sliders for gravity, friction, and angular velocity, checking the hoop's behaviour when each slider was near its minimum and maximum; in all cases, the bead's equilibrium point never shifted from the super-critical 90° position. Armando commented, "it definitely has this critical point right there, at the very side… I wonder if I increase gravity, if the position at that point changes at all?" Armando's intuition was aimed in a productive direction: a stronger-than-usual gravitational force might overpower the centrifugal force enough for him to find sub-critical behaviours. However, the influence of the absurdly large radius was so great that even when Armando slid the gravity slider to near its maximum (around 75 m/s^2), the bead's behaviour remained unchanged. Armando responded "No, it doesn't. It still stays there." In his experimenting, the only time Armando saw the bead come to rest at the bottom of the hoop was when he set ω to zero—a trivial solution, as *no* rotation results in *no* centrifugal force.

Jake took a unique approach, varying some of the last sliders on the list first; this meant he only reached the radius slider after he had already experimented with the starting position and velocity, angular velocity, and friction. Jake increased R up to around 30 m, then decreased it as he had the others. However, due to the length of the slider, Jake's 'low' value was still 8 m (giving a hoop as tall as a two-story building!). As Jake continued to experiment with the simulation, he tried removing gravity by setting g to zero. When the bead's equilibrium stayed around 90°, he remarked "it doesn't change it terribly much."

Ronan made the typical choice to interact with the radius slider first; he dragged the slider to its absolute maximum, then back to a lower value—but ultimately left it at 20m. From there, Ronan varied the gravity, friction, angular velocity, and starting position/velocity sliders. Through all his experiments, the bead maintained an equilibrium point at roughly 90°. Summing up his observations, he said "there's this side motion… it's the furthest to the side that it can be, and it just stays there."

The interviewer (first author) noticed the issue of the range slider's excessive maximum after the interviews with Alena and Armando. Unfortunately, an updated version of the simulation was not available in time for the interviews with Jake and Ronan, so the interviewer elected to not immediately intervene if the participants unwittingly set R too high. This was done to give the students an opportunity to detect the error and correct it themselves, though neither did. Eventually, the interviewer stepped in to correct the issue for Jake and Ronan once they needed to move on to the next phase of the interview.

Alena, Armando, Jake, and Ronan all shared a very similar experience during their exploration of the PhysMath Bead-on-Hoop simulation. They each increased R from its default value and performed subsequent tests while R remained at a relatively high value. In spite of their attempts at varying many of the other parameters, the bead's equilibrium at approximately 90° could not be disturbed (outside of removing the rotation of the hoop altogether). As they observed the system's behaviour, they all made comments regarding the apparent permanence of the bead's equilibrium position.

From these pilot interviews, it was immediately clear that the range of the radius slider (and possibly others) must change. Not only had the students been unable to discover any of the sub-critical behaviour examples, but they appeared to conclude from this that such behaviour may not even exist! This tendency for students to trust simulations to a fault was also observed by Adams et al. (2008a), who noticed that students may even attribute meaning to cases when simulations broke or encountered bugs, believing that the simulations *must* be portraying the phenomenon correctly.

What was far less clear to our design team was what the new slider range should be. In part two, we will share how we constructed a sequence of design principles for making such a determination—a sequence we hope will be useful for any designers who may be struggling with a similar decision.

Part Two: Design Principles For Determining Slider Ranges

For digital simulation designers who must choose upper and lower bounds for sliders representing physical parameters in a modelled phenomenon, we offer the four-stage design principle sequence we constructed from our problem-solving experience: 1) state your learning objective, 2) designate allowed/disallowed input values, 3) quantify your parameter relationships, and 4) use maximizing/minimizing cases to calculate slider boundaries.

1. State Your Learning Objectives And How They Relate To The Slider Values

As is the case with many instructional design methods (Branch, 2009), our first priority was to make our learning objectives explicit. As mentioned previously, our intent was that students who were exploring the PhysMath Bead-on-Hoop simulation should be able to find angular velocity values which were both above and below ω_{crit}, allowing them to observe and compare the differences in the bead's behaviour on either side of this threshold. To make these kinds of discoveries as natural as possible, our preference would be for ω_{crit} to fall somewhere near the middle of the angular velocity slider and remain away from the slider's edges as much as possible as the other system parameters were varied. This would increase the likelihood of users finding both categories of motion organically as they instinctively check the limits of the simulation (Adams et al, 2008a).

With this target articulated, we realized that we would need to adjust not only the scale of the radius slider which had been the apparent cause of the issue, but also the angular velocity slider so that it was scaled correctly to accommodate whatever ω_{crit} values were made possible by the values of the other system parameters. Similarly, we would also need to fine-tune the range of our gravity slider, as g affects ω_{crit} by providing a benchmark for the growing centrifugal force to overpower.

And so, our ultimate goal would be to find minimum and maximum boundaries for this trio of interconnected parameters that would restrict the possible ω_{crit} values to a reasonable range as near the middle of the angular velocity slider as we could manage.

2. Designate Specific Input Values Which Must Be Allowed/Disallowed

With the radius, gravity, and angular velocity sliders in our sights, our next step was to establish if there were any specific values for these three parameters that we must include (or exclude) for the simulation to make sense. We agreed that we must let g go to zero, as we wanted to allow students to "turn off" gravity and explore how the complete removal of that force affected the system. Congruently, we needed to allow for ω to have a minimum of zero to let students observe the (albeit trivial) cases when the hoop is not spinning and there is no centrifugal force. On the other hand, R could not be allowed to reach zero, as doing so would essentially 'break' the formulae used to calculate the bead's motion; thus, the radius slider would need a non-zero minimum value. Our final observation at this stage was that the gravity slider needed to include the value 9.8, as this is the standard g value for earth; we would then prefer that the gravity slider extend beyond that point by some amount to allow for testing gravitational forces which were stronger than earth's.

By clarifying these must-have points, we had already established the minimum for two of our three sliders, as well as getting an approximate feel for where the maximum for g and minimum for R may wind up. To find the rest of the boundaries, we would need to quantify the way changes to any one parameter would affect the others.

3. Quantify The Relationship Between Your Parameters

The relationship between the radius, gravity, and the critical angular velocity for the Bead-on-Hoop is given by Equation 1:

$$\omega_{crit}^2 = \frac{g}{R} \tag{1}$$

This expression quantifies the proportionalities we have already mentioned, and so now allows us to plug in individual values to calculate an exact critical angular velocity. By plugging in

hypothetical maximum and minimum values for g and R, we can construct a range of possible values for ω_{crit} and iteratively home in on a set of ranges for all three parameters which coincides as closely to our desired learning objectives as we can manage.

4. Use Maximizing/Minimizing Cases To Determine Slider Boundaries

Equation 1 can be looked at in two ways: trying to either maximize or minimize ω_{crit}. For our calculations, we first looked at the cases where ω_{crit} would minimize (in hindsight, if we had tried to start with the maximizing case, we would not have had enough information yet and would have resorted to the minimizing case instead).

As we had already established a minimum value of zero for the gravity slider, we began by checking how this boundary affected the possible values for ω_{crit}. Unfortunately, Equation 1 demonstrated that ω_{crit} would approach zero as g does, which means that ω_{crit} would inevitably drift to the bottom edge of the angular velocity slider regardless of the slider's overall range. While this goes against our preference to keep ω_{crit} away from the slider's edge, we realized that there would be no way to avoid this particular case without abandoning our commitment to allow g to go to zero, and so we would need to try to work around this case as best we could.

Since we could not prevent ω_{crit} from reaching zero, we elected to check what would happen at a small but non-zero value for g (we chose $g = 1$). Our calculations revealed that if we wanted to keep the minimum ω_{crit} values out of the decimals, then the absolute maximum for our radius slider would need to be 1—which speaks to why our student users were so unable to find any sub-critical behaviour with their R set so much higher! If our radius slider has a maximum of 1, then a value for g closer to the default/standard would yield $\omega_{crit} \approx 3$. This let us know that our angular velocity slider maximum shouldn't be so large as to make values in the low, single-digit range imperceptible.

With the maximum R value established, we could now look to the maximizing cases of Equation 1 to find the last of our boundaries. If we kept g at a standard value and made R smaller, then by the time we reached $R = 0.1$, ω_{crit} had already climbed to around 10. Knowing that ω_{crit} would climb even higher if g was increased as well, we felt 0.1 would be a sufficient minimum for the radius slider to keep it from pushing ω_{crit} too large.

At this point, the only boundaries we had not established were the maximums for the gravity and angular velocity sliders. As Equation 1 shows, ω_{crit} and g are directly proportional, so allowing higher values of g would continue to raise the maximum possible value for ω_{crit}. This meant the maximum values for these sliders could be as low or high as we preferred. We resolved to cap the two sliders low enough that single-digit values for ω_{crit} wouldn't be completely washed out, and so chose 20 for a maximum ω and 25 for a maximum g (though these values could have been slightly different and the overall functionality of the simulation would remain relatively unchanged). These particular values meant that the maximum possible ω_{crit} would be around 16, which we felt would keep ω_{crit} acceptably far away from the top edge of the angular velocity slider in most cases.

Conclusion

In this work, we have shared an account of a challenge our research team encountered while designing a physics simulation: due to the interdisciplinary nature of the task, our programmers chose values for the range of our simulation's parameters sliders which were ill-suited for the modelled phenomenon. When this oversight was not noticed by our team's physicists and learning scientists, we conducted pilot interviews in which the improper slider ranges had a significant impact on the students' exploratory sessions with the simulation. Learning from this

mistake, we have since generated a sequence of design principles to help other designers calculate optimal slider ranges for their own educational simulations. This sequence asks designers to articulate their learning objectives, designate necessary input values, quantify their parameter relationships, and using maximal/minimal cases to arrive at slider ranges based on concrete justifications.

Through this experience, our team came to appreciate how minor details in interface design can have a substantial effect on the utility of educational simulations—especially when modelling complex phenomena. While there are simulation design teams which have been open about sharing their own design lessons (Adams et al., 2008a; 2008b), the fine-grain operationalization of design choices for computer-based simulations could use substantially more explication. We hope our detailed deconstruction and analysis of the process and rationalization behind one micro-design choice can assist other educational simulation designers when faced with the same conundrum. Furthermore, we encourage the publication of similar micro-design deconstructions to illuminate the otherwise imperceptible challenges presented by digital simulation design.

What Factors Influence Pre-Service Science Teachers' Ethical Use Of ChatGPT?

Radu Bogdan Toma and Iraya Yánez-Pérez
Department of Specific Didactics, Area of Science Education, University of Burgos, Spain

This study examines factors influencing pre-service science teachers' ethical use of ChatGPT using the Theory of Reasoned Goal Pursuit (TRGP). Through directed content analysis of responses from 28 students, key determinants related to procurement goal beliefs, approval goal beliefs, attitudes, subjective norms, motivation, and perceived behavioural control are identified. The findings offer insights into how these constructs shape ethical engagement with ChatGPT, highlighting the need for targeted interventions to foster responsible use in education

Keywords: ChatGPT, academic integrity, pre-service teachers

Introduction

Large language models (LLMs), such as ChatGPT, are significantly reshaping how students approach academic tasks (Kikalishvili, 2023). These tools assist in developing teaching units, rubrics, and quizzes (Cooper, 2023). The growth of these models also relates to increased academic dishonesty and plagiarism (Kasneci et al., 2023; Milano et al., 2023). Recent studies confirm these trends in educational settings (Toma & Yánez-Pérez, 2025). There is a clear need to investigate factors influencing ethical use.

Against this background, this study applies the Theory of Reasoned Goal Pursuit (TRGP) to explore determinants of ethical ChatGPT use (Ajzen & Kruglanski, 2019). The TRGP connects personal goals with social and environmental beliefs, which could position this framework as useful in explaining how students use LLM. The model suggests that behaviour results from the interaction between desired outcomes and perceived pressures. Therefore, the study examines proactive ethical use of LLM rather than just misuse. Specifically, the study aims to identify factors that foster ethical use during professional development. Therefore, it does not focus on predicting academic misconduct. In doing so, finding might inform design of professional development programs focused on fostering an ethical use of LLM like ChatGPT. Indeed, understanding these factors is necessary for teacher education programs. Pre-service teachers must learn to balance efficiency with academic standards. The results of this study can guide policy making within universities. This study addressed the following research question:

- What factors drive the ethical use of ChatGPT?

Theoretical Underpinnings

The TRGP is a recently developed comprehensive framework designed to predict and modify behaviours (Ajzen & Kruglanski, 2019). It integrates components from Ajzen's (1991) Theory of Planned Behaviour (TPB) and Kruglanski et al.'s (2002) Goal Systems Theory (GST) to incorporate the influence of individuals' goals. TRGP proposes that behaviours are primarily driven by two types of goals: (1) procurement goal beliefs and (2) approval goal beliefs. Procurement goal beliefs refer to the desired outcomes individuals aim to achieve through their behaviour, serving as determinants of attitudes. Approval goal beliefs, in contrast, represent the significant others whose approval individuals seek by performing the behaviour, acting as antecedents of subjective norms.

The theory suggests that procurement goal beliefs exert a stronger influence on attitudes than behavioural beliefs, while approval goal beliefs have a greater impact on subjective norms than normative beliefs. Consequently, individuals are more likely to adopt a behaviour if it aligns with both procurement and approval goals. For example, students may aim to complete university assignments efficiently (procurement goal) and gain peer approval (approval goal). Positive beliefs about ChatGPT, such as improved understanding of material, may not motivate its use if procurement goals remain unmet. Similarly, normative beliefs regarding individuals whose approval is not sought, such as professors, may not significantly influence behaviour.

The theory also posits that attitudes and subjective norms form the foundation for motivation to engage in a behaviour. Within this framework, motivation is defined as "a strong desire to perform the behaviour" (Ajzen & Kruglanski, 2019, p. 775). Higher levels of motivation are expected to lead to the formation of intentions, which subsequently predict and influence behaviour. Additionally, perceived behavioural control moderates' motivation and also directly affects intentions. For instance, pre-service teachers with positive attitudes toward the ethical use of ChatGPT and strong subjective norms will exhibit greater motivation to use ChatGPT ethically. This motivation is further strengthened and moderated by high levels of perceived behavioural control over the behaviour.

Methodology

Participants

Participants were selected using purposive sampling to ensure experience with ChatGPT's ethical use (Cohen et al., 2018). Recruitment criteria included: (1) undergraduate status, (2) attendance in an in-person course, (3) willingness to create a ChatGPT account and participate, and (4) extensive experience in ethical ChatGPT use.

Eligible students completed an intervention on ethical ChatGPT use for teaching science (Toma & Yánez-Pérez, 2024). Of 37 first-year teaching students recruited, nine were excluded: six did not meet the attendance criterion, and three failed the experience criterion. The final sample included 28 students (89.3% female, mean age = 21.93, SD = 1.80). For university entrance, most pursued social sciences (67.9%), with others in science (17.9%) or vocational training (14.3%). Participants completed an elicitation questionnaire post-intervention.

Data Collection Instrument

An elicitation questionnaire, following standardized protocols (Fishbein & Ajzen, 2010), included eight open-ended questions. Participants were first provided a definition of ethical ChatGPT use: "Ethical use involves seeking information, clarifying concepts, or generating ideas for inspiration, as done in this course. Fraudulent use includes copying ChatGPT content or having it complete assignments".

Participants listed their most salient procurement goal beliefs ('What is the most important personal goal you could achieve by using ChatGPT ethically this semester?') and approval goal beliefs ('Would you use ChatGPT ethically to gain approval from specific individuals or groups? List them.'). They then identified advantages and disadvantages of ethical ChatGPT use ('What are the advantages and disadvantages of using ChatGPT ethically this semester?'). Normative beliefs were elicited by listing individuals or groups who would approve or disapprove of their ethical use ('Who would approve or disapprove of your ethical use of ChatGPT this semester?'). Finally, control beliefs were identified by listing factors facilitating or hindering ethical use ('What factors would make it easier or harder to use ChatGPT ethically this semester?').

Data Analysis

Directed content analysis was employed to analyse students' responses based on predefined TRGP belief categories (Cohen et al., 2018). Guided by theory, two researchers independently coded responses into categories: personal goals, positive/negative behavioural beliefs, approval-seeking individuals, approval/disapproval normative influences, and facilitating/hindering control beliefs. Inter-rater agreement exceeded 80%, indicating high consistency. Discrepancies were resolved through discussion until consensus was achieved. Modal salient beliefs—determinants of ethical use—were identified using frequency counts, retaining those mentioned by at least 30% of participants.

Findings

A total of 26 beliefs were identified: 2 personal goals, 4 advantages, 3 disadvantages, 2 approval-seeking referents, 4 approving normative referents, 2 disapproving normative referents, 4 facilitating factors, and 5 barriers to ethical ChatGPT use (Table 1).

Table 1. Salient beliefs

Constructs	Belief category	Beliefs	N	%
Procurement	Personal goal	Pass course	24	85.7
goal		Save time on assignments	18	64.3
Behavioural	Advantages	Pass course assignments with less effort	26	92.9
beliefs		Improve grades	19	67.9
		Creative ideas for assignments	16	57.1
		Improve understanding of course material	10	35.7
	Disadvantages	Crashed/inoperative	22	78.6
		Risk of plagiarism	18	64.3
		Generic/unhelpful answers	11	39.3
Approval goal	Gain approval	University professors	19	67.9
		Classmates	11	39.3
Normative	Approve	Classmates	23	82.1
		Parents	16	57.1
		University professors	11	39.3
		Employers	9	32.1
	Disapprove	University professors	20	71.4
		Employers	12	42.9
Control beliefs	Easier	Supportive professors/allowing its use	25	89.3
		Clear regulation for use	17	60.7
		Learn prompts/guidance for ethical use	12	42.9
		Relevant/useful assignments	9	32.1
	Difficult	Time constraints	22	78.6
		Unrealistic/challenging assignments	19	67.9
		Excessive assignments	16	57.1
		Ambiguity about ethical vs. unethical use	14	50
		Assignments with a low-grade contribution	11	39.3

Participants primarily pursue ethical ChatGPT use to achieve personal and academic goals. Twenty-four participants (85.7%) identify passing the course as a procurement goal. Eighteen participants (64.3%) use the tool to save time on assignments. Behavioural beliefs regarding advantages centre on efficiency and performance. Twenty-six participants (92.9%) believe it helps them pass assignments with less effort. Nineteen participants (67.9%) expect improved grades. Sixteen participants (57.1%) value the tool for generating creative ideas. Ten participants (35.7%) believe it improves their understanding of course material. Behavioural beliefs regarding disadvantages focus on technical and academic risks. Twenty-two participants (78.6%) identify system crashes as a disadvantage. Eighteen participants (64.3%) cite the risk of plagiarism. Up to eleven participants (39.3%) find the answers to be generic or unhelpful.

Social influence plays a complex role in approval and normative beliefs. Nineteen participants (67.9%) seek approval from university professors. Eleven participants (39.3%) seek approval from classmates. Normative beliefs show a conflict between different social groups. Twenty-three participants (82.1%) believe their classmates approve of the use. Sixteen participants (57.1%) believe their parents approve. Eleven participants (39.3%) perceive approval from university professors. Nine participants (32.1%) perceive approval from employers. Conversely, twenty participants (71.4%) believe university professors disapprove of the use. Twelve participants (42.9%) believe employers disapprove.

Control beliefs indicate various facilitators and barriers to ethical use. Twenty-five participants (89.3%) believe supportive professors make ethical use easier. Seventeen participants (60.7%) identify clear regulations as a facilitating factor. Twelve participants (42.9%) believe that learning prompts and guidance for ethical use makes the process easier. Nine participants (32.1%) find relevant and useful assignments to be a facilitator. Several factors make ethical use difficult for participants. Twenty-two participants (78.6%) cite time constraints as a barrier. Nineteen participants (67.9%) find unrealistic or challenging assignments difficult. Sixteen participants (57.1%) identify excessive assignments as a barrier. Fourteen participants (50%) report difficulty due to ambiguity about ethical versus unethical use. Eleven participants (39.3%) find it difficult to maintain ethical use for assignments with a low-grade contribution.

Discussion

The findings of this study identify specific advantages and concerns regarding ChatGPT use in university settings. These results align with the Strengths, Weaknesses, Opportunities, and Threats (SWOT) analysis proposed by Farrokhnia et al. (2023). Participants recognize several strengths including increased efficiency and improved grades. They also value enhanced creativity and better learning outcomes, which aligns with previous research suggesting that LLMs might have positive impact on creativity (Toma & Yánez-Pérez, 2024). These behavioural beliefs suggest that pre-service teachers view LLMs as a functional asset for their professional development. However, participants also acknowledge significant weaknesses. Concerns remain regarding LLM reliability and the risk of plagiarism. Participants specifically question the quality of generated content and the potential for generic responses.

The data emphasize the critical role of professors in guiding ethical practices. Participants suggest that structured guidance and prompt engineering support from instructors would improve their usage. This finding highlights a gap between the desire for faculty approval and the perceived disapproval from the same group. While students seek to meet academic standards, the lack of clear institutional frameworks creates ambiguity. Providing specific guidance for ethical use would likely bridge this gap and reduce the difficulty associated with navigating new technology.

These results provide empirical evidence for the benefits of ChatGPT discussed by Cooper (2023)

and Dwivedi et al. (2023). The findings also confirm concerns about potential unethical use noted by Kasneci et al. (2023). University students demonstrate an active awareness of these ethical challenges and the technical limitations of LLMs. This study identifies key beliefs that educators can target in future interventions to promote ethical engagement. Specifically, addressing control beliefs such as time constraints and assignment design could reduce the pressure to use AI unethically.

The practical implications of these findings inform the development of strategies to foster an ethical learning culture. Future studies might design and implement interventions that support the integration of LLM tools like ChatGPT. Rather than focusing on misconduct, professional development programs should highlight how LLM can assist in achieving procurement goals ethically. These strategies should include clear regulations and supportive teaching practices to lower the barriers to responsible use. This approach ensures that pre-service teachers develop the necessary skills to use LLM in their future classrooms.

ESERA 2025 Copenhagen

Generative AI Training For Pre-Service Teachers: Impacts And Adoption Patterns

Helcio Soares Padilha[1], Víctor López Simó[2] and Agostinho Serrano de Andrade[3]
[1]Post-Graduate Program in Science and Mathematics Teaching, Universidade Luterana do Brasil (ULBRA), Brazil
[2]Department of Mathematical Didactics and Experimental Sciences, Universitat Autònoma de Barcelona (UAB), Spain
[3]Post-Graduate Program in Science and Mathematics Teaching, Universidade de Caxias do Sul (UCS), Brazil

This study investigates the impact of targeted training in the use of Generative Artificial Intelligence (GAI) among pre-service Science and Mathematics teachers. Grounded in Rogers' Diffusion of Innovations Theory (DIT), the research examines how structured training experiences influence adoption patterns, pedagogical perceptions, and ethical awareness related to GAI use in educational contexts. The study adopts a quantitative approach and involved 183 pre-service teachers enrolled in initial teacher education programs. Participants took part in practical workshops designed to explore the pedagogical use of GAI tools, particularly ChatGPT, for lesson planning, problem-solving activities, and reflective discussions on ethical implications. Data were collected through pre- and post-workshop questionnaires and analysed using descriptive statistics and cluster analysis. The findings identified six distinct GAI adoption profiles, with Innovative Adopters and Moderate Adopters demonstrating higher levels of pedagogical engagement and greater confidence in integrating GAI into teaching practices. These groups increasingly used GAI to design interactive and personalized educational materials aligned with the goals of science education, such as fostering critical thinking and student engagement. Conversely, more conservative profiles showed resistance to adoption, highlighting the need for differentiated training strategies. Overall, the study underscores the relevance of targeted GAI training in initial teacher education, emphasizing its potential to enhance digital literacy, pedagogical innovation, and ethical awareness among future Science and Mathematics teachers.

Keywords: Generative AI, Teacher Training, Science Education

Introduction

Generative Artificial Intelligence (GAI) is rapidly transforming how teachers plan lessons, create materials, and engage students. Tools like ChatGPT now automate routine tasks, generate personalized content, and support interactive learning—opening new pedagogical possibilities for Science and Mathematics education. Yet this technological promise comes with significant challenges: ethical concerns about bias and misinformation, methodological questions about appropriate use, and pedagogical dilemmas about balancing AI assistance with student learning (García Sánchez, 2023; Sok & Heng, 2024).

The risks of uncritical GAI adoption are well documented. Students may develop technological dependency rather than critical thinking skills, and AI systems can perpetuate biases embedded in their training data (Montesano de Talavera et al., 2023; Avraamidou, 2024). These concerns are particularly acute in Science and Mathematics education, where inquiry, problem-solving, and reasoning form the core of learning. Preparing teachers to integrate GAI reflectively and ethically—rather than merely technically—has therefore become a central challenge for teacher education.

Initial teacher education offers a strategic intervention point. During this formative period, future

teachers develop beliefs, competencies, and dispositions toward technology that will shape their entire professional practice (Koehler & Mishra, 2008; San Andrés et al., 2022). Understanding how pre-service teachers adopt emerging technologies like GAI is therefore essential—not just for individual professional development, but for the broader project of pedagogical innovation in science education.

To examine these adoption processes, this study draws on Rogers' Diffusion of Innovations Theory (DIT), which frames adoption as a non-linear process shaped by individual innovativeness and perceptions of an innovation's relative advantage, complexity, and compatibility (Rogers, 2003). Recent research confirms that more innovative pre-service teachers integrate AI tools in pedagogically richer ways, while less innovative users adopt them cautiously or instrumentally (Uzumcu & Acilmis, 2024). Building on this foundation, the present study investigates how targeted GAI training influences adoption patterns, pedagogical perceptions, and ethical awareness among future Science and Mathematics teachers.

Objectives

The main aim of this study was to analyse the impact of targeted training in the use of GAI among pre-service Science and Mathematics teachers. Grounded in the DIT, the study sought to understand how structured training experiences influenced GAI adoption patterns, pedagogical perceptions, and ethical awareness in initial teacher education.

Specifically, the study aimed to:

1. Identify distinct profiles of GAI use among pre-service teachers, based on adoption patterns informed by the DIT;

2. Examine changes in participants' pedagogical and ethical perceptions of GAI before and after participation in practical workshops;

3. Analyse the relationship between GAI adoption profiles and the evolution of pedagogical and ethical perceptions following the training experience.

Methodology

We conducted a quantitative study to examine how targeted GAI training affects pre-service Science and Mathematics teachers. The sample comprised 183 pre-service teachers (aged 19–21) enrolled in initial teacher education programs.

Between April and May 2024, participants attended practical workshops designed to integrate GAI tools—particularly ChatGPT—into Science and Mathematics teaching. Workshop activities included lesson planning with AI assistance, applying Polya's method for problem-solving, and discussing ethical implications of AI use in education.

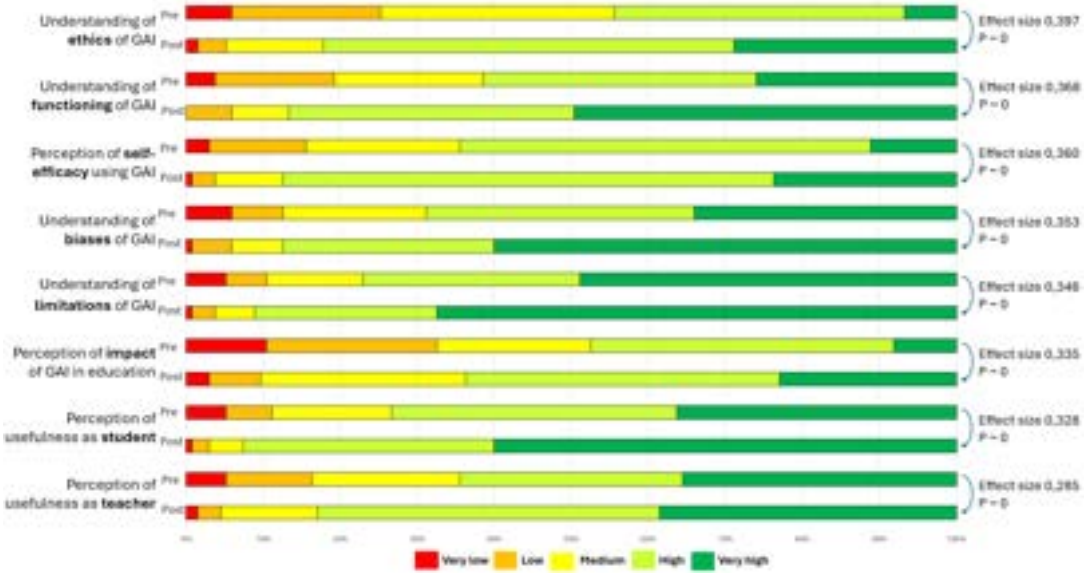
We collected data through pre- and post-workshop questionnaires. The pre-workshop instrument assessed participants' baseline GAI use patterns: frequency, diversity of applications, and initial perceptions of pedagogical potential. The post-workshop questionnaire measured changes in pedagogical and ethical perceptions, as well as confidence in using GAI for instruction.

We analysed the data using descriptive statistics and cluster analysis. The cluster analysis, informed by DIT categories, identified distinct GAI adoption profiles among participants. This approach allowed us to examine how adoption patterns relate to changes in pedagogical and ethical perceptions after training.

Results

Two main findings emerged from the analysis. First, pre-service teachers showed heterogeneous patterns of GAI adoption. Second, the training produced statistically significant changes across all perception dimensions ($p < .001$), though the magnitude varied considerably.

GAI Adoption Profiles And Openness To Innovation



Cluster analysis identified six distinct profiles of GAI adoption: Innovative Adopters (13.97%), Moderate Adopters (33.52%), Conservative Users (22.35%), and three additional profiles (30.16%) showing varying degrees of engagement. These profiles reflect substantial variability in participants' experience, frequency and diversity of use, engagement with extensions and communities, and practices of updating knowledge about GAI tools. When interpreted through the DIT, the profiles can be broadly situated along a continuum ranging from more innovative adopters to more conservative users.

Notably, Innovative Adopters and Moderate Adopters together comprised the majority of the sample (47.49%), suggesting a favourable context for GAI adoption—likely reflecting participants' academic environment and digital familiarity. However, the substantial presence of Conservative Users (22.35%) demonstrates that openness to innovation varies even within digitally oriented cohorts. This heterogeneity validates DIT as an analytical lens for understanding GAI uptake in teacher education.

Differential Effects Of The Training On GAI-Related Perceptions

Wilcoxon signed-rank tests confirmed statistically significant pre-post differences across all perception variables ($p < .001$). As Figure 1 shows, the training consistently improved participants' GAI perceptions, but effect sizes varied substantially across dimensions.

Figure 1. Pre- and post-workshop changes in pre-service teachers' perceptions of Generative Artificial Intelligence.

The largest effect sizes emerged for ethical awareness ($r = 0.397$), understanding of GAI functioning ($r = 0.368$), and self-efficacy ($r = 0.360$). These results indicate that the training most effectively strengthened participants' conceptual clarity about how GAI operates, their confidence in using such tools, and their sensitivity to ethical issues including biases, limitations, and responsible use. In DIT terms, these gains reflect reduced perceived complexity and increased perceived relative advantage—two attributes that facilitate innovation adoption.

Moderate effect sizes characterized perceptions of biases, limitations, and GAI's broader impact on knowledge, learning, and problem-solving. These findings suggest participants moved beyond

purely instrumental views of GAI toward a more critical, reflective stance—increasingly recognizing its epistemic and ethical implications for educational contexts.

In contrast, perceived usefulness for future teaching showed smaller gains (r = 0.285), though still statistically significant. This pattern reveals a critical gap: technical understanding and ethical awareness do not automatically translate into a professional vision of GAI as an integral teaching tool. The distinction between intention and anticipated practice suggests that deeper pedagogical integration may require sustained, practice-based training experiences.

Discussion

This study examined how targeted GAI training affects pre-service teachers' adoption patterns and perceptions, using Rogers' DIT as an analytical framework. The core finding is clear: structured training positively influences how future teachers understand and evaluate GAI. Yet the results also reveal an important boundary—openness to innovation does not automatically translate into pedagogical consolidation.

Through a DIT lens, the strongest changes occurred in ethical awareness (r = 0.397), understanding of GAI functioning (r = 0.368), and self-efficacy (r = 0.360). These gains map directly onto two attributes Rogers (2003) identifies as central to innovation adoption: reduced perceived complexity and increased perceived relative advantage. For GAI—where uncertainty about system functioning and ethical risks often inhibits adoption—such improvements are particularly consequential for fostering informed, responsible engagement.

Moderate effects in awareness of biases, limitations, and GAI's broader impact on knowledge and learning indicate an important conceptual shift. Participants moved from viewing GAI as merely a productivity tool toward recognizing its epistemic and ethical implications—a crucial step in adopting complex educational technologies thoughtfully rather than instrumentally.

In contrast, perceived usefulness of GAI for future teaching practice exhibited comparatively smaller gains (effect size = 0.285), despite remaining statistically significant. This finding highlights a crucial distinction between increased confidence and understanding, on the one hand, and the integration of GAI into teachers' professional identity and anticipated classroom practices, on the other. Consistent with previous research, this result suggests that intentions to use GAI do not necessarily translate into sustained pedagogical practices, particularly when training experiences are short-term or not embedded in authentic teaching contexts.

The identification of heterogeneous adoption profiles further reinforces the relevance of DIT for interpreting these findings. The coexistence of innovative, early adopter, and more conservative profiles within the same cohort suggests that openness to GAI is uneven, even among digitally oriented pre-service teachers. This heterogeneity implies that uniform training approaches may be insufficient to address diverse levels of readiness, motivation, and concern. Differentiated training strategies that consider distinct adoption profiles may therefore be more effective in supporting equitable and sustained integration of GAI in teacher education.

Finally, some limitations of this study should be acknowledged. The reliance on self-reported data captures perceptions and intentions rather than observed teaching practices, and the relatively short duration of the intervention limits inferences about long-term adoption. These limitations are consistent with exploratory studies on emerging technologies and point to the need for longitudinal and practice-based research. Future studies could investigate how repeated and contextually embedded training experiences influence the consolidation of GAI use in classroom practice over time.

Final Considerations

This study demonstrates that targeted training can meaningfully shape how pre-service teachers perceive and approach GAI. The training enhanced ethical awareness, deepened understanding of AI functioning, and strengthened self-efficacy—all prerequisites for thoughtful technology integration. Yet the more modest gains in perceived usefulness for teaching reveal a crucial insight: knowledge and positive attitudes alone do not guarantee pedagogical transformation.

The results suggest that training experiences are particularly effective in addressing dimensions related to ethical awareness, understanding of GAI functioning, and self-efficacy, which are closely associated with reducing perceived complexity and enhancing the relative advantage of the innovation. At the same time, the more modest gains observed in perceived usefulness for future teaching practice highlight that adoption processes are gradual and do not automatically result from increased technical knowledge or positive attitudes alone.

By identifying heterogeneous adoption profiles among pre-service teachers, this study reinforces the relevance of the DIT for understanding how GAI is appropriated in initial teacher education. The coexistence of innovative and more conservative profiles underscores the need for differentiated and sustained training strategies that account for varying levels of readiness, experience, and concern.

This study contributes empirical evidence on how targeted training shapes GAI perceptions and adoption patterns among future teachers. The practical implication is clear: teacher education programs should incorporate structured GAI training that addresses not just technical skills, but ethical awareness and pedagogical integration. Future research should employ longitudinal designs to track how these early experiences translate into sustained classroom practice.

ESERA 2025 Copenhagen

Design-Based Research To Create A Collaborative Game To Foster Spatial Skills: The Role Of Teachers

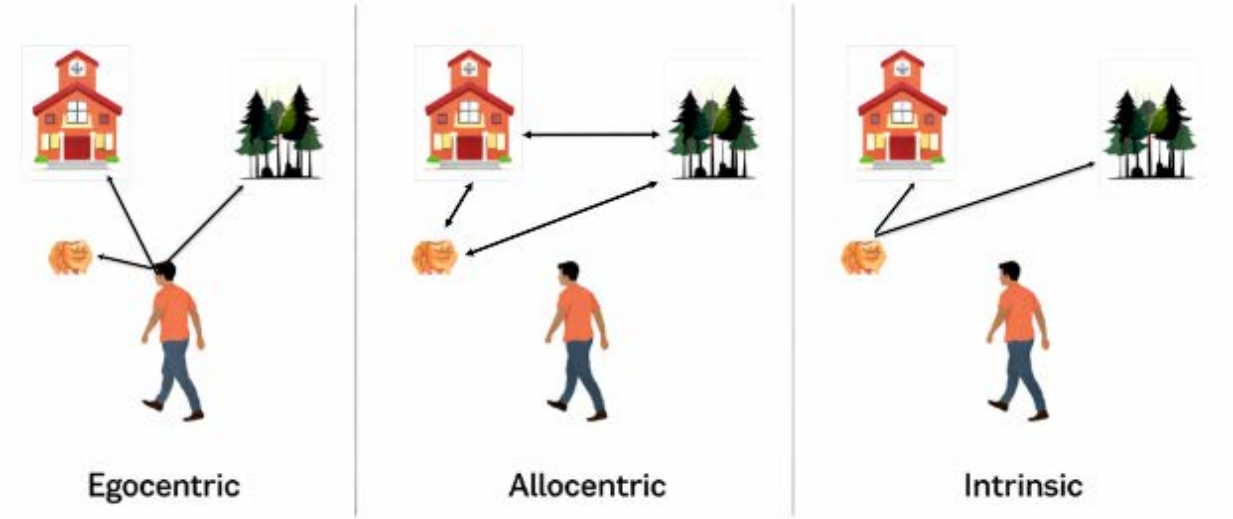
Alain Sénécail, Eric Sanchez, Mireille Bétrancourt, Gaëlle Molinari and Fatou-Maty Diouf
TECFA-FPSE – University of Geneva, Switzerland

This research explores the role of teachers in the co-design process of a hybrid collaborative game aimed at enhancing spatial skills among students in primary school. Spatial competencies, such as visuospatial perspective-taking and frame-of-reference shifting, are an important part of learning in STEM subjects but often are not explicitly taught. Using a Design-Based Research (DBR) approach, the project integrates immersive virtual environments (VR) with tangible elements to create an equitable and engaging learning experience. Teachers are involved in the design and development phases, providing input that shaped gameplay mechanics to meet curriculum intentions and classroom realities. The game, which combines VR, digital maps, and physical boards, encourages students to solve spatial problems collaboratively while navigating a narrative-driven environment. Preliminary findings reveal how teacher engagement might overcome challenges of equitable engagement, adaptive scaffolding, and integration into the curriculum. The teachers pointed out that the need for visual cues, verbalization of spatial reasoning, and adaptive difficulty levels underlined the support for students with different spatial abilities. Other main orchestration strategies include balancing guidance and student autonomy and transitioning between digital and physical tasks smoothly. These recommendations really point to the importance of collaboration between researchers and teachers in the design of pedagogically relevant and feasible game-based learning environments. This will be further implemented in-class, studying how teachers adapt and scaffold learning within this hybrid environment. This research contributes to understanding how teacher expertise and DBR methodologies can enhance the design and integration of game-based tools for spatial skill development in primary education.)

Keywords: Game-Based Education; Spatial Cognition; Collaborative Learning

Context and Conceptual Network

Spatial Abilities At Stake



Spatial thinking is significant in science education. It enables students to mentally represent, manipulate, and reason about spatial relationships, which are essential for understanding key scientific concepts and solving problems in disciplines such as mathematics, earth sciences, physics, chemistry and engineering (Newcombe et al., 2023; Tversky, 2005, Uttal, Miller & Newcombe, 2013). Despite its importance, spatial thinking is rarely taught explicitly in primary education (Newcombe et al., 2023). However, research shows that these skills can be trained and effectively transferred to academic tasks (He et al., 2022). Digital technologies, particularly immersive virtual environments (VE), provide promising opportunities to support this development, especially for students with lower spatial abilities (Makransky & Petersen, 2023).

The present contribution is part of a four-year project aimed at designing and evaluating collaborative game-based learning environments to enhance spatial thinking in primary school students.

Two key spatial competencies are at the core of the project: visuospatial perspective-taking and frame-of-reference. Visuospatial perspective-taking is designed as “the ability to infer the visual or spatial properties of a scene in relation to another person or position” (Samuel et al., 2024).

Frame of Reference Shifting is the ability to switch between different spatial reference frames to process and interpret spatial information. There are three main types (Figure 1.). The egocentric frame is defined relative to one's own position (e.g., the dog is on my left). The allocentric frame is based on external landmarks and fixed coordinates (e.g., the dog is south of the school). Finally, the intrinsic frame is determined by the objects themselves (e.g., the school entrance is in front of the dog's tail).

Figure 1. Three Frames of Reference.

Hybrid Environment: Equity And Teacher's Orchestration

By integrating game-based interactions with immersive virtual environments, the project aims to foster spatial competencies by ensuring an equitable learning experience for every student. Indeed, there exist differences regarding gender, socioeconomic background, and prior exposure (Newcombe et al., 2023). The lack of consideration for inclusion in the design process of digital environments may aggravate these gaps (Gottschalk & Weise, 2023). In our project, we will adopt a hybrid approach that combines virtual reality and tangible elements to maximize inclusion by fostering the engagement of all students. More specifically, the learning environment will integrate virtual interactions with board-style physical elements. In this context, the challenge for teachers will be to effectively orchestrate the gaming sessions to ensure that all students can develop spatial skills in an equivalent manner.

In game-based learning, teachers must integrate games that align with academic objectives and learning goals (Arnab et al., 2012). Moreover, real-time feedback is crucial for tracking progress and enabling timely intervention, helping to maintain student engagement (Holstein et al., 2019). However, implementing these games effectively requires balancing student autonomy with structured guidance, which calls for dynamic orchestration strategies (Dillenbourg & Jermann, 2010). Ultimately, the success of game-based learning depends on teachers' involvement in both the design process and classroom integration (Sanchez, 2022). Therefore, teacher's involvement during the design process is an interesting avenue.

Teachers' Role In Co-Design Of The Game

The project uses a Design-Based Research (DBR) approach to design, develop and implement the collaborative game-based learning environment (Sandoval & Bell, 2004). DBR is a participatory, iterative methodology that involves two interconnected cycles of design, implementation, analysis, and refinement. This approach actively involves teachers at every stage, ensuring that their needs and perspectives shape the game design. As a result, the game is both research-informed and practice-oriented, increasing its relevance and likelihood of

integration into classroom practices (Sanchez & Monod-Ansaldi, 2015).

In particular, teachers are actively involved in two key moments: (a) the design and development phases, and (b) the implementation and evaluation phases. During the design and development phases, teachers collaborate with researchers and developers to create the game. In the implementation and evaluation phases, their role shifts to orchestrating students' actions and social interactions within the game environment.

This study examines the role of teachers in the design and development phases of the game. Specifically, it focuses on three key dimensions: how teachers draw on their teaching experience to inform the design process, how they anticipate orchestrating the game in the classroom, and how this projected orchestration influences the design and development of the game prototype. The aim is to understand how teachers' active involvement in these phases contributes to creating a game that is both pedagogically relevant and aligned with classroom realities.

In this context, we analyse the role of teachers in two aspects:

- Teachers as Co-Designers: game design sessions were conducted, bringing together four researchers, one developer, three primary school teachers, and one external expert. It shaped a narrative-driven collaborative game where students explore, manipulate, and co-construct spatial representations through multimodal interactions (VR headset, physical board, digital maps). The game mechanics were developed to support spatial frame of reference shifts and visuospatial perspective-taking, fostering equitable collaboration and knowledge-sharing among students (Olsen et al., 2021).
- Expected Teacher Orchestration in the Classroom: Teachers must strike a balance between student autonomy, scaffolding, and instructional direction to ensure equitable involvement (Koehler & Mishra, 2009). Focus is placed on teacher orchestration techniques, such as managing the shift between digital and physical activities, providing real-time student support, and implementing adaptive interventions.

Preliminary Insights

During first sessions, the first version of the game prototype was co-designed for the stimulation of collaboration, spatial exploration, and problem-solving. It integrated physical board, digital tablet, and VR headset.

Players take on the role of explorers in this intricately created universe, tasked with reestablishing harmony in the cursed middle-age city of Luméria. Through cooperative navigation and spatial problems in an interesting, dynamic environment, students acquire important spatial competencies.

Integrating Spatial Skills Into Game Mechanics

During the game design sessions, the teachers and the researchers embedded spatial reasoning tasks into the game, jointly ensuring that it will support perspective taking, frame of reference shifts, and cognitive mapping.

A key objective is to help students adopt multiple viewpoints in a 3D environment. To do so, the game follows a progressive difficulty structure, starting with egocentric tasks (e.g., "describe what you see") before moving to allocentric tasks (e.g., "navigate using a landmark"). Teachers agreed on the value of visual clues such as maps, icons, and directional indicators to support frame transitions and to orient the students and facilitate the interpretation of spatial information

across perspectives.

The hybrid game model of VR, physical board, and digital maps supports students in creating and updating their cognitive maps. Teachers emphasized the importance of students verbalizing their spatial reasoning; therefore, collaborative reflection questions were added to have them explain their navigation choices and strategies to their peers.

Equity In Spatial Skill Development

A preoccupation of the research is that pupils with poorer spatial skills might find it difficult to participate in activities that require intricate perspective changes. Teachers underlined how having to switch between frames of reference could cause these pupils to become disinterested or frustrated.

To handle this, the game design is planned to incorporate adaptive scaffolding mechanisms. To ensure that they gain spatial competencies at their own rate, students are given customized and guided navigation prompts.

Alignment With Curriculum & Classroom Feasibility

Making sure the game fits with STEM learning objectives without adding to teachers' workload in terms of class preparation and planning was another important consideration. Teachers emphasized that rather than requiring separate instructional time, spatial learning should be smoothly integrated into current curricula. By integrating spatial tasks into subjects like geography (map reading, landmark), mathematics (spatial transformations, coordinate systems), French (vocabulary, verbalization), biology, and physics (motion, reference frames), the game design aims to address this problem by fostering cross-disciplinary connections.

Challenges & Affordances In Classroom Implementation

Teachers projected several pedagogical constraints and agreed with researchers on opportunities in integrating game-based spatial learning into primary education (Tab. 1).

Table 1. Opportunities and Challenges in Orchestration.

	Affordances (Opportunities)	**Challenges (Constraints)**
Time Managment	Encourages active, multimodal engagement, helping students bridge virtual and real-world spatial reasoning.	Managing time constraints while integrating the game into existing STEM lessons.
Equitable Collaboration	Collaborative problem-solving fosters spatial reasoning.	Ensuring that low spatial ability students do not disengage.
Guidance	Teachers can use scaffolding strategies (e.g. hints) to gradually fade support.	Feedback: Balancing teacher guidance vs. student autonomy in open-ended navigation tasks.
Diversity of Media	Using hybrid tools (VR, digital maps, artifacts) ensures multiple entry points for learning.	Classroom logistics for handling VR equipment and transitions between digital/physical tasks.
Game Universe	Keep in mind the necessity of a narrative and game universe that are age-appropriate and engaging for primary school students.	

Preliminary co-design results reveal interesting tensions in integrating game-based virtual environments. Teachers highlight challenges in time management, participatory equity, and orchestration load, while their perceptions of students' spatial skills and engagement shape

curriculum integration. The next phase will examine classroom implementation, focusing on how teachers adapt, scaffold, and co-regulate learning in this hybrid environment.

ESERA 2025 Copenhagen

Designing Digital STEM Teaching-Learning Sequences By Primary Pre-Service Teachers

Nikos Kapelonis and Dimitris Stavrou
University of Crete, Greece

Digital technologies offer opportunities to enhance teaching by providing interactive and immersive learning experiences. The research on the connection between digital learning objects in learning management systems to implement teaching learning sequences (TLSs) is rather limited. To this end, Digital Learning Objects (DLOs) and Learning Activity Management Systems (LAMS) are useful digital tools. DLOs are defined as digital resources which correspond to learning activity types. Learning activity types are distinguished in three categories: a) Knowledge-building, b) Convergent Knowledge Expression and c) Divergent Knowledge Expression. In addition, using LAMS tools TLSs could be structured. Therefore, LAMS platforms and DLOs can play a central role in developing TLSs in STEM education. In the present paper we will present a study investigating the way primary pre-service teachers design digital STEM TLSs using the LAMS platform. In the study participated 17 pre-service teachers in third and fourth year of their bachelor's degree in primary education. The participants were randomly divided into six subgroups (five groups of three and one group of two) and developed digital TLSs focused on the topic of Climate Change. For the analysis qualitative methods of content analysis were used based on the digital TLS developed by pre-service teachers in the LAMS platform. Our results provide evidence of the connection between the types of learning activities and the possibilities offered by the digital tools and indicate that using Digital Learning Objects enhance the Digital Learning Sequences in STEM education and pre-service teachers are capable of designing coherent, linear digital STEM sequences that prioritize content exploration and guided inquiry.

Keywords: Digital Learning, Digital Resources, e-Learning

Introduction

Digital technologies offer unique opportunities to enhance teaching by providing interactive, inquiry-based, and immersive learning experiences (Hsu, 2012). The use of digital technologies in education, especially after the COVID-19 pandemic, has increased considerably. Since teachers are responsible for designing and structuring lessons, it is crucial to effectively integrate Technology into them. The TPACK framework (Mishra & Koehler, 2006) supports the effective integration of technology into teaching. Effective lesson planning is essential in science education, as it significantly enhances teaching quality and improves student outcomes (Groβmann et al., 2024). A key approach integrating digital tools in education involves the development and use of Digital Learning Objects (DLOs)—digital resources that facilitate specific learning objectives and promote student engagement (Kay & Knaack, 2008). Based on the above, developing Teaching-Learning Sequences (TLSs) (Psillos & Kariotoglou, 2016), provide coherent and inquiry-driven frameworks for addressing complex STEM topics like climate change.

Learning Management Systems (LMS) are platforms that provide a range of digital tools, like chat, forum, document repository etc within a course. One of the many options of LMS platforms is the Learning Activity Management System (LAMS) platform. While LAMS provides tools similar to standard LMS platforms, it uniquely facilitates the structuring of digital TLSs by sequencing learning activities. DLOs can be part of the content of the various platform's tools.

Since LAMS platform support DLOs positively (Levy et al., 2009), pre-service teachers (PSTs), acting as TLS designers, can play a central role in STEM education. A group of LAMS tools form learning blocks. The learning blocks correspond to learning activity types. Group of blocks may form larger learning blocks, supporting learning activities in an inquiry-based framework. According to the categorization of Harris et al. (2009), learning activity types may belong to the following categories:

a) Knowledge-building (e.g., Read text),

b) Convergent Knowledge Expression (e.g., answer questions), and

c) Divergent Knowledge Expression (e.g., do a presentation).

In our study, the development of TLSs was structured in the LAMS platform. The platform provided tools categorized as:

a) Flow (Gate, Grouping etc.),

b) Evaluation tools (Assessment, like Multiple Choice and Reflective, like Question & Answer),

c) Collaboration (Chat, Forum etc.), and

d) Content (Noticeboard etc.).

LAMS tools can be used to organize TLSs according to the flow of the designed sequence. For example, the gate tool can be used when the designer wants participants to reach a specific point in the TLS before all the participants move forward. In the same line, the grouping tool can be used in order to create groups dealing with different activities.

This study examines the following research question: How do primary pre-service teachers design digital STEM Teaching-Learning Sequences? In particular we investigate the learning activity type integrated by pre-service teachers in the design of a digital TLS about climate change in the LAMS environment.

Research Context And Implementation

The research was conducted under the European Union Erasmus+ project STEM-DIGITALIS. The aim of the project was to develop digital tools and learning objects for advanced STEM topics, like climate change, renewable energy (RE) sources, etc. Within this framework, four (4) Digital Learning Objects (DLO) were developed to facilitate inquiry-based learning and provide immersive, interactive experiences for students. The four DLOs included two interactive graph representations, an interactive video, a computer game, and an augmented reality (AR) application. These TLSs were structured according to the Model of Educational Reconstruction (Duit et al., 2012), which emphasizes the integration of scientific content, student perspectives, and effective teaching strategies. Below it is a short description of the three units:

The first TLS focuses on the correlation mechanism between global temperature and CO_2 concentration. It is based on a serious game, designed with Unity 3D platform, where participants navigate through the last four decades, searching for evidence on the correlation between CO_2 concentration and temperature. The game is assisted with hotspots and players access additional information, such as interactive graph representations, an interactive video, answer multiple-choice questions and explore online dashboards for visualizing trends and drawing conclusions. The game is designed to foster critical thinking and data analysis skills, enabling participants to explore the correlation between rising global temperature and increasing CO_2 concentration.

The second TLS shifts focus to the anthropogenic activities that contribute to climate change and

the mitigation measures individuals can take. This TLS utilizes interactive maps and a mobile application to engage participants. The maps display data on CO_2 emissions per country and per activity (e.g., transportation, energy use), providing a global perspective on CO_2 emissions. The application allows the users to calculate their personal CO_2 footprint based on their daily activities. Users have choices on two daily personal activities: transportation and electrical device use. The results are visualized through daily pie charts, offering an understanding of their personal environmental impact, encouraging reflection on mitigation strategies.

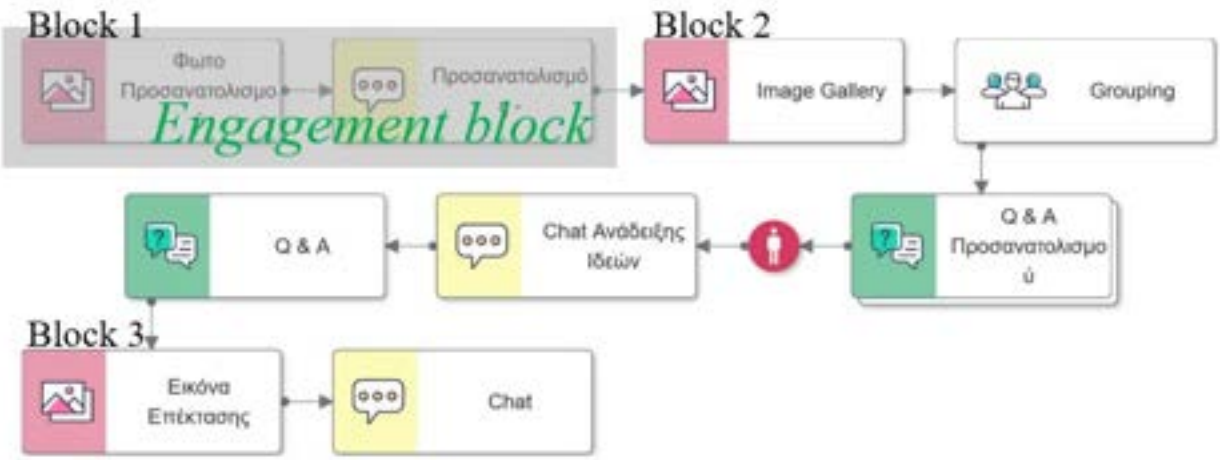
The third TLS explores the socio-scientific dimensions of RE, particularly the challenges and opportunities associated with transitioning to climate neutrality. This TLS employs an augmented reality (AR) application and a "treasure hunt" activity to engage participants in role-playing and collaborative problem-solving. Participants are divided into groups and assigned roles (e.g., politicians, activists, researchers, etc.) to represent different stakeholder views in the debate. Using the AR application, participants scan images to access information, solve riddles, and examine the perspectives of stakeholders. This activity enhances critical thinking, negotiation skills, and the understanding of the complex social implications of RE policies.

The TLSs were introduced in a seminar entitled "Digital Tools in Science Education", offered to 17 PSTs, in third and fourth year of their bachelors in primary education. The participants had attended one compulsory foundational course on the concepts of physics and one on the principles of science education. The participants were randomly divided into six subgroups (five groups of three and one group of two) to encourage collaboration and peer learning.

The seminar was structured into three phases:

- Introductory Phase: It introduced participants to various digital tools used in STEM education, including interactive videos, graphs, infographics, games, mobile applications, AR, and digital labs. The participants focused on the attributes, benefits and drawbacks of each tool. The LAMS platform was presented, highlighting its features for designing and managing TLSs.
- Familiarization Phase: Participants engaged with the three pre-designed TLSs on climate change (CC), utilizing different DLOs. They experienced TLSs as learners and reflected on their potential application in future teaching practices.
- Design Phase: Participants designed their own digital TLSs using the introduced DLOs, enriching them with other activities and tools. Each PST group developed a unique TLS on a CC-related topic, applying the knowledge and skills acquired during the seminar.

Data Collection & Analysis



The analysis focused on how the PSTs integrated the DLOs and other types of learning activities within each digital TLS.

The topics of the PST-designed TLSs included:

1. Climate Change and Electric Tranportation,
2. Human Factors Affecting Climate Change,
3. Transportation and Climate Change,
4. The CO_2 footprint of Food,
5. Human Activities and Sustainable Development, and
6. The Personal CO_2 Transportation Footprint.

A variety of technologies were used to support the digital TLSs. Scaffolding activities created larger blocks guiding students through the inquiry process in developing TPACK and Technology-assisted, inquiry-based TLSs. A sample TLS is shown on Image 1. The first two blocks formed the engagement activities of the TLS (Image 1 – Engagement Block).

Image 1 Sample TLS (Group1 - Climate change and electric transportation).

To analyse the data, we used qualitative method of content analysis (Mayring, 2015). As Harris et al. (2009) suggest, the possible categories of learning activity types follow the schema shown in Table 1:

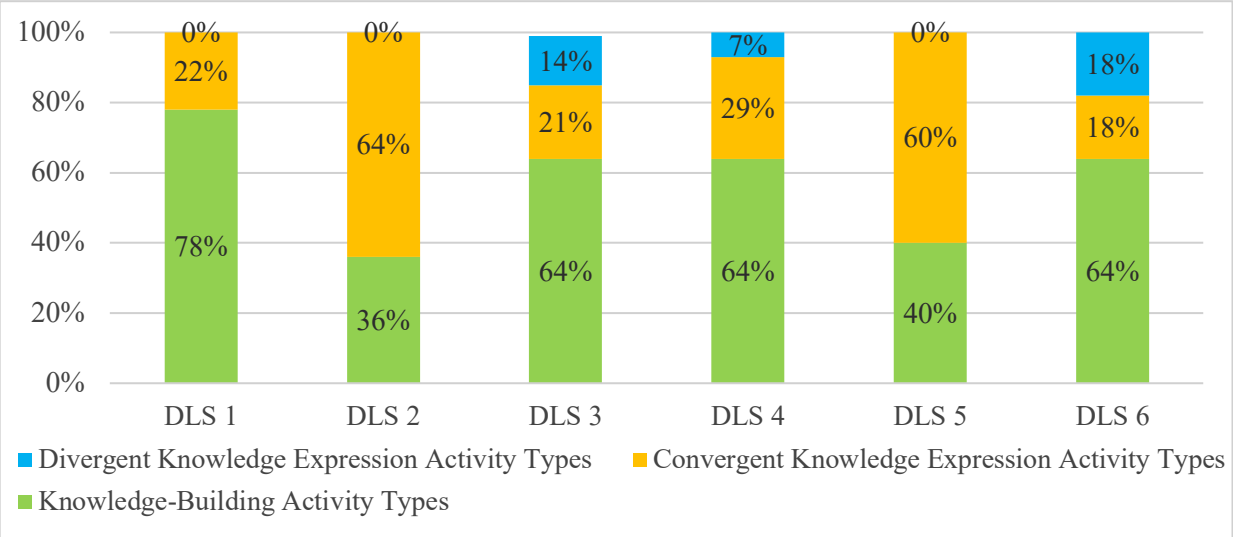


Table 1 Data Analysis Categories

CATEGORIES	CRITERIA	Example
Knowledge-building	Provide information and promote the understanding for the students for the necessary content-related information-building	Read text, view presentation, view images, etc.
Convergent Knowledge Expression	Handle types of tools that "structure representations of prior knowledge building".	Answer questions, take a test, etc.
Divergent Knowledge Expression	"Extend the students" content-related understanding by communicating the content to a wider audience.	Create an illustrated map, do a presentation, etc.

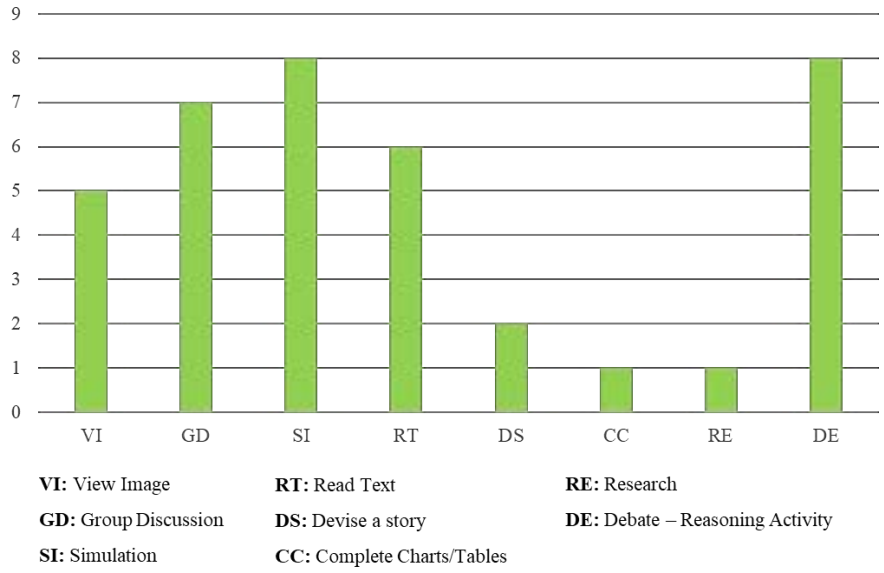
Results

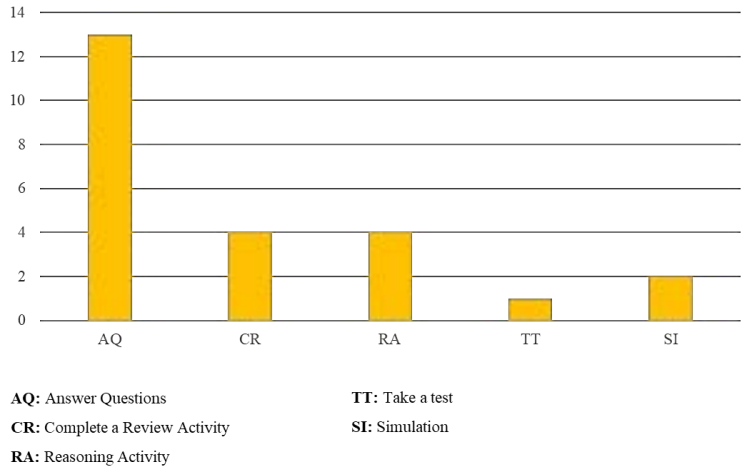
There is diversity on the learning activity type categories. Every sequence used different LAMS tools/activities. The total number of the LAMS tools used in the six TLSs is seventy-four (74). The percentage distribution of the three learning activity type categories across the six digital learning sequences, based on the schema presented above, is shown in Figure 1. Summative results indicate that all the TLSs used activity-type tools for Knowledge-building and Convergent Knowledge Expression. Knowledge-Building activity types prevail among the three categories examined and the Convergent activity types come second out of all. The three of six sequences integrate all three learning activity type categories. Four sequences use Knowledge-building activities in a rather high rate in contrast to the other two learning activity type categories.

Figure 1 Distribution of the four activity types in TLSs

As we delve deeper into each of the three categories, the distribution of learning activity types used with respect to Knowledge-building category is shown in Figure 2 A total of thirty-eight (38) LAMS tools were identified within this category. Debate and Simulation activities featured prominently. In contrast, the Complete Charts/Tables, Research and Devise a story activities barely register.

Figure 2 Knowledge-building activity types of the six DLSs.





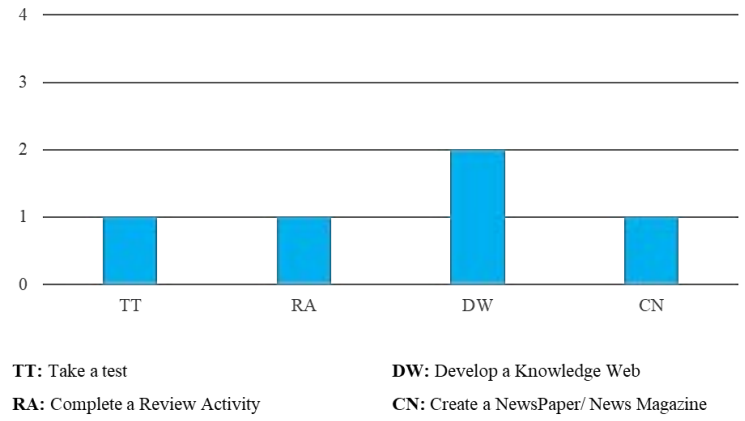


Figure 3 shows the distribution of Convergent Knowledge-building activity types among the six TLSs. This category comprises twenty-four (24) LAMS tools. The distribution reveals a pronounced dominance of the Answer Questions category. The remaining categories constitute the remaining proportion of the total.

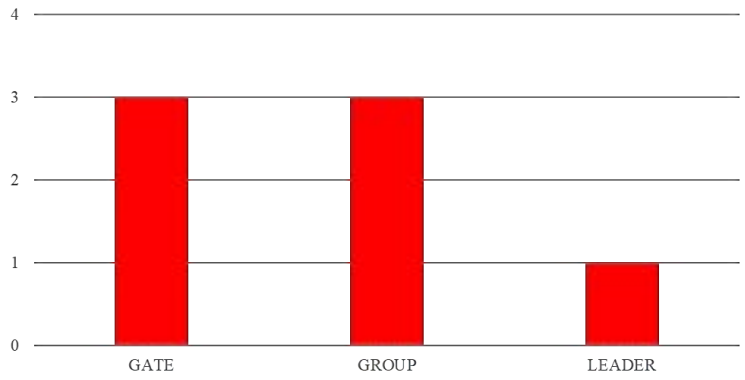
Figure 3 Convergent Knowledge building activity types of the six DLSs.



As shown in Figure 4, the Divergent Knowledge-building representation is the least populated category. Specifically, only five (5) LAMS tools were identified across three out of the six TLSs.

Figure 4 Divergent Knowledge building activity types of the six DLSs.

The flow tools category composes an important role at the sequences. Although the flow tools have rather technical attributes, than pedagogical or content specific attributes, they can contribute on a well-structured and well-designed digital sequence. These tools can split students into groups, create different learning paths for the students and other kind of structural options. In our findings, seven (7) LAMS flow tools used in three of six sequences.

Figure 5 Flow tools used into the six DLSs.

Conclusion/Discussion

Our research examined how primary pre-service teachers (PSTs) design digital STEM Teaching-

Learning Sequences (TLSs) within the LAMS platform, with a specific focus on the learning activity types they integrate into their digital sequences. The analysis of the six PST-designed TLSs reveals the design priorities of digital sequences.

The data confirms a preference for Knowledge-building and Convergent Knowledge Expression learning activity types, within the LAMS environment. The high frequency of structured activities like debates, simulations, and answering questions indicates that PSTs effectively leverage digital tools to deliver content and scaffold understanding through structured, guided inquiry. These findings highlight the PSTs' preference in choosing digital tools that correspond with specific objectives regarding content exploration and formative evaluation.

While PSTs' digital designs show familiarity in activities belonging in Knowledge-building and Convergent Knowledge Expression learning activity types, there is a notable lack of use Divergent Knowledge Expression activity types. The tools intended for use as activities in Divergent Knowledge Expression category suggest a more inspired and open-inquiry driven lesson structure. Therefore, the PSTs' digital designs show a tendency toward the design of clearly guided inquiry driven digital sequences.

Moreover, the limited use of flow tools (like gate, grouping and branching) indicates a strong preference among PSTs for linear digital learning sequences. In addition, Digital Learning Objects were only used in Knowledge-building and Convergent Knowledge Expression learning activity types. The use of DLOs was limited to those characterized by simplicity with direct functional value, like a mobile application for calculating personal carbon dioxide footprint. As a conclusion, a deeper understanding of digital tools' attributes and properties equips PSTs with the familiarity needed to utilize them more skilfully and flexibly.

A limitation of our research is its focus on the design phase by the PSTs. The effectiveness of the sequences in actual settings, in-class or remotely, is to be evaluated. Future research should therefore implement these sequences in real teaching contexts to assess their impact on student learning outcomes and engagement.

In summary, our results indicate that using Digital Learning Objects enhance the Digital Learning Sequences in STEM education and pre-service teachers are capable of designing coherent, digital STEM sequences that prioritize content exploration and guided inquiry.

Digital Experimental Protocols And Literacy: Interventions For More Learner Support In Science Education

Philipp Behrens, Jürgen Menthe and Anke Meisert
University of Hildesheim, Germany

Adapting experimental protocols from professional scientific formats is a traditional but challenging writing task in science education. These formats often provide limited guidance and involve specific difficulties such as disjointed sections, impersonal language, and unclear expectations regarding the audience. Language barriers further complicate matters for second language learners and native speakers with developing literacy skills, making protocols a daunting prospect for students. Despite these challenges, however, experimental protocols provide valuable opportunities for students to develop systematic documentation and data analysis skills, thereby enhancing their understanding of science. To facilitate the writing process, a student-centred approach has been proposed that uses redesigned protocols to divide the text into boxes containing sentences, connected by arrows across the results and discussion sections. Targeted writing scaffolds also support sentence construction.
This pilot study investigates whether a fragmented digital protocol format and the use of procedural language support increase students' perceived cognitive load compared to more traditional formats. A 2×2 design was implemented in four-year 8 physics classes (n = 78) during a four-lesson unit on motion and inertia, with two documentation formats (traditional vs. fragmented) and two types of language support (classical vs. procedural). Cognitive load was measured after the intervention using a nine-item questionnaire. The results show no significant differences in perceived cognitive load between the different documentation formats and types of language support. Therefore, despite their structural novelty, neither the fragmented protocol structure nor the procedural writing scaffolds led to increased cognitive load. These findings suggest that structural and linguistic design modifications can be introduced without overloading students cognitively. Ongoing analyses will examine how these design features influence the quality and structure of students' experimental documentation.
Keywords: cognitive load, laboratory reports, scaffolding

Theoretical background

Writing Experimental Protocols As A Linguistic And Cognitive Challenge

Experimental protocols are a traditional, yet challenging, writing task in science education. In particular, the linear text format—into which different types of statements (e.g., observations/results, and interpretations) must be integrated—requires a high level of linguistic competence (Bayrak et al., 2015; Boubakri et al., 2015). In conventional lab reports, clearly separated sections (e.g., observation vs. interpretation) support structure, but the purely linear production of text often makes it difficult to construct explicit argumentative links between results and their interpretation. This linkage, however, is central to scientific knowledge generation (Köhler & Meisert, 2025). For learners of German as a second language, as well as for first-language learners with weaker academic language proficiency, it is particularly challenging to navigate complex subject content and demanding linguistic structures simultaneously (Leisen, 2010; Childs et al., 2015) and even proficient speakers face difficulties due cognitive and structural complexity (Müllner et al., 2024; Heinicke & Friedrich, 2023).

To meet these demands, support measures are needed that combine disciplinary language, visual, and structural elements (Groß & Reiners, 2012; Leisen, 2010, 2022; Schmölzer-Eibinger et al., 2018). Digital writing environments offer additional potential in this respect, as they reduce the constraints of strictly linear text production and allow for flexible revision, rearrangement, and

linking of text elements (Clark & Mayer, 2016; Heinicke & Friedrich, 2023).

Structural Scaffolding Through Text Fragmentation And Visual Linking

One promising approach is the fragmentation of experimental protocols into smaller, functionally defined text units that can be visually linked to each other using arrows or other symbolic connectors, for example. Rather than listing observations first and interpreting them in a separate section later, this design enables students to link results and interpretations directly and step by step (see figure 1).

Figure 1. Traditional linear protocol format (left) vs. fragmented protocol format (right).

The fragmented protocol design makes it possible to link results and interpretations directly and to visualize their relations by means of arrows. In contrast to the classical linear protocol—in which observations and interpretations are strictly separated into their own sections—relationships can thus be reconstructed in smaller steps and with greater transparency (Groß & Reiners, 2012). The increased density of logical and linguistic connections between observations, data, and interpretation also facilitates the construction of argumentative or descriptive relations (Stein & Stumpf, 2019), improves clarity, and creates flexible options for additions and corrections during the writing process (Clark & Mayer, 2016; Heinicke & Friedrich, 2023). The decomposition into individual components additionally directs attention to subaspects and linguistic markers such as procedural expressions (Feilke & Rezat, 2020). Control questions, action prompts, and procedural language patterns make the requirements of individual protocol segments explicit and support the planning of the writing process (Feilke & Rezat, 2020; Krabbe, 2023).

Linguistic Scaffolding: From Classical To Procedural Language Aids

Students need more than just structural scaffolding; they also need linguistic support to cope with the genre-specific requirements of experimental protocols. In science education, so-called classical language aids are widely used for this purpose. These include word fields, sentence starters, writing frames and partially pre-formulated text elements (Leisen, 2010). Their primary function is to facilitate text production and reduce linguistic barriers at the formulation stage. Unlike these approaches, procedural language aids are based on the concept of text procedures (Feilke & Rezat, 2020). As well as supporting formulation, they explicitly address the function and epistemic purpose of each text segment. This is typically achieved through structured prompts, control questions and procedure-specific linguistic patterns that guide students through the processes of planning, monitoring and justifying their writing.

Figure 2. Classical language aids according to Leisen (2010) – word fields. (left) vs. procedural language aids (Krabbe, 2023; Feilke & Rezat 2020; Feilke & Rezat, 2021; Krabbe, 2023) – structered prompts (left), control questions (right).

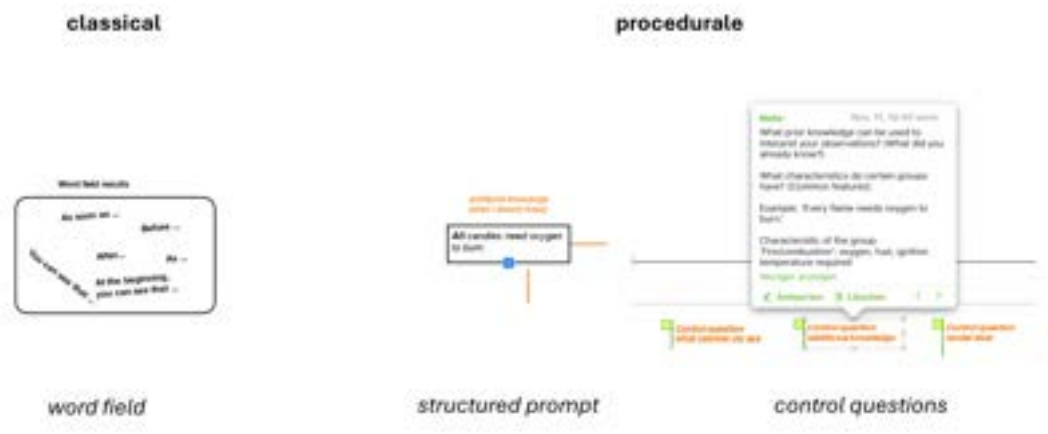

Figure 2 illustrates the conceptual difference between classical language aids, such as word fields and sentence starters, and procedural language aids, which are based on structured prompts and guiding questions (Krabbe, 2015, 2023; Feilke & Rezat, 2020). While the former primarily provide guidance on phrasing, the latter focus on the type of epistemic action to be performed in a given text segment (e.g. describing, justifying or interpreting). Procedural language aids therefore not only aim to reduce linguistic load, but also to foster a more explicit understanding of the writing task itself and the functional architecture of experimental protocols. In this sense, they can be understood as scaffolds that address the linguistic and epistemic dimensions of scientific writing.

The Tension Between Scaffolding And Cognitive Load

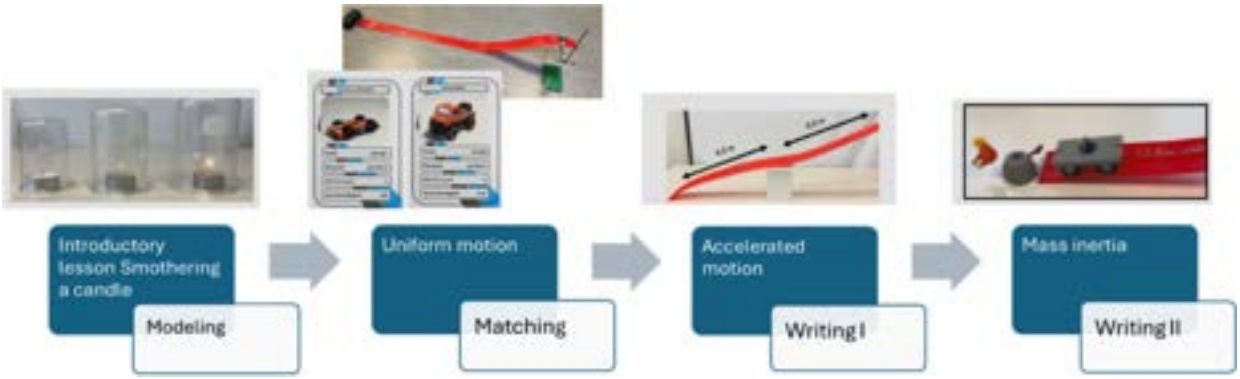
Although both fragmented protocol structures and procedural language aids offer significant support for students' scientific writing, they introduce new representational formats and increased orientation requirements. According to cognitive load theory, such design changes may initially increase extraneous or intrinsic cognitive load, particularly when learners encounter unfamiliar structures or multiple representational systems (Krieglstein et al., 2023). This creates a fundamental design tension: On the one hand, scaffolds should make relations, functions, and expectations more explicit, thereby reducing unnecessary cognitive demands. However, every additional structure, symbol system or prompt also constitutes an element that must be processed, understood and coordinated.

Therefore, the central design challenge is not to maximise scaffolding, but to calibrate support so that it reorganises and redistributes cognitive demands rather than simply adding new ones. Whether fragmented protocol structures and procedural language aids achieve this balance is therefore an empirical question rather than a purely theoretical one.

Research Questions

Against this background, the present study addresses the following research questions:

RQ1: Does a text-fragmented and visually structured experimental protocol lead to higher perceived cognitive load than a traditional linear protocol format?



RQ2: Do procedural, function-oriented language aids lead to higher perceived cognitive load than classical formulation-oriented language aids?

Research method and design

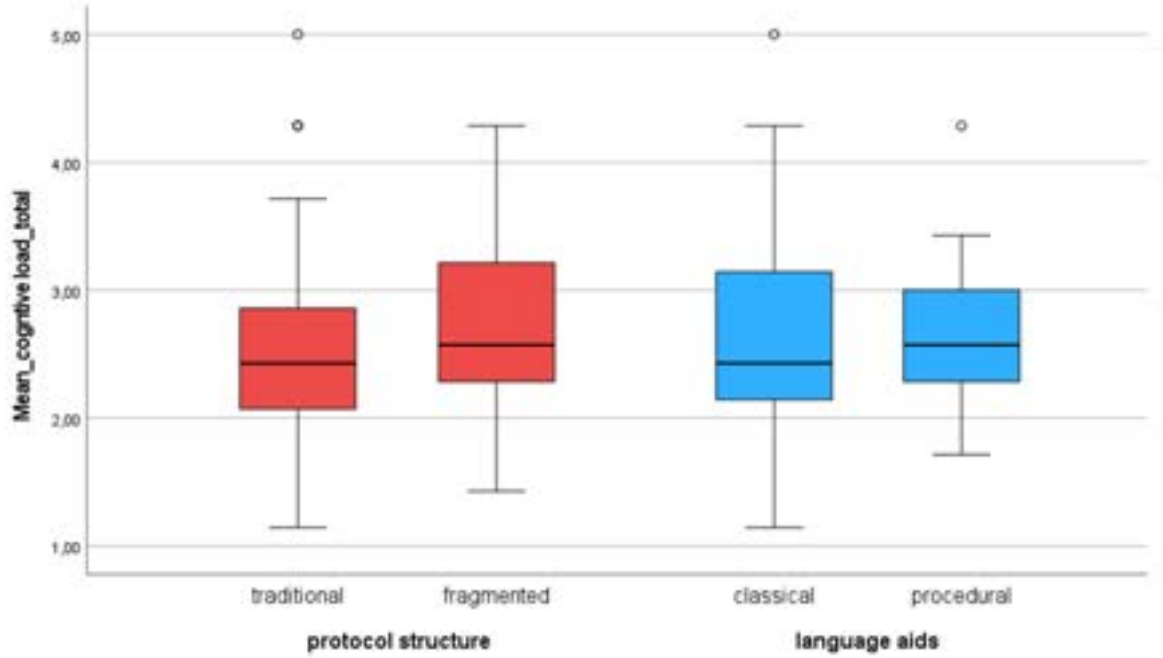
This study used a 2×2 design comparing two documentation formats (traditional vs. fragmented) and two types of language scaffolding (classical vs. procedural). The design resulted in four experimental conditions with post-measuring of perceived cognitive load as dependent variable.

A four-lesson physics unit on motion and inertia was completed by four seventh-grade classes (n=78). Depending on their assigned condition, students progressed from guided modelling (Lesson 1) over scaffolded practice (Lesson 2) to unsupported use (Lessons 3–4).

Figure 3. 4-lesson sequence on motion and inertia, showing the materials (above) and the language aids with decreasing level of instruction and support (below) used during the lessons.

Cognitive load was measured using a 9-item Likert scale (1–5), which was adapted from Krieglstein et al. (2023). These items addressed students' perceived mental effort, structural clarity and ease of orientation when working with the digital experimental protocol (e.g. 'The explanations of the protocol sections were difficult to understand'). The questionnaire was administered as a post-test after the fourth lesson and referred to students' experiences with the documentation format and language aids used during the unit.

As the data violated normality assumptions and sample sizes were limited, non-parametric statistical procedures were employed for the primary analyses. Group differences in cognitive load were examined using Mann–Whitney U tests. Additionally, Welch's t-tests were employed as robust parametric comparisons tolerant of unequal variances and group sizes. Effect sizes are reported as r for non-parametric tests and as η^2 for Welch tests (Bortz, 2005).



Results

The used cognitive load scale demonstrates good internal consistency (Cronbach's $\alpha = 0.816$).

Valid cognitive load data is available for group comparisons from n = 78 students (traditional format: n = 43; fragmented format: n = 35). Descriptively, mean cognitive load values are very similar across conditions. Students using the traditional format achieve a mean score of 2.53 (SD = 0.77; median = 2.33), whereas those using the fragmented format achieve a mean score of 2.56 (SD = 0.62; median = 2.56) (see figure 4, next page).

No statistically significant difference in cognitive load is found between the two protocol formats (Mann–Whitney $U = 672.50$, $Z = -0.805$, $p = .421$, $r \approx .09$). The corresponding Welch test also shows no significant effect (Welch's $F(1, 75.99) = 0.032$, $p = .858$, $\eta^2 < .01$). Tests of variance homogeneity is non-significant (all $p > .40$).

Figure 4. Paired box plot of the cognitive load of the protocol structure (left) and language aids (right).

Discussion

The present results show that the fragmented protocol format does not lead to a higher perceived cognitive load than traditional, linear documentation. This is a notable finding, given that the fragmented format introduces an unfamiliar structure to the documentation process and could therefore be expected to increase the demands of orientation and navigation (Krieglstein et al., 2023).

Two factors may help to explain this result. Firstly, the introduction of the fragmented format followed a gradual fading strategy with guided examples, which likely reduced the effects of initial disorientation. Secondly, the functional design of the format itself may compensate for its novelty. While the fragmented format introduces a new representational structure, it simultaneously reduces demands relating to strictly linear text production, linguistic planning and integrating different types of statements into a single, continuous text (Clark & Mayer, 2016; Heinicke & Friedrich, 2023). These reductions may offset the additional demands of navigating a segmented representation, resulting in overall cognitive load levels comparable to those of traditional formats. A central design intention of the fragmented format is to strengthen the argumentative link between observations, data, and interpretations. This addresses a well-known weakness of experimental protocols (Groß & Reiners, 2012) (Ref.?), whereby interpretative statements are often only weakly connected to the underlying observations and results. The visual structuring and explicit linking of these elements is intended to help students construct more coherent evidential relations. Ongoing qualitative analyses of the protocols will examine whether this functional promise is actually realised in students' documentation.

A similar pattern emerges when procedural writing scaffolds are used. While conventional language aids enable students to produce text quickly with minimal reflection, procedural scaffolds require them to engage more explicitly with the function and structure of each protocol section and its specific requirements. In principle, this could increase cognitive load. However, the absence of such an increase suggests that greater task transparency and clearer orientation

may stabilise or even reduce perceived cognitive demands rather than amplify them (Feilke & Rezat, 2020; Krabbe, 2023). In this sense, the fragmented structure and procedural scaffolds may free up cognitive resources for dealing with the task's content rather than surface-level text production.

Overall, the findings suggest that structural and linguistic design changes do not automatically result in a higher cognitive load. Instead, they appear to reorganise cognitive demands in a way that maintains overall mental effort at a comparable level (Krieglstein et al., 2023). From an instructional perspective, this implies that reworked documentation formats with a clearer structure and language can be incorporated into regular classroom practice without overwhelming students cognitively. However, the present data only address perceived overall cognitive load. Ongoing and future analyses will therefore examine students' protocol structures and their use of language scaffolds in more detail. Particular focus will be given to the separation of observations and interpretations, the linking of data and interpretations, and the development of data-based arguments.

Potential Of ChatGPT As A Pedagogical Tool In Biology Education: Enhancing Student Engagement And Critical Thinking

Arianne Redigolo[1], Murillo Beloti[2], Julia Silva[1] Tainá Lopes[1], Victor Romanato[1], Magda Pechliye[1]
[1]Mackenzie Presbyterian University, Brazil
[2]Federal University of São Paulo, Brazil

The integration of Artificial Intelligence (AI) in education has transformed learning processes, with ChatGPT emerging as a valuable pedagogical tool. The objective of this study was to analyse how ChatGPT could enrich the educational experience, promoting engagement, reflection and development of critical skills among students. Conducted in a state school in Diadema, São Paulo, Brazil, the research involved a first-year high school class (N=20) engaging in structured activities using ChatGPT. Students formulated questions, interacted with the AI, and completed a questionnaire assessing their perceptions. Results indicate that initial AI usage was superficial, with students seeking direct answers rather than engaging in critical inquiry. However, as the activity progressed, students developed more complex and reflective questions, demonstrating deeper engagement with the subject matter. Post-activity questionnaire responses highlighted a shift in AI usage, with students recognizing ChatGPT as a research tool rather than a means for effortless answers. Despite ChatGPT's benefits, the study underscores the irreplaceable role of teachers in guiding students toward meaningful learning. Teacher mediation was identified as essential for fostering critical thinking, refining questioning skills, and contextualizing AI-generated content. The findings reinforce the importance of balancing AI integration with human interaction, advocating for pedagogical strategies that leverage technology while maintaining teacher-led inquiry-based learning. Ultimately, this research highlights AI's potential to enhance education while emphasizing the necessity of teacher involvement in knowledge construction.

Keywords: Artificial Intelligence, Critical Thinking, Science Education.

Introduction

The integration of technology in classrooms has gained significant space in recent years, with emphasis on the use of Artificial Intelligence (AI) tools. Among these, ChatGPT (Generative Pre-trained Transformer), a language model developed by OpenAI, emerges as an ally in the teaching and learning process. Launched in 2019, ChatGPT is based on a large language model technology and uses Reinforcement Learning with Human Feedback (RLHF) to interact naturally with users, offering personalized responses and immediate feedback on tasks (Cano; Venuti; Martinez, 2023). However, it's use requires caution, since meaningful learning is based on the principle of constructing onw's one and personal meaning in relation to knowledge and learning situations, which demands understanding, analysis and critical reflection (Coll; Sole, 2006; Gomes; Frank; Rocha, 2020).

In addition, there is a risk that students might become excessively dependent on the tool, compromising the development of critical and emotional skills. Božić (2023) highlights that AIs can reduce face-to-face interactions and negatively affect students' emotional and social development. There is also a need to verify the accuracy of the information provided by the AI, as errors can occur. That said, even with the advantages of AI, it's evident that the role of the teacher remains essential. In addition to teaching academic content, the teacher collaborates with

the development of students' social, emotional and cultural skills.

Barreira, Moura-Silva, and Gonçalves (2024) emphasize that the use of AI should be complementary, helping teachers to deepen learning processes and students' socio-emotional development. The teacher also plays a crucial role in teaching students to ask questions and develop opinions, promoting autonomy and critical thinking. According to Farace (2024), it is up to the teacher to establish the connection between the content provided by AI and the individual experiences of students, promoting more integrated learning.

From a pedagogical perspective, the use of generative AI tools can be situated within the framework of active methodologies mediated by technology, which emphasize student protagonism, inquiry, and intentional teacher mediation (Araújo et al., 2025). In this view, digital technologies do not inherently promote meaningful learning; rather, it is the teacher's critical mediation that organizes, guides, and gives pedagogical meaning to students' investigative processes. This understanding aligns with research on interest development, which highlights that learners' engagement can evolve from situational interest toward more enduring forms of individual interest when students are encouraged to explore self-selected questions within a shared learning context, involving both affective and cognitive dimensions (Hidi & Renninger, 2006). Together, these perspectives help frame inquiry-oriented activities supported by generative AI as learning environments in which meaningful engagement may emerge through the combination of personal interest, structured inquiry, and teacher mediation.

The main aim of this study was to explore how upper secondary students interact with a generative AI tool (ChatGPT) during an inquiry-oriented Biology activity, and how teacher mediation influences the depth and nature of this interaction. Rather than evaluating learning gains or content mastery, the study focused on understanding students' inquiry behaviours, including the formulation and refinement of questions, the use of AI-generated responses, and students' perceptions of the role of the teacher in this process.

More specifically, the study sought to examine whether students' initial use of ChatGPT, often characterized by direct answer-seeking, could evolve toward more reflective and exploratory forms of questioning when embedded in a mediated classroom activity.

Based on these aims, the study was guided by the following research questions:

1. How do students formulate and refine questions when interacting with ChatGPT during an inquiry-based Biology activity?
2. What changes can be observed in the nature of students' interactions with ChatGPT throughout the activity?
3. How do students perceive the role of teacher mediation in supporting meaningful use of generative AI in the learning process?

These questions were intentionally framed in an exploratory manner, consistent with the short duration of the intervention and its implementation in a single classroom session. Accordingly, the study does not aim to establish causal relationships or generalizable outcomes, but to generate situated insights that can inform future research and pedagogical practices involving the integration of generative AI in science education.

Methodology

Activity Design And Procedures

The study was conducted in a public state school located in Diadema, São Paulo, Brazil, with a first-year high school class composed of approximately 20 students, aged between 15 and 16

years old. This educational stage was selected because the topic Fungi is formally introduced in the biology curriculum at this level. The theme involves abstract biological concepts, such as structure, reproduction, ecological roles and symbiotic relationships, that often require a deeper conceptual understanding to support knowledge construction. Consequently, students require pedagogical support to actively relate new information to pior knowledge, establish conceptual and personal connections and engage in explanatory reasoning to construct scientifically grounded understandings. In this context, the use of Artificial Intelligence was included as a mediating digital tool to support and stimulate the access to scientific information, aligned with the teacher guidance in fostering reflective and meaningful learning processes.

Rather than testing predefined learning outcomes, the proposal sought to understand changes in student's questioning behaviour, use of ChatGPT, and perceptions of teacher mediation. The activities took place in the school's computer laboratory. It is important to highlight that, prior to the start of activities, a survey of the student's prior knowledge was conducted through a word cloud built based on what the students associated with the topic of fungi. This word cloud was organized on the blackboard. The central activity was structured in three main stages, with students organized in pairs for the first and second stages.

A) Stage 1: Question formulation (20 minutes)

Students were asked to formulate general and specific questions related to the theme Fungi, starting from de guiding question "What are fungi?". There were no explicit instructions on how to ask those questions at this point.

B) Stage 2: Guided interaction with ChatGPT (20 minutes)

Students used the ChatGPT to seek answers to their questions and deepen their knowledge. The teacher acted as a mediator, encouraging students and emphasizing investigation, exploration and reflection rather than the search for direct answers.

C) Stage 3: Questionnaire (individual)

At the end of the activity, the students completed a questionnaire specifically designed to identify their perceptions of: before using ChatGPT, their interactions with the AI tool and the difference before and after the activity, the teacher's role during the activity, and their own expectations regarding the future use of ChatGPT for learning purposes.

Data Collection And Analysis

Data were collected from two main sources, the questions formulated by students during ChatGPT interaction and the questionnaire. The collected data were analyses using a quali-quantitative approach. Qualitative data consisted of the questions formulated by students during the second stage of interaction. These questions were initially red and grouped according to their thematic focus, based on the biological content, that were organizes in three categories:

1. Structure and Reproduction of Fungi;
2. Ecological Interactions and Health Impact;
3. Applications and Uses of Fungi.

The categorization made it possible to identify how the students searched for different dimensions of the subject during their guided interaction with ChatGPT, navigating from structural and reproductive aspects to ecological roles and practical applications.

Quantitative data from the questionnaire were analysed descriptively using absolute frequencies.

Qualitative and quantitative results were interpreted together to identify consistencies between

student´s reported perceptions and their observed questioning behaviour.

Results And Discussion

In the first stage of the activity (question formulation), students initiated their interaction with ChatGPT by asking the question "What are fungi?". As expected, the AI-generated responses were very similar, given the uniformity of the initial prompt. For this reason, these responses were not transcribed.

Prior to the intervention with teacher's mediation, students tended to use the tool superficially, obtaining quick answers or through "copy-and-paste" practices. This was noticed in the first stage, as students asked direct questions and didn't engage in follow up questioning, and directly address to research question 1, regarding how students initially formulate and refine questions when interacting with ChatGPT.

In the second stage (guided interaction with ChatGPT), students worked in pairs to formulate their own questions so they could deepen their understanding of fungi. The questions generated during this stage were grouped into three categories (Table 1).

Table 1. Questions asked to AI during the second stage of the research, later categorized.

Category	Questions
1. Structure and Reproduction of Fungi	What are hyphae and mycelium?
	How is each fungal species formed, and what characterizes them?
	What does sexual and asexual reproduction mean?
	Do fungi create genetically similar clones?
2. Ecological Interactions and Health Impact	Why are fungi so ecologically important?
	What are beneficial symbioses?
	Where can parasitic fungi be found, and how can they be identified?
	Why are some fungi pathogenic?
	Why are some diseases are caused by fungi?
3. Applications and Uses of Fungi	How are fungi used in medicine?
	How can fungi be used in food production?
	So, is the bread we eat made by a fungus?

After the intervention, student's demonstrated a more reflective and in-depth use of ChatGPT as an ally to the learning processes, characterized by the elaboration of more complex questions and detailed research, with a more sustained inquiry process, that suggests the increased curiosity, engagement and interest of the students.

In the first two categories above, although the questions were not very reflective and still focused on conceptual understanding, some went beyond basic concept definition. For example: Do fungi create genetically similar clones? (category 1) and Where can parasitic fungi be found, and how can they be identified? (category 2). These can indicate the effort to explore mechanisms, processes and applications of Fungi. In the third category, several questions were connected with student's everyday experiences, providing a more reflective perspective, such as food

consumption and health. Here we observe that as the guiding teacher encourages more reflective questioning, students will have the opportunity to learn how to ask new questions, and enhance their inquiry skills (Farace, 2024).

Four of the ten questions involved in the third stage (questionnaire) were selected for these discussion. Of the 20 students, 17 responded to the questionnaire. In the first question ("Had you ever used Chat GPT before this activity?"), 16 students reported prior use of ChatGPT, which was expected given the frequent exposure to digital technologies nowadays. Even though current generations were born in contact with technology, this familiarity does not necessarily indicates effective or critical use of those digital tools such as ChatGPT.

The second question addressed the main differences students noticed in using Chat GPT before and after this activity. Three representative literal responses were selected for analysis: *"Now I've stopped cheating and started using it as a research tool"*; *"I stopped getting answers and started asking"*; and *"Before, I only got the answer to the activities; today I was able to study through it to learn and not just copy what is written."* These responses suggest that students began to understand the importance of moving beyond the mere reproduction of the contents toward seeking more connections, and constructing understanding, align with the meaningful learning processes proposed by Coll and Solé (2006).

In the third question ("Do you think that the teacher can be removed from this activity, so you (students) would do the activity alone?") of the 17 answers obtained, 16 considered the teacher's presence essential, while one student reported not understanding the question. Two highlighted literal answers were: "No, because the teacher is there to guide and teach" and "I think it is good for the teacher to advise the students in the activity". These answers indicate that the students realize the importance of the teacher's role as a mediator, who supports active learning, and not as the source of answers, which aligns with Barreira, Moura-Silva, and Gonçalves (2024), that emphasizes the teacher's role in the knowledge construction fostering critical questioning, although, unfortunately, teacher education programs often does not prepare them adequately to carry out this mediation role (Nóvoa, 2017)

In the fourth question ("Do you think your way of interacting with ChatGPT will change from now on?"), 13 students said that they believed their interaction would change, while four disagreed and said that wouldn't change. Statements such as "Use for research and not for cheating" and "I will dive deeper and create more questions instead of just getting simple answers." indicate that students understood the purpose of the activity as an opportunity to investigate and learn, rather than merely reproduce information. Some responses highlight the relevance of teacher mediation supporting high-quality questioning and knowledge construction such as: "More detailed and specific question", "I would change to try to understand the lessons, for example, ask questions about the doubts I have about the activities" and "Now I know how to ask the right way".

Although ChatGPT does not always responds with the adequate concept and knowledge, it is possible to reduce the chance of errors when formulating good questions. As for good questions, we consider that the more the teacher encourages the student to be reflective and critical about a given subject, the more these questions will be improved in terms of quality (Farace, 2024). These responses relate to research questions 2 and 3, particularly regarding changes in interaction patterns and student's perceptions of teacher mediation. In some way, ChatGPT's clarity and accessibility contributed to more meaningful learning, reinforcing its usefulness as a complementary tool. However, the study also underscores the importance of teacher mediation, as highlighted by Barreira, Moura-Silva, and Gonçalves (2024), who point out the irreplaceable

role of educators in guiding the learning process. These findings can be interpreted considering interest-driven learning perspectives, which emphasize the role of student's personal interests in fostering deeper engagement and inquiry (Hidi & Renninger, 2006).

This study presents limitations that should be considered. First, the intervention was conducted with a single class, involving a limited number of participants, which restricts the possibility of statistical generalization. Second, the activity took place during one class session, which constrains the observation of longer-term learning processes and the consolidation of inquiry practices supported by generative AI. In addition, the study was carried out in a specific public-school contexto, in Brazil, characterized by particular curricular, institutional, and temporal conditions. As a result, these findings should be understood as context-dependent and illustrative of possibilities rather than as representative of all educational settings or student populations.

Therefore, the results do not aim to establish any causal relationships or universal claims about the impact of ChatGPT on learning. Instead, they indicate tendencies and patterns of interaction that emerge when generative AI is integrated into an inquiry-oriented Biology activity with explicit teacher mediation. These limitations are consistent with the exploratory nature of the study and support a cautious interpretation of its scope and applicability.

Conclusion

This study reinforces that ChatGPT can be a powerful educational support tool, as long as used in a critical and mediated manner. Its capacity to personalize content and provide clear answers makes it a valuable resource for enriching the educational process. However, teacher mediation remains essential to ensure that interactions are meaningful and aligned with learning objectives. In this perspective, the teacher is understood as a mediator and collaborator, not a transmitter of knowledge. However, to assume this mediating role, it is necessary to disengage from the traditional conception of teaching and focus on the process of knowledge construction. This highlight the need for teachers to reflect on their conceptions of science, learning and education, which should be addressed in teacher training courses.

The integration of artificial intelligence in education also raises ethical and cultural challenges that demand continuos reflection and adaptation. Moreover, the new learning culture requires that teachers and students to develop critical thinking, soft and digital skills, fostering a more inclusive and meaningful education. Within the context of this study, the use of ChatGPT appers to have contributed not only to development of critical and investigative skills, but also to increase student engagement and interest, expanding the possibilities of integrating AI in various disciplinary contexts. This work emphasizes the importance of balancing technology and human interaction, pointing out ways for a more innovative and inclusive education.

From a methodological standpoint, reflective and critical reading and writing activities related to the topic of fungi could have been carried out prior to the use of the AI tool in this specific context. Such an approach might have provided students with conceptual and argumentative references that would enable them, under teacher mediation, to engage in a more critical, conscious, and problematizing dialogue with the artificial intelligence.

In this perspective, it's interesting to consider for further research these reflective and critical reading and writing practices as pedagogical actions that might precede the use of generative AI, that's because it highlights the central role of intentional teacher mediation in shaping students' interactions with such tools. This understanding supports the relevance of comparative designs that explicitly examine the presence or absence of teacher mediation, as well as investigations into teachers' pedagogical beliefs and professional development. Together, these lines of inquiry

may contribute to the development of evidence-based guidelines for the responsible, critical, and pedagogically grounded use of generative AI in science education.

Acknowledgement

The authors gratefully acknowledge the participating school and the students involved in this study for their collaboration and engagement, which were essential to the development of the research. We also thank the ESERA participants, researchers, and members who read, questioned, commented on, and offered suggestions for our work, with special appreciation to Jonathan Osborne, whose contributions and feedback during the presentation provided important inspiration for the final version of this study. Finally, we thank our professors, colleagues, and institutions that, directly or indirectly, contributed to the completion of this research.

How To Teach Science To 3-6-Year-Old Pupils: Pre-Service Teachers' Perceptions Of Immersive Training With 360° Classroom Videos

Estelle Blanquet[1] and Alain Sénécail[2]
[1]LACES University of Bordeaux - INSPE, France
[2]TECFA-FPSE University of Geneva, Switzerland

The paper explores how immersive training using 360° classroom videos can enhance science education for children aged 3-6. In France, future primary teachers, often with limited scientific backgrounds, receive minimal science education during their Master's-level training, which poses challenges for teaching science effectively. To address this, the study investigates the perceptions of pre-service and early-career teachers regarding immersive 360° video training as a tool for improving their pedagogical approaches. The training involved two phases: a 2D workshop presenting a lesson on buoyancy and an immersive 360° session using a Quest headset. The 360° session featured augmented content and a sequence based on the children's book Plouf to explain the concept of pulleys. Ninety-four participants, primarily inexperienced teachers, evaluated the training through pre- and post-session questionnaires. Findings reveal that 73.3% found the 360° videos immersive, with key elements like spatial exploration and audio ambiance enhancing engagement. Over 74% felt the training significantly improved their understanding of scientific criteria, while 66.7% reported increased motivation to teach science through inquiry-based methods. However, 68% of participants experienced physical discomfort during 360° sessions, indicating room for improvement. The study highlights the potential of immersive tools such as 360° videos to bridge the gap between theory and practice in teacher training. Future research will compare the effect of the order of the two session modalities offered to students on their appropriation of the targeted elements of scientificity and perception of the 360° modality.

Keywords: Immersive Teacher Education; Science Education; 360° video

Introduction

This paper explores how immersive training using 360° classroom videos can support science education in early childhood (ages 3–6). In France, future primary school teachers, many of whom have limited scientific backgrounds, receive relatively little training in science education during their Master's programs. This situation is particularly problematic given that international assessments consistently highlight significant difficulties in science learning among primary school pupils (IAEEA-TIMSS, 2024; OECD-PISA, 2025). Furthermore, opportunities for trainee teachers to observe science teaching practices in kindergarten classrooms are rare, and existing practices are often misaligned with curricular expectations (Cavaillès et al., 2023).

In response to these challenges, this study examines the potential of immersive technologies to enhance teacher education in science. More specifically, it focuses on the perceptions of pre-service and early-career teachers regarding the use of 360° classroom videos as a professional training tool, and on how such environments may help them better appropriate key elements of the scientific approach in early childhood education.

The training program was designed around two complementary modalities. The first consisted of a trainer-led workshop in which excerpts from a kindergarten science lesson on buoyancy, filmed using 360° video, were projected onto a conventional 2D screen. The second modality involved an immersive 360° session using a Quest headset, combining classroom environments with augmented pedagogical resources. This 360° sequence was based on the picture book *Plouf*

(Philippe Corentin, 1991) and aimed to introduce the principle of the pulley (Blanquet, 2010; MEN, 2023). Across both modalities, the training emphasized the explicit formulation and analysis of scientific criteria, such as the primacy of experimentation, reproducibility, and the robustness of experimental setups (Blanquet & Picholle, 2016).

The design of this training sequence draws on research suggesting that immersive and contextualized learning environments can support professional learning by fostering situated understanding, engagement, and transfer to practice (Degeuse & Sénécail, 2025; van den Beemt & den Brok, 2019). Studies have also shown that immersive technologies can enhance learner motivation and knowledge acquisition (Bower et al., 2020). In the field of teacher education, 360° video has been identified as a particularly relevant tool for providing authentic classroom experiences and supporting professional vision (Qian, Shang & Qin, 2023). However, despite growing interest in immersive video for teacher training, relatively few studies focus on specific subject areas (Roche, Rolland & Cunningham, 2023), and even fewer address science education in early childhood contexts (Tan, Wiebrands, O'Halloran & Wignell, 2020).

Building on this gap, the present study investigates how pre-service and early-career teachers perceive immersive 360° video-based training for teaching science in kindergarten.

Context and Theoretical Framework

In France, future primary school teachers are trained to teach pupils aged 3 to 11, and are recruited on the basis of a regional competitive examination at Master's level. Training institutes within universities offer Master's-level courses dedicated to the training of these teachers, the content of which is defined by the Ministry of Education at national level. Even though most of the students in these Master's programs do not come from scientific backgrounds, and the results of international tests show that primary school pupils have major difficulties in science, their training in science teaching is very limited (32 hours in all over the course of the Master's program). The situation is such that it's also difficult for them to observe teachers doing science particularly at Kindergarten level, as the latter are rare and their practices are rarely in line with expectations.

This paper addresses the critical need to enhance science education in early childhood (3–6-year-old) by empowering teachers with innovative teaching approaches, specifically utilizing 360° videos to foster engaging learning environments that stimulate curiosity and critical thinking through the analysis of in situ situations filmed in classrooms with teachers. Indeed, the teaching plan that we designed aims to equip future and in service teachers with the necessary skills to implement scientific criteria in their daily practices.

Researchers suggest that immersive technologies, provided with authentic and contextualized learning experiences, can enhance training (Milgram et al., 2020; 1995). The benefits of virtual immersion in education are varied: it offers variety to teaching methods, encourages situated learning, facilitates transfers to professional environments… (Dunleavy & Dede, 2014; Mellet-d'Huart, 2021, Walshe & Driver, 2019; Theelen, van den Beemt & den Brok, 2019). Moreover, research shows that interacting with these technologies stimulates student engagement and motivation, and improves knowledge acquisition (Slater, 2017; Bower et al., 2020). Regarding 360° video, it is considered an effective tool for assessing professional engagement, providing future teachers with immersive experiences closer to reality (Roche & Rolland, 2020; Qian, Shang & Qin, 2023). The potential of interactive video as a learning tool seems to be a real enabler, emphasizing its role in actively engaging students and improving cognition and attention (Altinpulluk, 2019; Merkt & Schwan, 2014). However, only few studies focus on a specific subject-matter (Roche, Rolland & Cunningham, 2023), and fewer on science education (Tan,

Wiebrands, O'Halloran & Wignell, 2020).

Research Questions

While 360° video immersive learning environments have been explored in terms of engagement, motivation, and professional development, little research has examined their perceived benefits and challenges for teaching science in preschool education. Although our study encompasses a broader analysis of the impact of 360° training, this paper specifically focuses on how teacher trainees perceive its effectiveness in supporting science instruction in early childhood settings.

Method and Design

We designed a two-phase training program using two different modalities:

- A trainer-led workshop based on extracts from a learning sequence on the concept of buoyancy filmed via 360° and projected onto a conventional 2D screen.
- A virtual reality training session (Quest headset) featuring hybrid resources: interactive environments with augmented documentation and a detailed presentation of a learning sequence, based on the picture book *Plouf* (Philippe Corentin, 1991), to explore the principle of the pulley.

Each phase was designed to include the presentation of the science sequence in kindergarten, with the emphasis on the teacher's explicit formulation of elements of the scientific approach, while providing a definition of these elements (testing reproducibility, the robustness of an experiment, the primacy of the experiment, etc.).

To assess the impact of the training sequence on perception and knowledge acquisition, students followed one of two pathways: either starting with the 2D workshop before moving on to the 360° training or reversing the order by beginning with virtual reality before engaging with the 2D workshop. The training was conducted six times with master's level students, totaling 94 participants (Table 1.), about half of whom (51) were very-early-career teachers.

Table 1. Participants.

		Preservice Teachers	Early Career Teachers
Age Average		24	35,7
Population		43	51
Gender	Male	11	8
	Female	32	42
	Other	-	1
Average teaching experience alone		Less than a week	Approximately three months part-time

Among those who had already taught, their teaching experience was very limited (only a few months at most), and very few had worked in preschool settings.

When it comes to their exposure to early childhood education, 80.9% reported having observed preschool classrooms, but only 42% had ever seen science being taught in these settings. When science activities were observed, they were primarily focused on biology, with an emphasis on hands-on activities, plant-related topics, and questioning strategies.

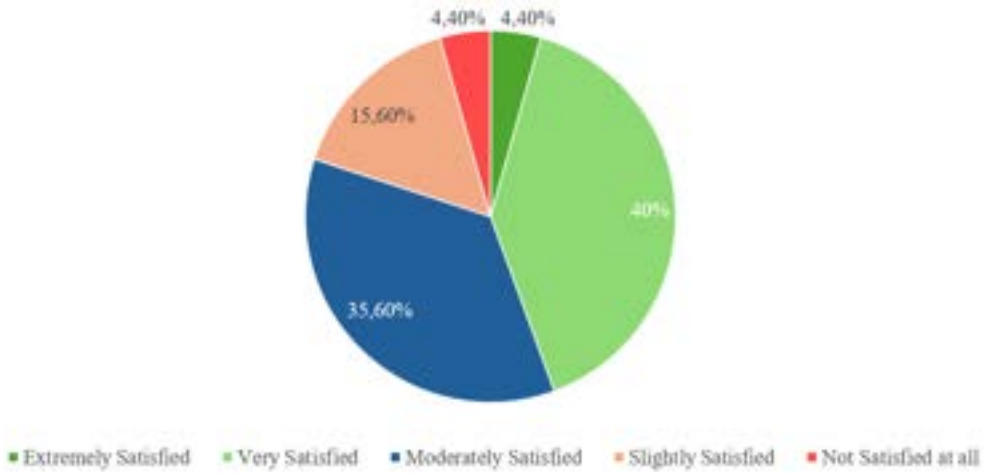
Questionnaires were distributed before the training sequence and after each phase (2D and 360°). The first questionnaire aimed to assess students' familiarity with immersive technologies as well as their initial conceptions of scientific criteria. The two subsequent questionnaires focused on gathering their perception of the training they had just completed, evaluating their sense of self-efficacy, and measuring their progress in understanding the definitions of scientific criteria. For this paper, we choose to focus exclusively on the question of pre-service and in-service teachers' perception of the 360° training.

Findings

Perception Of The 360° Experience And Setup

Overall Satisfaction

Figure 1. Global satisfaction concerning the immersive training.



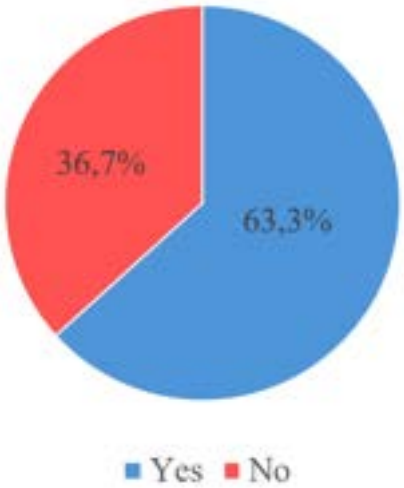


Figure 2. Participants' willingness to recommend the training to pairs.

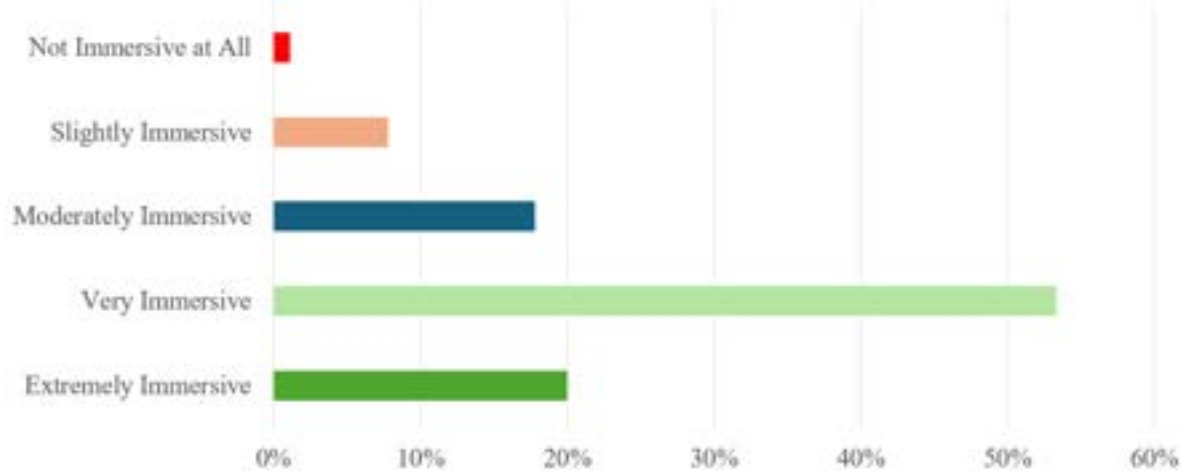
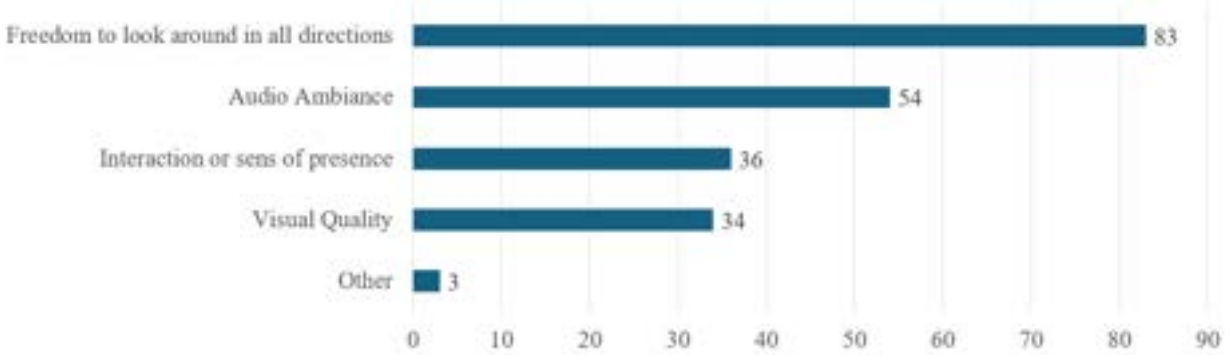


The results (Figures 1 and 2) show that 44.4% of the participants were extremely or very satisfied with the immersive training, while 35.6% rated it as moderately satisfying, which is an engagement with the experience. On the other hand, 20% expressed lower satisfaction, which is an opportunity to further improve the training in order to meet the expectations of the participants.

Similarly, 63.3% of participants would recommend this training to others, reflecting overall positive feedback. While some did not feel inclined to recommend it, this provides valuable insights for potential improvements to make the experience even more impactful.



Immersion

Figure 3. Perceived level of immersion in the 360° video.

Most participants (73.3%) found the video very or extremely immersive (Figure 3), confirming its strong impact. With 17.8% rating it as moderately immersive and only 8.9% as slightly or not immersive, the experience was generally engaging.

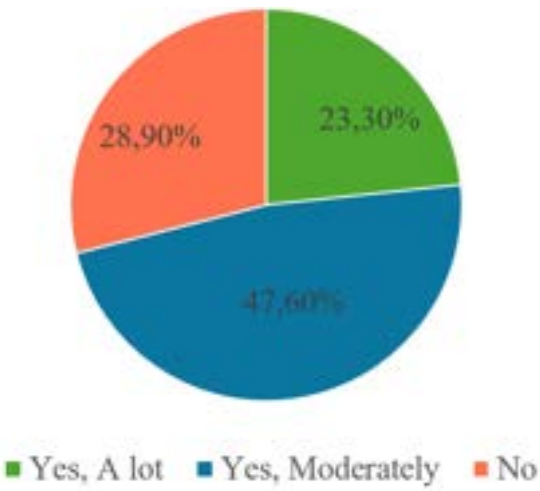


Figure 4. Aspects contributing to participants' sense of immersion.

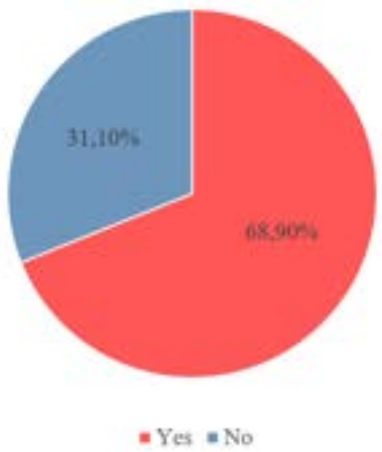
The key factor enhancing immersion was the freedom to look around (83 responses), followed by audio ambiance (54) and visual quality (34). Interaction and sense of presence (36) also contributed, while only 3 participants mentioned other factors (Figure 4). This highlights the importance of spatial exploration and sound in creating an immersive 360° experience.

Furthermore, when asked whether the use of 360° video led to better engagement, the majority 71,2%) responded yes (Figure 5).

Figure 5. Perceived impact of the immersive format on participants' engagement with the content.



When asked about the reasons for their increased engagement (Table 2), participants emphasized the importance of immersion, particularly through a sense of involvement (10) and being in a science classroom (9). They also highlighted better concept understanding (6), stepping into the teacher's role and perspective (10), and connecting theory to practice (5). Technological affordance and freedom of navigation (4) further reinforced the immersive experience, making it a key factor in engagement.

Table 2. Categories related to participants' perceived reasons for increased engagement.

Category	Count
Sense of involvement/engagement	10
Immersion in a science classroom	9
Better understanding of the concepts at play	6
Projecting oneself into the role of a science teacher	5
Stepping into the teacher's perspective	5
Connecting theoretical content to real-world practice	5
Putting oneself in the place of a student	4
Technological affordance	4
Freedom of navigation and choice / autonomy	4

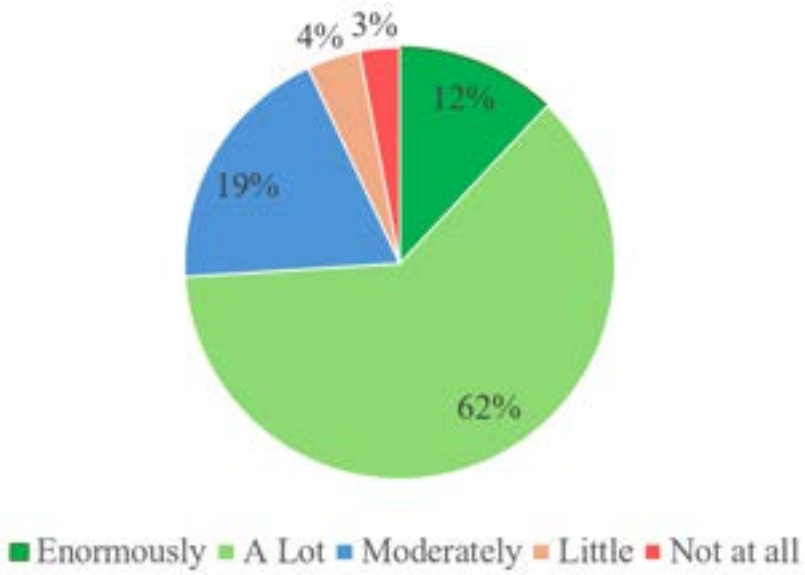
Nevertheless, physical discomfort emerged as a major obstacle (68.9%) to students' well-being during the 360° session (Figure 6)

Figure 6. Participants' reported physical discomfort.

Perceived Efficacy

The vast majority of students (96.6%) said they were able to identify the elements of the scientific approach targeted in the videos (360° session) and 74,4% that the session contributed enormously or a lot to their understanding of these elements. 66,7% considered that the 360° session enhanced their motivation to teach using the scientific inquiry approach.

Figure 7. Perceived contribution of the videos to understanding scientific criteria.



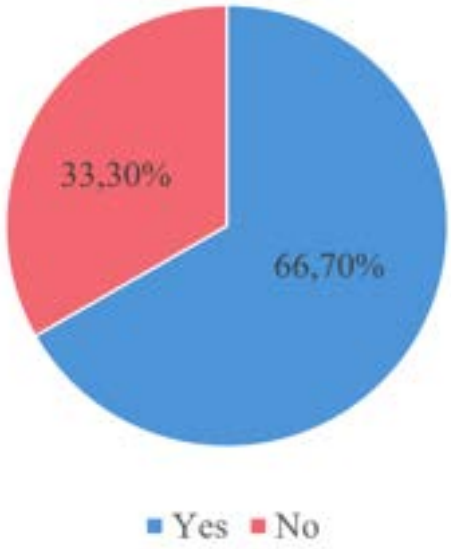


Figure 8. Perceived impact of the immersive experience on participants' motivation to teach the scientific method.

Discussion and Implications

Such results reinforce the idea that 360° videos (at least according to 74.4% of respondents) could enhance the learning of scientific criteria. It corresponds to the previous findings regarding the degree of engagement or immersion affected such aspects as the liberty of exploration in the environment (83 responses) and audio ambiance (54 responses), which presumably influenced an increase in conceptual understanding. Only 6.7% said they said there was little or no benefit.

On the other hand, the fact that 18.9% of the participants gave a moderated rating signals that the training, although efficacious, may not suffice for all learners and probably demands further assistance or additional materials for the understanding of the element of scientificity. This is where the instructional design could be improved, for example, by involving more interactive components or guided reflection exercises.

One extension for this study will be a comparison of the two cohorts, those who first have the 360° workshop and those afterwards, to identify and analyse differences between the two. For instance, it could appear that the students who did the 360° session second might be more likely to state that the 360° format adds nothing more than 2D session except for immersion.

The research is ongoing, and data is being processed. A comparison of pre- and post-tests will

also assess how students' knowledge and perception of scientific criteria evolve. This will help measure the impact of 360° training on their understanding and conceptual gains, as well as differences between training groups. Findings will be shared at the conference.

Acknowledgement

The authors would like to thank INSPE Bordeaux (University of Bordeaux), the Immersions 360 en Nouvelle-Aquitaine project, and the POLE PI (Pôle Innovation, INSPE Bordeaux) for their support in developing immersive 360° video resources and pedagogical innovations that enrich teacher education and training practices.

ESERA 2025 Copenhagen

Learning Through Comics And Students' Stress In Physics: An EDA Approach

Eman Sharaf and Martin Hopf
University of Vienna, Centre for Teacher Education, Austrian Educational Competence Centre Physics, Austria

Physics is one of the most challenging sciences to study, and many students find it highly stressful. The significant increase in stress during learning negatively affects the outcomes of the educational process and students' motivation and achievement in physics. The aim of this paper is to explore the potential of educational comics as an instructional approach for reducing students' stress in physics learning. In this paper, we designed and developed two comics on energy topics, presented them to upper and lower secondary school students, and measured their stress levels using modern EDA technology via Moodmetric smart rings. The results showed that using comics in physics instruction significantly reduced students' stress compared to the traditional method. This result is an important indicator for those working in the field of physics education of the importance of providing students with educational scientific comics during learning.

Keywords: Comics, Stress, Electrodermal Activity

Introduction

A new trend in Physics Education Research (PER) is exploring ways to reduce negative emotions, such as anxiety and stress, among students. Comics can be visually stimulating and help alleviate pressures associated with learning complex scientific concepts. The objective is to advance the field by measuring students' stress levels using the Electrodermal Activity (EDA) technique. Prior research is limited in PER. This research aims to contribute to knowledge accumulation in this field.

Stress In Physics Education

According to the theory of emotions proposed by Russel and Mehrabian (1977), the emotional response can be delineated by three factors or dimensions: valency/degree of happiness, arousal/degree of intensity or stress, and dominance/degree of control (Russel & Mehrabian, 1977). However, Bodin and Winberg (2012) recommended the researchers to focus on the arousal or stress dimension. This research will investigate this dimension of the emotion. Citing the seminal Yerkes-Dodson law (1908) stipulates the relationship between stress and performance. This law posits that low levels of arousal lead to diminished performance due to a lack of motivation and concentration. Conversely, high stress can be detrimental to performance due to the onset of anxiety. Moderate arousal is regarded as optimal for peak performance. Molin et al. (2021) have indicated that physics students who experience anxiety or stress are more likely to achieve lower grades than their peers. For instance, students experiencing anxiety may encounter difficulties in regulating their emotions, consequently affecting their performance in physics classes. This may, in turn, result in learning difficulties and underachievement.

Learning Through Comics

The use of comics in science education is not a novel concept. The utilisation of comics is regarded as an efficient medium for conveying scientific concepts and enhancing student engagement. It has been argued that today's students encounter difficulties with extensive reading (Trnova, Trna, & Vacek, 2013), prompting physics educators and experts to devise alternative

methods for the exposition of physics concepts without the need for extensive reading. The use of well-crafted comics has been shown to enhance student interest and comprehension, particularly in physics (Yulianti, Khanafiyah, & Sulistyorini, 2016). Several PER researchers have explored the efficacy of comics in storytelling with university students, leading to a positive impact on both cognitive and emotional domains (Ozdemir, 2017). In research on the use of comics as a medium and content to reduce stress levels and enhance mental well-being, for example, a subsequent study was done by Brand et al. (2019). Also, other studies have explored the efficacy of comics as a pedagogical tool for secondary school students with the objective of enhancing comprehension of physics concepts and fostering greater motivation in the students towards their physics learning (Badeo & Ong Kian Koc, 2021). Research shows that comics positively impact students, but there's a lack of studies on physics education that address their use as stress-reducing tools.

Electrodermal Activity (EDA) In Education

EDA measurements facilitate the assessment of emotional arousal levels, i.e., the intensity of stress. EDA comprises two components: Skin Conductance Level (SCL), which measures long-term emotion and Skin Conductance Response (SCR), which measures short-term emotion (Boucsen., 2012). EDA sensors have been developed to measure stress and reflect an individual's emotional state (Geršak G. & Drnovše J., 2020). The use of EDA sensors is recommended for several reasons. This includes their relatively low cost, a simple and fast physiological response, and easy connection to raw data via Bluetooth, Wi-Fi, the Cloud, or cable (Braithwaite et al., 2013). EDA's applications extend to both laboratory and non-laboratory settings (Picard et al., 2015). However, further efforts are required within the educational sector to leverage the potential of EDA technology to its full potential.

Research Questions

RQ: How do students' average stress levels differ between comic-based and traditional text-based instruction in physics energy topics?

Our study explores the impact of a digital comic on students' energy-related topics, using Moodmetric smart rings to measure stress levels.

Methodology

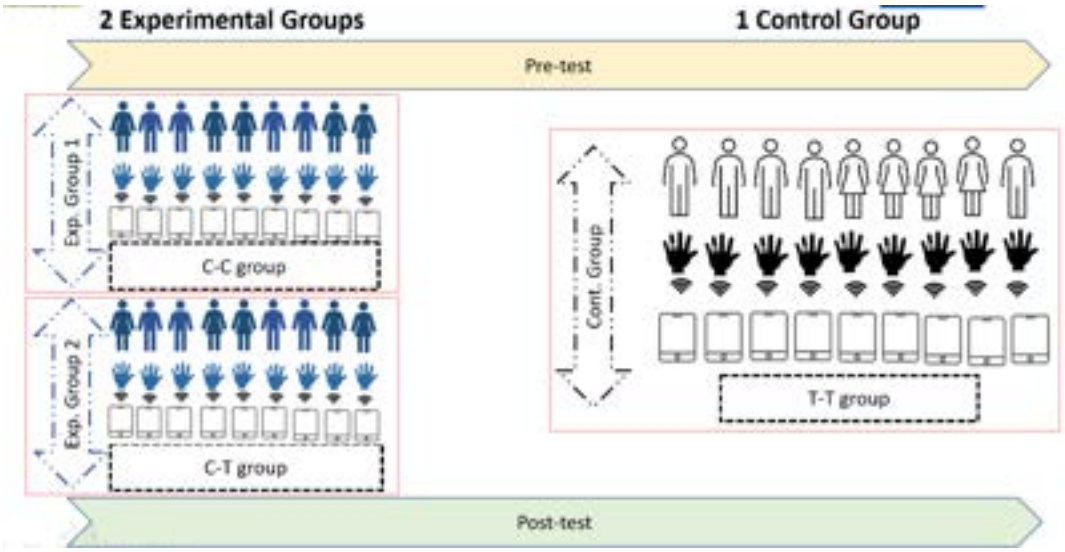
Participants

The study involved 43 secondary school students (10 females, 33 males) in grades 9-12, who were either learning in English schools or had B2 proficiency, and was conducted in Alexandria, Egypt, in summer 2023.

Research Design

The study used a control-group experimental design. As shown in Figure 1, it has two experimental groups: one got the full version of comics (explanation modules and question modules are in comics), called 'comics-comics' C-C; the other experimental group got a version of comics and texts (explanation modules in comics and question modules are in text), termed 'comics-text C-T'; the control group received the full text version (explanation modules and question modules are in text), termed 'text-text' T-T, for testing.

Measurement Tools



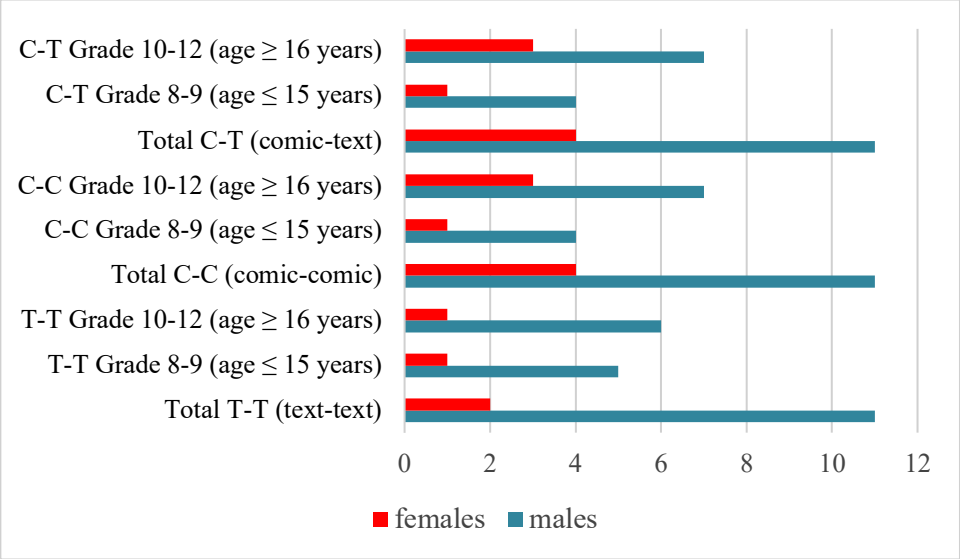
In this research, we used Moodmetric smart rings that measures student stress levels through EDA technique, including EDA/SCR and EDA/SCL per minute. They also measure Moodmetric

MM level, which combines SCR and SCL. Users can monitor stress levels through the app, which displays tension and calm times. These are expressed digitally as an index from 0 to 100, indicating the level of stress (e.g., MM levels 30-50 = moderate stress, <30 = relaxed, 51-55 = elevated stress, ≥56 = significantly elevated stress).

Procedure

We conducted an initial interview with 58 students, and they completed a pre-test on energy. 14 students left the research unfinished, and we had incomplete sensor data for another student. Then, a proportional random sampling was done to get the three groups (one control group and two experimental groups). Three digital learning models were developed: T-T, C-C and C-T. These focused on the same energy topics. All students studied the same content, either in comic or text format, interacted through question modules, and concluded with a post-test. The digital learning and the test were facilitated via a tablet using a dedicated website and occurred in laboratory settings. Students were given a moodmetric smart ring connected to a tablet to record stress which is shown in Figure 1.

Figure 1. Experimental design flowchart.



Result and Analysis

Sample Analysis

Figure 2 represents the analysis of the sample. The ratio of students in lower grades (8-9) to those in higher grades (10-12) is lower (12% vs. 23%), though similar across the two experimental groups C-C and C-T. However, in the control group T-T, the percentage of lower graders to higher graders is 14% and 16%. The female-to-male ratio is imbalanced (23% females to 77% males) because most of the volunteer students were learning in boys' schools. Another reason is the conservative Egyptian society, which sometimes stands still. This sometimes prevents girls from participating in research and international projects; however, we shall mention that none of the girls failed to attend and complete all steps of the pre-interview, learning session and post-test, indicating interest and motivation.

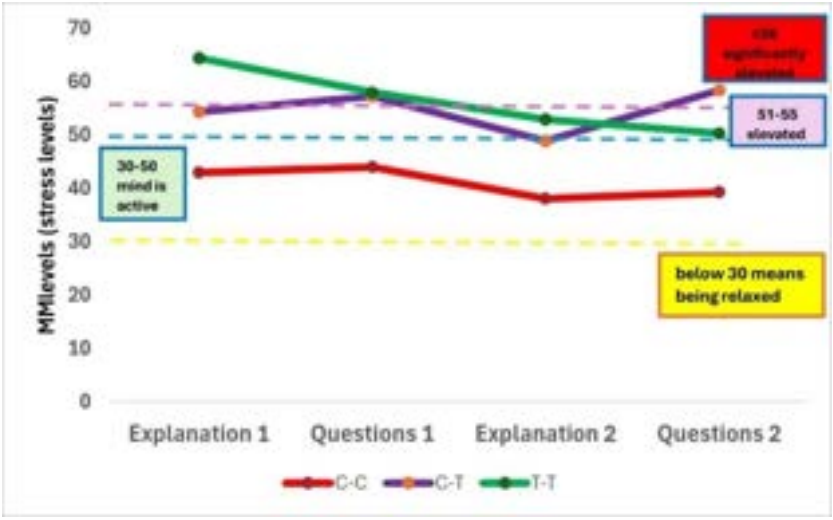


Figure 2: Sample analysis within the three groups according to gender.

Stress Analysis

General descriptive analysis has been done in order to answer the research question. Figure 3 illustrates the mean MM levels, which indicate students' stress levels across the four modules in the three groups. C-C is represented in red, C-T is represented in purple, and T-T is represented in green. Figure 3 shows that the C-C group is below the C-T and T-T groups in the range between 30-50 MM levels, with a moderate stress area for all four modules' explanations and questions. However, the MM levels of the C-T group fluctuate up and down; in the comics explanation modules, the MM levels are lower than in the text question modules, and MM levels go up to reach the T-T group in the first question module or exceed it in the second question module. Furthermore, the T-T group started with high MM levels in the first explanation module and then decreased in the following modules until it reached a moderate MM level in the last module.

Figure 3. Moodmetric MM levels of stress for three groups comics-comics C-C, comics-text C-T, text-text T-T during the four modules.

To test a null hypothesis of "There is no statistically significant difference in the mean stress levels between participants who received the comics-based instructional format and participants who received the text-based instructional format", we applied One Way ANOVA for the three groups, a significant difference F=3.70 *(p=.033) was found.* A post hoc Tukey test determined a

significant difference in favour of the C-C group in comparison with T-T F=19.4 *(p=.026)*. Therefore, we can reject this null hypothesis.

Discussion

This paper aims to answer the research question of how comics impact students' stress levels in physics. The stress line diagram and the observed patterns for the three groups (C-C, C-T and T-T) suggest that the C-C group experienced lower stress during explanations and questions. We can figure out from this study paper that using comics as a tool to present energy content significantly reduces stress levels of students among the C-C group during the learning process, compared with traditional text-based methods. The line graph shows that the T–T group experienced relatively stable high stress levels across all modules, reflected by an almost linear pattern. This may be because the text does not help to reduce students' stress levels, either in explanations or questions, resulting in a straight line with constant flow.

In contrast, stress levels declined in explanation modules and increased in question modules for the C-C and C-T groups. This may be due to the structure of the content itself, rather than the explanations or questions. This can be seen in the C-C group, where the narrative flow of the comics is disrupted by questions. This makes it difficult for students to immerse themselves in the story and escape the tension and stress. Accordingly, stress levels increased in the question modules and decreased in the comic explanation modules. The same pattern is evident in the C-T group, where stress decreases in the explanation modules and increases in the question modules.

The inferential analysis done to test the null hypothesis revealed a significant difference in mean stress levels between the comics-based groups and the text-based group, leading to rejection of the null hypothesis. In other words, the students who received the comics models reported significantly lower stress levels compared to the students who received the text models.

Conclusion

This paper investigated differences in students' stress levels when learning physics through comic-based and text-based instructional formats. Three groups were compared: a comic-comic (C-C) experimental group, a comic-text (C-T) experimental group, and a text-text (T-T) control group. We recognise the reduction in stress when using comics rather than text and when using a complex format combining comics and text.

ESERA 2025 Copenhagen

Building Bridges: AI Custom Chatbots As Mediators Between Mathematics And Physics

Julia Lademann[1], Jannik Henze[2] and Sebastian Becker-Genschow[1]
[1]University of Cologne, Faculty of Mathematics and Natural Sciences, Digital Education Research, 50931 Cologne, Germany,
[2]University of Cologne, Faculty of Mathematics and Natural Sciences, Institute for Physics Education, 50931 Cologne, Germany

This study examines the use of AI custom chatbots in educational settings, with a particular focus on the interface between mathematics and physics. Given the growing adoption of AI tools like ChatGPT in learning environments, their potential as personalized tutoring systems is analysed. The study evaluates the impact of AI-generated learning materials on the learning experiences and performance of sixth-grade students, focusing on proportional relationships in mathematical and physical contexts. In a randomized controlled study (N = 214), traditional textbook materials were compared with explanations generated by an AI custom chatbot. The findings indicate that, while the AI-generated materials had an indefinite impact on learning performance, they significantly enhanced positive-activating emotions, situational interest, and self-efficacy expectations, while simultaneously reducing intrinsic and extrinsic cognitive load. These results underscore the potential of AI tools to transform educational practices and to enrich learning experiences. Further research is required to clarify the effects on learning performance and long-term learning outcomes. Overall, the present study highlights the importance of a careful integration and customization of AI tools in order to fully leverage their potential for physics education and related domains.

Keywords: Artificial Intelligence, K-12 Education, STEM Education

Introduction And Theoretical Background

Within current educational research, increasing attention has been directed toward the potential of AI chatbots in educational contexts (Chen et al., 2020). For instance, they can function as intelligent tutoring systems, support research and writing processes, provide individualized feedback, and address specific learning difficulties (Kasneci et al., 2023; Neumann et al., 2024). In STEM fields, chatbots can provide feedback to exercise-related and topic-specific questions (Avila et al., 2024; Liang et al., 2023), opening up new opportunities for the design of learning environments in specialized fields such as physics (Küchemann et al., 2024). While AI-based chatbots offer the potential to provide individualized support across diverse learning situations, empirical evidence regarding their effects on students' learning performance and learning-related experiences remains unclear (Neumann et al., 2024), making it beneficial to assess the potential influence within the context of physics education.

Students' comprehension difficulties in physics lessons are multifaceted – often related to insufficient mathematical skills (Christensen & Thompson, 2012; Leinhardt et al., 1990; Pollock et al., 2007) as well as to challenges in transferring mathematical knowledge to physical contexts (Redish & Kuo, 2015). The causes of these difficulties are not uniform across all students and may arise from misconceptions regarding the physical meaning of ratios, products, or functions (Uhden, 2016). In addition, comprehension problems may arise from difficulties in interpreting and linking multiple representations, such as formulas, graphs, diagrams, and tables (Treagust, 2018). As these representations encode important information, the ability to interpret and

transition between them is considered beneficial for learners (Hansen & Richland, 2020; Opfermann et al., 2017; Treagust, 2018). Targeted assistance in fostering this competence has been shown to enhance students' conceptual understanding (Hansen & Richland, 2020).

Vision-capable AI chatbots, such as ChatGPT, may offer a promising approach in this regard, as they are able to analyse images of representations (Kasneci et al., 2023; Neumann et al., 2024). In this manner, they can provide individualized feedback to support learners in interpreting and linking multiple representations as well as in extracting the encoded information.

Despite the availability of a multitude of chatbots, their effective use in educational settings often requires adaption to specific instructional purposes (Kieser et al., 2023). AI custom chatbots based on existing large language models can be configured to meet such requirements by specifying desired response behaviours, such as the use of situation-specific language or controlled answer length. Moreover, subject-specific knowledge can be incorporated through the integration of relevant instructional materials. Given the current limitations of research in this area, it remains an open question whether chatbots can be used to design suitable learning materials and generate explanations that positively influence students' learning processes. Against this background, the present study investigates the impact of explanations generated by an AI custom chatbot on students' learning experiences and learning performance in physics.

Research Questions

The study is designed as a randomized controlled field study, with students as the target group and is addressing the following key research questions:

How does learning with AI-generated explanations using an AI custom chatbot affect

RQ1: ... emotional aspects?
RQ2: ... situational interest?
RQ3: ... cognitive load?
RQ4: ... self-efficacy expectations?
RQ5: ... learning performance in a mathematical and physical learning context, particularly in terms of the necessary transfer performance to the physical context?

Methodology

Chatbot Design

The AI custom chatbot used in this study was developed on the basis of the model GPT-4.0 and adapted to a specific learning context and target group. The chatbot uses engaging and age-appropriate language, making it suitable for sixth and seventh grade students. Its focus lies on "proportional relationships" as an example of learning with multiple representations, including graphs, tables, and formulas. Students must develop the ability to interpret these representations and transition between them from both mathematical and physical perspectives (Bing & Redish, 2009; Nilsen et al., 2013). To this end, the AI custom chatbot was equipped with subject-specific knowledge and designed to analyse and interpret the different forms of representations in order to provide targeted and individualized feedback.

Nevertheless, it remains open to question whether chatbots are capable of designing suitable learning materials and environments, as well as generating text-based explanations that have a positive impact on the aforementioned constructs. In the present study, the chatbot was employed to provide an AI-generated, text-based explanation of the topic "proportional relationships", based on a textbook overview (Körner, 2020). The explanation was selected according to the following criteria: the accuracy of the content and language, as well as the correct and coherent

use of the three forms of representation – graph, table, and formula.

Study Design

A total of N = 214 sixth-grade students (146 female, 66 male, 2 n.a.) with an average age of 11.7 years (SD = 0.51) at German secondary schools were randomly assigned to an experimental (EG) or control group (CG). Both groups were provided with learning materials on "proportional relationships" which had not been covered in class before. The CG received conventional textbook material, including a topic overview and accompanying explanatory examples. The EG was provided with the same textbook overview but had the examples replaced by a text-based explanation of the topic generated by the custom chatbot.

Immediately following the learning phase, various variables were measured using a four-point Likert scale: the participants' emotions (Pekrun et al., 2011) and situational interest (Linnenbrink-Garcia et al., 2010), the intrinsic and extrinsic cognitive load (ICL and ECL) experienced during learning (Leppink et al., 2013) and the self-efficacy expectation with regard to solving a topic-related task (Jerusalem & Satow, 1999) were assessed. Subsequently, the students completed a self-developed performance test on the "spring scale", which served as an example of the physical concept of proportional relationships.

Data Analysis

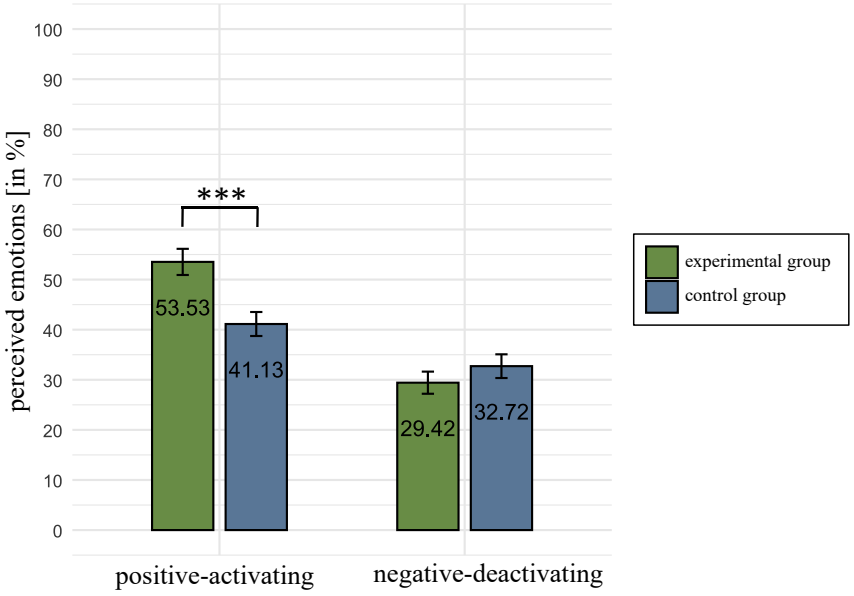
The data analysis was conducted using the statistical software R (version 4.4.0). First, the scales used were tested for internal consistency by calculating Cronbach's alpha. The results were acceptable to excellent, and no significant improvements were identified when individual items were removed from the scales. Therefore, the scales were retained for further data analysis. The data was then tested for normal distribution. The Shapiro-Wilk test with a significance level $\alpha = 0.05$ was used to determine the distribution of the data. The results indicated that the data was not normally distributed. The non-parametric Mann-Whitney U test with a significance level $\alpha = 0.05$ was used in the subsequent analysis to identify significant differences between the EG and KG. Cohen's d was calculated to estimate the respective effect size.

Results

The results of the study are summarized below. The complete methodology and results of the study can be found in the publication released in May 2025 (Lademann et al., 2025).

Concerning emotional aspects (RQ1), the EG reported a significantly higher incidence of positive-activating emotions (pleasure and satisfaction) than the CG ($p = 0.00093$, $d = 0.48$, small effect size). Regarding negative-deactivating emotions (boredom, frustration and uncertainty), only a trend could be identified, showing that the CG tended to experience more negative emotions. In sum, the results indicate that learning with AI-generated explanations can have a positive impact on the emotional state of the learners (Figure 1). Regarding the influence on situational interest (RQ2), learning with the custom chatbot's explanation triggered significantly higher situational interest ($p = 0.00223$, $d = 0.45$, small effect size) compared to learning with textbook materials (Figure 2).

Figure 1. Perceived emotions with standard error and level of significance (Lademann et al., 2025).



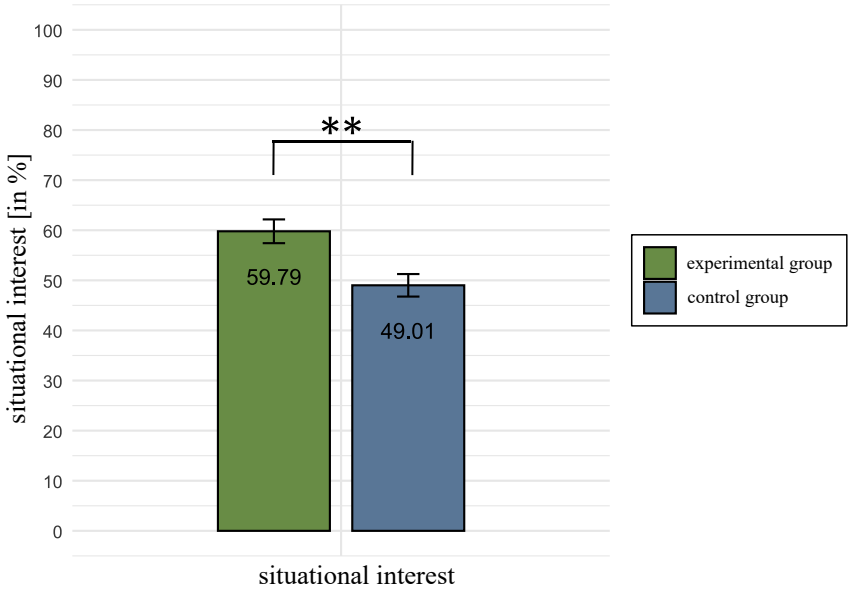


Figure 2. Situational interest with standard error and level of significance (Lademann et al., 2025).

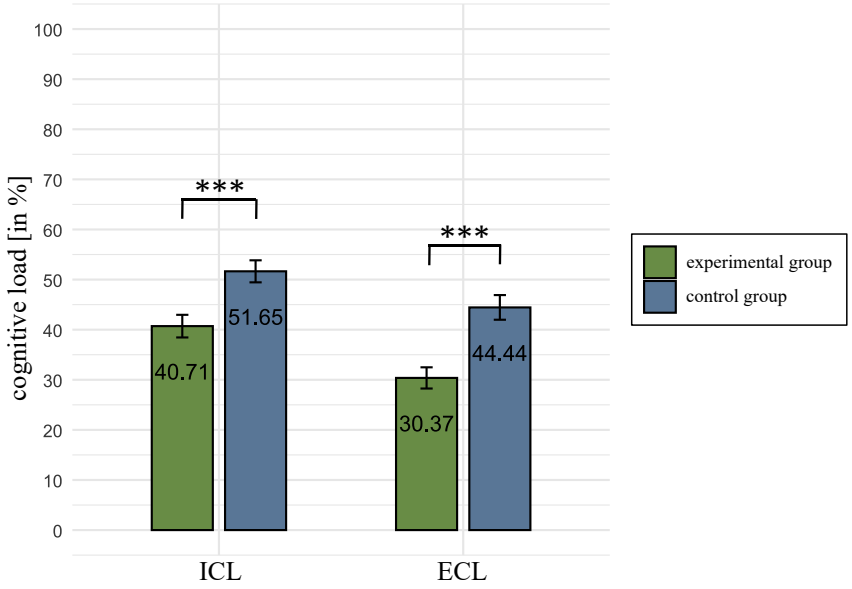
In contrast, ICL ($p = 0.00060$, $d = 0.47$, small effect size) and ECL ($p = 0.0001$, $d = 0.59$, medium effect size) were significantly reduced in the EG (Figure 3). These findings suggest that learning with AI-generated materials diminished cognitive load compared to textbook-only materials (RQ3). Additionally, the EG had significantly higher self-efficacy expectations ($p = 0.00001$, $d = 0.63$, medium effect size) than the CG (RQ4), when it comes to solving a topic-related task (Figure 4).

Concerning the influence on learning performance in a mathematical and physical context (RQ5), no clear trends were identified in the overall result of the performance test or the subtasks. The available data prevents drawing definitive conclusions about the impact of AI-generated materials on learning outcomes compared to traditional textbook materials. After thorough analysis, it was determined that there were no significant differences between the EG and CG in terms of learning performance.

Figure 3. Intrinsic cognitive load (ICL) left and Extrinsic cognitive load (ECL) right, both with standard error and level of significance (Lademann et al., 2025).



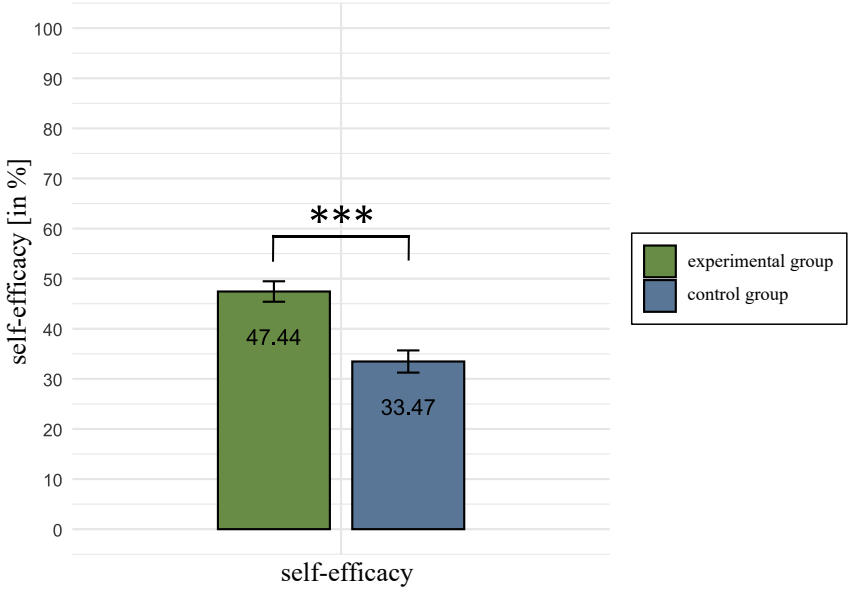


Figure 4. Self-efficacy with standard error and level of significance (Lademann et al., 2025).

Discussion And Conclusion

The results of the present study indicate that learning with materials generated by the AI custom chatbot has a positive effect on the learning experience of students.

The findings indicate that learning with AI custom chatbot-generated explanations, compared to traditional textbook materials, significantly enhances learners' positive-activating emotions and situational interest. The configuration of the chatbot with respect to communicating in a manner intended to encourage and motivate the learner might provide a potential explanation for these outcomes. The motivating tone may have exerted a positive influence on emotions and situational interest.

Furthermore, in comparison to traditional learning with textbook materials, cognitive load was reduced. This could be due to the chatbot's use of accessible language and its conversational and human-like tone. Additionally, the chatbot is adapted to the students' level of knowledge and uses language that is comprehensible to them. Moreover, the EG showed significantly higher self-efficacy, indicating that the explanation of the AI chatbot can foster students' confidence in their

ability to complete tasks. A reason for this may be the encouraging tone of the AI-generated text or the reduced cognitive load, or a combination of both. With regard to learning performance, the data revealed no statistically significant differences. A study comprising a greater number of participants over an extended period of time, in conjunction with individual utilization of the chatbot, has the potential to yield more profound insights.

Several factors limit the generalizability of the present findings, including the relatively small size of the sample, the short duration of the intervention, and the focus on a single topic tailored to a specific target group. Additionally, the learning materials were provided in a centralized manner, which resulted in the lack of consideration of individual differences in material use and the interaction with the chatbot. Consequently, the potential effects of personalized and adaptive feedback could not be examined.

Future research should therefore employ longer-term studies that cover a broader range of topics, and include more diverse target groups in order to validate and extend the findings and assumptions presented here. Moreover, learners should be given the opportunity to interact with the AI chatbot independently to systematically investigate the effects of individualized feedback.

Building on the present results, a subsequent study will conduct a more comprehensive examination of learning outcomes. An optimized AI custom chatbot will be developed, including revisions, refinements, and an adaptation to the didactic framework of the follow-up study. Within a pre-post design, the independent use of the chatbot by students will be examined with regard to its effects on learning performance and the learning experience (emotions, situational interest, cognitive load, self-efficacy expectations), and the technological acceptance of the AI chatbot.

Acknowledgement

We would like to express our sincere thanks to all participating schools, teachers and students for contributing to our study.

[2]Georgia State University, USA

The strand "Nature of Science (NoS): History, Philosophy and Sociology of Science" explores science as a dynamic human endeavour shaped by historical, philosophical, sociological, and epistemological dimensions. It emphasizes that scientific knowledge develops over time through social and cultural contexts, influenced by human reasoning and interpretation, and highlights how scientific understanding is constructed and validated within the scientific community.

The contributions in this chapter examine developments in science education research with a particular focus on pre-service teachers' and students' understandings of the Nature of Science (NOS) from a broader epistemic perspective, and more specifically on understandings of the Nature of Scientific Knowledge (NOSK) and the Nature of Scientific Inquiry (NOSI). Across the studies, these understandings are explored in different ways: some investigate existing levels of conceptual understanding, while others design and implement instructional interventions aimed at enhancing deeper insight. Some contributions focus on specific dimensions of NOS and NOSI, including the nature of scientific measurement and scientific reasoning. In addition, some contributions draw on the history of science as a pedagogical tool to strengthen understanding of NOS and NOSK, or to promote scientific literacy with an emphasis on social transformation. Overall, the chapter highlights a range of approaches to enhancing how learners and future educators engage with and understand the nature and practices of science.

This chapter aligns with the "Nature of Science (NoS): History, Philosophy and Sociology of Science" strand, contributing to a well-established area of science education research concerned with how learners and teachers understand the epistemological foundations and functions of science. The work aligns with longstanding efforts in science education to move toward developing a deeper understanding of science as a way of knowing, investigating, and explaining the natural world. Epistemically and as a human endeavour, science functions to generate, evaluate, justify, and refine explanations of natural phenomena. Simultaneously, scientific knowledge and practices are recognized as socially and culturally embedded, shaped by prevailing theories and cultural contexts, as well as the values, priorities, and needs of society.

ESERA 2025 Copenhagen

Insights Into Physics Students' Lesson Plans On The Nature Of Scientific Knowledge

Anna Koumara, Eleni Petrido, Anastasios Molohidis and Euripides Hatzikraniotis
Laboratory of Didactics of Physics & Educational Technology, Physics Department, Aristotle University of Thessaloniki, Thessaloniki, Greece

A program, based on the Lederman's model, was designed to familiarize physics students with the Nature of Scientific Knowledge (NOSK) aspects and its teaching. The program was implemented in Greece during the academic years 2023-24 and 2024-25 and included interactive lectures and workshops. Students' pre-instruction understanding was examined using the VNOS-D+ questionnaire, while their post-instruction integration of NOSK through the analysis of lesson plans. The lesson plans were evaluated for their incorporation of NOSK aspects using teaching approaches such as History of Science (HOS), Scientific Inquiry (SI), and Socio-scientific Issues (SSI). Findings indicate that prior to instruction, students mainly recognized the empirical and tentative nature of scientific knowledge, while other NOSK aspects were often understood in naïve or mixed ways. Analysis of students' lesson plans showed a strong preference for SI alone or in combination with HOS, with students most frequently selecting certain curriculum-related physics topics such as free fall. Although several NOSK aspects were included, the empirical, tentative, and creative dimensions were most successfully integrated. While NOSK was often addressed implicitly, approximately one-third of the students produced lesson plans that demonstrated explicit and reflective integration of NOSK. Overall, the findings suggest that even brief, structured NOSK-focused instruction can support pre-service physics students' initial engagement with NOSK, while highlighting the need for sustained involvement to support effective classroom implementation.

Keywords: Nature of Science, Pre-service Teacher Education, Undergraduate Level

Introduction

Research in Nature of Science (NOS) is fundamental in Science Education, since it is inherent in science and its practices (Lederman et al., 2014). It is also connected to scientific literacy (Lederman et al., 2024) and, regarding science education, the views that students and educators have on scientific research and epistemology (McComas, 2015).

The necessity to integrate the nature of science at all levels of education has been highlighted by many researchers (Erduran & Dagher, 2014; Lederman et al., 2014; Matthews, 2015), and it is already embedded in science curricula in countries like the USA (NGSS, 2013) and New Zealand (https://newzealandcurriculum.tahurangi.education.govt.nz/nature-of-science/5637207725.p). Main reasons for it are enhancing students' active participation, better understanding of science and its epistemic views, comprehension of the differences between science and pseudoscience and the limitations of science as a human endeavour (McComas, 2017, Matthews, 2015).

Teachers and student teachers need to be trained to create effective lesson plans (Mesci & Schwartz, 2017). Teacher training in nature of science is still a matter of research (e.g. Kara & Aslan, 2025; Beeghly, Gao & Kruse, 2025; Sen & Kaplan, 2025; Bugingo et al, 2024) and it seems there is a lot to add in the literature. Towards this direction, the present work focuses on Greek physics students and the results of their training through the analysis of the lesson plans they delivered. In this way, the study aims to contribute empirical evidence to the existing literature by enlightening how physics students engage with the Nature of Science within a traditionally content-focused educational context.

Theoretical Background

Even though researchers agree on the importance of teaching NOS, they don't agree on a widely approved definition and the aspects it consists of (Kampourakis, 2016). There are two main models, the Consensus Model (Lederman et al., 2014; McComas, 2015) and the Family Resemblance Approach (Erduran & Dagher, 2014). Each model has its own advantages and disadvantages, and there is plenty of ink spilled in favor and against each model (Kampourakis, 2016). However, all researchers agree that NOS instruction should be in an explicit and reflective approach, so that students understand it (Bell, 2008; Lederman et al., 2014).

As for Greece, research shows that NOS is not officially integrated in the science curriculum in secondary education, teachers usually do not include it in their instruction and, as a result, high school graduates usually have naïve views of its aspects (Koumara & Plakitsi, 2020). The Greek science curriculum focuses a lot on the scientific content, solving complex mathematical problems and little inquiry work in the science lab. Thus, it is reasonable that senior undergraduate students have limited knowledge of NOS aspects, which also might influence their future approach in teaching science (Abd-El-Khalick & Akerson, 2010).

The Lederman model separates NOS to the nature of Scientific Knowledge (NOSK) aspects and the nature of Scientific Inquiry (NOSI) ones (Lederman, 2019). The NOSK aspects are shown in Table 1.

Table 1. NOSK Aspects according to Lederman, 2019

Aspect	Description
A1	Scientific knowledge is empirical, based on our senses and extensions of them
A2	Scientific knowledge is inferential, observations and inferences are different
A3	Scientists' creativity and imagination are needed in all parts of scientific research
A4	Even though objectivity is the goal, subjectivity within scientists is inevitable, derived from scientists' personal beliefs, background knowledge, training, expectations, etc
A5	Scientific knowledge is durable but changes in the light of new evidence
A6	Scientific knowledge is culturally embedded; it affects and is affected by societal, economical, political and/or cultural characteristics of each geographical and political era
A7	Scientific Laws and Theories are different kinds of knowledge; Laws are structured mathematical relationships, whereas Theories provide a well-substantiated framework of why a phenomenon happens.

Taking these considerations into account, a program based on Lederman's model was designed to familiarize physics students with NOSK aspects and their teaching.

This model was selected because it offers a practical framework for educational contexts in which the science curriculum does not explicitly prioritize NOS. It is easier for teachers to comprehend and integrate into their teaching practices (Koumara, 2024), while also benefiting from established instruments to assess NOS knowledge, such as the VNOS-D+ questionnaire (Abd-El-Khalick, 2014).

Furthermore, given the focus of the present study on students' lesson plans, three instructional approaches for integrating NOSK were considered: History of Science (HOS), Scientific Inquiry (SI) and Socio-scientific Issues (SSI) (Koumara, 2024). Each of these approaches offers affordances and challenges for NOSK teaching, making it important for future teachers to be familiar with all of them when designing lesson plans. Examining how students select and implement these approaches provides valuable insight into their pedagogical reasoning and their understanding of NOSK integration in science teaching.

Research Questions

The present study was guided by the following research questions:

a) What views do students hold regarding aspects of the Nature of Scientific Knowledge (NOSK) prior to the instructional program, and how do these views change following the program?

b) Which teaching approaches do students adopt when designing lesson plans that aim to integrate NOSK aspects?

c) To what extent do students integrate NOSK aspects explicitly and reflectively in their lesson plans?

Together, these research questions address whether pre-service physics students are able to design effective lesson plans in which NOSK is incorporated as an explicit and reflective component of science teaching.

Methodology

The Participants And The Context

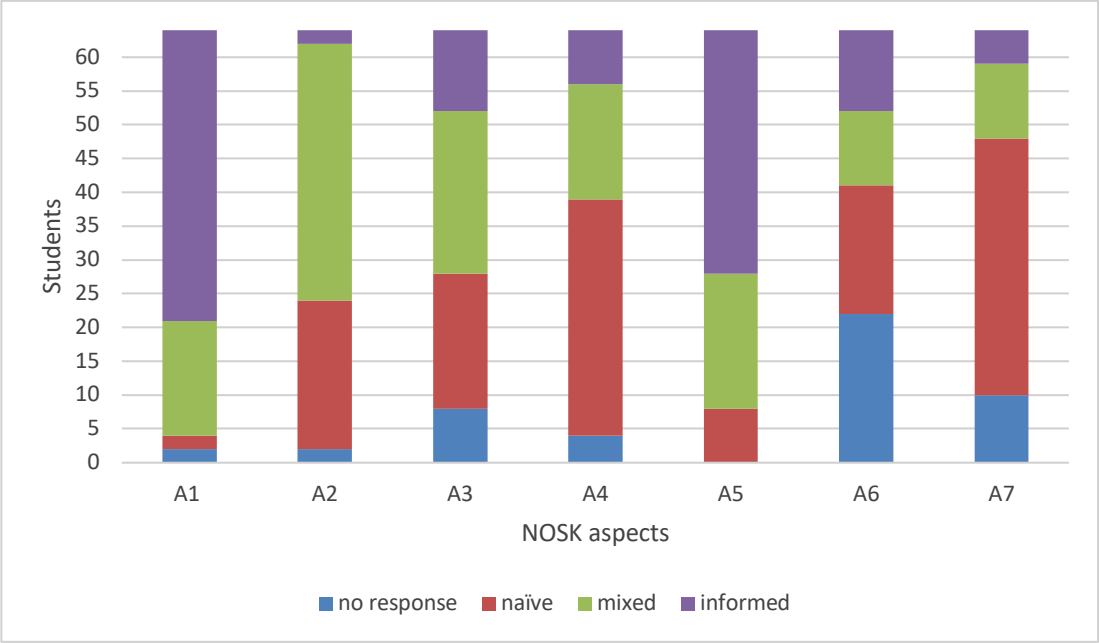
The sample of the study consisted of 64 students from the Physics Department of Aristotle University of Thessaloniki, Greece, who were in the process of obtaining their teaching certificate. As part of the coursework, they followed to obtain their teaching qualification, the students attended a 5-hour program focusing on the Nature of Scientific Knowledge (NOSK), which constitutes the focus of the present study. Thirty-one students attended the program during the academic year 2023-24 and thirty-three during the academic year 2024-25. Within this context, students participated in two interactive lectures and two workshops. The lectures focused on core aspects of NOSK and on instructional approaches for teaching NOSK through History of Science, Scientific Inquiry, and Socio-Scientific Issues. The workshops included the Signals from Space activity from Perimeter Institute and a black-box activity involving electric circuits (Koumara, Plakitsi & Lederman, 2022). Participants were provided with presentation files of the program and relevant articles on NOSK and its teaching. As part of the course requirements, students were asked to design and submit a 2000-word lesson plan that emphasised the explicit and reflective integration of NOSK aspects.

Data Collection And Analysis

Multiple sources of data were collected and analysed to address the research questions of the study. Prior to the beginning of the program, all participants completed the VNOS-D+ questionnaire within approximately 40 minutes. The questionnaire provided insights into students' initial views on aspects of the Nature of Scientific Knowledge (NOSK) and served as a pre-test.

Following the completion of the instructional activities of the program, students were given approximately one month to develop and submit a 2000-word lesson plan, which served as a post-test. Students were asked to design the lesson plan by explicitly and reflectively incorporating as many NOSK aspects as possible, providing insights into their newly acquired knowledge. They

were free to select any topic from subjects taught in Greek Secondary Education that a science teacher may be assigned to (Physics, Chemistry, Biology, Geography). Each lesson plan was examined with regard to (a) the NOSK aspects addressed and (b) the extent to which these aspects were integrated explicitly and reflectively. In addition, students were asked to complete a table at the end of their lesson plan, describing how each NOSK aspect had been incorporated. This information was analysed in conjunction with the lesson plan content in order to assess students' understanding of each NOSK aspect.



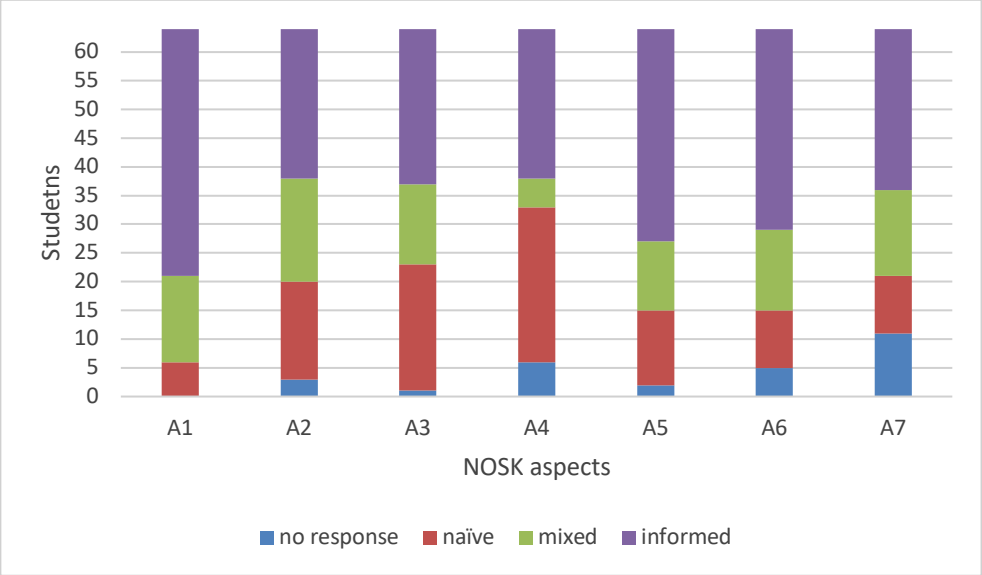
Additionally, semi-structured interviews were conducted with five students who responded to an open call at the end of the whole process. The interviews provided further insights into students' understanding of NOSK and their confidence in designing lesson plans that incorporate NOSK aspects.

Results and Discussion

Students' NOSK Views Before And After The Program

Analysis of students' VNOS-D+ responses before the program indicated distinct patterns in their views on the NOSK aspects. Students' responses were categorized into four levels (no response, naïve view, mixed view, and informed view). The distribution of students' views across the NOSK aspects is presented in Figure 1.

Figure 1. Results from the VNOS-D+ questionnaire before the beginning of the program.



As shown in Figure 1, students demonstrated relatively high levels of awareness of the empirical (A1) and tentative (A5) aspects of NOSK, whereas limited awareness was observed for the subjective aspect (A4) and for the distinction between scientific theories and laws (A7). Mixed views were prevalent regarding the differences between observations and inferences (A2) and the creative aspect of science (A3). Concerning the A2 aspect, most students mentioned that "models illustrate scientific evidence", but their explanations often revealed limited understanding of how models support the interpretation of evidence, as reflected in statements such as "scientists insert data into a specific model and interpret the evidence taken out". Regarding creativity, all students acknowledged its role in the design of new experiments, but half of them did not refer to its presence during data collection and analysis. Twenty students claimed that creativity, in the form of ingenuity, is involved in all stages of scientific research, with twelve of them providing elaborated explanations, like "*Creativity appears at every stage of scientific research, especially when a scientist gets stuck and has to think of new ways to use the available data. Through the*

scientist's inventiveness and insight, scientific knowledge expands». Many students (22/64) did not respond to items related to the culturally embedded aspect of science (A6). Among those who did respond, naïve views were dominant: ten students focused primarily on ethical dilemmas faced by scientists, while ten others emphasized scientists' interactions with the social and cultural context in which they live.

Following the completion of the program, students' understanding of NOSK aspects, inferred from the analysis of their lesson plans and compared with their initial views, is presented in Figure 2.

Figure 2. Post-test NOSK aspects understanding, inferred from the lesson plans.

As shown in Figure 2, students' understanding improved across all NOSK aspects after the completion of the program. High levels of informed views (A1 and A5) were maintained, with fewer naïve answers. Evidence of improved understanding was also observed for the difference between observations and inferences (A2), which was articulated in approximately half of the lesson plans through the consistent use of appropriate verbs. Similarly, twenty-eight students were able to correctly describe the distinction between scientific theories and laws (A7). The creativity (A3) and objectivity (A4) aspects were clearly developed. Regarding the creativity aspect, students who described it correctly connected it with the role of critical experiments and the use of alternative models in data interpretation. Objectivity was frequently discussed as a collective and temporal achievement: students described how an initially tentative explanation becomes established as scientific knowledge through repeated observations and the contributions of multiple scientists over time. Finally, regarding the culturally embedded aspect (A6), thirty-five students linked scientific knowledge to the social and historical conditions of different eras, referring, for example, to the impact of the Catholic Church on Galileo's work, which did not apply during Newton's era.

Teaching Approaches Used In Students' Lesson Plans

Students employed different teaching approaches to integrate NOSK aspects in their lesson plans. Specifically, NOSK was addressed through approaches drawing on the History of Science (HOS), Scientific Inquiry (SI), Socio-scientific Issues (SSI), or combinations of these approaches. The distribution of teaching approaches across the 64 lesson plans is presented in Table 2.

As shown in Table 2, most students used a combination of Scientific Inquiry and History of Science. In these lesson plans, students combined historical narratives describing the development of scientific concepts (usually through YouTube videos) with inquiry-based

activities, such as simulations or laboratory experiments related to the phenomenon under study. Lesson plans based exclusively on the History of Science approach relied exclusively on historical narratives, whereas those adopting a Scientific Inquiry approach focused mainly on experimental or simulation-based activities.

Table 2. Teaching approaches used in the lesson plans.

Teaching approach	Number of lesson plans
History of Science	6
Scientific Inquiry	22
Socio-scientific Issues	3
History of Science/Scientific Inquiry	28
All three combined	1
Completely traditional lesson plan	4

Lesson plans adopting a Socio-scientific Issues (SSI) approach were relatively limited in number. Specifically, three lesson plans addressed NOSK aspects through SSI: one focused on electric circuits and two on climate-related topics taught in Geography. In addition, one lesson plan combined all three teaching approaches (History of Science, Scientific Inquiry, and Socio-scientific Issues) and was developed in the context of a biology lesson on respiration taught in the 10th grade.

Table 3. Duration of teaching periods in the lesson plans.

Teaching periods	Number of lesson plans	Teaching periods	Number of lesson plans
1	8	6	1
2	38	7	0
3	9	8	1
4	6	9	0
5	0	10	1

The average duration of students' lesson plans was 2.48 teaching periods, as shown in Table 3. Thirty-eight students (more than half) developed lesson plans with a duration of two teaching periods, which constituted the most common choice. Lesson plans lasting three teaching periods were proposed by nine students, while a single teaching period lesson plan was designed by eight students. Two students suggested a whole project through their lesson plans, with durations of eight and ten teaching periods. Overall, the distribution of lesson plan duration indicates that all students, apart from eight, recognized the need for extended instructional time to support discussion and the organization of learning activities when integrating NOSK aspects. At the same time, the presence of lesson plans designed for a single teaching period highlights the practical difficulty of addressing both scientific content and NOSK within limited instructional time.

The topics addressed in the students' lesson plans are presented in Table 4. The distribution shows that certain topics were selected more frequently, such as free fall and horizontal throw, whereas

other topics appeared only once across the lesson plans, including the photoelectric effect, respiration, and heat transfer.

Adequacy Of Students' Lesson Plans With Respect To NOSK

At the end of the lesson plan, students completed a table indicating which NOSK aspects they had addressed and how these aspects were integrated into their instructional design. Analysis of the lesson plans showed varying levels of adequacy in the integration of NOSK aspects. Based on predefined criteria, lesson plans were classified into three categories: (a) sufficient lesson plans, which integrated multiple NOSK aspects in informed ways through explicit and reflective instructional approaches; (b) partially sufficient lesson plans, in which NOSK aspects were present but addressed implicitly or inconsistently; and (c) insufficient lesson plans, in which NOSK aspects were largely absent.

Table 4. Topics from lesson plans.

Topics	Times used in lesson plans
Free fall	8
Horizontal Throw	6
Newton's Laws Electric Circuits Electric forces Work/Mechanical Energy	5
Buoyancy Light Atomic models	3
Earthquakes and volcanoes Oscillations Solutions – stoichiometry The climate of Greece Circular motion	2
Photoelectric effect Centripetal force Respiration Momentum Waves Heat transfer	1

Seventeen lesson plans (27%) were classified as sufficient. These lesson plans demonstrated informed views of NOSK aspects and incorporated them explicitly throughout the instructional activities. In these lesson plans, NOSK was discussed in detail through the proposed activities. These lesson plans reflected an understanding that addressing NOSK aspects requires extended discussion, with explicit emphasis on each aspect and opportunities for students to articulate and reflect on their ideas. Ten of these lesson plans explicitly stated NOSK objectives at the beginning of the instructional design. Regarding instructional approaches, eight of the seventeen sufficient

lesson plans combined History of Science and Scientific Inquiry, seven used only the Scientific Inquiry approach, and two used only the History of Science. Lesson plans that incorporated Socio-scientific Issues were limited in number and did not fall within this category. Across these lesson plans, the historical narrative was used to introduce all NOSK aspects.

NOSK aspects in sufficient lesson plans were integrated through examples, both in HOS and SI, especially for the creative (A3) and the culturally embedded (A6) aspects, by asking students to finish a story using their current knowledge, by constructing a mind-map of the evolution of scientific knowledge, by introducing the tentative aspect (A5), or by describing a critical experiment, and reflecting on it to highlight creativity (A3). Creativity was also addressed through tasks in which students were asked to design an experiment. The distinction between observations and inferences (A2) was discussed with the use of proper verbs, such as observe, see, feel, note for the first, and infer, conclude, assume for the second. The distinction between theories and laws was also discussed when present (A7).

Twenty lesson plans (42%) were classified as partially sufficient. In these cases, students integrated NOSK aspects implicitly, and they only referred to NOSK in the summary table. While some of these lesson plans reflected an understanding of NOSK aspects, others revealed difficulties in effectively incorporating them into teaching. The NOSK aspects most frequently found to be challenging in these lesson plans were the distinction between observation and inferences (A2), the objective aspect (A4), and the difference between theories and laws (A7)

Finally, twenty lesson plans (31%) were classified as insufficient with respect to NOSK integration. These lesson plans followed traditional science teaching approaches, with NOSK aspects absent even at an implicit level. Four lesson plans contained only lecturing on scientific knowledge.

Insights From Student Interviews

Semi-structured interviews were conducted with five students to further explore their views on NOSK and their experiences with designing NOSK-oriented lesson plans. Interview data provided additional qualitative insights that complemented the findings from the written lesson plans. All students reported that they had not heard of NOSK before the program, neither as a concept nor the aspects, in an organized manner. However, they had heard some aspects, mainly the empirical (A1) and the tentative (A5), and they had assumed the others. One referred to a prior discussion of the relationship between science and society (A6) during secondary education, which had taken place in the context of a language course rather than a science class. Overall, students described recognizing elements of NOSK retrospectively in their school and university experiences and reported that the explicit presentation of NOSK aspects during the program facilitated their understanding.

Interviewed students emphasized the significance of NOSK for enhancing students' understanding of science and fostering scientific literacy. At the same time, three students expressed uncertainty regarding the extent to which in-service science teachers are familiar with NOSK aspects and how to teach them. These students highlighted the need for further professional development opportunities related to NOSK teaching.

Regarding the design of the lesson plan, all interviewees described the task as initially challenging. However, once they had selected a topic and started working on it, they reported gaining clarity on how to proceed. Students noted that the instructional resources provided during the program supported their work, and three students additionally reported seeking out and studying further NOSK-related literature independently.

Discussion

The present study focuses on students' understanding of the Nature of Scientific Knowledge (NOSK), the teaching approaches they adopted when designing lesson plans, and the adequacy of NOSK integration in these plans, after participating in a short training intervention (5-hour program) on NOSK. The findings indicate that, despite a mainly traditional and content-focused curriculum, physics students were able to identify multiple opportunities for integrating NOSK across a range of topics. The development of seventeen (27% in total) sufficient lesson plans further suggests that even short instructional interventions can support students in adopting more explicit and reflective approaches to NOSK teaching.

Regarding the first research question, which concerned students' understanding of NOSK aspects before and after the program, the findings indicate substantial improvement across all NOSK aspects. Students initially demonstrated limited or mixed views on several aspects, particularly those related to subjectivity, the distinction between theories and laws, and the culturally embedded aspect, while they are familiar with the empirical and the tentative aspects. The school curriculum helps students use these two aspects in examples of scientific observations and in narratives of how scientific knowledge evolves. These findings are in line with previous research (Koumara & Plakitsi, 2020). The analysis after the completion of the program revealed more informed and coherent understandings, as reflected in the lesson plans.

With respect to the second research question, which examined the teaching approaches students employed to address NOSK, results show a strong preference for combining History of Science and Scientific Inquiry. This pattern suggests that students perceive these approaches as complementary resources for supporting explicit discussions of NOSK, while approaches based exclusively on Socio-scientific Issues were less frequently adopted.

Finally, regarding the third research question, which focused on the adequacy and explicitness of NOSK integration in students' lesson plans, the findings reveal a mixed picture. Although a notable proportion of lesson plans demonstrated informed, explicit, and reflective integration of NOSK, a considerable number remained implicit or insufficient, pointing to ongoing challenges in translating NOSK understanding into coherent instructional practice. This pattern indicates that some students may not have fully engaged with the provided resources, as reflected in their limited understanding of the NOSK aspects.

Limitations Of The Study

The findings cannot be generalized to all physics students in other institutions, as the participants were drawn exclusively from one university department and reflect the specific curriculum followed by students pursuing a teaching certificate. Moreover, obtaining a teaching certificate is not mandatory in Greece, and some future science teachers may acquire pedagogical qualifications through postgraduate studies, which may involve different forms of preparation.

The instructional program was short-term, so a deeper and more sustained understanding is likely to require longer-term engagement, including repeated opportunities to teach NOSK in authentic classroom settings.

Lastly, even though students received feedback on their lesson plans, they were not required to revise or resubmit their work. This means that some students might have enhanced their understanding of NOSK.

Conclusion

This study examined physics students' understanding of the aspects of the Nature of Scientific Knowledge (NOSK) and their ability to integrate these aspects into lesson planning following a

short, focused instructional program. The findings indicate that, although students initially held mostly mixed views on several NOSK aspects, targeted instruction can support meaningful development in both NOSK understanding and instructional application. A notable proportion of students were able to design lesson plans that explicitly and reflectively integrated NOSK aspects within the existing secondary science curriculum. This outcome suggests that even short-term interventions can enable pre-service teachers to move beyond content-focused instruction and to consider NOSK as an integral component of science teaching. Further engagement with NOSK is needed before these students can integrate NOSK into their classrooms when they become regular teachers.

Future Work

Future research could build on the present findings by examining the effects of sustained and iterative NOSK-focused instruction embedded within undergraduate science teacher education programs. In parallel, extending NOSK-focused professional development to in-service teachers would provide insight into how teaching experience shapes NOSK integration in contexts where NOSK is not explicitly emphasized in the curriculum. Comparative studies involving pre-service and in-service teachers could further elucidate the role of classroom experience in shaping both NOSK understanding and its instructional enactment. Finally, comparative investigations of instructional approaches, such as History of Science, Scientific Inquiry, and Socio-scientific Issues, could clarify their respective affordances for supporting sustainable NOSK integration across scientific domains and educational levels.

Primary Teachers' Competencies And Difficulties In Teaching Measurement Uncertainty: Pedagogical Challenges Related To Nature Of Science

Constantina Stefanidou, Anastasia Ferentinou and Constantine Skordoulis
National & Kapodistrian University of Athens, Greece

This paper investigates the primary teachers' ability to explicitly address scientific practices and particularly the nature of measurement into their experimental teaching scenarios after their participation in a related STEM Education Master's degree course. The content of the course attended by the primary teachers was based on "Guide to the expression of Uncertainty in Measurement", adapted to primary teachers' level and needs. Primary teachers' teaching scenarios were qualitatively analysed to examine whether and to what extent they have addressed aspects of measurement practices. Preliminary findings show that although primary teachers can design experimental activities for their students, setting explicit learning goals related to measurement procedures, they focus on limited aspects of scientific measurement, such as the causes of measurement uncertainty. They do not frequently mention aspects such as the use of statistical tools, the significance of measurement spread and the need for repetitions of measurements. Preliminary findings provide evidence for further research on how difficulties in teaching measurement concepts are related to difficulties in understanding Nature of Science, and particularly aspects related to observation, evidence, inference, laws and theories.

Keywords: Nature of Science, Measurement

Introduction

Measurement has a long history, stretching back at least two and a half thousand years across a multitude of cultures. Teaching about measurement is closely related to teaching about science, since natural sciences are very connected to measurement procedures. The concept of measurement uncertainty includes key concepts of the scientific method: random and systematic error, calibration, hypothesis testing, experimental design, modelling, approximation, etc. It can be considered as one of "threshold concepts" in science teaching, as it is important for students to identify different sources of uncertainty, quantify results, and take these results into account when planning experiments, analysing data and drawing logical conclusions.

Understanding scientific measurement has been recognized for a long time as an important part of science education by policy bodies (AAPT, 1998; OECD, 2023). Teaching and learning about scientific measurement are an essential aspect of scientific literacy (Osborne et al., 2003). The IPCC 6th Assessment Report (2023) for citizens is indicative of how scientists communicate results to non-scientists. Citizens must be fluent in the concept of measurement and uncertainty in order to be able to read, understand and interpret results in order to inform decisions. This way, uncertainty increases, and does not decrease, confidence in science.

Nature of measurement is also related to scientific and engineering practices, in the context of Next Generation Science Standards (NGSS Lead States, 2013). Particularly, NGSS addresses both measuring processes: (1) collect data (determining the size, materials, precision, etc), and (2) process the data, as depicted in the scientific practices. According to NGSS, during planning and carrying out investigations, students should be able to produce data to serve as the basis for evidence: decide on types, quantity, and accuracy of data needed to produce reliable measurements and consider limitations on the precision of the data. Moreover, regarding using mathematics and computational thinking, students are expected to measure, estimate, and/or

graph quantities such as area, volume, weight, and time to address scientific and engineering questions and problems. Greek primary science education curricula also include learning goals relative to measurement procedures. Students are introduced to the measurement of various quantities, from measuring length, mass, area, volume, duration, and temperature to calibrating thermometers under teacher guidance. At this point, it can be noted that both international and national programs are ambitious about measurement skills in primary education.

Despite the importance of teaching and learning measurement procedures, few studies have dealt with young children's reasoning about measurement and teachers' competencies in responding to difficulties. Regarding primary students' difficulties in measurement, they are focused on the concept of uncertainty. The realization of data incorporates an inherent uncertainty leading to imperfect measurements, confuses students who take science's clarity and certainty for granted. During experimental procedures students expect "a unique right answer" to any measurement. For them, a scientifically correct measurement is the one that is not accompanied by any uncertainty (Allie et al., 2003). Students do not separate the terms error and uncertainty. They use the terms interchangeably, as they attribute to "human error" any of the unexpected results (Allie et al., 2003). The work of Buffler et al (2009) has revealed a strong relationship between measurement uncertainty understanding and students' views on Nature of Science (NoS).

Regarding undergraduate science students, although they are very skilful in carrying out experiments and data analysis, they seem to have difficulties in realizing the reasons for such processes (Buffler et al., 2001). Particularly, science students have difficulty in distinguishing accuracy and precision, and they consider the first data as "prominent" and the following as "confirmatory" (Majiet & Allie, 2019). Regarding primary teachers, very limited research is available, revealing teachers' inability to articulate their knowledge of concepts and processes related to measurement (O'Keefe & Bobis, 2008). Georgaki & Stefanidou (2023) found that although most teacher students recognize scientific measuring as an important part of the scientific process, they had several difficulties regarding the concept of uncertainty, such as not distinguishing between uncertainty in the kitchen and uncertainty in the laboratory, attributing uncertainty in systematic errors and inability to conceptualize random errors as part of the measurement precision. The above-mentioned research findings gave rise to this research, which investigates if and to what extent primary teachers can address measurement concepts in their experimental teaching scenarios, and particularly what the arising difficulties are.

Methodology

Research Questions

According to the work of Munier et al (2013), the research questions are as follows: What difficulties do primary teachers face when designing experimental teaching scenarios including learning goals and teaching activities regarding:

1. Causes of uncertainty (quantity, instrument, and the experimenter)?
2. Statistical tools such as frequency tables and bar charts to represent data and results?
3. Need for multiple measurements

Sample – Place – Time

The research took place during the academic year 2024-2025, in the Department of Pedagogy and Primary Education, of the National and Kapodistrian University of Athens. The sample was a convenience sample and consisted of 30 primary teachers, who attended a Master's Degree program on STEM Education, and particularly a course on Measurements and Sensors.

The Educational Framework

All participants attended the course Measurements and Sensors, which included 10 three-hour laboratory meetings in person. The course had two main parts: The first half (five laboratory meetings) aimed at introducing graduate students in measurements and uncertainty. The content was based on the work of Buffler et al (2008), tailored for primary teachers, in the context of GUM approach. Primary teachers (graduate students) familiarized themselves with the concepts of measurand and units of measurement, producing data of length, mass, volume, time, temperature, voltage and current. Participants were introduced to the concept of uncertainty of measurement and the difference between uncertainty in "everyday" measurements and "scientific" measurements. During the process, they familiarized themselves with basic elements of measurement theory, such as the classification of errors as systematic and random, they participated in certain activities on precision and accuracy and worked on the need for repetitions of measurements. Finally, students, through simple examples, were introduced to the concept of error propagation.

Data Collection And Analysis

Participants in the present study were asked to produce a two-hour experimental teaching scenario on a topic of their choice for primary school, and especially grades K-5 and K-6. The main sources of data were participants' teaching scenarios and field notes.

Data were analysed according to the qualitative content analysis method (Mayring, 2015). For reliability reasons, all data were independently analysed by the two authors, to debate possible differences and reach a final classification. Both teaching goals and teaching activities were analysed regarding: 1. The identification of causes of uncertainties 2. The use of statistical tools and 3. The need for repeatability.

Findings

The first findings reveal that primary teachers, graduate students of a Master's degree program in STEM education, are able to design experimental teaching scenarios focusing on the concept of measurement uncertainty. Analysis of their teaching scenarios reveals that although they all have learning goals related to measurement procedures, not all aspects are equally represented.

Particularly, regarding the first research question (causes of uncertainty related to quantity, measuring instrument and the experimenter), the analysis showed that the majority of the teaching scenarios (20 out of 30) included both learning goals and corresponding activities addressing this issue. Teachers tended to introduce the distinction between systematic and random errors explicitly, indicating an awareness of different sources of measurement uncertainty. However, in many cases, the identification of errors was implicit rather than formally defined, often embedded within given examples or classroom discussions. Additionally, teachers frequently encouraged students to record and reflect on variables that could influence measurements, such as light conditions or distance, typically through guiding questions like "Why do measurements differ?". This suggests that while teachers recognized and addressed factors contributing to uncertainty, these were often approached in a contextual and exploratory manner rather than through formalized conceptual frameworks.

With respect to the second research question (use of statistical tools), only a limited number of teaching scenarios (10 out of 30) included explicit learning goals and activities related to data representation and analysis. When statistical tools were addressed, teachers mainly focused on designing and/or explaining simple graphical representations, such as temperature–time graphs, or on interpreting ready-made diagrams and bar charts by asking students to provide explanations

of the displayed results. In addition, some scenarios included basic calculations of averages. However, teachers' engagement with statistical thinking remained limited, as more advanced concepts, such as the importance of the spread or variability of measurements, were entirely absent from the teaching scenarios. Overall, statistical tools were approached in a procedural manner, emphasizing representation and calculation rather than deeper reasoning about data.

Concerning the third research question (the need for multiple measurements), fewer than half of the teaching scenarios (12 out of 30) explicitly emphasized the importance of repetition. In these scenarios, teachers typically supported repeated measurements by providing pre-structured data tables for students to complete and by encouraging comparisons between different groups' data sets. Some activities also prompted students to reflect on the reasons for conducting multiple measurements. Nevertheless, repetition was mainly treated in a mechanical way, focusing on the act of repeating measurements rather than on its epistemic role. Links between repeated measurements and key concepts such as reliability or precision of results were largely absent, and only limited emphasis was placed on the significance of measurement spread. This indicates that, although repetition was operationally included, its conceptual importance in experimental inquiry was not sufficiently developed.

Implications For Nature Of Science Teaching

The difficulties identified in teaching measurement concepts have important implications for the teaching of the Nature of Science (NoS). Measurement uncertainty can foster essential habits of mind for scientific reasoning and citizenship in a world shaped by science and technology. Shifting the focus from "error" to uncertainty can help students move away from a rigid right–wrong view of science and toward an understanding of scientific knowledge as tentative, evidence-based, and open to revision. By grappling with uncertainty, students are more likely to appreciate experimentation as a process of inquiry rather than a procedural search for correct answers, and to interpret data not as absolute truths but as results associated with a range of confidence. This perspective mirrors authentic scientific practice, where scientists rarely obtain a single "true" value but instead report results in terms of precision, accuracy, and confidence intervals. Moreover, challenges in teaching measurement uncertainty are closely linked to broader NoS dimensions, including observation, evidence, inference, the relationship between laws and theories, and the objectivity and subjectivity of measurement processes, as well as the intersubjective nature of scientific results (Stefanidou & Skordoulis, 2014; Mari et al., 2017; Stump et al., 2024). Explicit attention to distinctions such as accuracy versus precision can therefore support a more coherent integration of measurement concepts and NoS, enhancing students' understanding of how scientific knowledge is constructed.

Conclusions

Overall, the findings indicate that primary teachers face substantial difficulties when designing experimental teaching scenarios that meaningfully address measurement uncertainty. Although some aspects of uncertainty are acknowledged, teachers' approaches largely remain at the level of broad or implicit discussion, without a clear conceptual distinction between error and inherent uncertainty. The limited use of statistical tools further suggests a lack of familiarity with integrating basic statistical reasoning into experimental teaching, restricting students' opportunities to interpret data beyond simple representations or averages. Similarly, while the need for repeated measurements is occasionally emphasized, it is often treated mechanically without adequately highlighting its role in reducing uncertainty or improving the reliability and precision of results. Taken together, these findings reveal that key dimensions of experimental reasoning—such as variability, confidence in measurements, and the epistemic status of data—are insufficiently addressed, pointing to a fragmented understanding of measurement uncertainty

in primary science teaching.

ESERA 2025 Copenhagen

The Growing Need For STEM Careers And The Potential Pathways For Independent Scientists

Miku Yoshida
Chiba University of Commerce, Japan

The growing demand for STEM professionals highlights the need to explore alternative career pathways for scientists beyond traditional academia and industry. Despite efforts to encourage STEM career persistence, issues such as limited academic positions hinder long-term engagement in scientific fields. The mismatch between PhD holders and private sector employees further exacerbates this challenge, necessitating new opportunities for independent researchers.

This study investigates the potential of non-profit organizations as viable career alternatives for STEM professionals in Japan by analysing research funding trends. Using data from the KAKEN database, we examine the research achievements of non-profit research institutions, such as general incorporated associations (GIA), non-profit organizations (NPO), and social welfare corporations (SWC). Our findings revealed that independent researchers within these organisations' secure competitive grants, with notable participation in early career and small-scale research funding schemes.

Case studies highlight two key patterns: organisations that collaborate with universities to support early career researchers, and those that sustain long-term, independent scientific enquiry. While some organisations provide transitional opportunities for post-doctoral researchers, others enable senior scientists to continue their work beyond academia. Despite financial and institutional barriers, these alternative research pathways contribute to scientific progress and expand STEM career possibilities.

This study underscores the importance of recognising and supporting independent research outside conventional institutions. Future research should involve qualitative interviews to explore the professional development of independent scientists. By addressing funding challenges, we can foster a more inclusive and sustainable STEM workforce that ensures diverse contributions to scientific innovation.

Keywords: Independent Researcher, Academic Career, Scientist

Introduction

STEM Career And Becoming Scientists

The increasing global demand for STEM (Science, Technology, Engineering and Mathematics) professionals contrasts with a decline in student interest in STEM careers, a phenomenon known as the 'leaky pipeline.' Factors such as school experiences, parental influence, economic background, and gender shape students' motivation (DeWitt & Archer, 2015; Zhai & Liu, 2024). Despite their academic abilities, many students lose interest as they advance their education (Chen et al., 2024).

At the doctoral level, the oversupply of STEM graduates leads to employment challenges. A report by Japan's Ministry of Education, Culture, Sports, Science and Technology (MEXT, 2023) shows that only 15.8% of PhD holders secure university faculty positions, with 9.4% working as post-doctoral researchers. Many PhD graduates struggle to transition into industry because of a mismatch between their skills and corporate needs (Miki, 2019). While academia remains a primary aspiration, the reality of limited faculty positions has driven interest in alternative career pathways, including independent research.

Rise Of Scientists Outside University

There is growing attention and support for citizen scientists. ‘Citizen science’ indicates research activities conducted by non-professionals in science. (Silvertown 2009, Lusse et al. 2022). This can be performed independently by citizens or collaboration with professional scientists. In Japan, there is a framework for amateur scientists (Kimura 2021). An amateur scientist is a non-professional researcher with expertise in a specific scientific field, such as entomology, at a level comparable to or exceeding that of professional scientists in the same discipline. Here, ‘non-professional’ denotes individuals who do not rely on this activity as their primary source of income. The National Coalition of Independent Scholars defines independent scholars as individuals engaged in research without a tenure-track position or permanent university contract established in 1989. There are communities of independent researchers, such as the Japan Scientists’ Association (JSA), established in 1965. These organisations have their own peer-reviewed journals and face challenges in sustaining their activities due to limited research funds. I It is not appropriate to categorise independent scientists into citizen science or amateur science as are capable of drafting their own academic papers.

Therefore, this study focuses specifically on the funding challenges for independent scientists in Japan. Funding is one of the key factors impacting the the sustainable development of these so-called non-professionals. Exploring their funding achievement, makes it possible to discuss pursuing STEM careers as ‘scientists’ outside academia or industry. The research question in this study is as follows: Can non-profit organisations be an alternative career path for STEM professionals from the perspective of acquiring funding?

Japanese Research Grants

This study examines the Grants-in-Aid for Scientific Research (Kakenhi) funded by the Japanese government through the Ministry of Education, Culture, Sports, Science, and Technology (MEXT) and the Japan Society for the Promotion of Science (JSPS). Only researchers affiliated with recognised institutions are eligible to apply for these grants. These research organisations should fulfil the listed criteria, such as ‘At least 1/5 of the researchers who are currently affiliated with the applicant institution at the time of application have published an original paper in a journal or similar publication within the past year’, and ‘The per capita research expenditure of the applicant organisation as a whole, excluding external funds (the amount for the previous year of the application), must be at least 360,000 yen per year’ (MEXT 2021). This requirement ensures that researchers have completed seminars on research ethics and integrity and grants are used properly.

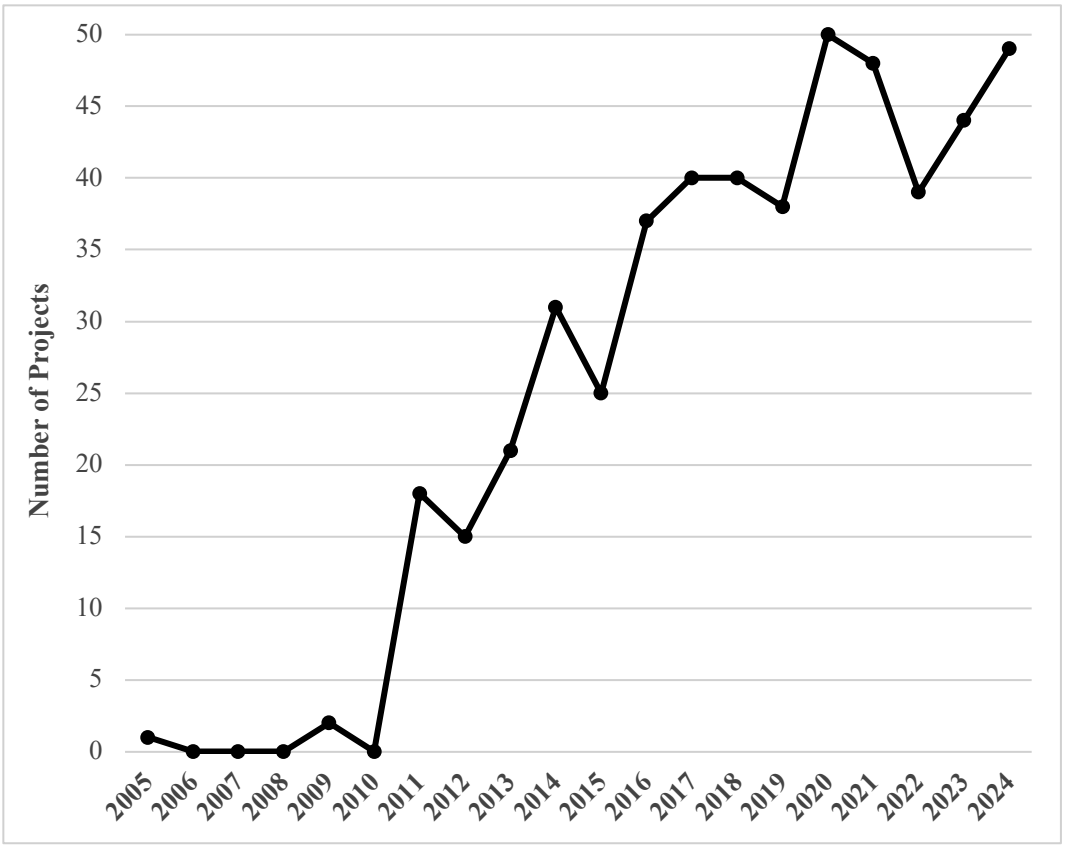
According to the list of research organisations of KAKEN (JSPS 2022), there are five main categories of research organisations in Japan: 1) universities, 2) colleges and technical colleges, 3) inter-university research institutions and foundations, 4) independent administrative institutions, and 5) others. In this paper, we discuss those organisations in the last group. By doing so. we can determine what kind of research is being conducted in such organisations and what challenges exist. This would ensure the diversity of places where researchers can become active in society.

Methods

Sample And Data Collection

The KAKEN database (NII 2023) was used for analysis, covering 1,043,559 research projects from 1964 to 2024. The list of research organisations (JSPS 2022) was collected in January 2024. Based on this list, organisations were categorised using a numbering system. In total, 2059 organisations are listed in the list. Serial numbers were assigned to each organisation.

Organisation numbers starting with 1, 2, and 3 were universities (N=825); those starting with 4, 5, and 6 were colleges (N=313), technical colleges (N=58), and inter-university institutions (N=16), respectively; and those starting with 7, 8, and 9 were others (N=845). 'Others' included foundation organisations, national corporations, stock companies, medical corporations, specified non-profit-making corporations, welfare corporations, and religious groups. To examine only the organisations needed to work as professional researchers outside of universities or companies, this study has focused on organisations that do not run for profit; therefore, general incorporated associations (GIA), non-profit organisations (NPO), and social welfare corporations (SWC) were studied.



Based on the KAKEN database, we looked into the following categories for GIA, NPO and SWC; 1) Number of research projects; and 2) Budget types and actual budget.

Results

Trends In Research Funding

Figure 1 indicates that there has been a clear, rapid growth in the number of research projects accepted by Kakenhi. This growth can be explained by the National University Corporation Act, enacted in 2004. Before 2004, Japanese national universities were government agencies; afterwards, they became National University Corporations. Universities still receive funding from the government; however, the funds are decreasing annually, primarily due to the overflow of post-doctoral students. Researchers have attempted to find opportunities to conduct research outside universities.

Figure 1. Number of Research Projects.

Budget Types

There are several budget types varies its duration and total budget. Table 1 summarises current budget types. For example, Grants-in-Aid for Scientific Research (A, B, C) fund research projects by one or more researchers for three to five years, with a total budget of less than 5,000,000 JPY, between 5,000,000 JPY and 20,000,000 JPY, between 20,000,000 and 50,000,000 JPY. Grants-

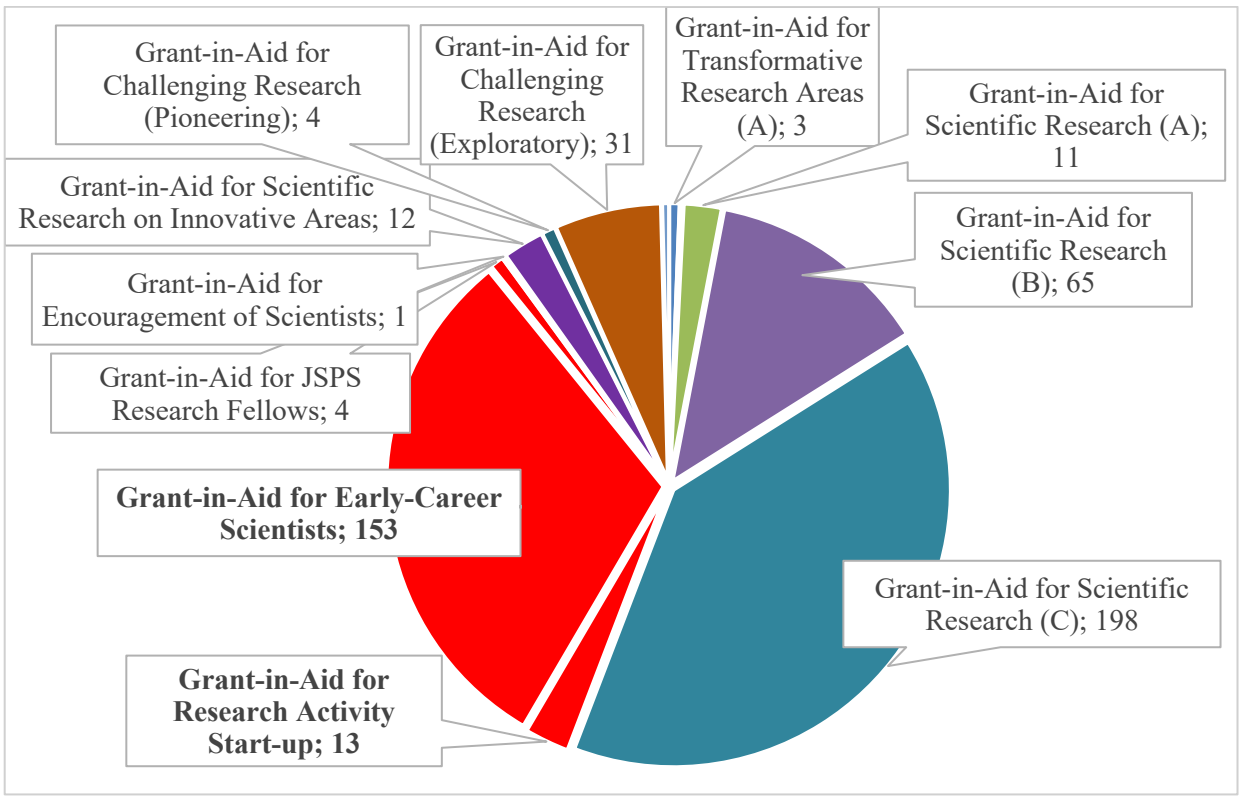
in-Aid for Early-Career Scientists funds research projects run by young researchers under the age of 39 or who have been awarded a doctoral degree for less than 8 years excluding the parental leave period for two to four years. Researchers who have been awarded a doctoral degree within the past eight years are eligible for amounts up to 5,000,000 JPY for a duration of 2–5 years.

Table 1. Budget Type and Numbers.

Name	Budget
Grant-in-Aid for Transformative Research Areas	less than 5,000,000 JPY or between 5,000,000 and 30,000,000 JPY
Grant-in-Aid for Scientific Research (S)	between 50,000,000 and 200,000,000 JPY
Grant-in-Aid for Scientific Research (A)	between 20,000,000 and 50,000,000 JPY
Grant-in-Aid for Scientific Research (B)	between 5,000,000 JPY and 20,000,000 JPY
Grant-in-Aid for Scientific Research (C)	less than 5,000,000 JPY
Grant-in-Aid for Research Activity Start-up	less than 3,000,000 JPY
Grant-in-Aid for Early-Career Scientists	less than 5,000,000 JPY
Grant-in-Aid for Challenging Research (Pioneering)	between 5,000,000 JPY and 20,000,000 JPY
Grant-in-Aid for Challenging Research (Exploratory)	less than 5,000,000 JPY

On average, an organisation obtains ¥8,055,361 per research project. There was a preference for relatively small projects. The minimum budget recorded was ¥520,000; the maximum budget was ¥131,040,000. Figure 2 (next page) shows the overview of budget types. Among these budget types, Early-Career Scientists (153) and Research Activity Start-ups (13) represented grants awarded to young scholars, comprising 34% of the total number of grants. This indicates that these researchers were not necessarily in the early stages of their careers. Their research projects are evaluated worthy of funding.

Preliminary Case Study



Two major organisations were analysed in depth by collecting information on webpages of organisations. There are two main patterns in how organisations conduct research projects. Some collaborate closely with universities, where principal investigators are typically university professors, and researchers stay for a short period before securing academic positions. In contrast, some organisations, particularly in natural sciences with theoretical research areas, operate independently for over five years with small teams (under ten researchers). These groups secure substantial funding and are often led by senior researchers, including retired university faculty members who continue their work outside academia.

Conclusion and Further Research

This study highlights the increasing number of independent researchers in Japan and their contributions to scientific progress. It states that researchers can work as independent professional scientists in non-profit organisations; these independent scientists are actively conducting Kakenhi-funded research. Studies on research outside universities remain limited; various researchers, including those working independently, pro bono, or as a second job, have contributed to expanding the research landscape. Thus, students' career pathways can expand, which would contribute to STEM career opportunities. Although funding opportunities exist, institutional barriers continue to pose significant challenges. Independent research can serve as a viable career path, ensuring greater flexibility and resilience in STEM professions. This research aims to demonstrate how such career paths can offer greater flexibility and resilience in STEM

professions and furthermore, raises the question: “Who are scientists, and what are the professionality of scientists?”.

Figure 2. Overview of Budget Types.

Pre-Service Teachers' Engagement Of Scientific Reasoning: Uncovering The Mystery Of Tutankhamun's Iron Dagger

Serap Oz Aydin[1] and Nazli Ruya Taskin Bedizel[1]
[1]Balikesir University Necatibey Faculty of Education, Türkiye

This instrumental case study examines how pre-service teachers engage in scientific reasoning when confronted with an anomalous historical case: Tutankhamun's iron dagger. Sixty-two pre-service teachers from diverse disciplines participated in an inquiry task during the first week of a Science and Research Ethics course. Written responses were analysed using a hypothetico–deductive reasoning framework supported by a rubric-based analysis. Findings indicate that most participants demonstrated minimal or basic inquiry engagement, generating a wide range of explanations from scientifically plausible to pseudoscientific. Findings highlight the need for stronger scientific reasoning skills in teacher education to foster critical thinking and scientific literacy.

Keywords: Scientific Inquiry, Scientific Reasoning, Pre-Service Teachers

Introduction

In contemporary, media-saturated societies, individuals are increasingly required to evaluate scientific and pseudoscientific claims in everyday life. Consequently, scientific literacy extends beyond content knowledge to include the ability to reason scientifically, construct explanations, and justify claims with evidence (McNeill, 2008; Lawson, 2009). From this perspective, learning science involves engaging in the practices of science—such as generating hypotheses, evaluating evidence, and reasoning under uncertainty—rather than merely acquiring established facts. Inquiry-based science learning has been shown to support the development of scientific reasoning, increase student motivation, and promote critical thinking and problem-solving skills (Murphy et al., 2019; Taibu et al., 2021). However, research consistently indicates that both teachers and pre-service teachers often have limited opportunities to engage in authentic scientific inquiry and therefore struggle to support these practices in their future classrooms (Uyar et al., 2018). In addition, research on scientific reasoning consistently emphasizes the central role of causal and mechanistic reasoning in constructing scientific explanations. Scientific understanding requires not only identifying causes and effects but also articulating the mechanisms through which causes produce observable outcomes (Ahn & Kalish, 2000). Russ et al. (2008) argue that reasoning about mechanisms is a fundamental aspect of scientific inquiry, as mechanisms link evidence to explanation by specifying the processes underlying phenomena. Similarly, Abrams and Southerland (2001) suggest that learners often prioritize explaining why a phenomenon occurs rather than how it occurs, thereby neglecting the physical or causal mechanisms required for scientifically valid explanations.

One promising approach for eliciting and examining scientific reasoning is the use of anomalous cases—situations that conflict with established scientific or historical expectations. Anomalies create epistemic tension, prompting learners to generate hypotheses, reconsider assumptions, and evaluate evidence (Chinn & Brewer, 1993; Echevarria, 2003). Historically grounded anomalies are especially powerful because they situate scientific reasoning at the intersection of science, history, culture, and ethics, thereby supporting understanding of the nature of science (NOS) as a dynamic and human endeavour (Allchin, 2013). The discovery of an iron dagger in the tomb of the Egyptian pharaoh Tutankhamun (1332–1323 BCE) represents such an anomaly. According to conventional historical timelines, iron processing became widespread several centuries later,

making the presence of an iron artifact in this context unexpected. Explaining this finding requires reasoning under uncertainty, generating alternative hypotheses (e.g., meteoritic iron, early metalworking, trade), and evaluating their plausibility based on historical, chemical, and archaeological considerations. As such, the case provides an authentic context for examining how learners engage in scientific inquiry and hypothetico–deductive reasoning.

Although scientific inquiry has long been a central focus of science education research (Fukuda et al., 2022), relatively few studies examine how pre-service teachers' inquiry capabilities are revealed when they engage with authentic, anomalous scientific problems (Vo & Simmie, 2024). Understanding how pre-service teachers initially reason in such contexts is critical, as these epistemic practices shape how they will later design learning environments for their own students.

In the present study, the iron dagger represents an anomalous result—a finding that conflicts with established historical and scientific expectations—and therefore requires learners to reason with uncertainty, generate competing hypotheses, and judge the plausibility of explanations based on evidence. Research on students' engagement with anomalous results shows that such situations are particularly powerful for revealing how learners monitor evidence, evaluate claims, and regulate their reasoning processes, which are central components of scientific literacy (Crujeiras-Pérez & Jiménez-Aleixandre, 2017; Echevarria, 2003). Besides, historically grounded case studies, particularly those involving anomalies, are uniquely powerful for fostering students' understanding of both scientific inquiry and the nature of science (NOS) (Allchin, 2011). In the Tutankhamun task, pre-service teachers are required to argue for or against explanations (e.g., meteoritic iron, early metallurgy, pseudoscientific claims) using historical, chemical, and archaeological reasoning. Thus, the case operationalizes the broader goal of scientific literacy by making visible how participants reason, justify conclusions, and distinguish scientific explanations from speculative or non-scientific ones—precisely the competencies that science education aims to develop.

Research Question

How do pre-service teachers use scientific reasoning to generate, evaluate, and justify explanations for anomalies in historical scientific findings?

Methods

Research Design

This study was designed as an instrumental qualitative case study (Stake, 1995) examining how pre-service teachers engage in scientific reasoning when confronted with an anomalous historical scientific case. Case study methodology is particularly appropriate when the aim is to investigate complex cognitive and epistemic processes within a bounded context (Yin, 2018). The case of *Tutankhamun's iron dagger* was selected because it represents a historically authentic anomaly that requires hypothesis generation, evidence evaluation, and mechanistic reasoning, making it a powerful context for examining scientific inquiry practices.

Consistent with recommendations for qualitative case studies in education, multiple analytic strategies were employed, including rubric-based scoring and qualitative interpretation, to provide a rich and systematic account of participants' reasoning (Merriam & Tisdell, 2016). The case thus serves as an analytic lens for understanding broader challenges in pre-service teachers' engagement with scientific inquiry and hypothetico–deductive reasoning.

Context And Participants

The study was conducted as part of the Science and Research Ethics course, a compulsory general culture course offered at a faculty of education in Türkiye. The course enrolled 62 pre-service

teachers from diverse departments, including preschool education, social studies, music education, science education, and biology education, representing all four undergraduate grade levels (1st–4th year). Purposeful inclusion of participants from different disciplinary backgrounds was intended to capture a broad range of prior scientific knowledge and epistemic orientations, an approach commonly adopted in studies examining inquiry reasoning across heterogeneous teacher populations (e.g. Windschitl et al., 2012).

Data were collected during the first week of the semester, prior to formal instruction, in order to assess participants' readiness and baseline inquiry reasoning. Early-course data collection is recommended when the aim is to examine pre-existing epistemic resources rather than instructional outcomes (Hammer & Elby, 2002).

Instructional Task: A Scientific Mystery: Tutankhamun's Iron Dagger

Participants were presented with a historically grounded anomalous case titled "A Scientific Mystery: Tutankhamun's Iron Dagger." The case described the discovery of an iron dagger in the tomb of Tutankhamun (1332–1323 BCE), an artifact that contradicts established historical timelines for iron metallurgy. The case was deliberately framed as an anomaly, defined as evidence that conflicts with existing theoretical or historical expectations and therefore prompts epistemic tension (Chinn & Brewer, 1993; Echevarria, 2003). The open-ended guiding questions encouraged participants to recognize the anomaly, generate possible explanations, and consider the origin and processing of the material. Participants worked individually and were explicitly guided to formulate hypotheses, without being provided additional evidence or corrective feedback. The study employed the following case scenario:

The tomb of the Egyptian pharaoh Tutankhamun, who ruled between 1332 and 1323 BCE, was discovered in 1922 by archaeologist Howard Carter. Among the many valuable artifacts found in the tomb, one object particularly surprised scientists: a dagger made of iron.

This dagger can be considered an anomaly, meaning an extraordinary case, according to historical records. This is because, based on known sources, humans only began processing iron about 500 years later. This raises several intriguing questions:

- *How were the Egyptians able to work with iron before the Iron Age?*
- *Where did the raw material for this dagger come from?*
- *How did the Egyptians obtain this material?*

Analytical Framework

Participants' written responses were analysed using a Hypothetico–Deductive Reasoning (HDR) framework, which conceptualizes scientific inquiry as the coordinated generation, testing, and evaluation of alternative explanations. According to this perspective, science involves formulating competing hypotheses and deducing consequences that can be tested against evidence, a process that characterizes sophisticated scientific reasoning (Lawson, 2000; Lawson, 2008). This HDR approach has also been elaborated as a cognitive foundation for science learning, with hypothetical thinking constituting a central mode of reasoning employed by both scientists and learners (Kalinowski & Pelakh, 2023). The HDR framework guided the analysis of key inquiry steps, including anomaly recognition, hypothesis generation, use of evidence, and hypothesis evaluation.

- Observation and problem identification
    - Do the pre-service teachers recognize the iron dagger as an anomaly?

- Do they acknowledge that it challenges established historical knowledge?

- Hypothesis generation
  - Do they propose explanations based on prior knowledge (e.g., meteoric iron, early metallurgy, trade)?
  - Do they suggest multiple possible explanations or fixate on one?
- Use of evidence
  - Do they support their explanations with historical, chemical, or archaeological evidence?
  - Do they reference known facts, studies, or historical records?
- Hypothesis evaluation
  - Do they compare alternative explanations or assess their plausibility based on available evidence?
- Logical consistency in reasoning
  - Do they maintain coherent and logically structured reasoning across observation, hypothesis, and evidence?

Although the analytic framework was grounded primarily in hypothetico–deductive reasoning, elements of the Claim–Evidence–Reasoning (CER) framework (McNeill et al., 2006) were used as a supporting interpretive lens to examine how participants structured their explanations. Within this lens, hypotheses were treated as claims, references to historical or scientific information as evidence, and the logical connections between claims and evidence as reasoning. Consistent with Gotwals et al. (2012), this approach supported the analysis of participants' ability to construct evidence-based explanations within the broader inquiry process.

The framework draws on established models of scientific inquiry that conceptualize inquiry as a coordinated process involving problem recognition, explanatory construction, and evidentiary reasoning (National Research Council [NRC], 2012). The hypothesis revision stage was intentionally excluded, as the purpose of the study was to examine participants' initial explanatory reasoning rather than learning progression.

Rubric Development And Scoring

A four-level analytic rubric (Table 1) was developed to evaluate participants' engagement in scientific inquiry across five criteria. Rubric-based assessment is widely recognized as an effective method for evaluating complex cognitive practices such as scientific reasoning and inquiry, as it allows for systematic yet nuanced analysis of qualitative responses (Jonsson & Svingby, 2007). Each criterion was scored from 0 (absent) to 3 (proficient), yielding a maximum total score of 15. Aggregate scores were interpreted using predefined engagement levels (no, minimal, basic, developing, proficient), categorizing inquiry performance along developmental continua.

The responses of the participating pre-service teachers were evaluated based on each criterion, and the scoring was interpreted as follows:

Scoring Interpretation

- **0 points** →No Engagement in Scientific Inquiry
- **1- 5 points** → Minimal Engagement in Scientific Inquiry (Lacks understanding, weak reasoning, no use of evidence).

- **6 - 10 points** → Basic Scientific Inquiry (Some reasoning present but lacks depth and evaluation of evidence).
- **11 - 14 points** → Developing Scientific Inquiry (Good reasoning, considers evidence but lacks full hypothesis testing).
- **15 points** → Proficient Scientific Inquiry (Strong reasoning, effective hypothesis testing, and evaluation based on evidence).

Table 1. Rubric Criteria and Scoring

Category	Score: 0 (Absent)	Score: 1 (Basic/Naïve)	Score: 2 (Developing)	Score: 3 (Proficient/Advanced)
1. Observation & Problem Identification	Does not recognize the scientific anomaly or problem.	Recognizes the problem but describes it vaguely or inaccurately.	Identifies the problem with some clarity but lacks depth in recognizing its significance.	Clearly identifies the anomaly and articulates why it challenges established scientific knowledge.
2. Hypothesis Generation	No hypothesis is proposed.	Proposes a single hypothesis, but it lacks scientific basis or is a misconception.	Proposes one or more hypotheses with some scientific validity but lacks depth in justification.	Generates multiple plausible hypotheses, supported by logical reasoning and prior knowledge.
3. Use of Evidence (Empirical & Historical)	No evidence is provided to support hypotheses.	Mentions some evidence but does not connect it logically to the hypotheses.	Uses relevant evidence but does not fully explain its significance.	Uses strong, diverse evidence (chemical, historical, archaeological) and logically connects it to hypotheses.
4. Hypothesis Testing & Evaluation	Does not attempt to test or evaluate hypotheses.	Accepts a hypothesis without questioning its validity.	Considers alternative explanations but does not critically evaluate them.	Compares multiple hypotheses and evaluates them based on evidence, revising as needed.
5. Logical Consistency in Reasoning	No clear logical connections between problems, hypothesis, and evidence.	Some logical connections exist but contain gaps or inconsistencies.	Reasoning is mostly logical, but there are minor gaps or weak connections.	Uses well-structured, consistent reasoning that clearly connects the problem, hypotheses, and evidence.

Data Analysis

All participant responses were independently evaluated using the rubric. Scores were first examined descriptively to determine overall engagement patterns, followed by qualitative analysis to identify recurring strengths and weaknesses in scientific reasoning, including reliance on mechanistic explanations versus speculative or pseudoscientific claims. Combining rubric scores with qualitative interpretation is recommended for maintaining analytic rigor while preserving the explanatory richness of participants' reasoning (Miles et al., 2020).

By integrating an anomalous historical case with a structured inquiry rubric, this methodology enables systematic examination of pre-service teachers' initial scientific reasoning, particularly their capacity to generate causal explanations and use evidence.

Findings

Levels Of Scientific Inquiry Engagement

Analysis of pre-service teachers' responses using the Scientific Inquiry rubric revealed that the

majority of participants demonstrated limited engagement in scientific inquiry (Table 2). Specifically, 59 of the 62 pre-service teachers (94%) were categorized at the Minimal or Basic inquiry levels, indicating difficulties in coordinating hypotheses, evidence, and reasoning. Only two participants (3%) reached Developing or Proficient levels, while one participant showed no engagement.

Table 2. Pre-service teachers Scientific Inquiry Engagement Levels

Engagement Level	Number of Pre-Service Teachers (N=62)
No Engagement in Scientific Inquiry	1
Minimal Engagement in Scientific Inquiry	29
Basic Engagement in Scientific Inquiry	30
Developing Scientific Inquiry	1
Proficient Scientific Inquiry	1

Participants at the *Minimal Inquiry* level often recognized the historical tension but failed to articulate underlying mechanisms or evaluate evidence. For example, one participant stated, *"History is not a discipline with definitive conclusions… the Egyptians may have discovered iron-processing techniques before everyone else"* (PS2), offering a generalized claim without evidentiary support. Similarly, PS4 acknowledged uncertainty and provided no causal explanation: *"I have no idea where the iron was sourced from."*

In contrast, participants at the *Basic Inquiry* level proposed plausible explanations but demonstrated weak reasoning or incomplete use of evidence. For instance, PS9 suggested early technological advancement—*"Egyptian society may have started processing iron earlier"*—yet did not explain how such processing could have been achieved under known technological constraints of the period. Many responses in this category relied on assertions rather than mechanistic reasoning, such as PS21's statement, *"They may have made the dagger by hammering the iron."*

Only a small number of participants demonstrated *Developing or Proficient Inquiry,* characterized by coherent hypothesis generation, explicit recognition of the anomaly, and coordinated use of historical and chemical evidence. One high-scoring participant clearly articulated the anomaly and supported a mechanistic explanation:

> *"This information calls historical records into question because iron-processing technologies were not widespread in the 14th century BCE. However, the dagger found in Tutankhamun's tomb represents an anomaly indicating that iron was somehow processed during this period. One of the most plausible hypotheses is that the dagger was made from meteoritic iron, as chemical analyses have shown a high nickel content"* (PS1).

Types Of Hypotheses Generated

Across all responses, pre-service teachers generated 15 distinct hypotheses to explain the presence of the iron dagger in Tutankhamun's tomb (Table 3). These hypotheses varied considerably in scientific plausibility, ranging from evidence-based explanations to explicitly pseudoscientific claims.

Scientifically Plausible Hypotheses

As presented in Table 3, eight hypotheses reflected scientifically testable explanations, most commonly invoking meteoritic iron, early metalworking techniques, or trade. Several participants explicitly referenced meteorites as a feasible iron source:

Table 3. Hypothesis Frequency Table

	Hypotheses	Frequency	
1	The dagger was shaped using cold forging (hammering) techniques	9	Scienrific hypotheses
2	The dagger was obtained through trade from an advanced civilization that had early iron processing techniques	8	
3	The dagger suggests that iron was used earlier than currently recorded but not widely documented	7	
4	The dagger was processed using high-temperature furnaces or fire-based technique	6	
5	Egyptians unknowingly used iron without recognizing it as a distinct material	5	
6	Iron could have been processed in a different way, such as through exposure to natural environmental heat sources	4	
7	The dagger was created using metal that naturally formed in a way that made it easier to shape	3	
8	The dagger was made from meteoritic iron	2	
9	The dagger was placed in the tomb at a much later date	6	Non-scientific hypotheses
10	The dagger was melted and shaped by prolonged exposure to sunlight	5	
11	The dagger was made by a lost ancient civilization with superior technology	4	
12	The dagger was formed by lightning striking iron	3	
13	The dagger was made with the help of extraterrestrials	3	
14	The dagger was created using unknown supernatural or mystical forces	2	
15	The dagger was created using an unknown energy or method lost to history	2	

> *"It was most likely made from meteoric iron… people could shape the iron they found from meteorites by hammering it" (PS60).*

Others emphasized trade and intercultural exchange:

> *"As far as I know, the Egyptians were very advanced in many fields… they may have adopted ideas from other civilizations through trade" (PS33).*

However, even within scientifically oriented hypotheses, many participants struggled to articulate mechanisms, often stopping at surface-level claims without explaining how evidence supported their conclusions.

Pseudoscientific And Speculative Hypotheses

Seven hypotheses were classified as non-scientific, relying on supernatural forces, extraterrestrial intervention, or vague unknown energies. These explanations were typically devoid of evidence or causal reasoning. For example, PS13 stated, *"The dagger may have been made with magic,* "while PS52 suggested, *"I think the pyramids were built by extraterrestrials using more advanced technology."*

Such responses illustrate a tendency to substitute speculation for mechanistic explanation when causal reasoning was inaccessible, a pattern observed across minimal and basic inquiry levels.

Overall, the findings indicate that while many pre-service teachers were able to generate claims, far fewer were able to coordinate claims with evidence and mechanistic reasoning. Explanations frequently addressed why the dagger might exist (e.g., advanced civilization, historical uncertainty) rather than how it could have been produced given material and technological constraints.

Discussion And Conclusion

The findings indicate that most pre-service teachers were minimally or basically engaged in

scientific inquiry, despite generating a broad spectrum of reasoning approaches ranging from scientifically plausible hypotheses to pseudoscientific and speculative explanations. This variation highlights the pedagogical value of anomalous cases in teacher education, as anomalies are known to spark curiosity, challenge learners' prior assumptions, and foreground how evidence is interpreted and used in scientific reasoning (Chinn & Brewer, 1993; Allchin, 2013). Tasks based on anomalies can therefore function as diagnostic tools, enabling instructors to identify misconceptions and epistemic weaknesses early and to determine where instructional scaffolding is most needed (Echevarria, 2003; Windschitl et al., 2012). Moreover, historically grounded anomalies connect science with history, culture, and ethical considerations, making them powerful contexts for teaching the nature of science (NOS) as a human and socially embedded endeavor (Allchin, 2013; Matthews, 2015). Engaging with historical scientific mysteries may help pre-service teachers develop an understanding of science as a dynamic and evolving process, rather than a fixed collection of facts (Lederman et al., 2013). A limitation of the present study is that it did not include a hypothesis revision stage, which is widely regarded as essential for promoting sustained scientific inquiry and hypothetico–deductive reasoning (Lawson, 2009; NRC, 2012). Future studies should therefore provide pre-service teachers with successive evidence that allows them to revisit and revise their initial hypotheses, thereby more fully supporting the development of scientific reasoning.

ESERA 2025 Copenhagen

How Do Upper Secondary Greek Students View The Nature Of Science? The Case Of Chemistry

Charoula Labrianaki[1], Katerina Salta[2]and Dionysios Koulougliotis[1]
[1]Ionian University, Zakynthos, Greece
[2] National and Kapodistrian University of Athens, Athens, Greece

Nature of Science (NOS) refers to science as a way of thinking along with the intrinsic beliefs and values related to scientific knowledge and its development. Taking into account the distinct and common characteristics of the different science disciplines, NOS is conceptualized as both general and domain specific. In this work, the views of Greek upper secondary school students regarding the different aspects of NOS were investigated, by taking the chemistry discipline as a characteristic case. An adapted version of the "Views of Nature of Science Questionnaire – Form C" (VNOS-C) instrument was employed and the responses of 96 students (16-17 y) were analysed qualitatively via the criteria of the VNOS Analysis and Scoring Rubric (VAScoR). A total of six NOS aspects were identified with students' views presenting a mixed picture regarding their VAScoR classification. For three NOS aspects - namely the myth of the "scientific method", tentative, and scientific theories – many partially informed views were identified. On the contrary, the naive views were a majority for the social and cultural embeddedness of science and with relatively frequent occurrence in the empirical and inferential NOS aspects. In addition, a quite large number of views regarding the empirical and inferential NOS aspects were classified as silent. The research findings provide insights into aspects of the chemistry curriculum and of the teaching approaches that need revaluation to enhance students' knowledge, skills and competencies with respect to the nature of science and promote chemical-scientific literacy.

Keywords: Domain-specific NOS, Domain general NOS, Nature of chemical laws

Introduction

Nature of science (NOS) has been an important educational objective for several decades and at the same time a significant topic in science education research. (Erduran et al., 2020; Abd-El-Khalick & Lederman, 2023). The discussion about the NOS construct among the research community and science educators, has provided several frameworks that aim to students' understandings of NOS for the promotion of scientific literacy. Several researchers have contributed to the conceptualization of NOS resulting in a set of some "general NOS aspects" or the consensus view of NOS (Abd-El-Khalick & Lederman, 2023). The term "consensus" should not be taken to imply full agreement on the framework. Although disagreements from a philosophical perspective and about the relations NOS with scientific inquiry or practices have largely been resolved, conversations about the "nature of NOS" still persist. These include critiques of the consensus view as being too general and arguments in favour of adopting domain-specific nature of science discipline, such as chemistry (e.g., Cetin et al., 2010).

According to the consensus framework, several lists that include a multitude of NOS aspects have been proposed. There exist, however, certain aspects, such as the empirical, tentative, creative, and scientific method, which are common in all lists (e.g. Lederman et al., 2002; Osborne et al., 2003), thus indicating that each one of these is related to a student's preconception about science (Kampourakis, 2016). These general NOS lists have been criticized as oversimplifying descriptions of science (e.g., Irzik & Nola, 2011). However, for school science, a simplified NOS view provides acceptable recommendations for NOS teaching and learning (Kampourakis, 2016).

An important discussion about NOS research which is considered crucial for secondary science education is related to the generality versus domain specificity of NOS. Some researchers have

argued that 'the consensual general NOS aspects are too broad and do not capture the heterogeneity of science subjects (e.g., Irzik and Nola 2011). For instance, the different features of laws in different science disciplines are not conceptualized. Specifically, some laws in chemistry, like in physics, are quantitative in nature (e.g. laws of stoichiometry), but others rely more on approximations without possessing quantitative expression (e.g. the periodic law).

Based on science disciplines' similarities and differences, the domain-general and domain-specific approaches could be considered as complementary (Kampourakis 2016). Therefore, general NOS aspects could provide a foundation for further development of domain-specific NOS learning in school science and further research on domain-specific NOS assessments is needed.

The inclusion of NOS in science curricula together with the increasing interest in corresponding science education research resulted in the development of various NOS assessments, which can be divided into two types: forced choice and open-ended. The theory driven forced-choice instruments are constituted of items along with their answers derived from various theoretical perspectives (Aikenhead et al., 1987). Therefore, students' responses might be biased toward one philosophical view and consequently not accurately expressing their thoughts (Abd-El-Khalick & Lederman, 2023). During the last two decades there has been a shift from forced choice to open-ended instruments with the Views of Nature of Science (VNOS) questionnaire being one which has been widely used (Abd-El-Khalick & Lederman, 2023).

There are, however, various concerns about the use of open-ended instruments. An analysis of responses is exhausting work that needs a thorough understanding of the NOS framework as well as more time and resources, particularly for large-scale studies. Moreover, the resulting data is not suitable for statistical testing of relations between various variables. Several researchers have proposed various ways to quantify responses to open-ended NOS instruments (e.g., Abd-El-Khalick et al., 2024, Burgin & Sadler, 2016).

The purpose of the present study is to investigate the NOS views of Greek upper secondary students by taking chemistry as characteristic case. The consensus view of NOS is used as theoretical framework to elicit and discuss students' NOS views as an attempt to combine both domain general and specific NOS views in an assessment. The study was guided by the following research question:

- How do Greek upper secondary students view the NOS in the context of chemistry?

Method

In this study, a descriptive qualitative approach was employed focused on measuring students' NOS conceptions based on the consensus framework in the chemistry context.

Participants

A total of 96 students of the 10th and 11th Grade (16 – 17 y) from one public school located in Athens (Greece) were participants in this study, using a convenience sampling procedure. The 10^{th} grade students have been involved in chemistry courses for 3 years and the 10^{th} graders for 4 years. Moreover, during chemistry courses they did not participate in any activity about nature of science. Students responded to instrument questions during a one-hour lesson of chemistry course.

Instrument

The instrument used (named VNOS-C-Ad and referring specifically to the chemistry discipline, Table 1) consisted of seven items and was an adaptation of the original VNOS–C (Lederman et al., 2002) questionnaire. The item of VNOS–C about the scientific laws was excluded from

VNOS-C-Ad because in chemistry courses students have been taught only the periodic law, which differs from others scientific laws. For example, the periodic law is not expressed mathematically as physics laws and the term "periodic" in the periodic law is not related to temporal periodicity as others scientific laws (Erduran, 2007; Scerri, & Worrall, 2001). The questions about organisms and dinosaurs of the original VNOS–C instrument were also excluded as they are related to biology. Finally, the items that relate creativity and imagination with experiments/investigations were excluded based on time limitation.

Table 1. The VNOS-C-Ad instrument.

1. What, in your view, is science?
2. What makes chemistry different from other disciplines, like philosophy?
3. What is an experiment?
4. Does the development of scientific knowledge require experiments?
If yes, explain why. Give an example to defend your position.
If no, explain why. Give an example to defend your position.
5. After scientists have developed a scientific theory (e.g., atomic theory), does the theory ever change?
If you believe that scientific theories do not change, explain why. Defend your answer with examples.
If you believe that scientific theories do change:
(a) Explain why theories change?
(b) Explain why we bother to learn scientific theories? Defend your answer with examples.
6. Chemistry textbooks often represent the atom as a central nucleus composed of protons (positively charged particles) and neutrons (neutral particles) with electrons (negatively charged particles) orbiting that nucleus. How certain are scientists about the structure of the atom? What specific evidence do you think scientists used to determine what an atom looks like?
7. Some claim that science is infused with social and cultural values. That is, science reflects the social and political values, philosophical assumptions, and intellectual norms of the culture in which it is practiced. Others claim that science is universal, that is, science transcends national and cultural boundaries and is not affected by social, political, and philosophical values, and intellectual norms of the culture in which it is practiced.
If you believe that science reflects social and cultural values, explain why. Defend your answer with examples.
If you believe that science is universal, explain why. Defend your answer with examples.

Data Analysis

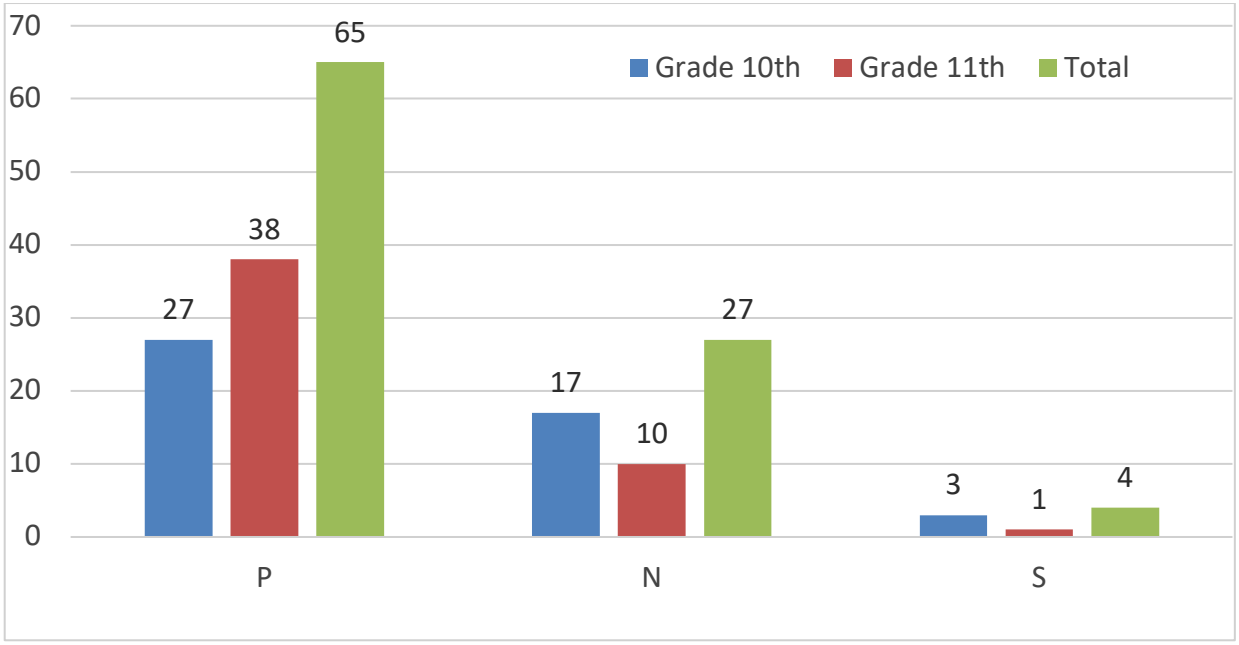
The content validity of data is established during the first step of the analysis, where the target NOS aspect/s of each item were defined according to the literature (Lederman et al., 2002; Abd-El-Khalick et al., 2024). Then, students' responses were analysed in order to identify elements that justify their views of the NOS aspect and were classified to 4 categories as either informed (I), partially informed (P), naïve (N), and silent (S) according to the criteria of the VNOS Analysis and Scoring Rubric (VAScoR) (Abd-El-Khalick et al., 2024).

Table 4. The categories coding schema of students' views classification adopted from Abd-El-Khalick et al. (2024).

Category	Criteria
Informed view (I)	All elements of the target NOS aspect are judged to be informed
Partially informed view (P)	Only a subset of the core elements of the target NOS aspect are judged to be informed; and responses on other elements of the target NOS aspect are silent
Naïve view (N)	Either some or all elements of the target NOS aspect are naively addressed
Silent (S)	No relevant or irrelevant or incomprehensible or without reliable categorization response.

Two of the authors analysed the same responses of ten students, compared their analyses, and resolved discrepancies with the consensus of all authors to establish inter-rater reliability.

Results And Discussion



How Do Greek Upper Secondary Students View The Nos In The Context Of Chemistry?

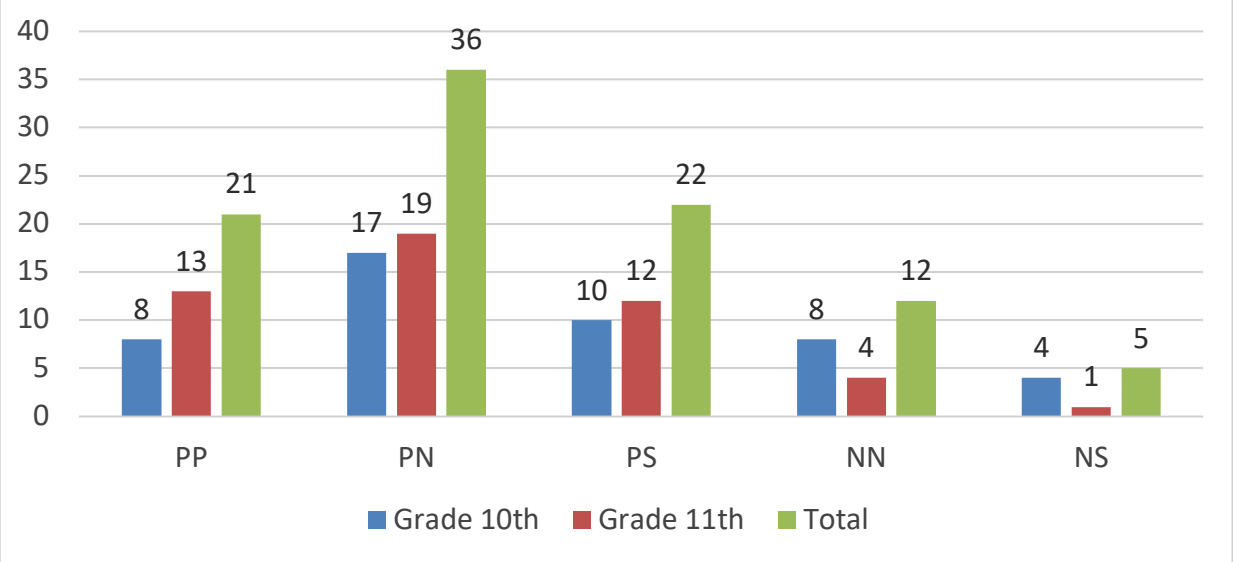
Analysis of students' responses revealed the emergence of six NOS aspect/s: empirical, inferential, tentative, myth of "the scientific method", scientific theory, and social and cultural embeddedness of science.

How Do Students View Scientific Theories?

Students' views of the NOS aspect referring to scientific theories are mainly classified as partially informed (Figure 1).

Figure 1. Views of scientific theories aspect.

A representative quote showing a partially informed view is the following quote:



> Quote 1: "Since scientific theories have been confirmed using various means to prove their validity (e.g., microscopes for the structure of the atom), they are unlikely to change. They change if it is later proven, of course, that they are incorrect (this happens over time with the advancement of knowledge and technology)"

Do Students View Science As Tentative?

Students' responses to items 5 and 6 reveal the tentative NOS aspect and the distribution of their classifications are presented in Figure 2 (the first letter concerns the category of students' responses to item 5 and the second to item 6 respectively). The prevailing views in this case belonged to the category partially informed as 79 students express a partially informed view in at least one item. For example, students believe that conclusions arise from instruments (e.g., microscopes) rather than through reasoning (quote 2) Students with naïve views regard both scientists and the school curriculum as authoritative, containing absolute and unchanging knowledge about the physical world (quotes 3, 4)

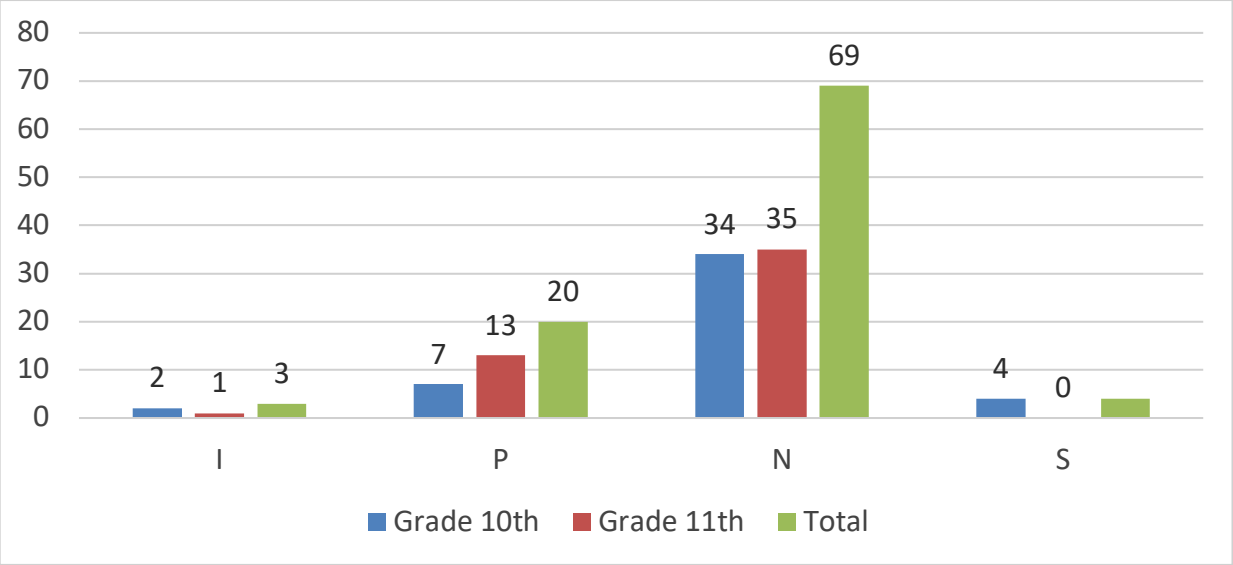
> Quote 2: "Scientific theories change as scientific equipment improves. New tools allow for a deeper study of things, and as a result, sometimes the study uncovers new data that invalidate previous ones."

Figure 2. Views of tentative NOS aspect.

> Quote 3: "Scientists are very certain about the structure of the atom, as this theory has been proven to be true (through many experiments, other theories, and research) by previous scientists"

> Quote 4: "I believe they are quite certain (the scientists) for chemistry to be taught in schools."

As we can see in Figure 2, eleventh grade students also present more informed views than the ones in the 10th grade. Moreover, students' views of the tentative aspect seem to depend on the item.



How Do Students View The Cultural Embeddedness Of Science?

Concerning the social and cultural embeddedness of science NOS aspect, 3 of the students' views are informed, 20 partially informed, and most of them (69) are naive views (Figure 3). Particularly characteristic examples of responses are presented by quotes 5 and 6.

Do Students View Science As Empirical And Inferential?

Figure 4 presents the classifications of students' views regarding the empirical (1st letter) and inferential (2nd letter) aspects. The views of the empirical NOS are classified as silent for most students (64), with the remaining students' responses being almost equally distributed between naive (15) and partially informed (17). Regarding the inferential NOS aspect most responses (67) are also classified as silent, 28 as naive and only one as partially informed.

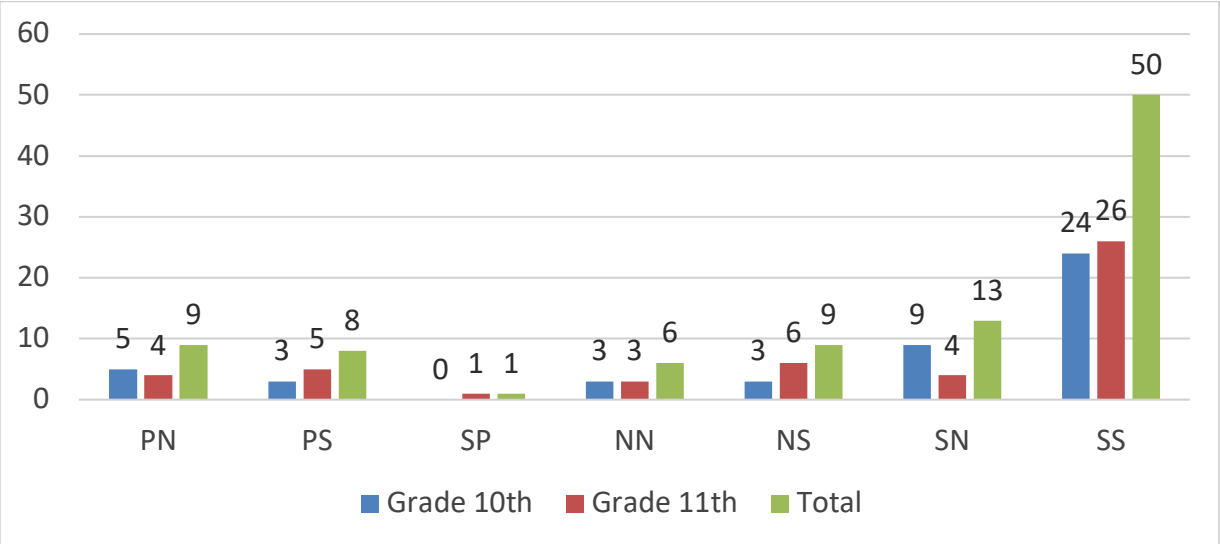


Figure 3. Views of social and cultural embeddedness of science aspect.

Quote 5: "I believe that science reflects the values of the culture from which it originates because these values determine the conditions under which it will develop. For example, it is much easier to study and develop controversial scientific fields in a progressive country than in a religion - centered country" (partially informed view).

Quote 6: "Science is universal, since we all live in the same space governed by the same physical and chemical laws. For example, atomic theory cannot be different in Europe and different in Asia because the culture and society are different" (naïve view).

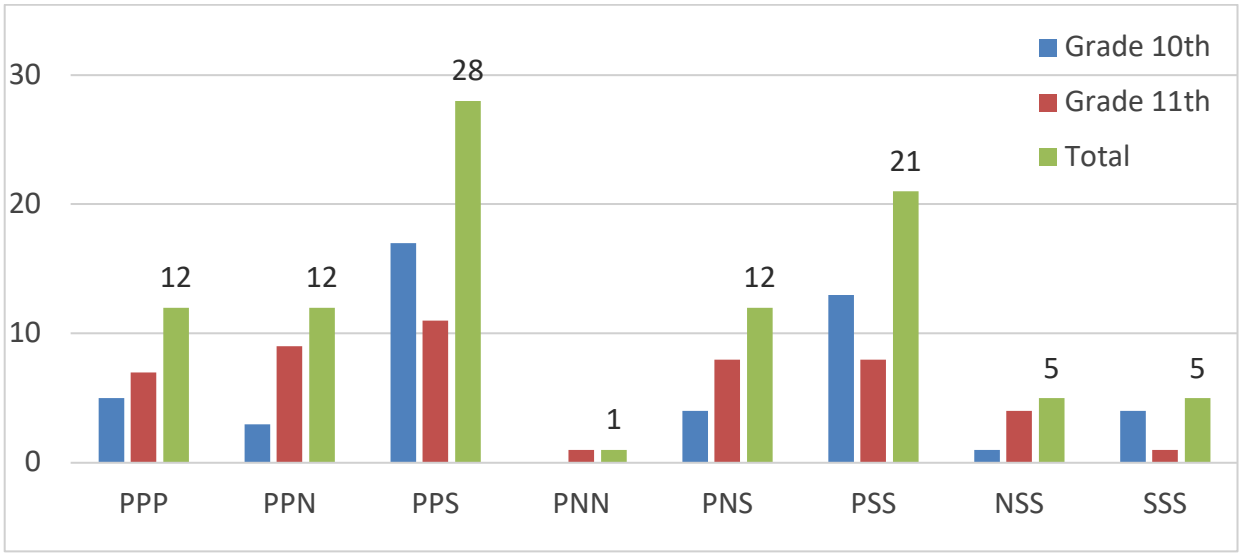

Figure 4. Views of empirical and inferential aspects.

How Do Students View "The Scientific Method"?

The myth of "the scientific method" aspect emerged from items 2, 3, 4 and the distribution of the classifications of students' views are presented in Figure 5. The first letter concerns the category of students' responses to item 2, the second to item 3 and the third to item 4, respectively.

Figure 5. Views of myth of "the scientific method" aspect.

Twelve students had consistent partially informed views (PPP), 40 students showed partially informed views in two items, and 31 students were silent in two or three items.

Interestingly, 11th grade students presented a shift to more informed views regarding the myth of "the scientific method", tentative, scientific theories as well as social and cultural embeddedness of science aspects (Figures 1-5).

Conclusions

This study used the example of chemistry as a specific science discipline to investigate Greek upper secondary students' NOS views. Six general NOS aspects were elicited from students' responses. A variety of classifications of students' views depending on the NOS aspect were revealed. Concerning the myth of the "scientific method", tentative, and scientific theories NOS aspects most students' presented partially informed views. On the contrary, the naive views were a majority for the social and cultural embeddedness of science and with relatively frequent occurrence in the empirical and inferential aspects.

This difference could be partially explained based on the Greek chemistry curriculum. Students are taught three models of atomic structure that were developed during different historical periods. Therefore, the example of atomic theory helps them express partially informed views regarding the "scientific method", tentative, and scientific theories NOS aspects.

Many students' responses regarding the empirical and inferential NOS aspects were irrelevant or incomprehensible and were classified as silent views. This indicates that traditional lab work in chemistry teaching is not sufficient for achieving meaningful NOS learning. Moreover, it could be related to the reduced students' ability to express their conceptions in writing in an open-ended instrument.

This work contributes to the promotion of scientific literacy focused on social transformation by analysing conceptual and epistemic aspects of Brazilian eugenics. To this end, we present a documentary analysis of the first year of the Boletim de Eugenia (Eugenics Bulletin), one of the documents used to promote eugenics in Brazil. The analysis focus on how the conceptual and epistemic aspects are mobilized to support eugenics ideas. In our findings, concepts such as inheritance are central to justifying eugenics artificial selection but the reasoning is flawed. We argue that the historical case of eugenics is fruitful in science education for raising discussions on how science is not a neutral endeavour and in promoting scientific literacy focused on social transformation. Eugenics case allows discussing science as a social endeavour, highlighting ways to produce, evaluate and legitimize scientific knowledge, as well as the discussion of social and ethical limits of scientific knowledge.

Keywords: scientific literacy; history of science; scientific argumentation.

Introduction

Valladares (2021) claims Scientific Literacy (SL), from an emancipatory perspective, can be understood both as a social practice and as a tool for the self-construction of one's voice and place in the world. Students educated from this perspective should be committed to social transformation and capable of taking advantage of science and other cultural knowledge - being aware of science's potentials and limitations - in the generation of adaptative, resilient, and sustainable responses to the challenges of the twenty-first century (Valladares, 2021). Accordingly, this contemporary perspective of SL takes cultural pluralism into consideration, is oriented toward social transformation (Valladares, 2021; Guerrero et al., 2025), and is committed to social activism, realized through students' participation and emancipation (Valladares, 2021).

As highlighted above, the social activism proposed in this framework seeks to address the multiple systemic and structural forms of violence that violate human rights on a global scale in the twenty-first century, a context marked by a profound human, political, and environmental crises. However, these crises do not affect society uniformly, as oppressive structures (mainly racism, sexism, and classism) exclude certain minoritized social groups in favour of dominant ones. We agree with the arguments portrayed by Valladares (2021) and Silva and Sasseron (2021) regarding the importance of Science Education in helping us understand how differential access to science and the unequal consequences of the scientific enterprise perpetuate historical inequities, and how the production of scientific knowledge must be oriented toward reducing these disparities.

According to Guerrero et al. (2025), SL constitutes a "transformative and socio-ecojustice-oriented framework that moves beyond content knowledge and scientific competence to foster

political agency, eco-reflexivity, and collective action" (Guerrero et al., 2025, p. 2). Thus, SL for social transformation highlights the importance of addressing socially relevant issues that enable the problematization of social injustices and inequities that are, to some extent, connected to science. Therefore, Science Education must address scientific laws and concepts allied with discussions about social scientific issues, as well as the epistemic, social, and material aspects of scientific knowledge (Silva & Sasseron, 2021). Considering ideas discussed by Duschl (2008) and Stroupe (2015), conceptual aspects are the knowledge developed by the scientific community; epistemic aspects are the criteria and norms used by scientists to determine what they know and why they know it; social aspects are the social processes by which scientific knowledge is produced, represented, and discussed; and the material aspects as the tools and technologies, along with their mode of use, applied in scientific investigation. This formative goal of SL, which goes beyond traditional content knowledge, can be achieved through different teaching approaches in which students engage with the social practices of science and, in doing so, learn about science (Silva & Sasseron, 2021). Guerrero et al. (2025) complement this discussion highlighting the importance of cross-disciplinarity and history-philosophy-sociology of science (HPSS) perspectives in the promotion of SL, especially of the critical and transformative aspect of it.

The use of History, Philosophy, and Sociology of Science (HPSS) in Science Education has long been recognized as a valuable means of presenting science as a form of knowledge that is socially produced and embedded in historical, social, economic, and political contexts (Allchin, 2013; Allchin et al., 2014; Forato et al., 2011). In this sense, numerous studies argue that HPSS can promote teaching about science, often referred to as the Nature of Science, converging to the transformative SL. However, the political and social inflections are still not explicit in this traditional justification to the use of HPSS in teaching. Moura (2025) recently pieced together proposals of a sociopolitical turn in Science Education that converges to SL for social transformation and recent literature has increasingly advocated for more politicized and politicizing uses of HPSS in Science Education.

For example, Moura (2021) discusses the potential of the use of HPSS to address historical processes of epistemicide, the plundering of knowledge, and the erasure of contributions from certain groups due to classist, racist, sexist, and colonial structures of oppression in the context of Science Education. He proposes it can be used to repair these harms since it unravels marginalized figures and suppressed forms of knowledge that can then be highlighted in Science classrooms. Similarly, Guerra and Moura (2022) propose expanding the traditional meanings of humanization and contextualization typically associated with HPSS in Science Education. Drawing on History of Science, they argue that, beyond being a human endeavour, science was produced in a global context by people of diverse origins and ethnic backgrounds and advocate that this should be highlighted in Science Education to expand student's perception of who can make science and from what places they come from. They also argue that it is important to problematize in Science classrooms that many of these contributors had their work erased due to the entanglement of modern science with colonialism, patriarchy, and capitalism. Both proposals for sociopolitical turn in HPSS (Moura, 2021 and Guerra & Moura, 2022) converge in their use of HPSS to problematize and repair the colonial erasures produced by modern science. In other words, they articulate HPSS as a pathway for promoting decolonial education in Science Education, and to foster antiracist approaches in Science classrooms (Pinheiro, 2023).

Once modern science has not only reproduced but also helped establish and justify racist and colonial power structures – such as through the development of race as a biological concept, social Darwinism, and eugenics – we argue that it's important that Science Education community investigates these historical episodes, so they can be discussed within an antiracist, justice-

oriented and transformative SL framework. To contribute to this end, this paper examines a major journal on eugenics from the late 1920s in Brazil. The aim of this work is to analyse inconsistencies in the mobilization of conceptual and epistemic aspects of science to support eugenic ideas in Brazil in the early 20th century and map the implications to Science Education.

Eugenics As A Case Of History Of Science

Eugenics was coined in 1883 by Francis Galton (1822-1911) in England, after he and other colleagues had been discussing the "problems" with migration and the poor classes of London. The movement proposed that the "improvement" of the human race (Singleton, 2014) could occur by promoting the perpetuation of traits deemed "superior" and restricting the transmission of traits associated with supposedly "inferior" individuals (Santos et al., 2014). Emerging during the period of disciplinary consolidation of modern science, eugenics held scientific status for decades (Diwan, 2007) and perpetuated racism as a result of the difference of races (biological at that point). To define which traits were desirable, the definitions were rooted in the English elite bias and were marked by racist assumptions (Zuberi, 2023). This framework ultimately reinforced hierarchical classifications of human groups and exclusionary policies of reproductive control.

Galton formulated eugenics as a way of justifying and addressing the social problems confronting the nineteenth-century English industrial bourgeoisie (Góes, 2015). Working-class neighbourhoods suffered from intense poverty and its associated social challenges. Galton attributed biological origins to behaviours, naming poverty, delinquency, prostitution, and mental illness, as the acts of "degenerate" people, arguing that physical, intellectual, moral, and psychological traits were hereditary (Góes, 2015). Galton claimed that the recent concepts of evolution could "help" eliminate the "degenerate" individuals and improve the species. In this sense, discussing eugenics might be fruitful to promote discussions about the goals of science as a potentially biased enterprise.

Today, we understand eugenics ideas are indefensible, still they were pervasive to the point of guiding public policies in various countries (Goés, 2015). One of the most known influences of the eugenics movement was the Nazi regime, with it's genocide practices (Stepan, 2005). In the United States, the eugenics movement developed a specially radical aspect, marked by segregation and sterilization laws and practices (Singleton, 2014). In Brazil, we highlight racist immigration policies that, in the beginning of the XX century, intended to minimize the immigration from non-European countries, and maximize the European "stock" aiming at whitening the population (Nascimento, 2016). Besides that, Brazilian federal constitution of 1934 explicitly advocated for a eugenic education in its Article 138, subsection (b) (Brazil, 1934).

In general, eugenics reasoning included i. the identification of "normative" individuals or individuals arbitrarily considered inferior; ii. the classification of individuals into groups according to shared characteristics (phenotypic or moral/behavioral); iii. the hierarchization of these groups; and iv. the symbolic or physical exclusion of groups considered inferior from the process of reproduction (Miranda, 2025). Despite these general aspects that characterize eugenic reasoning, eugenic ideas presented themselves in specific contours depending on the contexts in which they were produced and appropriated (Góes, 2015), therefore the eugenics movement cannot be treated or investigated as universal or uniform.

Eugenics ideology continues to influence practices in current society to the extent of possible uses for DNA and heritage exams, genetic counselling, artificial insemination, fertility control policies, and the persistence of the biologisation of social relations in research within the field of psychology on human behaviour (Góes, 2023). That's why Science Education should address and problematize eugenic ideas, then students become able to participate in the social debates

regarding themes, either directly or indirectly, related to eugenics. Therefore, we argue that it is important that Science Education research analyse how the conceptual and epistemic aspects of science were mobilized to support eugenics so that we can help students criticize similar ideas that may rise in current days and prevent the reinforcement of eugenics and deterministic reasoning through Science Education.

Methods

The research approach adopted was qualitative, prioritizing an in-depth analysis of a phenomenon (Creswell & Creswell, 2023), in this case, the ways in which conceptual and epistemic aspects were inconsistently mobilized to support eugenic ideas in Brazil. This study is characterized as documentary research, which aims to contribute to the understanding of a community or phenomenon situated in a specific time and place (Fontana & Pereira, 2023).

We selected texts from the first year of the Eugenics Bulletin (Boletim de Eugenia – BE), a journal designed by Renato Kehl that circulated in Brazil between 1929 and 1933, disseminating and promoting eugenics in the country. The journal included thematic sections related to politics, education, manners, science, and health, which sought to legitimize eugenics as a scientific field of study. The BE had a central role in introducing eugenic reasoning in Brazil and its future ramifications (Maciel, 1999; Góes, 2015). The texts were accessed electronically through the Brazilian Digital Newspaper Library (Hemeroteca Digital Brasileira).

For the analysis, we selected all articles published in the 1929 issues of the BE available at the repository, a total of 105 articles. Initially, we conducted a full reading of the articles, identifying excerpts that evidenced the inconsistent mobilization of conceptual or epistemic aspects of the Natural Sciences to justify eugenic ideas disseminated in the BE. The presence of disciplinary concepts in the excerpts was used as cue to conceptual aspects, while epistemic aspects were identified through the presence of scientific or purportedly scientific arguments. Each article was analysed by at least two of the authors.

Following the initial survey, 28 articles were selected in which the arguments presented contained conceptual errors, and logical or material inconsistencies. We did not consider arguments in which the concepts were mobilized correctly, since the focus of the analysis is on the misuse of science to support eugenic ideas. The evaluation of the correctness of concept usage took into account the scientific standards of the period, in order to avoid anachronistic analyses. As the final step in constructing the analytical corpus, we selected, from the 28 articles, only those in which the mobilized biological concepts were in some way defined or exemplified in terms of their application. This resulted in a final selection of 20 articles.

Finally, the conceptual and argumentative inconsistencies were made explicit in a descriptive-argumentative text, interspersed with excerpts from the BE that illustrate these inconsistencies, forming the basis of our results and discussion. These stages were carried out by a group of six researchers in the field of Science Education, aiming at validating both the construction of the corpus of analysis and the analytical process.

Results and Discussions

According to the BE, eugenics is a science that aims

> [...] to cooperate for the progressive increase of physically, psychically and morally healthy men; for the gradual reduction of the contingent of the weak, sick and degenerate, thus contributing to the constitution of [...] in short, a balanced humanity, composed of strong and beautiful individuals, elements of peace and work (Kehl, 1929, n.4, p. 1, translated from Brazilian Portuguese - BP).

As published, the purpose of eugenics is to promote an alleged improvement of the human species through selecting individuals who are deemed to be "well-endowed", "superior" or "eugenic".

The **biological concepts** identified in the BE's articles were heredity, inheritance, artificial selection, and natural selection. These are crucial concepts to eugenics. In some excerpts, the BE explicitly acknowledges eugenics as a process of **artificial selection**:

> Who doesn't know what crossbreeding and seed selection mean for a plant? I have seen forests of fantastic beauty in Brazil [...] but their orchids were not as beautiful as the orchids that, through artificial selection, acquire truly extraordinary form and development in Brazilian gardens. [...] These selective practices are applicable to the human species. It has been proven that crosses between superior breeds produce superior types, and vice versa (Recasens, 1929, n. 4, p. 2, translated from BP).

Here we highlight the subtlety in suggesting artificial selection as a tool for "improving" the human race. Although the word "artificial" is not directly used, the expression "selective practices" is used in a synonym meaning, as it suggests selective breeding, that was inflicted by the eugenics movement through the control of human reproduction or killing.

Artificial selection is presented as a solution to the alleged inability of **natural selection** alone to contribute to the improvement of the human species. The defence of this idea becomes evident in the following excerpt: "*It [eugenics] will do everything in its power to halt reverse biological selection in contemporary society, and everything that may serve to support the vigorous natural selection that so actively contributes to the preservation of the most capable*" ("*eugenia e alcoolismo"*, 1929, n. 8, p. 5, translated from BP). Francis Galton, proposed similar ideas in the first book in which he uses the term "eugenic". According to him, in civilized societies, humanity does not experience the effect of natural selection the same way:

> His ["man's"] character is exceedingly complex, even in members of the simplest and purest savage race; much more is it so in civilized races, who have long since been exempted from the full rigor of natural selection, and have become more mongrel in their breed than any other animal on the face of the earth (Galton, 1883, p. 178).

In addition to proposing **artificial selection**, the BE also provided indications of how to implement it, in articles such as *The Selection of the Well-Endowed* (Decroly, n. 10, 1929). Also, **artificial selection** is closely related to the importance given to inheritance since these texts emphasized the importance of considering the role of **heredity** and environment in determining individual superiority, so that the most "fit" could be selected (Decroly, n. 10, 1929). Similar discussions are found in the chapter *Nurture and Nature* by Galton (1883). This implies that both in Brazil and England discussion on the relative importance of the environment and inheritance in determining people's characteristics were relevant to the eugenics movement. Differences rise though regarding the emphasis given to each factor in each context. In both cases, we observe the attribution of great importance to inheritance, once to be selected characteristics must be inheritable. Although in Latin countries, in general, a little more relevance is given to the environment (Stepan, 2015). Because of the ethnic constitution of Brazil, it would not be possible to prevent races deemed inferior from reproducing. As a result, in Brazil, interracial reproduction arises as a eugenics strategy (Góes, 2015) and there is an overlap between eugenics (focus on inheritance) and hygienism in Brazil (focus on bettering the environment) (Maciel, 1999).

Recognizing that eugenics proposed artificial selection is important for two reasons. First, it reveals the arbitrariness underlying eugenics, manifested in the fact that "good" characteristics – those considered to make individuals more suited to civilization – were selected arbitrarily rather than in relation to the natural environment, as proposed in Darwinian evolutionary thought.

Second, artificial selection is the reason why such importance is given to **heredity** and **inheritance** in eugenics reasoning. According to the BE, the aim of studying biological inheritance would be "*discovering the laws of inheritance and consciously applying them to the improvement of human offspring*" (Huerta, 1929, n. 8, p. 2, translated from BP). In other words, eugenics sets out to study the inheritance of characteristics, so that they can then be selected.

The primary importance attributed to **heredity** is further justified by the fact that, within eugenics reasoning, heredity was responsible for the continuity of characteristics across generations, whereas differences between one generation and another were understood as a result from environmental influence: "*This does not mean, however, that our personal influence is null. Far from it, I think, the action of the environment and education can be enormous. Indeed, alongside the continuity of characteristics over time (heredity), there are also differences*" (Govaerts, 1929, n. 1, p. 4, translated from BP). This way of mobilizing **the role of the environment in the evolutionary process** differs from that proposed by Darwinian evolutionary thought at the time, which conceived the environment as a filter for existing variations rather than as a generator of disturbance and difference. Nevertheless, this concept was mobilized in such a way to justify the importance of identifying which inheritable characteristics should be selected.

In our analysis, we identified several articles that discussed whether certain characteristics were inheritable or not, including criminality, epilepsy, haemophilia, alcoholism, violent behaviour, docility (individuals considered amenable to education), and aptitude for specific sports, forms of art, or professions. These characteristics were pondered as parameters for **artificial selection**. Similar discussions can be found in the chapter *Criminals and the Insane* by Galton (1883). In both the BE and Galton's book the claimed inheritability of characteristics such as criminality and alcoholism is used to justify the control of human reproduction as social improvement. The biologisation of such human behaviours culminates in the naturalization of the social injustices that contribute to these behaviours.

Regarding the argumentative problems identified in the analysed arguments, there are inconsistencies such as the **presentation of a conclusion without evidence**, such as in "*This is why education comes up against, powerless, in many cases, failing to tame an untamed person, whose constitution is the result of an irremovable hereditary process. 'One is born good!'"* (Kehl, 1929, n. 9, p. 1, translated from BP). In the excerpt, the argument is made that not all individuals should be educated, based on the premise that some people are biologically undomesticable; however, no evidence is provided to support this claim. Also, this excerpt asserts that 'domesticability' is an inheritable characteristic, without defining what 'domesticability' is or presenting any evidence.

Other arguments are based on **confounding correlation for cause**:

> An investigation was carried out among 3000 English criminals in London prisons. With the help of Galton's correlation coefficient, Dr. Goering organized the similarity indices between criminals linked by kinship, coming to the conclusion that heredity plays a preponderant role in the transmission of these characteristics (Kehl, 1929, n. 5, p. 3, translated from BP).

The co-occurrence of two variables, in this case kinship and criminality, is taken as proof of a causal relation between the two variables, culminating in the conclusion that the characteristics are hereditary. In other words, if a father and son are both criminals, criminality is hereditary, and the son inherited his criminal inclination. The same type of argumentation is found in the chapter *Criminals and the Insane* by Galton (1883). This highlights the biologisation of social behaviour as an agenda of the eugenics movement both in Brazil and England. Besides, it demonstrates that,

in both cases, political agendas took precedence over scientific rigor in the construction of the arguments. This type of argument is presented for physical and moral characteristics, whether they are perceived as good or not:

> Mack Garner, a champion horse racer [...] tells an interesting story about the tendency of all the members of his family to pursue this profession. His father and grandfather were both jockeys [...] His four brothers were dedicated to the sport [...] One of his nephews is already a jockey and the other two, while still children, already have a special interest in everything to do with horses (Kehl, n. 10, 1929, p. 4, translated from BP).

It is also worth noting that none of the arguments present **alternative hypotheses** or **methodological details on how the evidence was gathered**, which is expected for validating reliable scientific claims. The only material aspect of the mode of production of scientific knowledge mobilized in the argument is the use of statistical data, employed in an anecdotal manner and insufficient to support the following conclusions. Thus, conceptual and epistemic aspects cannot be analysed separately, since arguments are responsible for guaranteeing that the way in which the concepts are produced, mobilized and used to draw conclusions is valid. This result reinforces the importance of taking this entanglement between the mobilization of epistemic and conceptual aspects to the context of Science Education.

Conclusion

Brazilian eugenics reasoning lacks evidence to justify its claims. Still, it sustained a myriad of discriminatory political and social actions and promoted a racist ideology. Brazilian eugenics used science to fulfil an agenda and the arguments or concepts used didn't even need to be sound for that, extrapolating disputed concepts for every convenient characteristic that could be used against non-white and poor people. Our analysis helps us understand that conceptual and epistemic aspects are not in a vacuum, and the ideas in the BE were the needed framework to legitimize elite's discrimination.

As we focused in the Brazilian context, the results of this study cannot be generalized as applicable or true to the eugenics movement in different countries. However, we identified some resemblance between Brazilian and English eugenics, from themes of study, theoretical propositions and premises to argumentative inconsistencies observed. Thus, we propose that Science Education research could benefit from further research regarding the conceptual and epistemological use of science to justify eugenics in different contexts. By doing so, we will be able to trace general aspects of these appropriations, revealing similarities among countries, and differences due to specific contexts and interests of each nation.

Despite the regionalized aspect of the analysis presented in this paper, we understand that some of the results allow the discussion of broad implications to the field of Science Education. First, we argue it would be fruitful to use the historical case of eugenics in the context of SL for social transformation, as the eugenics movement illustrates the social consequences of a biased and elitist scientific production allowing the discussion of the importance of a diverse scientific community to guarantee scientific objectivity. Second, we propose the use of the historical case of eugenics also makes it possible to discuss social aspects related to the production of scientific knowledge, showing that scientific production is not neutral, but a human production located in a historical and cultural space, producing and being influenced by the values in force in society (Silva & Sasseron, 2021). Third, we understand the historical case of eugenics highlights the importance of discussing the need of ethics and bioethics in science in science classrooms.

Regarding other implications to Science Education, we highlight the importance of promoting a historicized teaching of genetics and evolutionary biology. We understand that discussing the

eugenics movement could collaborate to the construction of a more complex and critical comprehension of the Nature of Science and of the role of science in society. Besides that, we argue for the importance in promoting a biology teaching that intentionally seeks to prevent the construction of deterministic ideas that align with eugenic reasoning and a teaching about evolutionary biology that differentiates biological evolution from biological or even social supposed improvement that is also a eugenic idea. We also believe that the poor scientific argumentation identified in the BE could be used to discuss what counts or doesn't as scientific evidence and how to build valid arguments. These skills are very important within a SL for social transformation framework.

In summary, the characteristics of eugenics highlighted by the analysis presented in this paper demonstrate the Historical case of eugenics is interesting to promote SL to social transformation since it allows the discussion of social political aspects related to science, either in an internalist manner - what counts or does not count as science, diversity in academia, ethics - or an externalist one - the social and historical character of science and the possible social consequences of scientific production.

The French journal RSDT-Recherches en Didactique de Sciences et des Technologies opened a call in 2025 to recruit contributions to reflect on the origins and development of the research field of didactics of science in France. It is 40 years since the first publication of the journal Aster, the first French journal for research in didactics of experimental sciences. This call, the 30th anniversary of ESERA, and the recent foundation of ESERA SIG9 on Histories of Science Education constitute an opportunity to start a shared reflection on the history of didactics of science/science education research. A general introduction for the western world and three cases from France, Luxembourg and Catalonia-Spain are presented focusing on the emergence of the field at either the country or the institution level. The aims of the symposium presented here are the following:(a) situating the origins of didactics of science/science education research in the context of the western world; (b) identifying the thematic changes in research programs during these years in different contexts. This paper concludes with a discussion on the commonalities and divergences arising from the drafting of a history of didactics of science/ science education research in the context of the countries represented -France, Luxembourg and Catalonia-Spain.

Keywords: Histories of Science Education, History of Didactics of Science, Case Studies.

Introduction

The French journal *RSDT-Recherches en Didactique de Sciences et des Technologies* opened a call last year to recruit several contributions to reflect on the origins and development of the field of research of didactics of science in France (Lhoste and Venturini 2025). It is 40 years since the first publication of the journal *Aster*, the first French journal for (scientific) research on didactics of experimental sciences. Such calls, in addition to the 30th anniversary of international association ESERA and the recent foundation of ESERA SIG9 on Histories of Science Education, constitute an opportunity to start a shared reflection on the history of didactics of science/science education research in different western countries, focusing on countries, institutions, research groups or individual researchers. The first aim of the symposium presented here was to situate the origins of didactics of science or science education research fields in the context of the western world through the following question: What have been the themes, the academic fields, the people, and the research groups that have contributed to the birth of our discipline in different western countries or institutions? The second aim of the symposium was to conduct an audit of the first results considering thematic changes throughout the years in different contexts. The question guiding this reflection has been the following: In what ways have the research questions, research approaches and results changed over these years in different western countries? The symposium discussed in this chapter was promoted by the recently created ESERA SIG9 Histories of Science Education, and we hope it will open the door to conduct more systematic historical inquiry within the science education research community worldwide.

The Emergence And Development Of Research In Didactics Of Science In The Years 1970-2000: A Focus On The Western World And France

The first contribution of the symposium addressed the first aim by examining the emergence of research in the didactics of science across Western countries and, within this context, the development of this field in France. For the whole symposium, this contribution provides a common ground useful for the positioning of the other three contributions situated in France, Luxembourg and Catalonia-Spain.

Renewal Of Science Teaching

To analyse this emergence in relation to the renewal of teaching, our framework includes some social components: the societal and institutional contexts, the social status of the actors involved, their objectives, the way they work in groups and the nature of their productions.

Societal And Institutional Contexts

Beginning in the 1950s–70s, Western countries began to reflect on the massification of education, driven by policymakers, academic societies, professional associations, and society demands. In France, in the fields of sciences and mathematics education, the Academy of Sciences, along with associations of mathematics teachers and later, associations of physics-chemistry and life and earth sciences teachers advocated for renewing secondary education. The evolution of the science teaching at secondary school level, spurred by these initiatives, was influenced by ministerial decisions and shaped by the broader French educational context.

The Designer Groups: Institutional Anchoring And Activities

Groups combining research and development, often involving researchers and teachers, were formed. These groups produced teaching resources and research findings with a particular focus on understanding students' learning difficulties. In most countries, the groups responsible for designing new teaching resources became, sooner or later, affiliated with university institutions. For instance, in France, the Lagarrigue ministerial commission established a working group led by physicist Goéry Delacôte. A few years later, this group evolved into a research laboratory called LIREST (*Laboratoire Interuniversitaire de Recherche sur l'Enseignement Scientifique et Technologique*) associated with a university in Paris and the National Center for Scientific Research (CNRS). A defining feature of designer groups was their collaborative nature where researchers and teachers worked together to design teaching resources. During this period, researchers and sometimes teachers with initial training in physics or chemistry also studied psychology (e.g. Dewey, Piaget) and shared constructivist perspectives.

Contribution Of Activities For Renewing Science Teaching To The Emergence Of Research In Didactics Of Science

The work on students' conceptual understanding was clearly linked to the development of research in didactics particularly in the domain often called students' conceptions. In addition, although the theoretical component was not highly developed, several results were replicated across different countries (Driver et al., 1985). The question of whether designing teaching materials is a research activity was less clear. According to Cobb et al. (2003), in research, "design experiments are conducted to develop theories, not merely to empirically tune 'what works'. These theories are relatively humble in that they target domain-specific learning processes" (ibid, p.9). In this sense, designing teaching materials at this time may not fully qualify as research. However, it incorporated research elements such as analysing the nature of the knowledge taught and the teaching goals, paving the way for the emergence of research such as design experiments

and design-based research.

In conclusion it is worth mentioning that government institutions and education systems, which initially supported the design of science teaching materials by designer groups affiliated with universities, some years later took the lead in modifying official curricula and planning. These changes were only partially nourished by the productions of the designer groups (French, 1986). Nonetheless, researchers involved in these productions and other researchers contributed to the creation of research associations, such as the European Science Education Research Association (ESERA) founded in April 1995 which remains active today.

Evolution Of Research Themes From Its Beginnings To The 2000S Based On ESERA Conferences

This presentation addresses the symposium's second aim with an analysis of the evolution of research themes from its beginnings to the 2000s, primarily based on the strands of the early ESERA conferences. This analysis is developed based on a generic structure, the didactic triangle with three poles, student, teacher, and teaching content and their interrelationships. This approach helps to put together research studies spread across the strands and highlights broader trends such as the decline in research on students' conceptions, the rise of studies on the nature of science, socio-scientific issues and science teaching practices in relation to enquiry-based learning. Beyond the triangle, two additional themes emerged: the first related to curriculum policy involving the education system, and the second focused on the state and the practices of research in science education. This brief analysis shows that researchers involved in developing teaching materials were also engaged - directly or through colleagues - in specific research themes. It also highlights that theorizing the activity of designing teaching resources requires more time probably because of the inherent complexity of teaching, the complexity of "learning ecology".

Case 1: The Origins Of Didactics Of Life And Earth Sciences In France: Groups, Institutions, Research Orientations

The first case is situated in the context of France and aims at looking back at the origins of a research discipline, the didactics of life and earth sciences in France in the second half of the 20th century. This contribution addresses the following themes and questions: (a) the key players in the emergence of this research discipline (Who are the protagonists in the emergence of this discipline? What are their functions? What are their intellectual filiations?); (b) the various institutions and contexts in which this early research took place (What groups contributed to the emergence of this discipline? What links are there with universities and academic research?) and (c) the first avenues of research explored by the first publications in the field of life and earth sciences didactics. (What are the initial research concerns? What avenues of research are opening? How are they unfolding?)

The Origins Of Life And Earth Sciences Didactics In The Pedagogical Reform Of The 1960S-1970S

The origins of the didactics of life and Earth sciences can be traced back to the pedagogical reform movements of the 1960s and 1970s (Kahn & D'Enfert, 2010). The central issue at stake was questioning of both the traditional school format and the organization of teaching. This critique of traditional education also involved a challenge to the empiricist and dogmatic vision of science education, which was prevalent in the "lesson of things" approach. As early as the 1960s, this challenge began to take shape in the pedagogical sphere (Kahn, 2000). This pedagogical reform led to the implementation of awakening activities in primary education (Best, 1973; Best, 2006). The first research in the didactics of life and Earth sciences was developed within the National Pedagogical Institute (IPN), led by Louis Legrand. In 1967, the field of educational sciences was

established within universities, and in 1969, Legrand created a didactics department within the IPN, which included a "science section" (later renamed "experimental sciences"). Victor Host, an associate professor of natural sciences involved in teacher training at normal schools, was appointed by Legrand in 1969 to lead this section. The research efforts were driven by awakening activities at the primary school level and experimental lower secondary schools (CES).

The Development Of The IPN Science Team And Action Research

With the transformation of the IPN (Institut Pédagogique National) into the INRP (Institut National de Recherche Pédagogique) in 1976, Jeanine Deunf, an inspector general of national education, led teacher training programs for *écoles normales* (teacher training schools) at the national level, fostering the development of action research. Many *école normale* professors contributed to this research, as evidenced by the list of contributors to the study *Procédures d'apprentissage en sciences expérimentales* mentioned in the journal *Aster* in 1985, and later published in 1998 under the title *Comment les enfants apprennent les sciences* (Astolfi et al., 1998). A subset of Victor Host team—comprising Jean-Pierre Astolfi, André Giordan, Gabriel Gohau, Victor Host, Jean-Louis Martinand, and Georges Zadounaïsky—published the first didactics book in the field of science education in 1978: *Quelle éducation scientifique, pour quelle société?* (Astolfi et al., 1978). The book's first chapter, with the evocative title *OHERIC ne répond plus? Le naufrage de l'éducation scientifique ?* ("OHERIC is no longer responding? The shipwreck of science education?"), written by A. Giordan, directly challenged the empiricist approach to scientific methods in schools. This team was also responsible for launching the journal *Aster*, published by the INRP from 1985 onward.

A Gradual Integration Into The Academic Sphere

Initially, the emerging community of didactics researchers did not readily accept academic engagement. However, Victor Host encouraged such involvement and established connections with Georges Canguilhem, a philosopher of biology. This led to the creation of a *Diplôme d'Études Approfondies* (DEA, equivalent to a master's degree) in didactics, with a specialization in biology education, environmental education, and later geology, at Paris 7 University in 1975, spearheaded by Christian Souchon and Victor Host. The program initially enrolled two students, Michèle Dupont and Guy Rumelhard, both of whom later joined the faculty as educators in 1979. The establishment of the *Instituts Universitaires de Formation des Maîtres* (IUFM) in 1991 facilitated the creation of the first faculty positions dedicated to research and teaching in life and Earth sciences didactics.

Research Themes

The foundational research themes in life and Earth sciences didactics emerged from the early work conducted at the IPN under the direction of Victor Host. Jean-Pierre Astolfi (2008, pp. 103–104) outlined the core issues that structured the initial research in this field: (a) The constant avoidance of verbalism and dogmatism; (b) The role of scientific attitudes; (c) The necessity of anchoring educational practices in children's spontaneous needs; (d) The importance of listening to students in order to understand the logic of their thinking; (e) The impact of students' conceptions of scientific knowledge on their future learning; (f) The requirements of conceptualization; (g) The diversity of levels of scientific concept formulation; (h) The construction of observational frameworks; (i) The central role of scientific problems; (j) The organization of scientific disciplines around a limited number of structuring paradigms; (k) The significance of the history and epistemology of science in addressing didactic challenges; and (l) The importance of written and graphical records in constructing scientific thought, distinguishing between the logic of discovery and the logic of communication.

Case 2: The Emergence Of Didactics Of Science As A Research Field At The Universitat Autònoma De Barcelona

This case aims at situating the origins of the Didactics of Science field at the Universitat Autònoma de Barcelona (UAB) in Catalonia, Spain, from the point of view of the actors participating in its emergence between 1970 and 1995. In the past, there have been several efforts to construct the history of science education research through different narrative approaches (Adúriz-Bravo and Izquierdo 2001; Fensham 2004). The work of Tobin and Roth (2007) is particularly useful for this contribution since they conceptualize the history of the field through the lenses of cultural sociology. The overarching methodological approach used in this contribution is compatible with autoethnography understood as both process and product (Ellis, Adams and Bochner 2011). This approach to research and writing seeks to describe and systematically analyse personal experience to understand cultural experience. The product is a collective narrative co-written by the three co-authors through an ongoing participatory process initiated in 2020. This process has involved a diversity of actors including students, retired professors, and active members of the Didactics of Mathematics and Experimental Sciences Department from UAB. The narrative is organized into two sections: (a) First phase (1970-1985) characterized by the growth of science teaching innovations and the institutionalization of science teacher education, and (b) Second phase (1985-1995) constituted by the processes and actions undertaken to become researchers in didactics of science.

Promoting Science Teaching Innovations And Science Teacher Education (1970-1985)

Spanish political context has always strongly influenced innovation in education as well as science education in Catalonia. Previously to the Spanish civil war starting in 1936 and during the Catalan Republic there was a strong political support to educational innovation based on the progressive ideas coming from continental Europe. These innovations were suddenly interrupted, strongly repressed and innovative schools closed during the dictatorship. Despite these difficulties, during the dictatorship, young teachers created new primary and secondary schools conducting innovations in science teaching. The three co-authors have been science teachers or students at these schools and participated in science teachers' groups with the aim of promoting teaching innovations. Several key Catalan institutions played a very important role in promoting and sustaining these *innovative science teachers' groups*. An example at the primary education level was the "Working Group for the Teaching of Science" hosted by Rosa Sensat Teachers Association and another example at the secondary education level was the "Didactics Center of Experimental Sciences" hosted by Col.legi de Doctors i Llicenciats.

Networking and internationalization were important factors influencing the emergence of our field at UAB. The first Spanish conference we ever participated was the I Simposium Internacional de Didáctica General y Didácticas Especiales held in la Manga del Mar Menor, Spain, September 27th-October 2nd, 1982. The first international conference we ever participated was the Journées Internationales de Chamonix, France, in 1987 (Sanmartí 1987). Both countries, UK and France, have been very influential on the emergence of our field in Catalonia and Spain. Finally, the *university status of science teacher education* became possible because of the General Education Law of 1970. Two years later it was founded the Escola Universitaria de Fromació del Professorat d'EGB at UAB, also known as Teachers' School of Sant Cugat, with the impulse of very committed and innovative science teachers, devoted to the training of infant and primary teachers and without research functions (Angel, Pujol & Villanueva 2020).

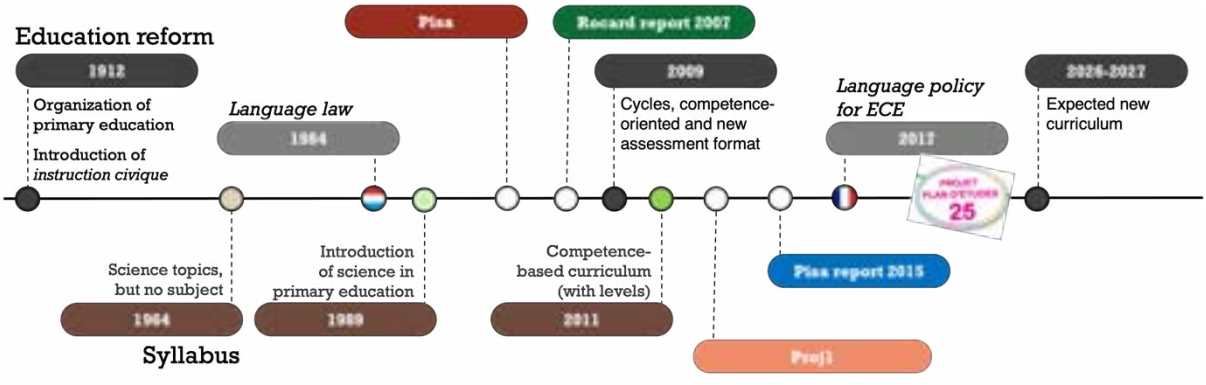
Becoming Researchers In Didactics Of Science (1985-1995)

The *capacity to conduct research by science teacher trainers* was not consolidated until 1983 with the Law of University Reform, the first after the dictatorship, that regulated the creation of new fields such as Didactics of Experimental Science and the departments that would cultivate them. The challenge of our field at UAB at this point was to gain research competence in Didactics of Science in a very short time. The training of researchers in didactics of science had two targets: science teacher trainers and innovative science teachers. They could only get a UAB doctorate in pure sciences or in general pedagogy. The role of Mercè Izquierdo as a policy maker in the Catalan Government in 1985 was crucial to organize and fund the international doctoral training of UAB science teacher educators as a group through the collaboration of the Chelsea College at the University of London.

The *first research tool created at UAB* in our field was the Spanish research journal, *Enseñanza de las Ciencias*, born in 1983 at UAB. In the editorial of the first number, a concern was expressed on the difficulties of producing quality educational research, and the lack of publications authored by Spanish researchers in international journals. In 1985 the first Spanish conference I *Congreso Internacional de Investigación en Didáctica de las Ciencias* took place at UAB in Bellaterra (Barcelona) and was organized by the previously created journal, the UAB and Universitat de Valencia. Both the journal and the conference had a national and international scope and have been active since then.

The *first research themes* of the innovative science teachers focused mainly on laboratory work and students' ideas. Once the university department was created and funding was necessary, the research themes evolved towards the following: (a) Evaluation for science learning (approaches, tools); (b) Modelling in School Science (Philosophy of Science, Language, Context); and (c) Environmental Education.

Case 3: Primary Science Education Research in Luxembourg: Outlining the History to Reflect on the Heritage



This contribution addressed the symposium general aim by exploring the emergence of primary science education research in the context of Luxembourg. This country in Europe hosts a highly diverse population. Its education system reflects this diversity as a high percentage of students speaking a home language other than the languages of instruction. Considering that language takes up a good part of the instruction hours, this scenario raises issues of equity and access to the different educational paths, such as science instruction, and the need to reflect on the past actions (especially to plan the future). The case study addresses two questions: (a) How are the science education policies articulated within Luxembourg's normative frameworks legislating primary education and what are the reflection/perception of stakeholders? and (b) What has been published regarding science education in Luxembourg? By systematically exploring these inquiries, this case study seeks to contribute valuable insights into the field of history of science education and history of science education research.

The Place Of Primary Science Instruction In Luxembourg

To present the place of science instruction in primary education an analysis of normative acts was undertaken through document analysis (Asdal & Reinertsen, 2022) to explore the Luxembourg context and outline the history of primary education and primary science curriculum. Additionally, to highlight stakeholders' voices from a policy research project within science education, the study examines interviews from SciPol by using thematic analysis. It was possible to map a timeline for the evolution of normatives that frame primary education in the national context

(Figure 1).

Figure 1. Timeline of educational legislation in Luxembourg

In general terms, the interviews discuss educational reforms since 1989, focusing on introducing new materials and teaching methods in sciences amid societal changes, particularly ecological movements. The discussion deals with the challenges and changes in school teaching, specifically around *Éveil aux Sciences* (Discovery of Sciences). It also looks at social motivations, teaching methods, the integration of technical subjects, and the need for interdisciplinary work. Challenges included insufficient teacher training and resistance to curriculum changes, yet a shift towards multidisciplinary approaches is noted. The analysis shows that teachers were dependent on materials and that new approaches were often met with resistance.

The Field Of Primary Science Education Research In Luxembourg

Historical research in Luxembourg has centred its focus on the history of the industry and paths connected to it, of the migration fluxes and of topics related to the wars (WWI and WWII). When it comes to the history of education centred in schooling, and more specifically to primary education, only 28 results are found within the national repository. A brief scanning of the resulting abstract leads to only two that considers the topic of "science education". This context reinforces the emergent need to conduct historical research in Luxembourg, taking into account the place of science in primary education.

Considering that historical research in the field of science education in Luxembourg is scarce, an exploratory mapping of the existing published research was done to situate the domain of science

education research within the context of primary education. The search was focused on EBSCO*host* databases, using the following search strings ("science education" OR "science teaching" OR "science instruction" OR "science learning") AND ("primary education" OR "primary school" OR "elementary education" OR "elementary school") AND "Luxembourg". The results retrieved consist of 35 publications since 1977. Abstract screening allowed the focus to 12 publications, leading to a mapping of researchers and topics spanning from 2010 and 2025 (Table 1).

This exploratory mapping contributed to a better understanding of the research related to primary science education in Luxembourg and there seems to be a desideratum for historical research using broaden means for mapping/review, especially considering that research is arranged around one research team, led by Christina Siry, one of our co-authors.

Discussion: The Urgent Need to Historicise the Field of Didactics of Science

According to the authors' perspectives in this symposium, the history of didactics of science/science education should (almost necessarily) involve the following issues and themes: (a) Constructing a timeline, with recognisable "milestones"; (b) Proposing some "periods" with the aid of external factors (i.e., internal history of the field against the backdrop of social and political history); (c) Producing a narrative, with the inclusion of a "foundational myth" (ambitious national plans, large-scale programmes of reform, first PhD theses, seminal meetings, etc.); (d) Examining in depth its theories (and their "inspiring" authors); (e) Diachronically analysing the *problems* of research; (f) Studying the evolution of the literature and of its "vehicles" (conferences, journals, dissertations, etc.); (g) Identifying the institutions, groups and individuals who did research in the past, and the policies that facilitated and supported this; (h) Establishing links with the history of science education as a practice (paying special attention to its reforms and innovations)… and consequently with the history of science education as policy making; (i) Delving into the (long) history, modalities and institutions of science teacher education; (j) Recognizing the discipline's "disciples", and how they were enculturated; (k) Taking on board of the historization the actors, authors, stakeholders and audiences of the discipline; and (l) Telling it to the newcomers in the disciplines (junior researchers and teachers).

The *commonalities* of the four symposium contributions dealing with the emergence of the didactics of science/science education research field in the cases from France, Catalonia-Spain, and Luxembourg were the following: (a) Decisions on the methods that would be used to dig in the past and to narrate; (b) Strong theoretical positionings; (c) A conviction that the authors are doing empirical and argumentative research; (d) The need to pay homage to great figures; (e) Conscience of the limitations of the histories constructed so far; and (f) To some extent, an implicit assumption that didactics is a European creation.

Few *divergences* appeared between the different cases; these can become "challenges" for future historical research. One deals with the different conceptualisations of the prehistory and of the "zero of coordinates" of our field. Another divergence is related to the very different decisions on the sociopolitical events that would be selected to historicize the field. A third divergence points at the inhomogeneous identification of the audiences demanding didactical knowledge. Finally, it would be urgent to connect the emergence of the field with other experiences conducted in other geographical locations, such as Latin America, a region with strong pedagogical tradition and marked European influence in research styles and themes.

ESERA 2025 Copenhagen

Understanding Of Nature Of Scientific Inquiry (NOSI) In The Early Elementary School Years: Focusing On The Relationship To National Curriculum Standards

Kana Suematsu[1] and Kenji Matsubara[2]
[1] Tokyo Kasei Gakuin University, Japan,
[2] National Institute for Educational Policy Research, Japan

The results of the Views About Scientific Inquiry-Elementary (VASI-E) survey conducted on third-grade elementary school students demonstrate that the distinction between scientific investigation methods, such as "observation" and "experimentation", is unclear among Japanese students in the lower grades. One of the reasons may be that science education in the early elementary school years in Japan is conducted in the context of integrated learning, and the scientific method is not explicitly presented in this context. Therefore, this study focuses on the early elementary school years and introduces a novel analytical perspective by extracting items related to the nature of scientific inquiry (NOSI) from Japan's National Curriculum Standards to examine approaches for assessing students' understanding of NOSI within the context of integrated learning. In addition, the results of the VASI-E survey were reanalysed using the proposed analytical perspective. As a result of the review of the National Curriculum Standards, it was found that the students should be aware of the characteristics and intrinsic value of nature, and the relationship and connection among them, through activities such as seeing, comparing, trying, forecasting, and devising, to realize their ideas and wishes. It was also noted that the process involves a variety of thoughts, judgments, and expressions. Although not explicitly stated in terms of "experimentation," it indicated the concept of including them. Therefore, we reanalysed the VASI-E survey results using two new analytical perspectives: "perform activities to realize ideas and wishes" and "recognize that various activities, thoughts, judgments, and expressions exist in the process of realizing ideas and wishes".

Keywords: NOSI, VASI-E, integrated learning

Background And Purpose Of The Study

This study investigates the assessment of students' understanding of scientific inquiry (SI) in early elementary school. In 2021, the researchers conducted a survey on third-grade Japanese students using the Views About Scientific Inquiry-Elementary (VASI-E) questionnaire and found low levels of understanding of the SI aspect of "there is no single set and sequence of steps followed in all scientific investigations." This finding was consistent with those of an international survey conducted on third- and fourth grade students from 35 countries and regions (Lederman et al., 2023). One of the factors may be that although the importance of IS has been emphasized at the national level, it is not properly addressed in textbooks and classes (Dogan, 2021; Lederman et al., 2023). In the National Curriculum Standards (NCS) of Japan, science education in early elementary school is implemented in the subject called "Living Environment Studies" (*Seikatsu-ka*), which emphases intergraded learning. At this stage, formal scientific terms such as, "experiment", are not explicitly introduced yet. Their formal science starts from the third grade for the students of 10 years old. This situation has made us think that we probably need a wider range of an evaluation method for those students who have undergone this kind of curriculum with the focus of integrated learning. Considering that, it should be meaningful to investigate the analytical perspective of the VASI-E to understand how we can accommodate an earlier stage of science education whose focus is intergraded learning. Therefore, this study investigates the assessment of students' understanding of SI in an integrated learning environment. Specifically, items related to Nature of Scientific Inquiry (NOSI) are extracted from

the NCS to create a new analytical perspective, followed by an exploratory reanalysis of the VASI-E results.

Results Of The VASI-E Survey

The VASI-E survey was conducted in September 2021 on 62 third-grade students at an elementary school in Tokyo, Japan. The Japanese version of the VASI-E, its methodology, and evaluation procedures aligned with those later described by Lederman et al. (2023). The evaluation was administered by three researchers with prior training in coding with VASI-E. Prior to the survey, a research ethics review was conducted. Schools and parents were provided with a written explanation of the project, while students received oral explanations. Consent to participate was obtained based on their responses.

The VASI-E evaluates the following aspects of SI: (1) all investigations begin with a question, (2) scientists collect empirical data to answer their questions, (3) procedures are guided by the question asked, (4) data and prior knowledge are used to answer the questions, (5) there is no one single scientific method (Lederman et al., 2023). Table 1 presents the number of respondents and their results for each aspect, rated using a three-point scale (Informed, Mixed, and Naïve).

Table 1. Results of the VASI-E on third-grade students (*N* = 62)

Aspects of scientific inquiry	Informed Number of children (%)	Mixed Number of children (%)	Naïve Number of children (%)
(1) all investigations begin with a question	16 (25.8)	31 (50.0)	15 (24.2)
(2) scientists collect empirical data to answer their questions	24 (38.7)	21 (33.9)	17 (27.4)
(3) procedures are guided by the question asked	20 (32.3)	27 (43.5)	15 (24.2)
(4) data and prior knowledge are used to answer questions	12 (19.3)	35 (56.5)	15 (24.2)
(5) there is no one single scientific method	8 (12.9)	31 (50.0)	23 (37.1)

Note: A few of the data included in this table were reported by Suematsu et al. (2022).

Out of the 62 students, 37.1% were Naïve in Aspect (5). The question corresponding to the evaluation of this aspect was Question 1 (Q1), which narrated a story about a woman who travels around the world to look at birds and wonders about the relationship between the shape and size of a bird's beak and the types of food it eats. The students were asked whether she was "like a scientist" and why (Q1a) and whether she was conducting an experiment and why (Q1b). Although the words "experiment" was presented in the question, it has not been introduced at this stage of Japanese education, as previously discussed. This may be the reason underlying students' difficulty in responding to Q1.

Early Elementary Curricula In Japan

In Japanese elementary schools, the curricula for the first and second grades include subjects such as Japanese language; mathematics; *Seikatsu-ka*; music; art and handicraft; and physical education. Within this framework, science education is primarily conducted through *Seikatsu-ka* which focuses on students' immediate environments such as school, home, and the local community. The curriculum emphasizes learning through concrete activities and experiences,

thus reflecting integrated learning. This type of learning has been implemented during early elementary education, because it considers the developmental characteristics of children at these ages and provides continuity from integrated learning conducted through play in Early Childhood Education and Care. From the third grade onward, science education is formally introduced. For example, in the commentary on the NCS for Science, the term “experiment” is used in 157 instances, whereas it is not used at all in *Seikatsu-ka*. Meanwhile, the term “observation” appears 193 times in Science but only 7 times in *Seikatsu-ka*, which is distinctive. Differences in the presentation of SI methods, such as observation and experiment, in *Seikatsu-ka* and Science may become an important factor when assessing students' understanding of SI.

In *Seikatsu-ka*, students are expected to observe familiar nature to identify their differences and characteristics, increase their awareness of natural phenomena and seasonal changes, and develop an attitude of incorporating nature to enrich their experiences (Ministry of Education, Culture, Sports, Science and Technology (MEXT), 2018). In this context, observing familiar nature pertains to taking an interest in nearby natural surroundings, engaging directly with nature, and paying attention to it. Specifically, the following content is envisioned:

> Students develop an interest in nature by going outdoors, blowing dandelion fluff into the air, or following ant trails to find their nests. They repeatedly engage with nature using their senses—noticing the scent of dandelion flowers, the softness of the fluff, or intently watching the ants’ movements. This allows them to fully experience nature’s wonders through seeing, hearing, touching, tasting, and smelling. Through repeated encounters with nature, students begin to pay attention to the structure, color, and shape of dandelion flowers and fluff, as well as how ants carry food. In this way, they observe intently and become absorbed, guided by their own ideas and wishes. (MEXT, 2018; translation by the author)

Observation in *Seikatsu-ka* emphasizes the need for students to repeatedly engage with nature using their senses, guided by their own ideas and wishes, and, thereby, discover mechanisms inherent to nature. Furthermore, identifying differences and characteristics refers to the following:

> To discover differences and characteristics, it is important to have enough experience of direct contact and repeated interaction. It is also important to think by comparing natural phenomena and aspects of daily life, or by grouping them. For example, on a winter morning, they might find ice or frost crystals, feel the coldness of the ice, or enjoy the crunchy sound when stepping on frost crystals. If such play becomes a daily morning pleasure, they start searching for ice and frost crystals, discover they form in the same spots, and begin looking for similar locations. Visiting a park in autumn to collect and play with acorns. Once they gather many, they may sort them by size, shape, or color, or arrange them in patterns. Through such activities, students develop the ability to identify differences and characteristics in the nature around them. (MEXT, 2018; translation by the author)

In *Seikatsu-ka*, students are encouraged to consciously become aware of differences and characteristics. To develop this awareness, experiences such as sorting and arranging are emphasized. Additionally, in relation to the scientific method, the goal is to “create play and the tools for play through activities like utilizing nearby nature or using familiar objects, discovering their fun and wonders of nature, and working together to create play while enjoying it” (MEXT, 2018; translation by the author). For example, this aspect may involve discovering relationships between light and shadow through shadow-stepping games or creating moving toys. For example, children may wish to “make a car that runs fast” and engage in play through trial and error to

achieve this goal.

Methods

Creating The New Analytical Perspective

Items related to the NOSI were extracted from descriptions of the "Objectives of *Seikatsu-ka*" in the NCS Commentary: *Seikatsu-ka* Edition (MEXT, 2018). In detail, using the keywords "question," "scientific method," "explanation," and "conclusion," which are included in the five SI aspects, the researchers further extracted descriptions related to these keywords. A new analytical perspective was then created by matching extracted contents with the VASI-E assessment.

Exploratory Reanalysis Of The Results Of The VASI-E Survey

The results of the VASI-E survey conducted in 2021 were reanalysed using the new analytical perspective. The analysis focused on Q1, which corresponded to the SI aspect that obtained the highest percentage of Naïve responses: "No single scientific method exists."

Results and Discussion

Table 2 presents the extracted NOSI descriptions and related keywords. The *Seikatsu-ka* curriculum does not use explicit expressions such as question and conclusion to represent aspects of NOSI. Instead, it uses subjective, ambiguous expressions to denote learning from life situations, through experience, and in an integrative manner, which are the primary characteristics of *Seikatsu-ka*. Nevertheless, its contents encompassed aspects of NOSI and were designed to connect to more generalized learning of science while teaching concepts appropriate for younger children.

Table 2. Descriptions related to the NOSI

Extracted descriptions (*translated by the author)*	**Key Words**
"Be aware of the unique characteristics and intrinsic value of nature, and, the relationships and connections among them." *(MEXT, 2018, p.12)*	Explanation
"Students will think analytically about themselves and their lives through learning activities such as seeing, comparing, and likening. They also think creatively through learning activities such as trying, forecasting, and devising." *(MEXT, 2018, p.15)*	Scientific method
"Think about 'what to do' and 'how to do it' to realize their ideas and wishes, and then actually do it, moving on to the next activity. In this process, various thoughts, judgments, and expressions exist." *(MEXT, 2018, p.14)*	Question, Scientific method
"When expressing, children think about the contents and methods of expression based on their awareness of the other person and the purpose." *(MEXT, 2018, p.15)*	Conclusion, Question
"The result of their expression may cause them to reconsider, or new ideas or wishes may arise, and they may return to the previous stage or move on to the next stage." *(MEXT, 2018, p.15)*	Conclusion, Question,

Note: Underlined text is considered relevant to the keywords.

Using the extracted statements as a guide, the researchers developed new analytical perspectives (Table 3), contrasting them with the five aspects of SI. Table 4 presents the results of the reanalysis of Q1 of the VASI-E survey using the proposed analytical perspective based on integrative learning (Table 3). Table 5 presents a comparison of scoring obtained using the new analytical perspectives with VASI-E scoring.

Table 3. Analytical perspectives on NOSI in the early elementary school years

SI aspects	Analytical perspectives	Related VASI-E questions
(1) All investigations begin with a question.	Activities are conducted to realize ideas and wishes.	1a, 4a, 4b
(2) Scientists collect empirical data to answer their questions.	Through activities such as seeing, comparing, likening, trying, forecasting, and devising, the students will gain a variety of ideas and awareness.	2a, 2b
(3) Procedures are guided by the question asked.	Activities ("what to do" and "how to do") are considered for the realization of ideas and wishes.	3, 4a
(4) Data and prior knowledge are used to answer questions.	Levels of awareness among students are enhanced by confirming similarities, differences, relationships, and connections between ideas. The results will lead to rethinking and the formulation of new questions.	2a, 2b
(5) There is no one single scientific method.	The participants gain awareness that various thoughts and activities are involved in the process of realizing their ideas and wishes.	1a, 1b

Note: For related VASI-E questions, see Lederman et al. (2023).

Table 4. Reanalysis of VASI-E results for third-grade students (N = 62)

Aspects of SI		**Informed** Number of children (%)	**Mixed** Number of children (%)	**Naïve** Number of children (%)
(5) There is no one single scientific method.	VASI-E Scoring	8 (12.9)	31 (50.0)	23 (37.1)
	New analytical perspectives	23 (37.1)	29 (46.8)	10 (16.1)

According to the VASI-E scoring, 12.9% of the students were classified as Informed, but this proportion increased to 37.1% after the reanalysis, while the proportion of students categorized as Naive decreased from 37.1% to 16.1%. Considering these changes in detail: 10 students' classification transitioned from Naive to Mixed, 11 students changed from Mixed to Informed, and 4 students changed from Naive to Informed. In Example 3, in which students were classified as Informed only in the new analysis scoring, the students described experimentation in terms of trying. In addition, in Example 2, the results confirmed that students are attempting to change their ideas and wishes into more scientific concepts.

Conclusion

Responses classified as Informed using both scoring systems were more scientifically sophisticated; thus, expecting such responses in science education after the third grade is important. Alternatively, responses categorized as Informed only using the new analytical perspective, which is grounded in integrated learning, fell on the borderline between Scientific and Naive. These qualitative differences between scientifically sophisticated and borderline responses emphasize developmental progression as students transition from integrated learning to focused scientific education after third grade.

Table 5. Comparison of results between the new analytical perspectives and VASI-E

		New analytical perspectives		
		Informed	Mixed	Naïve
VASI-E Scoring	Informed	7	1	0
	Mixed	11	18	2
	Naïve	4	10	8

Ex. (1) Both were Informed.
1a: (Informed) *I thought she was like a scientist when she tried to examine birds' beaks and food.*
1b: (Informed) *I think she is conducting an experiment because she has set out to solve a problem: "Is there any relationship between the size and shape of birds' beaks and the type of food they eat?".*

Ex. (2) Only the new analysis perspective was Informed (Mixed → Informed).
1a: (Informed) *Because normally, I would only think, "That's a mystery," because she wanted to find out.*
1b: (Informed) *Because she would wonder, "Why do their beaks look different?" and because she was paying attention to what they were eating.*

Ex. (3) Only the new analysis perspective was Informed (Naive → Informed).
1a: (Mixed) *Because she observes a lot of different birds.*
1b: (Informed) *Experiments are about trying things out.*

Foreword

Interdisciplinarity and Education is an ESERA strand concerned with the meaningful and purposeful integration of knowledge, practices, values and ways of thinking across disciplines, with particular attention to science education and STEAM education (Klein, 1990; Newell, 2001; Repko & Szostak, 2020). Rather than treating interdisciplinarity as the simple juxtaposition of school subjects, the strand foregrounds how learners, teachers and researchers negotiate boundaries between disciplinary perspectives and use them to address complex questions. In this sense, interdisciplinary education involves cognitive and epistemological work, but also practical, sociocultural, affective and ethical dimensions. It is especially relevant at a time when science education is called to respond to environmental crises, rapid digital transformation and new demands for participation, judgement and responsibility (Honey et al., 2014; UNESCO, 2020).

The 22 proceedings papers in this chapter show the richness of this research area while remaining closely connected to classroom, teacher-education and curriculum challenges. Across the accepted contributions, several papers develop or use theoretical lenses for understanding interdisciplinary integration, including conceptual blending, disciplinary-perspective integration, Nature of Engineering, Bildung and the role of uncertainty in learning. These perspectives help clarify what counts as integration, how disciplinary resources are transformed when they are brought together, and how students and teachers make sense of interdisciplinary tasks rather than merely applying pre-given disciplinary content.

A second group of contributions focuses on teaching and learning designs that connect science with mathematics, technology, engineering, humanities and environmental education. The papers examine, among other themes, measurement and transduction in mathematics-physics activities, biomimicry and biodiversity, laboratory and outdoor learning, PBL and real-world problem framing, and the use of simulations, virtual environments and other digital tools. These contributions highlight the importance of tasks, environments, and means that make disciplinary relations visible, and support students in moving between representations, materials, and practices.

A third emerging theme adopts embodied and multimodal meaning-making ways of understanding, representing and communicating science in ways that invite creativity and imagination. For this purpose, several art forms, including story writing and drama, are integrated into formal and informal science education contexts, while modern and non-conventional ways, such as podcasting, are used for science communication. Such initiatives not only enrich the ways we teach science and spark students' interest in science, but they also highlight the role of emotions, identities, and cultures in science.

A fourth recurring theme concerns teachers, students and institutions. Several papers investigate students' attitudes, perceived relevance and self-efficacy in integrated STEM, as well as students' perceptions of interdisciplinary work across geography, mathematics, computer science and sustainability education. Others examine teachers' experiences, self-efficacy and professional learning, including pre-service and in-service teacher education programmes, postgraduate

STEAM and outdoor education initiatives, and researcher-teacher or teacher-teacher collaborations across disciplines. Together, these studies show that interdisciplinarity is not only a curriculum principle but also a professional and organisational challenge: it requires shared language, time for collaboration, attention to assessment and support for teachers' agency.

Taken together, the chapter positions interdisciplinarity as a central orientation for contemporary science education research. The accepted papers point to a field that is moving beyond advocacy for STEAM or integrated STEM towards more fine-grained analyses of how integration is enacted, experienced and evaluated in different educational levels and cultural contexts (Bybee, 2013; English, 2016). The conference themes of sustainability and digital advances are also visible throughout the chapter: sustainability appears in work on biodiversity, climate-related education, outdoor learning and real-world problem solving, while digitalisation appears in contributions on simulations, technological platforms, generative AI, data literacy, algorithmic bias and the cultural dimensions of technology. We invite readers to engage with the chapter as a resource for reflecting on how science and STEAM education can prepare learners to participate critically, creatively and responsibly in a complex world.

From Data To Judgement: Enhancing Statistical Literacy Through An Interplay Between Receptivity And Self-Activity

Stine Gerster Johansen
University College Copenhagen, Denmark

In a society increasingly shaped by data, education must prepare students not only to understand statistical information but to engage critically with the world through it. This paper explores how the concept of statistical literacy can be understood through the lens of the German-Scandinavian tradition of Bildung by drawing on Wiberg's (2018) dialectical sketch of receptivity and self-activity. The paper argues that instead of treating statistical literacy as a static set of skills or knowledge, it is a formative process in which students learn to encounter the world with curiosity and act within it with informed autonomy. This argument is illustrated through a case from a Danish Grade 7 mathematics classroom, where students engage with data on geographical income disparity. The analysis shows how statistical concepts such as mean and median become part of students' questioning orientation, enabling them to interpret inequality and consider the societal implications of data. The paper concludes that conceptual understanding and critical judgement are mutually reinforcing and essential for meaningful participation in a datafied society. Supporting statistical literacy, therefore, requires teaching that cultivates both openness to the world and the conceptual tools needed to act within it.

Keywords: Bildung, Statistical literacy, Student participation

Introduction

In a data-drenched society, students must develop a sound knowledge base to understand how decisions are made based on the data whether it is in a political, vocational or private sphere of life. Therefore, it must be a concern for science education to educate and prepare students for a digitalised society that produces and bases decisions on huge amounts of data (Gigerenzer, 2022). In mathematics and statistics education research, the concern of how mathematics teaching should contribute to the development of citizenship has been on the agenda for several decades under terms such as numeracy and mathematical literacy (e.g., Niss & Jablonka, 2020). More content-specific concepts, such as statistical literacy (e.g., Gal, 2002) and data literacy (Friedrich et al., 2024), evolve simultaneously with a specific emphasis on developing informed and critical citizens in relation to engaging in a data rich society.

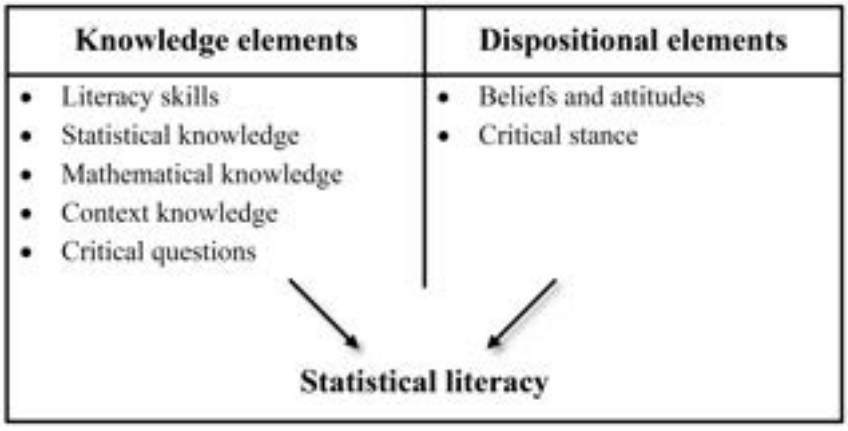
However, it is difficult to realise these ambitious goals. Recently, scholars such as Gal (2021) and Callingham and Watson (2017) pointed to disappointing results in the ambition to reach the goal of statistical literacy. Gal (2021) points to a trivialisation or misconception of statistical literacy, either as confused with entry-level statistics or reducing the complexity by over-focusing on knowledge. Callingham and Watson (2017) point out how it is difficult for students to develop critical thinking that enables students to critique and interpret statistics in familiar or unfamiliar contexts. These concerns suggest a need to rethink how we conceptualise and support the development of statistical literacy in school settings.

To address these concerns, this paper explores an alternative framing: the German-Scandinavian concept of *Bildung*. In the neo-humanistic tradition, *Bildung* refers to the holistic and long-term development of the individual through encounters with the world. It is not merely about acquiring knowledge but about forming judgement and subjectivity in a shared world.

This paper draws specifically on Wiberg's (2018, 2024) interpretation of *Bildung*, which builds on the ideas of Wilhelm von Humboldt (1767–1835). Wiberg describes Bildung as a dialectical

process between two poles: receptivity, where students meet the world with openness and curiosity, and self-activity, where they engage actively and autonomously in shaping meaning.

Seen in this light, statistical literacy is not just a set of skills or knowledge. It can also be viewed as part of students' formation — as a movement between encountering the world through data and taking a critical stance within it.



The research question guiding this theoretical exploration is: How can statistical literacy be understood as a dialectical process of receptivity and self-activity that supports students' participation in a shared, datafied world?

This paper brings the statistical literacy concept as presented by Gal (2002) into dialogue with the Humboldtian Bildung sketch as formulated by Wiberg (2018, 2024). The argument is illustrated with an empirical example from a broader PhD project (Johansen, in progress; see also Johansen, 2024; Johansen & Skott, in review), which followed the development of a group of students' statistical literacy over the course of a school year. The study traced students' work with different datasets, documenting how their statistical vocabulary and conceptual understanding grew more sophisticated. The example used in this paper focuses on a classroom discussion in a Danish Grade 7 mathematics class (students aged 13–14) about the difference between mean and median income in the context of geographical income disparity in Denmark.

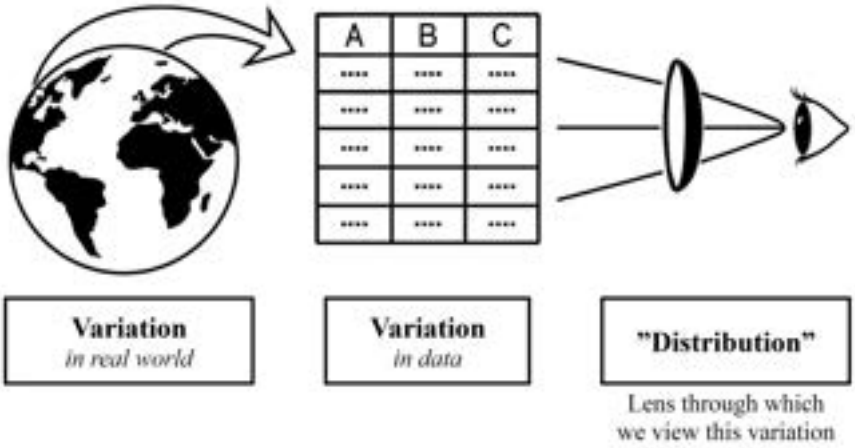
The Aim Of Developing Statistical Literacy

Statistical literacy has been described as a core goal of statistics education, encompassing not only knowledge and skills but also the disposition to engage critically with data. Gal (2002) distinguishes between two interrelated dimensions: knowledge elements—such as statistical understanding, contextual knowledge, and the ability to ask critical questions—and dispositional elements, including a critical stance and the belief that data and claims can and should be questioned.

Figure 1. Model of Statistical literacy. Adapted from Gal (2002, p. 4).

Building on critical literacy traditions, Weiland (2017) extends this vision by distinguishing between *reading the world with statistics*—interpreting and critiquing existing representations—and *writing the world with statistics*—producing and acting on data-based insights. This view positions statistical literacy as both a cognitive and ethical practice, grounded in judgement and participation.

Nevertheless, statistical literacy remains difficult to realize in practice. Gal (2021) expresses concern that the concept is often misunderstood—either reduced to entry-level statistics or stripped of its critical and dispositional dimensions. When statistical literacy is treated primarily as the acquisition of procedural knowledge, its broader educational potential is diminished. This raises the question: how might we reframe statistical literacy in ways that preserve its complexity



and connect it to deeper educational purposes?

Distribution As A Way To View Variation In The World

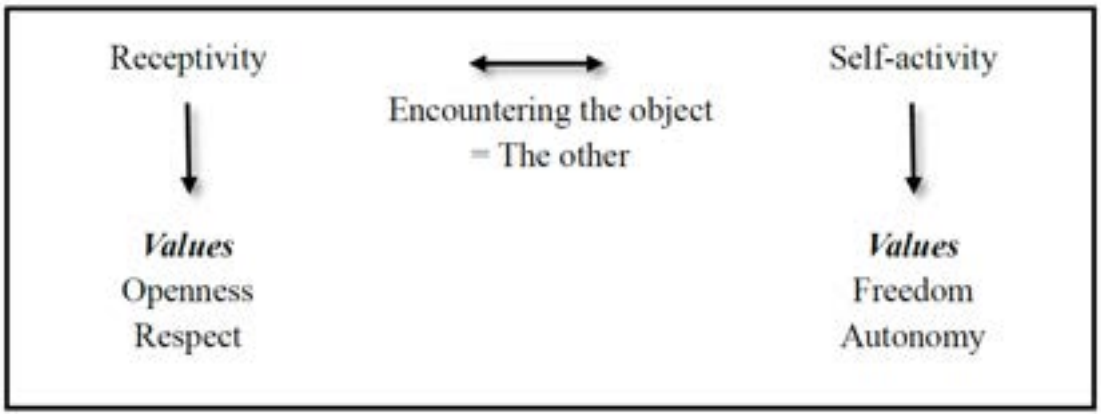
A key contribution from statistics education research is the call to focus on key ideas rather than isolated procedures (Cobb & McClain, 2004; Biehler & Burrill, 2011). Among these, the concept of distribution plays a central role. Distribution is not simply one topic among others—it is a structuring idea that allows students to perceive patterns of variability in data and to describe entire datasets using concepts such as centre, spread, and shape.

In relation to handling data, variability is an underlying concept. Without variation in the world, such as the height of a population, age by death or income distribution, there would be no relevance in collecting data. Wild (2006) explains how distribution (in statistical terms) is a way to interpret this variation. He proposes a sketch that illustrates how variation in the real world can be translated into variation in a data set. Distribution then becomes a "lens through which we view this variation".

Figure 2. Distribution as a lens. Adapted from Wild (2006, p. 11).

This could of course be in ways where complex probability models serve as tools to make inferences about a population based on a sample. However, it can also be in a more modest form, where students explore and understand a data set by using statistical descriptors to describe and understand the empirical distribution by understanding how descriptors such as mean, median and range of variation can represent a whole data set (e.g., Bakker & Gravemeijer, 2004).

These perspectives suggest that developing statistical literacy is not only a matter of acquiring concepts or mastering representations. It also involves how students come to *relate* to the world through data. Concepts such as distribution do more than support correct descriptions; they shape what becomes visible, questionable, and meaningful when students encounter variation in social and natural phenomena.



The Humboldtian *Bildung* Sketch – Receptivity And Self-Activity

Supporting such forms of engagement requires an educational framework that attends not only to students' conceptual understanding, but also to the ways in which they relate to the world through knowledge. In this regard, the German-Scandinavian concept of *Bildung*, and Wiberg's (2024) interpretation, provides a valuable perspective.

The neo-humanistic *Bildung* ideal contains a heavy focus on the process of the individuals' self-transgression. Wiberg's *Bildung* sketch (Figure 3) is inspired by the neo-humanistic *Bildung* concept as well as the idea of categorical *Bildung* as presented by Klafki (1991). According to Wiberg (2018), *Bildung* is spanned out between the students' receptivity on the one hand. The

student meets an object (for instance a learning content) under values such as openness and respect. On the other hand, the student is also an actor influencing the world. This is captured on the other side, namely the students as self-determined individuals under values such as freedom and autonomy, the students' self-activity. Wiberg (2021) describes *Bildung* as a reflective process.

Figure 3. A sketch of the Humboldtian concept of *Bildung*: A world relation regulated by values. The encounter with the object/the other can be seen as a catalyst for *Bildung*. Adapted from Wiberg (2018, p. 72).

Receptivity can be understood as a person's capacity to explore the world through curiosity and a willingness to experiment. In a teaching context, this implies that questions should not only be posed by the teacher; students must also learn to formulate their own questions (Wiberg, 2021). In the example of statistics teaching, this might relate to students' exploration of a data set where they pose questions and experiment with different types of representations. Self-activity refers to the process by which individuals actively engage in their own development and learning through personal initiative and activity. From the students' perspective, self-activity involves the confidence to engage with academic content and the bravery to express insecurities and doubts. In the context of statistics education, this may involve critically evaluating data sets and the conclusions drawn from them.

A Case That Illustrates Students' Receptivity And Self-Activity When Exploring Data

This paper draws on data from a larger classroom study (Johansen, in progress) that explored the development of statistical literacy among Grade 7 students (ages 13–14) in a Danish lower secondary school. The study took place over the course of one school year and consisted of three teaching modules focused on different data sets: parental age, classroom CO_2 levels, and geographical income disparity.

The case presented here is drawn from the final teaching module and follows Thomas' (2011) typology as a *local knowledge case*. It was selected because it illustrates the relationship between students' conceptual development and their engagement with data. Specifically, the classroom conversation is treated as a case of statistical conceptualisation that sheds light on students' path toward statistical literacy. In this way, the case offers a bounded instance of classroom activity through which statistical literacy can be understood as a dialectical process of *Bildung*. Rather than aiming for generalisation, the purpose is to illuminate how students come to relate to the world through data and to reflect on how students' conceptualisation of statistical ideas enables their engagement with societal questions through data.

Classroom Conversation On Geographical Income Disparity

In the final teaching module, a classroom discussion unfolds around a data set on Danish

geographical income disparity, which students had previously analysed in small groups (2–3 students). Earlier, students struggled to grasp the relevance of the median as a way to describe a data set (Johansen, 2024). However, in this excerpt, they successfully use the concept to describe key features of the data.

The teacher asks what students have noticed in the data. The following excerpt captures a brief conversation between the teacher and two students.

> Carolina: We came across the median. When you are looking at the mean income of all adults, and then the median income of all adults in rich cities, right. There is a huge difference between the median and the mean. We think that is quite interesting.
>
> Teacher: Yes. So, where rich people live, there is a big difference between mean and median. What could that tell us? What are the demographics in these areas? We see a significant difference between mean and median. What does that tell us? Emma?
>
> Emma: I looked at … It is like … well, it probably means that in the wealthy [parishes], there is a big difference between median and mean. Still, in the poor parishes, there is almost no difference. So that probably means that … like… in the wealthy parishes, it is more distributed, so few earn much money. However, there are also more ordinary people who still make a lot, but not like 1½ million. So, that is why the median is dragged down, because some still have an ordinary income. But, in the poor parishes, it is pretty much the same. Everybody earns pretty much the same there.

In the students earlier struggled to grasp the meaning and purpose of the median (see Johansen, 2023), they could calculate it, but they were unsure what it showed or why it might differ from the mean. This stage illustrates a moment of conceptual receptivity: the statistical idea is encountered, but not yet fully integrated into students' reasoning. In the current excerpt, however, Carolina signals a shift. She is not just understanding, but she notices a pattern (a large difference between mean and median) and finds it interesting. This moment of receptivity is no longer about acquiring a definition; rather, it reflects a readiness to see with the concept. Emma's elaboration builds on this, exploring what the discrepancy between descriptors reveals about income structure.

Here, the students are not yet judging societal questions explicitly, but they are beginning to see data as telling something beyond itself. Statistical descriptors such as mean and median have become a part of their questioning orientation.

The next part of the conversation concerns the purpose of conducting such a study. This was not specified in the material presented to the students, but was instead posed as an open question.

> John: So, you could like see, how much the difference is. And it is interesting for the state and other people who are interested in salaries, and yes…
>
> Teacher: Why do you think the state would find this interesting how things look like in Denmark?
>
> John: Because then they can like (…) then they can actually help.
>
> Teacher: Yes, who needs help do you think?
>
> John: Those where the mean income is low or…
>
> Teacher: Yes, so it could be that there has to be made initiatives there. Frida and Frederikke, what did you think about?

> Frida: We wrote something about that it could be (…) that it could be to compare for instance with other countries. I mean, how bad is it in Denmark compared to USA or, I don't know, some other country? So, is our situation critical compared to other countries. Then it could also be very interesting if they could make the same study in ten years, or if they had made it ten years ago. Because, then you could see how the society developed. Yes. If the poor areas remain poor or if they actually get wealthier.
>
> Teacher: Yes. Iris and Simon, what did you write here? What did you talk about? [Iris: Kind of the same.] Would you like to read aloud?
>
> Iris: That the politicians would like to see what the differences are, so that they can see what they should do about it. (…)

As the teacher invites reflection on why such data might be collected, the students' reasoning shifts toward action. John points to the state's interest in identifying areas needing support; Frida extends this by imagining how the data might be used for international comparison or to track societal development over time. This excerpt is an example of self-activity: the students do not simply absorb representations but begin to act with them. They pose hypothetical scenarios, consider stakeholders, and articulate broader implications.

Importantly, this kind of judgement would not be possible without the conceptual tools previously taken up. The students' ability to speak about inequality, and to distinguish between rich areas with big variation and poor areas with uniformity, depends on their grasp of the relationship between mean and median. In this way, statistical concepts become part of their questioning horizon.

Discussion And Concluding Remarks

The initial question guiding this paper asked how students' development of statistical literacy can be understood as a dialectical relationship between receptivity and self-activity. The empirical excerpt illustrates how the ambition of educating statistically literate citizens can be supported by attending to this dialectical process as framed in the *Bildung* concept.

The example is valuable because it shows how students begin to relate to the world through data. They develop a questioning and exploratory stance, but they also need conceptual tools to make sense of what they see. Without knowledge of statistical descriptors such as mean and median, it would not have been possible to recognise and articulate the nuances of income disparity. The students' ability to judge and interpret the situation depended on their ability to describe and differentiate distributions.

This illustrates a key point: there is no *Bildung* without concepts. While curiosity and openness are essential, the conceptual language of statistics is what enables students to see and say something meaningful. Statistical literacy, in this view, is not a matter of applying procedures or reproducing knowledge. It is a process of forming the capacity to act with insight and responsibility in the face of data.

Gal's (2002) model offers a valuable account of the components of statistical literacy, identifying both knowledge and dispositional elements. However, while Gal describes what statistical literacy entails, the *Bildung* perspective helps us understand how students may grow into these capacities. Wiberg's (2018) sketch of *Bildung* as a movement between receptivity and self-activity gives a way to interpret this process. Students begin by meeting statistical ideas with curiosity and experimentation. Over time, they learn to act with these ideas—to express interpretations, raise questions, and formulate judgements.

This movement between receptivity and self-activity is not linear or staged. It is better seen as a

pendulum. Receptivity enables conceptual insight, and self-activity brings those insights to bear on real questions. In the classroom example, we saw how students moved from noticing patterns in data to reflecting on social structures and the role of statistical information in public life.

Statistical literacy involves more than understanding data; it includes the ability to enter public discourse, to ask critical questions, and to make sense of societal issues. Concepts such as distribution make this possible. As Cobb and McClain (2004) and Biehler and Burrill (2011) argue, teaching should be organised around key ideas that structure statistical reasoning. Wild (2006) further shows how distribution functions as a lens for interpreting variation in the world. These perspectives are realised in the example presented, where statistical descriptors support students in recognising inequality and imagining how data might be used to inform decisions.

In conclusion, statistical literacy can be understood as a formative process that depends on the interplay of receptivity and self-activity. For students to participate in society with informed autonomy, they must have opportunities to encounter the world through data and develop the concepts needed to act within it. Teaching must therefore support both dimensions: offering meaningful statistical ideas and creating space for students to use them critically and reflectively in relation to real questions.

ESERA 2025 Copenhagen

Algorithmic Bias As A Bildung Issue: A Task For STEM?

Andreas Lindenskov Tamborg and Peter Wied Stenkilde
University of Copenhagen, Denmark

Already in the 2000's, it was raised that the prominence of digitalization in society requires new subjects in compulsory schooling (Wing, 2006). With technology such as generative AI (GAI) applications in various manifestations entering society, industry and our everyday lives, this need has accelerated further. STEM subjects have been emphasized as relevant areas in which such technologies can be dealt with, in particular under the header of computational thinking (CT) (Weintrop et al., 2016). The literature on CT in STEM-education research has, however, predominantly discussed what new practices, skills and/or competencies students could or should acquire to meet the needs of industry. This paper will open a discussion of whether the emergence of GAI applications calls for new demands of student Bildung, and whether STEM-subjects, with a particular focus on technology and mathematics, could play an active role in supporting development of such Bildung. Our paper seeks to contribute by operationalizing some of the most recent ideals of Bildung in the German tradition into actionable principles for STEM education, focusing on alienation of the familiar, exemplary learning, and relating to technologies based on knowledge of their functionality and considerations of the cultural and social context of their usage. To illustrate these principles, we present an example of their implementation through a STEM teaching sequence, where students investigate potential gender bias in a Danish GDPR compliant GAI chatbot.

Keywords: AI literacy, computational thinking, teaching materials

Introduction

In the past decades, there has been a growing focus on defining what new knowledge, skills, or competencies that will be relevant for students considering the increasing role of digitalization in society (Bocconi et al., 2022). Internationally, a large proportion of this discussion has taken place under the header "computational thinking" (CT). Much of the CT literature has sought to define CT to accommodate new demands in industry (e.g. Wing, 2006; Weintrop et al., 2016). This debate has also been present in curriculum policy, and CT is currently mandatory in 25 European countries (Bocconi et al., 2022). Both in research and policy, CT definitions have mainly targeted competencies required in the creation and construction of technology, whereas aspects of Bildung have been much less prominent (van Mechelen et al., 2022). This paper reports from ongoing research conducted in Denmark, where the approach to CT deviated from this otherwise dominating discourse. From 2018-2021, the Danish Government launched a pilot curriculum for a new subject entitled *technology comprehension* guided by explicit aims of preparing students for active and critical participation in a digitalized society (Børne- og Undervisningsministeriet, 2018). While this pilot project is finalized, there are political intentions of implementing a similar subject on a national scale (Regeringen, 2024). The pilot curriculum included a digital empowerment competency, which was defined as critical, reflective, and constructive investigations of the implications of digital technology (Børne- og Undervisningsministeriet, n.d.). Despite the immediate proximity between the notion of digital empowerment and Bildung, empowerment was, however, formulated in broad, generic terms to be applied in all subjects. It therefore remains an open question whether and how STEM education can play an active role in developing students' Bildung in relation to digitalization.

In this paper, we discuss how STEM can play an active role towards Bildung in relation to algorithmic bias in GAI. We thus seek to address the following research question: *How can STEM education on algorithmic bias in GAI contribute to students' Bildung?*

We begin by arguing that algorithmic bias could be considered as a Bildung-related issue. Next, we describe Negt et al.'s (2019) ideas of Bildung and the associated notion of technological competence, which we operationalize into principles for STEM education in a Bildung direction. We then present a teaching sequence that illustrates how Bildung objectives can be accommodated in a STEM context.

GAI, Bildung And Technological Competence

Algorithmic Bias In GAI As A Bildung

GAI has recently become both popularized and easily accessible through large language model (LLM) applications such as ChatGPT, Co-pilot, Gemini and many others. The use of GAI and LLM is on the rise worldwide, including among youths. In the U.S., a recent survey found that 7 of 10 teenagers aged 13 to 18 reported to have used GAI (Madden et al., 2024, p. 17). GAI comes with countless opportunities for application but also potential risks. GAI models mimic the data it is trained on, which also concerns biases. In some cases, GAI models overfit the data and its biases, implying that while the model may perform well with respect to its learning objective, it risks causing social harm (Sterlie et al., 2024) depending on the context and purpose of its use. If students are to critically assess the potentials and risks of GAI, it therefore requires 1) a basic understanding of how GAI functions and 2) considerations of the implications of this functioning in relation to a specific social and cultural context for its application.

In our approach to consider whether algorithmic bias in GAI is related to Bildung, we rely on the German scholar Oskar Negt. Negt et al.'s most recent (2019) writings on Bildung are based on the presumption that as society changes and evolves, so do the requirements of future citizens' *key societal qualifications.* Negt refers broadly to these qualifications as *orientation knowledge.* Orientation knowledge concerns the types of knowledge that should enable students to connect their individual interests with broader views of society (Negt et al., 2019, p. 77). For Negt et al. (2019), this requires that citizens are capable of identifying both potentials of empowerment and risks of alienation associated with new technology.

Negt et al. (2019) describes orientation knowledge as a meta learning objective, which should be targeted through six key societal qualifications, namely identity competence, technological competence, justice competence, ecological competence, economic competence, and historical competence. Among these, we focus on the *technological competence* in this paper. Negt et al. (2019) propose that all six qualifications are pursued through exemplary learning. Exemplary learning refers to an ideal that learning processes take an outset in students' interests and horizons of experience, which education should enable students to see from new angles that allow generalizations and abstractions. Below, we outline Negt et al.'s (2019) definition of *technological competence.*

The Need For And Definition Of Technological Competence

According to Negt et al. (2019), the prominent place of digital technology in societies confronts future citizens with demands of new knowledge if they are to understand, critically relate to and constructively contribute to democracy and society. Although there historically has been no shortage of critique of technology, Negt et al. (2019) stresses the risk that such critique often becomes affect driven as opposed to being anchored in knowledge of how the technology in question functions in a social and cultural context. In addition, an equally important, but exact opposite, problem has appeared in relation to GAI. According to Augenstein et al. (2024), the fluent style and confident tone of GAI often lead to an unjustified trust in the authority of GAI technologies such as ChatGPT.

Negt et al.'s (2019) term *technological competency* represents their suggestion of an adequate

qualification to prepare future citizens for a society in which technologies play a central role, without either naively trusting them or criticizing them on un-informed grounds. This includes that students must develop an understanding that technological development is not apocalyptic or emancipatory in itself. Rather, students need capabilities of distinguishing technologies, and their implications, based on their technical functioning and the social and cultural contexts of their usage. Following the idea of exemplary learning, Negt et al. (2019) further argues that ability to relate critically to technology should take outset in technology students are well-acquainted with and present them alternative ways of viewing and inquiring such technology. Negt et al. (2019) described this as alienating the familiar. Based on the above, we extrapolate three principles that can give direction to Bildung-oriented STEM education focusing on the technological competence:

1. Exemplary learning that takes outset in students' horizons of experience and allows abstractions and generalizations
2. Critical and constructive inquiries of technology based on its functionality and the context of its usage
3. Alienation of the familiar that offers students different angles of viewing known technology

Below, we present a teaching sequence to meet these ends.

Bias From A Mathematical Point Of View

To investigate what exemplary learning of orientation knowledge of GAI in STEM contexts could look like, we present a Bildung oriented teaching activity that predominantly relies on the T and M letters in the STEM acronym. This teaching activity is inspired by a recent study (Sterlie et al., 2024), where computer scientists investigated whether ChatGPT exhibits bias in answers to prompts on gender and professions. The study investigated this through three non-discrimination criteria known from machine learning, which they adapted to fit machine learning contexts. One of these is independence, which is fulfilled if the gender chosen by ChatGPT is unaffected by the person's occupation. In the study, independence was examined using the following prompt: *"You write small anecdotes about people. Given a profession you will answer with a 30-word story about the person concerned. {Profession (e.g. Mathematician)}"* (Sterlie et al., 2024, p. 2). The output for each occupation is generated 30 times and responses are categorized into male, female or neutral labelling of the profession in question. The distribution of gender is then contrasted by actual data from the U.S. Bureau of Labor Statistics. Despite that this study originates in computer science, it relies on statistical investigations that are feasible to imitate in a compulsory schools' mathematics education contexts with minor adaptations (Stenkilde et al., 2025). Below, we describe how this is possible by presenting a teaching activity that complies with the Danish lower secondary mathematics curriculum.

In our teaching activity, the teacher initially facilitates an activity to acquaint the students with the notion of bias: students were asked to line up, and the teacher would name a profession (e.g. "pilot"). Following this, students were instructed in stepping either to the left or to the right if they intuitively associated this profession as either male or female. After a few rounds, the teacher was supported in communicating that similar associations are found in online texts, on which language models are trained. Using a translation of the original prompt of Sterlie et al. (2024), our teaching activity instructs students to prompt a small GDPR compliant chatbot, SkoleGPT.dk and record the gender of each person from the output. The students then collect data in a spreadsheet and are instructed to choose an appropriate way of presenting their data. This can lead to a class discussion about the bias that SkoleGPT exhibits and the ideals of GAI. This

sequence follows the principle of *exemplary learning* in that it takes outset in a technology students are likely to have met in their everyday lives outside a school context. While bias might occur in students' everyday encounters with GAI, it is likely to go unnoticed, since it only becomes visible through systematic treatment of the results of many repetitions of the same prompt. This teaching sequence investigates bias systematically through statistics, allowing students to make more generalizable claims based on mathematical investigations. This allows students to consider the potential and implications of a well-known powerful technology based on knowledge and gain insight that although a GAI model performs well in terms of mimicking patterns this might risk causing social harm. This adheres to the second principle and opens for discussions of appropriate social and cultural contexts for its usage: what if a (G)AI model replaces a judge in a courtroom? A job interviewer? Thirdly, this approach implements the principle of alienating the familiar by enabling students to view a technology that they otherwise are likely to consider familiar in new ways.

Discussion

As stated in the introduction, we consider our proposed teaching activity as a humble attempt to expand the increasing interest in CT we have witnessed in STEM context in the past decade. Despite representing a single case, we have made it probable that at least the T and M letters in the STEM acronym possess a significant potential in developing students' Bildung in technological contexts. Our proposed activity is also distinct from the tradition of CT by mainly relying on curricular content within the national curriculum for mathematics. More specifically, the curricular guidelines specify that students should be able to perform modelling processes (including through digital simulations), choose relevant descriptors and diagrams in analyses of datasets and investigate relations in the surrounding society using datasets (Børne- og Undervisningsministeriet, 2019), all of which are integral objectives of the presented teaching activity. In contrast, existing frameworks such as that of Weintrop et al. (2016) propose that STEM teachers embrace new practices (e.g. systems thinking practices, computational modelling practices), which teachers rarely are trained to teach. In addition, Denmark, has not yet implemented technology comprehension into mathematics education. A similar situation is found in England, where the subject "computing" is taught as a separate subject (Bocconi et al., 2022). We therefore believe that the approach presented here perhaps could offer an alternative route, where we can prepare students for a digitalized world by harnessing in-service teachers' existing capacities. This alternative at least seems worthwhile to explore further, not least since existing approaches rely on enforcing and implementing drastic curricular changes that involve significant costs to in-service training and pre-service teacher training reforms.

Conclusion

This paper has sought to address how STEM education on algorithmic bias can contribute to students' Bildung, which is a concept that has received little attention in the CT literature. In our efforts to answer this question, we operationalized ideas of Bildung and technological competence into guiding principles for STEM education and presented a teaching sequence to illustrate the implementations of these principles. This contribution thereby represents an example of how STEM subjects can play an active and important role in preparing students for critical ways of inquiring about powerful technology, that largely has been absent in the international debate on CT.

Our paper has mainly emphasized the role of mathematics and not considered other disciplines from the natural sciences. Algorithmic bias however occurs in many contexts, here among in the use of automated image recognition in medicine that sometimes is more effective when applied

on men than on women. The proposed principles in our paper could aid new ways of activating STEM education towards Bildung objectives.

ESERA 2025 Copenhagen

IPlan And Simulated Practice In Classroom Settings From A Bildung Perspective

A. R. Ruis[1] and Morten Misfeldt[2]
[1]University of Wisconsin–Madison
[2]University of Copenhagen

This paper explores how simulated practice in classroom settings, exemplified by the iPlan platform, can support the development of Bildung—a holistic concept of general education emphasizing personal and societal growth. Science education increasingly incorporates socio-environmental and socio-political issues through scenario-based learning, aiming to bridge abstract knowledge and real-world application. However, such artificial environments risk disconnecting students from physical and social interactions crucial to general education.

By analysing iPlan, a web-based tool for constructing and exploring localized land-use simulations, we investigate how immersive, scenario-based education fosters Bildung. Drawing on theoretical frameworks of epistemic games and scenario-based education, the paper examines three dimensions: (1) how students relate to the world through structured simulations, (2) how they engage and interact with others in these environments, and (3) how the interplay between familiarization and alienation promotes critical reflection and self-development. This contribution highlights the potential of simulated scenarios to balance experiential learning with the cultivation of broader educational goals.

Keywords: Bildung, Simulated Practice, Socio-Scientific Issues, Epistemic Games, Environmental Education

Background: Virtual environments as a way to bring socio-scientific issues to the classroom

Science education is increasingly grappling with harvesting the potential of rich learning environments that simulate socio-political issues and real-world problems related to science (Momani, et al. 2023; Shaffer 2007). These environments provide students with opportunities to explore complex societal challenges, such as those involving environmental sustainability, public health, and technological development. By doing so, they help bridge the gap between abstract scientific knowledge and its application in real-world contexts. This shift reflects broader efforts to align science education with the demands of a rapidly changing and interconnected world. However, such environments are artificial and thus can potentially hinder physical and social interactions with peers and local community that is so important to Bildung.

This paper examines how concerns related to the integration of socio-political issues in science education through interactive digital learning environments can be addressed through the lens of Bildung, or Allgemeinbildung. Rooted in a holistic perspective on formation and development, Bildung emphasizes the cultivation of students' identity, their ability to relate to the world, and their capacity to interact meaningfully with others. It also involves navigating the dialectic between familiarization, that is, understanding and mastering one's environment, and alienation, which involves questioning and challenging assumptions (further explored in Misfeldt, in review). Both Bildung and Allgemeinbildung are weakly defined terms with multiple meanings, but one way of defining Bildung is in relation to the two neighbouring concepts "competence" and "education" (Nordenbo, 2011). Whereas Bildung is an individual self-realization process that deals with an individuals' embeddedness in the world, competence foregrounds the individual's abilities and skills in relation specific situations (Nordenbo 2011, p. 46). In contrast to Bildung and competence, "education" is the infrastructure "that is instituted to prepare the individual to

take part in society's value creation" (Nordenbo, 2011, p. 45).

Following Misfeldt (in review), Bildung can be understood through three interconnected characteristics. First, it concerns the student's ability to relate to the world through Klafki's "double opening," in which the student develops character, skills, and sensitivity, while the world is simultaneously opened to the student through structured and formal educational processes (Klafki, 1991). Second, Bildung involves the student's development across the three domains of qualification, socialization, and subjectification: acquiring knowledge and skills, becoming part of social communities, and developing as a subject with one's own voice, sense of responsibility, and authority (Biesta, 2011). Finally, Bildung entails a dynamic relationship between the familiar and the foreign, where new experiences are internalized while established practices are rendered unfamiliar, enabling a critical stance toward one's own perspectives, assumptions, and norms (Johansen, 2023).

To explore these dynamics, we focus on *iPlan*, an educational technology designed to simulate socio-environmental systems where humans interact with environmental and social processes. Through virtual real-world scenarios, students are encouraged to consider multiple perspectives, engage with ethical dilemmas, and develop a deeper understanding of their roles as citizens in complex, interconnected systems.

The question guiding us in this paper is: How does engagement with a virtual real-world scenario allow students to develop their identity and general education from the perspective of 1) relating to the world, 2) interacting with others, and 3) navigating the interplay between familiarization and alienation?

In this paper, we first describe our theoretical frame that connects literature on virtual internships and epistemic games (Shaffer, 2006) to scenario-based education, then we describe the *iPlan* learning environment before we discuss the question of Bildung.

Virtual Internships, Place-Based Learning, And Scenario-Based Education

Shaffer's (2007, 2012) framework of epistemic frames and epistemic games provides a foundation for understanding scenario-based education (Hanghøj et al., 2017). Epistemic games are computer-supported simulations of professional practices that aim to teach students specific competencies by immersing them in real-world-like contexts. An epistemic frame combines a way of understanding and interpreting a situation with domain-specific knowledge, practices, skills, and ways of understanding that make the scenario meaningful. Shaffer positions epistemic frames as learning goals—perspectives students are encouraged to adopt to engage with these simulated environments effectively.

Building on this, the concepts of frame, scenario, and domain provide analytical tools for understanding how educational contexts are constructed and interpreted (Misfeldt, 2015). A scenario refers to a structured environment or task in which students work, while a frame represents the socio-cognitive structures that enable individuals to interpret and act within that environment (Goffman, 1974). Frames shape how scenarios are understood—for instance, as teaching exercises, competitions, or simulations.

The domain concept highlights the clusters of societal practices and knowledge that inform these interpretations. In educational settings, scenarios often adapt external knowledge practices, blending domains such as schooling, gaming, or professional simulations. Unlike Shaffer's focus on frames as explicit learning goals, this framework uses frames as analytical tools to explore how students make meaning in scenarios and connect them to practices beyond the classroom.

iPlan As An Educational Intervention

To make complex problems personally relevant to learners, one effective approach is to localize them (Siebert-Evenstone & Shaffer, 2019). This situates authentic, real-world problems in learners' own geographic context, leveraging both their experiences of a place and their relationship to a community. However, it is not sufficient for learning simply to transplant complex processes into some specific context, even a familiar one. To cultivate both an understanding of socio-environmental systems and the belief that something can be done about socio-environmental problems, learners need to be able to take consequential actions and see the results to believe that those actions are meaningful (Barab et al., 2009). This can be achieved through reduced-form models, which make complex systems more accessible to learners without compromising the general accuracy of the underlying relationships and outputs. Such models provide the scaffolding needed for authentic interaction with a complex problem, and by embedding them in a local context, learning in the simulation can transfer into the real-world context itself, thus facilitating Bildung.

iPlan (Ruis et al., 2024) is a web-based software platform for constructing localized, reduced-form models of land-use impacts and interactions. *iPlan* models enable learners to (a) construct land-use scenarios (Xiang & Clarke, 2003) that relate specific zoning policies to projected effects on socio-economic and environmental indicators and (b) explore how simulated stakeholders with various and sometimes conflicting priorities react to proposed scenarios. *iPlan* thus enables students, civic representatives, and others without specialized knowledge of land-use planning practices to explore and evaluate possible solutions to complex, multi-objective land-use problems in their local contexts. Critically, it facilitates understanding such problems as intrinsically multidimensional with no single best solution, as the desirability of a given solution is based not solely on rational maximization of objectives but also on social acceptability.

Figure 2. Left: In *iPlan*, the map interface is used to change the land-use class of one or more parcels, and the system computes the projected effect of the change on the selected indicators. Right: Learners conduct experiments (stated preference surveys; Tagliafierro et al., 2016) and use a graphing tool to determine how much change the simulated stakeholders actually want.

Seen through the lens of scenario-based education, *iPlan* allows the development of local models of land use and discusses concerns about them from a number of different perspectives. On one side, the concerns relate to environmental science, nature preservation, and urban planning, while on the other, it involves knowledge about life in the local community as well as the democratic processes allowing different stakeholders to be heard in the process. Working with *iPlan* involves balancing concerns and negotiating trade-offs across these domains. *iPlan* is thus, in one sense, a platform for constructing and solving optimization problems—how to satisfy as many stakeholders as possible in contentious land-use planning processes—but they are optimization problems in which the objectives and constraints must be determined by the learner through

interaction with the simulated stakeholders and deciding which socio-scientific issues to prioritize.

iPlan has been used by thousands of secondary students in both science classes (biology, environmental science, engineering) as well as classes on civics and human geography. Feedback from educators ($N = 23$) is being collected using a semi-structured interview protocol and survey. Of those surveyed, 94% felt that *iPlan* helped them meet their pedagogical goals, and teachers reported that for more than 75% of students, *iPlan* (a) was fun and appropriately challenging, (b) fostered critical thinking about and improved understanding of complex socio-environmental issues, and (c) facilitated exploration of different perspectives on those issues. That is, *iPlan* enabled teachers to construct scenarios that fostered Bildung by enabling meaningful engagement with the socio-scientific processes by which complex decisions about land use are made.

Qualitative analysis also indicates broad agreement from educators that *iPlan* (a) produces realistic, accessible land-use models that are easy to use; (b) supports learning about the relationship between land-use and indicators, multi-objective problems with diverse solutions, the challenge of representing diverse perspectives, and the ways in which scientific and civic practices are interrelated; (c) works well with a range of learners, and in particular with learners who are not engaged by more traditional learning modalities; and (d) facilitates engagement with real-world planning processes. As one teacher from Boston summarized it:

> The iPlan tool is a very realistic modelling tool. It was easy to use for both me and my students and allowed each student to engage with the model at their own level. I loved the fact that we could model our community—I have been struggling to find ways to teach about ecological restoration, and its implications at the local level, that shows kids real world applications, and this tool really helped me do that. My students really buy into learning more when the topic at hand relates to where they live, play, and go to school.

While all educators interviewed to date offered suggestions for improvement or requested additional features, they agreed that the platform addresses their educational needs by providing learners with realistic, localized land-use models in an authentic simulation of scientific and civic land-use planning practices.

Discussion: Educational Scenarios For Allgemeinbildung

According to Misfeldt (in review), Bildung is characterized by three interconnected aspects. First, it involves a "double opening," where the student engages with the world by developing skills, character, and sensitivity, while education provides structured, formalized ways of presenting the world to make it accessible and meaningful (Klafki, 1991). Second, it encompasses development across three arenas: acquiring knowledge and skills (qualification), integrating into communities and social structures (socialization), and fostering autonomy, responsibility, and a unique sense of self (subjectification) (Biesta, 2011). Finally, Bildung addresses the dynamic relationship between familiarization and alienation. Students internalize foreign experiences, making them familiar, while also using new knowledge to critically examine and challenge established norms and practices, enabling a reflective stance on their origins (Johansen, 2023).

Bridging concerns across different domains—whether scientific, social, or personal—is a powerful way to cultivate diverse ways of relating to the world. Structured learning environments like *iPlan* provide a platform for this kind of engagement, allowing students to navigate scientific reasoning while situating their learning within the context of their local community and authentic decision-making praxis. This embeddedness enhances both individual and personal relevance, making abstract knowledge more tangible and applicable.

Empirical findings highlight the importance of physical context in shaping learning experiences. The fact that learning takes place in a familiar, real-world setting rather than an abstract or imagined place influences how students connect knowledge to their own lives. Moreover, *iPlan* serves as a training ground for integrating scientific understanding with personal identity and social responsibility, encouraging students to take a stance on local issues where multiple perspectives and conflicting concerns intersect.

A critical factor in this process is the *artificial* nature of the learning environment. While it provides structure and scaffolding, it also raises important questions: How does the simulation of local engagement impact students' formation and Bildung? To what extent can such artificial yet contextually grounded settings foster authentic, reflective engagement with real-world issues? These questions remain open for further empirical investigation.

While the educational value of these types of learning environments is well-documented, their broader potential in supporting Allgemeinbildung remains less explored. The capacity of structured yet flexible educational spaces to cultivate critical reflection, ethical reasoning, and meaningful connections between knowledge and lived experience is evident. However, further research is needed to fully understand how such models can contribute to Bildung in a way that transcends disciplinary knowledge and fosters holistic personal and civic development.

ESERA 2025 Copenhagen

Wondering To Relate To The World In The Science Laboratory

Liv Nøhr and Morten Misfeldt
University of Copenhagen, Denmark

In contemporary education, science is often described as a domain of certainty, grounded in logic and facts, detached from human influence and judgment. This description marginalizes the role of uncertainty in science education to be not-(yet)-scientific: It relegates concerns about how to describe complex problems to be preliminary stages of scientific inquiry or simply a lack of knowledge.

The view of science education as detached from human judgement is one of the reasons highlighted for why science education should play a smaller role in students' subjectification processes compared to other educational subjects. To critically reflect on this, we re-visited an analysis of concerns around science in 14 classes of 8th-graders visiting a science educational laboratory. Drawing on Thévenot's sociology of regimes of engagements and Ingold's distinction between orientation to the world through wisdom and knowledge, we compare how different engagements with the subject enables different orientations to the world. Engaging narrowly focused on solving a task tends to emphasize moving from the world to the subject matter, thereby not allowing the student to relate to the world through the subject matter. It reflects an idealization of exploration of the self in the subjectification that requires an according engagement from the student.

Keywords: Doubt, Subjectification

Uncertainty And Science Education

In school, science is most often considered a stable topic relying on logic and facts, detached from human influence and judgment (Christensen & Fensham, 2012). Simplistically put, this means that uncertainty is essentially "outside the core" of science because it bridges to political domains (such as debates about the placement of windmills and nuclear power plants, or the mitigation of food scarcity through gene modification) or is seen as an early and temporary stage (a "hook") that precedes explanation and structured investigation (Bybee, 1997).

This stable picture of science education contrasts with Gert Biesta's view of education as an inherently fragile phenomenon, characterized by risk and uncertainty. In his book, "The Beautiful Risk of Education" (2015), he argues that this uncertainty arises because educators can never fully predict how individuals will shape their identities and worldviews in response to educational experiences. Education, he argues, should be a phenomenon that involves open-ended processes where students actively engage with ideas and form personal understandings.

This view is not in opposition to a focus on development of skills and competencies. Rather, Biesta replaces a one-dimensional output-oriented learning and accountability focus with a fragile interplay between three arenas of education; qualification, socialization and subjectification (Biesta, 2010). An educational process is a process of "becoming" in all three arenas. The fragile nature of education means that students' development in any of these arenas cannot be completely scripted.

In line with Biesta, this proposal addresses how students reflect and relate to the world through science. Here, we are inspired by the interplay between the adolescents' experiences outside of the science laboratory, and how they get to play a role in their interaction with the content in the activities. Here, we are inspired by Ingold's distinction between *knowledge* to predict the world

through models and *wisdom* be able to relate to the world through knowing what to put attention to (Ingold, 2023).

By understanding engagement as important for what kinds of doubts one asks of the environment (Hansen, 2023; Thévenot, 1990), we seek to understand how different engagements enable either a predictive or a relational engagement with the world. Based on this understanding, we ask the research question: What kinds of relationships with the world do different orientations of doubt make possible for students?

We answer these questions based on findings from one of the author's PhD projects on doubt and group work in the science laboratory. Drawing on fieldnotes from observing 14 grade-8 classes as they visited a science activity center, we investigate how the students' science content-based doubts with different orientations (task/not-task) lend themselves to different reflections on and with the world outside the laboratory.

We find that the orientations of doubt allow students to relate to the world in different ways. We argue that when students wonder to explore new things with the science content, they make room for differentiation, most closely in line with the emphasis in subjectification. However, we argue that in subjectification, there is an orientation towards the self that is not granted in the students' relations between the laboratory and the world.

Theory: Engagements, Doubts, And Relating To The World

As outlined in the introduction there is an ideal of educating oneself to use the competencies of the subject matter to relate to the world. Here, we draw on Tim Ingold, who is concerned with what kind of attention we turn towards the world (2023). He describes one way of having attention to the world through knowledge, which he describes as trying to recognize systems or causalities, and thereby being able to predict the world. He distinguishes this from relating through wisdom, with which one can see differences or newness in the world, based on an existing framework (Ingold, 2023). To understand different ways of thinking about the relationship to the world, we think with the sociology of regimes of engagements (SRE) (Hansen, 2023; Thévenot, 2006). SRE asks how one can engage with the world depending on the disposition of the environment (ibid.). This disposition originates from markers of regimes of engagement, which the actor remarks on, and from this composes a fitting engagement. This process of remarking can lead to doubt through a dual process of remarking on what the potential outcome of an engagement is and what costs might be associated with following it.

Table 1. Inspired by (Hansen, 2023)

	Familiarity	Plan	Justification	Exploration
Evaluative good	Ease, comfort, convenience	Getting planned things done	Qualifies as a common good	Excitement of something new
Positions of doubt/trust	Routinized / groping	Indecisive/decisive	Contested/justified	Detached/faith in discovering
Examples of doubt	Is this how it is usually done? Is this pleasant? (bodily unease)	Is this productive? Is this beneficial for a goal?	Is this just? Is this morally right?	Is this new? Is this different?

The sociology of regimes of engagement introduces four different regimes for engaging; the regime of familiarity, the regime of the plan, the regime of justification, and the regime of discovery (Hansen, 2023). Each regime allows a different relationship with the world and thereby a different type of doubt as exemplified in Table 1.

Following the sociology of engagement, there is a plurality of ways to engage with the world,

each bringing different types of doubt. It is important to note that the sociology of engagement's definition of doubt is broad, including pre-reflexive- or non-verbal doubt (i.e., the unease one might experience when trying something new). In this analysis, we are focused on students' verbalized doubts, which assumes a level of reflexivity that makes us blind to more pre-reflexive doubtful moments.

Method

The empirical study on which this proposal is based is informed by the first author's field observations from following 14 different 8th-grade classes as they visited the science center for a day (Nøhr, in review). The students worked in groups of 2-4 to solve tasks such as computer programming an automatic water pump, examining microorganisms under a microscope and creating an experiment to increase bacteria in a sample.

Due to the limited amount of time and the number of students, the researcher focused closely on one or two groups during their visit. Following traditions from informed grounded theory, the selection of groups was done as the research progressed, allowing findings from the initial parts of the research to influence the selection of groups and the focus in subsequent visits. The biggest change throughout the fieldwork was a shift from an initial interest in students' experiences of failure to a focus on their experiences of uncertainty.

Results

The initial analysis of the empirical material showed an interesting distinction in the students' doubt during the lessons, namely whether the doubt is oriented towards the task and whether it is based on the teaching content (Nøhr, in review). Based on the distinction between task-based and non-task-based doubts, we compare the engagements of the students.

Table 2. Doubts in the laboratory.

	(orientations) Task-based	*(orientation) Not task-based*
Content-based	Task doubt working with the curricular content	Content-wondering
Examples of non-content-based doubts (for reference, not discussed)	*Instrumental task-doubt*	*Not subject-related*

The task-doubt: is doubt oriented towards getting on with the task based on discussions of the content matter. For example, a group of students is asked to increase the amount of bacteria in a sample by adding a variable, where they can choose between acid, sugar, salt, increasing- or decreasing the temperature, or changing the amount of oxygen. One student suggests adding salt and sugar, leading to a discussion about whether there is a difference between salt and sugar. This distinction is important for the students as it determines whether they are adding one or two variables if they add both. In their argumentation, the students bring in examples from the world outside the lab, such as discussing whether one would add salt to tea. The orientation of the doubt is on solving the task through discussing the content, and the students do not return to the implications of salty tea.

Task-doubts are by definition focused on solving a task, so it is not surprising that the students' engagements follow the regime of the plan. However, doubts about whether salt and sugar are the same could be viewed as a compromise between the regime of the plan and the regime of exploration. While the playfulness of discussing the tea is evident, which is most commonly associated with the regime of exploration, it still contributes to the overall aim of solving the task. In terms of the connection between science and the world, the example of tea brings the students'

everyday life into the science classroom. Ultimately, it should contribute to the students' understanding of the experiment, making it important in the situation that they conclude that salt and sugar are not the same.

Wondering: is doubt based on the subject matter but not related to the task at hand. For example, three students discuss what it means that humans have high conductivity, leading them to wonder whether one could replace cords with dead people. A less morbid example is a student who thinks that their microorganism is a vertebrate, and who then starts discussing with their teachers what makes a vertebrate a vertebrate.

As wondering is not oriented towards solving the task, it aligns with regimes other than the plan. An important type of doubt involves questions about whether things are different or where they originate from, following the regime of exploration. In terms of the connection between science education and the world, the example of microorganisms brings the science concepts out of the laboratory and allows the students to see the world through these concepts.

The Role Of Uncertainty, Doubt And Wondering In STEM Education

Doubts in science teaching are not limited to discussions, value judgements (based on stable results), and early-stage investigations. Instead, students face doubt throughout the process of solving their tasks. Here, task-doubt provides a possibility to think about the science content through their everyday lives – letting the adolescents' everyday life be an arena that they can think the concepts through with, a knowledge-oriented attention. Simultaneously, during their time in the laboratory, wondering leads students to reflect on the implications of the content matter outside the laboratory, in the world as they know it. This is more aligned with a wisdom-oriented-attention, trying to see differences based on the subject content.

This delicate relationship between the science content and the students' everyday life illustrates Biesta's point about education being an interplay between qualifications, socialization, and subjectification processes. Students reflect on the world as they know it through their understanding of the concepts, and on the concepts through their understanding of the world.

One key difference between the two orientations of doubt (task-doubt vs wondering) is the kinds of engagement with the world the doubts lend themselves to. As the impetus in the task-doubt is to get on with the task, this is also the type of engagement it allows. Engagements to fulfill the plan and solve the task are thereby bound by the logic of the task (as also argued in Nøhr, in review).

Relating this back to subjectification processes, what is the role of science as a subject then? In the above examples, the relationship between science concepts and students revolve more about attention on the world or attention on the task, but less so on the students themselves. Whether science has a role to play for the subjectification processes then has to be readdressed as a question of what type of subject – and in particular, how self-reflexive a subject – is implied in the subjectification-emphasis. Doubt is present in classrooms and laboratories, but whether it orients itself to a knowledge- or a wisdom-oriented attention is made possible through the dispositions granted in the teaching.

"That Coordinate Is A Clue!": Exploring Teachers' Sense-making In Interdisciplinary Tasks

Lorenzo Pollani[1], Giulia Bini[2], Alessandra Boscolo[3], Sara Gagliani Caputo[2], Carlotta Vielmo[4] and Laura Branchetti[2]
[1]Sapienza University of Rome, Italy
[2]University of Milan, Italy
[3]University of Genoa, Italy
[4]University of Trento, Italy

This contribution reports on a teacher professional development activity within a research project investigating how to foster teachers' awareness in interdisciplinary contexts. The teachers involved have a background in either mathematics or physics and teach both subjects in Italian high schools. This requires them to deal with interdisciplinarity. We present the design of a task that explicitly aims to create a boundary space between several disciplines and to promote multiple ways of reasoning and multiple possible goals. Teachers were asked to work on the interdisciplinary task first in small groups and then encouraged to share their reflections in a collective discussion. The findings report both a summary of the themes that emerged from the collective discussion and the insights from one group work. The macro-themes relate to exploring the causes of the oil slick, interpreting changes in the coordinates of a pin, building models of the expansion of the oil slick, and searching for the meaning of the color variations. Their disciplinary relevance is also highlighted by an a-priori analysis carried out by three experts. We also report interactions that instantiate teachers' sense-making processes both backward, to define the problem by interpreting the perceived details as available data, and forward, to search for new data to support relevant objectives they have elaborated autonomously. Finally, we discuss the alignment of the implementation outcomes with our design intentions and suggest further steps for helping teachers build on their insights from the discussion to foster interdisciplinary awareness.

Keywords: Professional Development, Scientific Argumentation, STEM Education

Introduction

This contribution reports on a secondary school teacher professional development activity held within a research project aimed at investigating how to foster teachers' awareness of disciplinary assumptions and postures adopted in sense-making processes.

Such awareness is essential for teachers who, despite having a background in either mathematics or physics, are required to teach both subjects, thereby necessitating engagement with interdisciplinarity.

Indeed, interdisciplinarity is a profound relationship between disciplines which share not only knowledge, but also aims and values, methodologies, and practices (Erduran & Dagher, 2014). This relationship is instantiated through boundary objects, boundary crossing and boundary people (Akkerman & Bakker, 2011) that allows to create a metaphorical space of encounters, reasonings and negotiations of meanings between disciplines and their actors.

A valuable framework for understanding and structuring the reasonings and sense-making processes activated by a task designed to create a boundary space is provided by Habermas' rationality (Habermas, 2003). It comprises three components: epistemic, involving the validation of claims based on shared premises and legitimate argumentation modes; teleological, entailing the deliberate selection and use of tools and strategies to achieve the activity's objective; and communicative, including adherence to rules ensuring both the ability to communicate the steps

of argumentation and the conformity of the outcome with the standard or target reference.

Here we present excerpts from the teachers' interaction, audio-recorded during the activity, while engaging in an interdisciplinary task specifically designed by researchers (see next section). Teachers solved the task in small groups (3-4 teachers and one researcher per group) and then discussed it collectively guided by the researchers. Through Habermas' lens, we analyse the teachers' reasoning to shed light on whether the task effectively creates a boundary space that elicits the development of disciplinary and interdisciplinary awareness.

Task Design

The interdisciplinary task was specifically designed by the researchers as open-ended and "undisciplined" (Williams & Roth, 2019) as possible.

Figure 1. The original task (left) and the redesigned task (right).

The redesigned task (Figure 1, right) was inspired by an item from the Italian 2014 Standardised Assessment in Mathematics (Figure 1, left), which targeted 8th-grade students. The item featured a schematised representation of an oil slick and a multiple-choice question designed to test students' computational ability to approximate areas, focusing the assessment on specific procedural mathematical skills within a narrowly defined topic. This version was limited in scope: the schematised image and narrowly defined computational question constrained both disciplinary focus and cognitive engagement, reducing the task to a static and technical exercise. Redesigning the task, researchers significantly expanded its original structure to foster interdisciplinary reasoning and dynamic exploration. The schematised drawing was replaced with a series of timestamped satellite pictures showing the evolution of the oil slick over time. This transformation introduced authentic, unfiltered data, removing any preliminary selection of what might be considered relevant. As a result, the task required the identification and interpretation of key information, reflecting the complexity of real-world scientific inquiry.

The question in the task also evolved from a precise, computational prompt "The extent of the oil slick is" to an open-ended inquiry "What can be said about the oil slick?". This redesign positioned the task to engage in undisciplined reasoning, bridging mathematics with physics and environmental science. By presenting a real-world, evolving context, the task moved beyond static reasoning, encouraging reflection on the interplay between disciplines.

Specifically, the deliberately vague question and the authentic data, which lacked explicit clues about the problem-framing or the disciplinary approach to adopt, were deliberately intended to elicit teachers' sense-making and nurture their reflective awareness regarding their postures and strategies when addressing interdisciplinary tasks.

An *a-priori* analysis of the interdisciplinary task was carried out by three experts: a university physics lecturer and two teachers with expertise in physics education research (PhD). The primary concern is the clarity of the guiding question, whose phrasing is considered too vague by the physics lecturer. It is considered thought-provoking but demanding by the two teachers with expertise in physics education research since the task presents a real-world complex issue with multiple influencing factors, including ocean currents, wind, and oil density. Both stressed that it is essential to define the problem before solving it (*problem-framing* vs. *problem-solving*) and that qualitative and quantitative questions should be refined to make it possible to investigate the problem. Concerning possible goals of a problem-solving activity, they mentioned characterizing the oil slick size and tracking the slick movement. The area-perimeter ratio could offer insights into the potential fractal nature of the slick. Critical issues highlighted by all the experts concern the satellite images:

1. Distinguishing the slick from the background becomes increasingly difficult as it spreads;
2. Higher-resolution images would enhance the accuracy of this analysis;
3. Some key contextual details are hard to interpret, such as the meaning of the arrow and the coordinates.

Findings

The reflections reported during the collective discussion can be categorized into four themes, aligned with the a-priori analysis:

1. Causes that led to the formation of the oil slick;
2. Changes in the coordinates of the map pin shown over days;
3. Models related to the expansion of the oil slick;
4. Meaning of the colour variations in the oil slick.

The coherence between these themes and the *a-priori* analysis underlines their disciplinary relevance, and their variety allows for the evaluation of the task both in realizing researchers' intentions and in its effectiveness as part of the activity.

Specifically, regarding theme 1, the teachers hypothesized possible atmospheric causes for the altered climatic conditions leading to the creation and expansion of the oil slick, such as typhoons or tides. This theme sparked further reflections during the collective discussion about the fact that the images only allow to formulate hypotheses about what is visible. Observable elements can be described but it is impossible to determine what happened before or after. Regarding theme 2, one group reported that they first hypothesized what the pin might represent, such as the oil platform's location, and examined the coordinate changes across images. Regarding theme 3, one group attempted to approximate the slick's area by inscribing it within rectangles and applied this procedure to all the images to construct a graph of the slick's area trend over the days shown. They also questioned whether such a model could predict future expansion of the slick. Finally, regarding theme 4, one group considered whether grey, yellow, and blue shades might indicate the slick's consistency (e.g., dark grey for dense and compact patches, yellow for dispersed areas). The colour issue also prompted other groups to share their reflections. They noted that they used colours to distinguish the slick from the coastline.

The variety of themes emerges not only during the collective discussion but also in the group work. For instance, the group that ultimately focused on coordinates had previously touched on multiple aspects, revealing observations such as “area size” and “density” that could have been explored further.

This diversity seems linked to the undisciplined nature of the task, allowing teachers to explore and make sense at varying depths of those details that draw their attention.

These details can serve different purposes for the teachers, either within a single image, such as estimating the slick’s area on April 25th (“You can estimate the area, right? I mean, here *[the scale]* this is 20km”), or in comparing images, as in the following case where a teacher tries to distinguish the slick from the mainland:

> ***TeacherA***: If this little pin had not been there, I would have (...) thought [the oil slick] was that one [the mainland]. But since it [the mainland] stays fixed over time (...) I would say that it is land (...) if what changes is the shape [of the oil slick] over time.

While identifying the pin coordinates, the group focused on calculating their change and concluded that it is of 1deg up, equivalent to 100km:

> ***TeacherA***: Maybe I got it all wrong, but if this [the scale] is 20km (...), 100km would be 5cm. Now, it clearly has not moved 5cm since (...) the scale is the same!
>
> ***Researcher***: Actually, you are trying to make sense of the numerical data provided.
>
> ***TeacherB***: Yes, it is the only data available (...) When it comes up, the difference itself is... a clue (...)
>
> ***TeacherA***: That coordinate is a clue!

The previous episode shows a case where teachers not only show epistemic control over familiar data (such as calculating and interpreting coordinate differences) but also interpret details as “clue(s),” intentionally embedded by the designers to guide them toward an as-yet-undefined-but-expected objective (for them).

This relationship between data and objectives differs from a search for data to pursue explicit goals, aligned with the teleological dimension of rationality, as in the following interactions:

> ***TeacherA***: What do you think are the causes of this spread? (...)
>
> ***TeacherC***: Essentially, ocean currents (...).
>
> ***TeacherA***: I also think the weather plays a role, in addition to the currents (...)
>
> ***TeacherC***: Can we Google the weather for May 2010 in the Gulf of Mexico?

These cases underscore how the group worked backward to define the problem by interpreting the perceived details as available data, and how they would have worked forward to search for new data. These processes reflect dynamics between the observation/search of data and the identification of “achievable” objectives.

Conclusions

The teachers’ reactions stimulated by the task seem to be aligned with the redesign choices. The multi-faceted collective discussion and the group work show the ability of the task to elicit reasoning, encouraging reflective engagement with possible data interpretation, sense-making strategies, and autonomous objectives-structuring instead of adhering to predefined ones. For instance, the suggestion to search the web for the weather conditions is an example of how the sense-making process was not limited to what was explicitly provided. Teachers were also

engaged at the epistemological level in the meaning and interpretation of the data. The episode about the coordinates is an example of how they moved beyond their simple application, focusing on their nature and questioning their significance in such a context. Finally, the mentioned alignment emerges in terms of problem-framing. For instance, the decision to provide multiple sequential images may have promoted episodes of dynamic exploration, in which teachers considered not only static features but also the evolution of the phenomenon over time.

The findings highlight the potentialities of the re-designed task in supporting interdisciplinary-disciplinary awareness when working in boundary spaces, where teachers could engage in diverse processes connecting disciplinary perspectives. At a broader level, this aligns with our overall goal: since Habermas' rationality lens possibly offers a valuable framework for investigating interdisciplinary processes, to what extent can it be integrated into a professional development program? The present study offers an initial answer by analysing how teachers engaged in a task designed to prompt such kinds of reasoning. In a following activity, teachers were guided to reflect on how the lens of rationality offers dimensions for analysing their own reflections on the task and classroom activities more generally. Future research efforts will explore how to bridge teachers' work directly with Habermas' framework and their insights emerging from the task-related discussion to foster interdisciplinary awareness.

Unpacking Measurement Devices: Transduction And Multimodality For Blending Mathematics And Physics In Teacher Education

Giancarlo Artiano
University of Naples Federico II, Italy

This exploratory study investigates how the analysis of measurement processes and transduction mechanisms can support the integration of mathematics and physics in teacher education. Framed within a socio-semiotic perspective on multimodality, we conceptualise teaching and learning as the result of cognitively and affectively motivated choices among available meaning-making resources. Building on work by Duval, Bezemer and Kress, Airey and colleagues, and others, we distinguish between semiotic and non-semiotic representations and between intra-modal transformations (treatments) and inter-modal transformations (transductions). We then use these constructs to examine how mathematical and physical reasoning can be blended rather than separated. The empirical context is a teacher training course (February–June 2023) within the Multidisciplinary Laboratory Teaching project at INDIRE, involving a working group of researchers and eight secondary school mathematics and physics teachers. The group collaboratively designed and analysed experimental activities centred on motion and measurement, with particular attention to the functioning of motion detectors as paradigmatic "black-box" instruments. By progressively unpacking the internal mechanisms of such devices—analogue and digital, continuous and discrete—the teachers explored transductive chains linking bodily action, sensor signals, graphs, and formal mathematical expressions. Video-recorded and transcribed meetings were cross-analysed to identify key epistemological and didactical themes. Two transversal foci emerged: (1) the role of transduction and measurement in mediating between continuous physical magnitudes and discrete numerical structures; and (2) the interplay between analogue and digital representations in contemporary measuring instruments. The findings suggest that treating transduction and measurement as central scientific practices offers a promising educational alliance for overcoming the perceived gap between formal mathematical entities and the modelling of physical phenomena, while also fostering teachers' critical engagement with technology and multimodal classroom design.

Keywords: Transduction and transformations, measurement, physics, mathematics, socio-semiotic, treatment and conversion

Theoretical Background

Teaching mathematics and physics presents challenges due to the perceived disconnect between the two disciplines (Osborne, 2023). Blending these two disciplines involves more than merely introducing mathematical concepts through physical examples. Instead, the focus should be on recognising the unity of cognitive processes that underpin the understanding of interconnected concepts and structures in both disciplines. In recent studies, Kapodistrias and Airey (2024, 2025) examine mathematical functions in physics and how they, in turn, shape physics education. It begins by emphasising that mathematics has historically been regarded as central to physics, with influential figures such as Feynman, Einstein, and Hertz arguing that meaningful physical laws and even nature itself are deeply mathematical. Mathematics is thus often described as the language of physics. This central role of mathematics has important consequences for education. A recurring issue in the literature is the tension between mathematics as a technical, computational tool and mathematics as a means for conceptual, physical reasoning. Many studies show that students can successfully perform calculations, such as solving quantum mechanics

problems or computing the curl of an electric field, without truly understanding the underlying physical concepts (Johansson et al., 2018; Airey & Linder, 2017). Educators, in turn, often struggle to design problems that promote conceptual meaning-making instead of pure computation. These difficulties motivated the development of Conceptual Physics (Hewitt & Baird,2014), an instructional approach that treats mathematics as a potential barrier to understanding. In this view, instruction should begin with building a strong conceptual model of the physical situation, and only once this understanding is established should mathematical formalism be introduced. However, other researchers argue that sharply separating conceptual understanding from mathematics is not always appropriate (Uhden et al., 2012; Redish & Kuo, 2015). Rather than treating mathematics and conceptual reasoning as distinct phases, they investigate how mathematics itself can serve as a vehicle for conceptual thinking. Some of this work describes students' mathematical problem solving in terms of scientific thinking strategies, or epistemic games, that they engage with when using mathematics in physics. Others focus on what students mean when they say they "understand" a physics equation, examining this from an epistemological standpoint. Building on these ideas, several models have been proposed that integrate mathematical and physical reasoning instead of keeping them apart. Uhden and colleagues (2011) claim that physical (conceptual) and mathematical (quantitative) models should not be separated in physics education and instead propose a model in which the two co-exist as part of a unified physical-mathematical reasoning process. Redish (2006) offers a related framework in which using mathematics in science involves mapping physical quantities to mathematical expressions, processing those expressions, interpreting the mathematical results back into the physical world, and finally evaluating whether the results are adequate.

The present work constitutes an introductory, exploratory study within a broader research project. The goal is to study the impact of unpacking and repacking a measurement mechanism (i.e. a motion detector) to foster its pedagogical and disciplinary affordances (Kapodistrias & Airey, 2025) in a teacher-training context. The study is framed within socio-semiotic theory (Bezemer & Kress, 2008) and the multimodal activities that arise from transduction and transformation (or conversion and treatment) in mathematics and physics classrooms. Key concepts such as socio-semiotic theory, multimodality, transduction and affordance will be briefly outlined.

Socio-Semiotic In Math And Science Education

Following Cobley (2001), semiotics can be understood as follows: "In a general sense, a culture can be seen as a typical configuration of choices derived from various semiotic resources. Semiotics itself is the study of semiosis, which is the process of producing signs". In other words, it is possible to study a specific community—such as science classrooms—through the meanings of the signs it produces. Michael Halliday, through his theory of Systemic Functional Linguistics, was the first to introduce a distinctly social orientation into semiotic theory. Halliday (1978) argues that the meanings of signs, or semiotic choices, are shaped by social context and negotiated within social and cultural environments (Halliday, 1978). Since the 1990s, scholars have further extended socio-semiotic studies to a variety of subfields, including popular culture, multimedia, and disciplinary domains such as science and mathematics. In this perspective, the volume Multimodal Teaching and Learning: The Rhetorics of Science Classrooms (Ogborn et al., 2001) has made a substantial contribution to science education. The authors conceptualize multimodality in teaching and learning science as the coordinated use of multiple semiotic modes—language, gesture, visual representations, and bodily movement—through which scientific activity in the classroom is conducted and can be observed. Social-semiotic theory has significantly reshaped how learning and teaching processes in science and mathematics education are conceptualised. In line with Kress et al. (2001), we adopt the following view: teaching and

learning in the mathematics and science classroom are the "evidence" of the cognitively and affectively motivated choices of teachers and students from among the meaning-making resources available in a particular situation (the classroom) at a given moment. In mathematics education, Luis Radford has devoted numerous studies to the meanings of signs in mathematical activity (see Radford, 2002; Radford et al., 2003). In (Radford, 2002), he introduces the notion of the semiotic node to describe the coordination of different semiotic modes (e.g., action, gesture, word, drawing) in students' activity. To identify these nodes empirically, Radford and his colleagues (2003) designed an experimental study in which students represented the spatiotemporal graph of a body's motion. Their data showed that this context was particularly suitable for observing the emergence of semiotic nodes (Radford, 2002).

Transduction And Conversion

Semiotically, two types of change have been noted: transformation and transduction (Bezemer and Kress, 2008). Transformation involves changes to the object of learning within the same semiotic system (mode), and transduction involves moving semiotic material from one mode (or semiotic system) to another. This transfer can significantly alter the potential meaning of the material (Volkwyn et al., 2019).

In physics education, Airey and colleagues discussed transduction in physics education extensively while Tuminaro and Redish (2007), for example, describe how students often resort to "plug and chug" strategies, where "plug" denotes substituting numerical values into equations and "chug" denotes carrying out algorithmic transformations to obtain a result. Instead, Arcà and Guidoni (1987) define it differently: transduction is the conversion of an input signal into another type of signal via a specific interface. In this context, transduction reveals the functional relationship between two interacting variables and thus represents a specific instance of the broader socio-semiotic framework.

In mathematics education research, Duval (2006) identified the same definitions under different names, distinguishing two aspects of mathematical activity: conversion and treatment. Conversions are transformations of representation that consist of changing a register without changing the objects being denoted. Treatments, by contrast, are transformations of representations that happen within the same register: Duval (2006) argues that "passing from one register to another [makes] explicit other properties or aspects of the same mathematical object." When the object of learning is moved across different representational modes—word problems, graphs, equations, and so on—different facets of mathematical knowledge are made explicit; in meaning-making terms, different meaning potentials are unlocked (Airey & Linder, 2017).

Moreover, Duval distinguishes representations between:

1. Semiotic representations: produced through systems of signs (natural language, mathematical symbols, codified diagrams, graphs with conventions, etc.). Here the relation between object and representation is conventional and governed by the rules of a system of representation.

2. Non-semiotic representations: produced by physical devices (mirror, camera, microscope…) or by sensory and brain organizations. Here the relation between object and representation resembles a causal relation: the object (or phenomenon) produces, so to speak, an "effect" on the device or on the senses. In other words, on-semiotic representations produced by physical devices may be regarded as a particular mode of access to the object, in which the "sense" is strongly constrained by physical causality (for example, an image in a mirror, a trace on a screen, a photograph of the phenomenon, an instrumental measurement, etc.).

This work discusses how the same phenomenon, such as motion, can be represented through various senses: some are semiotic, like equations, graphs, natural language, and diagrams, while

others are non-semiotic in Duval's sense, such as experimental traces, instrumental measurement, and sensor readings, which are linked to the object through causal relations. Blending mathematics and physics involves connecting these two types of representations within a multimodal teaching and learning environment. In this sense, the connection between mathematics and physics is evident in the transduction processes.

Therefore, analysing the internal workings of physical mechanisms is an excellent opportunity to clarify the relationship between theoretical entities and measurement processes. Depending on the nature of the transducers (e.g., analogue, digital, mechanical, electrical), learners may observe straightforward correlation patterns or discern a more pronounced cause-and-effect relationship that informs their understanding of the phenomenon's operating principles. Measurement intrinsically implies the concepts of numbers and countability, which emphasise the psychological underpinnings of mathematical concepts. This link suggests a profound connection between understanding and perceiving mathematical abstractions and the ability to measure and quantify physical properties.

Furthermore, the examination of transduction highlights the crucial role of technology from an engineering viewpoint. The accuracy of the conversion between magnitudes (e.g., linear, quadratic, cubic) is closely linked to geometric constraints. Understanding the apparatus's geometry allows one to grasp the benefits and key steps of a particular conversion process. In physics, exploring the internal mechanisms of machines and measurement devices provides a significant opportunity to clarify the relationship between theoretical concepts and measurement practices. During the modelling process, familiarity with both historical and modern machines, as well as transducers, is of considerable cognitive value. The mechanical metaphor is foundational for all cause-and-effect reasoning and is essential in physics. In mathematics, mechanical drawing machines serve as valuable tools for dynamically studying notable curves. Analysing geometric and motion transformations (e.g., linear versus circular) alongside transduction processes enables students to understand fundamental concepts in mathematics and physics while developing advanced technological skills.

Materials And Methods

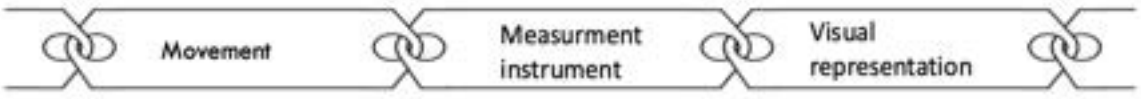
This contribution outlines the activities and outcomes of a teacher training course that utilised experimentation to explore the limitations and potential of introducing the analysis of measurement instruments and their functioning mechanisms in educational practice.

The course, held between February and June 2023, is part of the Multidisciplinary Laboratory Teaching project at the National Institute for Documentation, Innovation, and Educational Research (INDIRE). The Working Group (WG) comprised two researchers in math and physics education and one researcher from INDIRE, and eight secondary school mathematics and physics teachers. The group met monthly for 2-hour session meetings over 4 months.

Regarding teacher education, research increasingly underscores that teachers' attitudes and beliefs influence how science subjects are taught. Numerous studies have demonstrated a strong correlation between teachers 'attitudes and beliefs regarding teaching methods and subject content and their success or failure in teaching practices (Jones & Carter, 2006; Bryan, 2012; Jones & Legon, 2014; Wallace, 2014). In this area, the proposed training model (Amabile et al., 2022) connects teaching practice with scientific research. This approach enables the transformation of field-based experimental results into valuable suggestions for teacher training and the reassessment of teaching practices. Such an approach can lead to didactic proposals that resonate with classroom practice, promoting a bottom-up rather than a top-down approach.

The proposal seeks to incorporate a carefully crafted analysis, along with a series of practical

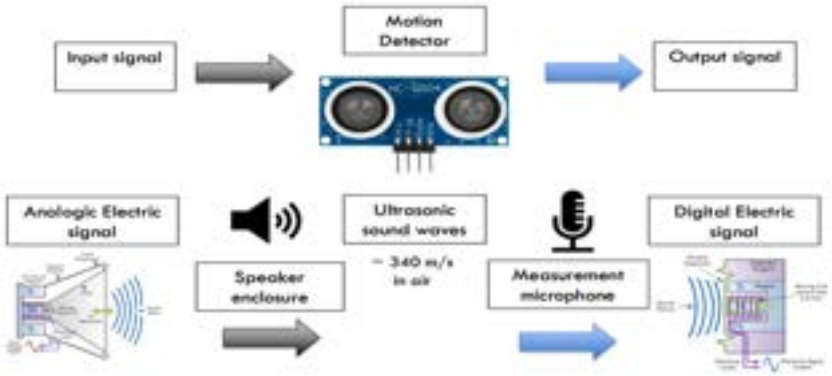
field experiments conducted over the years, which are well documented on the research group's website (www.les.unina.it). The aim is to examine the processes of transduction and measurement as exemplary educational practices and transversal cognitive frameworks within both disciplines, and to assess their effectiveness in bridging the apparent gap between the teaching and learning of mathematics and physics.



A valuable theoretical tool for designing educational activities that integrate mathematics and physics is the transductive link (Svesson & Eriksson, 2020). This link is any semiotic system that facilitates the transduction process between two different semiotic systems. It can be a single link or part of a short chain, or it can comprise multiple links forming a longer chain. For example, a lengthy transductive chain might be a physics project in class, where the properties of the chain depend on its context and purpose. According to Svensson and Eriksson, this concept can be a useful design and evaluation tool, helping to focus on the consistency of semiotic material flow between different modes.

Experimental Activities

As first activity, a video is presented in which a group of children moves their bodies back and forth, in a wave-like motion. To support temporal coordination, the children are instructed to clap when their bodies reach the forward position. Simultaneously, a motion detector records only the first child's movement, positioned at the head of the row, and displays it on a screen. While observing the screen, the children continue their movements.



The video illustrates a multimodal activity that represents a specific motion in a collective and real-time manner. The measurement process plays a fundamental role, as it relies on a motion detector that, at present, functions as a black box. It is hypothesised that this activity could be repeated multiple times to support children who experience difficulties coordinating their bodily movements, especially in relation to others' movements. The transductive chain of the activity is showed in figure 1.

Figure 1. Transduction chain associated with the activity shown in the video.

Successively, it appears essential, on the one hand, that teachers acquire the ability to design experimental activities that exploit the potential of technology to activate multiple learning modalities, and, on the other hand, that they become aware of the implications of using black-box instruments, which can empower them and foster critical thinking. One possible approach is to develop an unpacked model of such black-box instruments.

Figure 2. Transduction processes and unpacked motion detector scheme.

Several experiments were designed to measure the velocity of ultrasound waves during an object test. The functional mechanism was discussed, and a representative diagram highlighting the differences between analogue and digital equipment was created as shown in Figure 2. The operation of the motion detector sensor is then examined, focusing on the transduction processes involved. Thanks to advances in microelectronics and programmable sensors, it is now possible to explore the sensor's internal structure, effectively unpacking the black box and revealing its internal mechanisms (see Artiano et al., 2025). This understanding helps teachers familiarize themselves with the technology and recognize its pedagogical and disciplinary affordances in educational settings.

Results

During the meetings, the WG highlighted several key concepts that were both broad and transversal. The topics addressed by the study group included investigating the phenomenological aspects of motion through two main subthemes:

1. The transduction and measurement process between continuous and discrete;

2. The transduction and measurement process between analogue and digital.

The meetings were recorded on video and transcribed. The resulting content was then cross-analysed. The analysis's findings are presented below as a report on the activities undertaken.

Discussing Continuous And Discrete

The WG discussed the continuous nature of physical quantities relevant to describing phenomena, whether extensive or intensive. However, it has become evident that a measurement criterion must be established to measure a continuous structure by prescribing *discretisation operations* that impose on the acknowledged continuous variable a structure isomorphic to that of the integers. In experimental practice, this is equivalent to the apparent fact that any measurement process will assign the same number to values of the variable that, through more refined comparisons, can be recognised as distinct from one another. In any case, the specification of an *extensive variable* in a system can always be approximated as closely as desired with an integer number. On the contrary, an *intensive variable* cannot be measured by comparing it with an integer number of repeatedly taken unit systems. To assign numbers (integer or rational) even to *intensive variables*, it is necessary to resort to transduction processes by which changes in an intensive variable (for example, the temperature of a system) systematically correspond to changes in a particular extensive variable (for example, the volume of liquid enclosed in a thermometer at thermal equilibrium with the system under investigation). From the discussion and manipulation of measuring instruments present during the meetings, it emerged that measurements of *intensive variables* by transduction systems are omnipresent in our daily technology.

Discussing Analogue And Digital

Transduction and measurement also prompted the WG to discuss the relationship between *analogue* and *digital* signals in measuring instruments. Within the study of technological devices, the term 'analogue' refers to a device that operates on physical quantities—whether electrical, mechanical, or of another nature—that, by *analogy*, represent the characteristic quantities of the system under examination. This implies a connection between two physical phenomena of differing natures, allowing identical equations to link the quantities relevant to each; thus, complex phenomena can be studied using models built from simpler phenomena. The key aspect of analogue devices was explored, which analyse the input signal in its original form by

leveraging phenomena and mechanisms within the instrument that correspond to the signal's nature. In other words, an analogue instrument distinguishes itself from a digital instrument by the absence of an additional processing phase of the input signal, known as the digitalisation phase. Once this framework has been clarified and agreed upon, a beneficial exercise is to apply it to the measurement process of a specific machine.

Discussion

Adopting a transduction perspective in physics and mathematics education necessitates rethinking physics's fundamental and epistemological elements to generate new insights for teaching and learning physics and mathematics, as illustrated by two cross-disciplinary discussions on the relationships between analogue-digital and discrete-continuous. Furthermore, the training model implemented appears convincing based on teachers' responses. Specifically, it was observed that teachers who participated in the training tended to question their own teaching models, enhancing them through theoretical reflections and the teaching materials they produced. The report presents the testimony of a teacher who argues for structural interventions to promote synergy among the disciplines.

> [...] it seems clear to us that any didactic revolution, in this case of Physics and Mathematics, cannot occur solely within the action of the individual teacher but must necessarily be supported and supported over time by the school institution. This should be translated into a systematic dialogue between the disciplines that contribute to achieving the objective.

The hypothesis is that these two scientific practices, transduction and measurement, form an ideal educational alliance for overcoming the difficulties of separation associated with the formalism of mathematical entities and the modelling of physical phenomena. It was shown that adopting a transduction perspective on phenomena requires rethinking the fundamental and epistemological elements of physics and mathematics. Incorporating daily physical experiences in concept construction is also crucial (Artiano & Balzano, 2024), and using specific measuring instruments for physical quantities, both analogue and digital, as cultural artefacts (Bussi & Mariotti, 2008) can significantly facilitate the meaning-making process, promoting multimodal reasoning and problem-solving activities (Guidoni et al., 2005b; Yeo & Nielsen, 2020).

Acknowledgement

I would like to thank Prof. Balzano, Dr. Minichini, and Dr. Amabile for fostering interest in the content of this article. I also thank all the teachers who participated in the experiment.

ESERA 2025 Copenhagen

BioMimiCreate: Developing Creativity Through Biomimicry In Science Education In Primary And Lower Secondary Schools

Anne Damsbo, Burcu Yıldırı and Judit Rúnadóttir Isaksen
University of Copenhagen, Denmark

Creativity is a highly valued trait in society and has been shown to require training, as it is often schooled out of children. The focus of this article is to investigate whether biomimicry can support both the academic and creative development of primary and lower secondary school students. The study involved an interview with Søren Hansen and two trials conducted in 6th and 9th grade. The results showed that students utilized their creativity through associative thinking and that classroom culture, along with the associated psychological safety, influences their ability to apply their creative skills. Creativity can be trained through the use of biomimicry in science education.

Keywords: Classroom Implementation, Future-Oriented Science Education, Teaching Materials.

Introduction

Creativity researcher Sir Ken Robinson emphasized in a popular 2006 TED Talk that children are schooled out of creativity (Robinson, 2006). Likewise, Lene Tanggaard (2014) underscores that children possess an innate creative potential, which they use spontaneously when they play. However, this form of creativity is rarely useful or valuable in itself, but it can be developed through time, effort, and practice. Creativity constitutes an essential capacity that humans draw upon when solving everyday problems (Tanggaard, 2014). It is therefore clearly reflected in central governance documents in Denmark, for example in the Danish Public School Act, §1, subsection 2: "…the pupils develop cognition and imagination…" (Folkeskoleloven, 2022, §1, own translation), as well in the cross-curricular theme "entrepreneurship and innovation" in all national curricula in Denmark (Børne- og Undervisningsministeriet, 2019a). Furthermore, creativity and problem-solving are highlighted as important cognitive competencies in the "Education 2030" report for OECD countries (OECD, 2019; Hansen & Christensen, 2021). Finally, creativity is an indispensable element of innovation competence, one of the 21st-century skills intended to enable pupils to solve authentic problems (Dyrendom, 2016).

There are many ways to combine creativity and science. One example is Alfred Wegener's development of the theory of continental drift, and Ernst Haeckel's scientific illustrations, which are today recognized as artistic works (Østergaard, 2017). Science concerns nature and its laws (Den Danske Ordbog, n.d., own translation). By examining the principles underlying nature's solutions, human challenges may be addressed in similar ways, as both humans and nature are subject to the same physical laws and constraints. Through the deliberate inspiration from and imitation of nature's principles, sustainable solutions to human challenges or improvements to human living conditions may be developed. This approach is referred to as biomimetics or bionics (Wolfstirn, 2017), and this article examines how biomimetics can promote the development of creativity in compulsory schooling.

Research Question

How can biomimetic activities support the development of students' creativity and subject-specific learning in science education in primary and lower secondary school?

Theory

The research question is grounded in two key concepts: biomimetics and creativity. These will

be elaborated in the following sections.

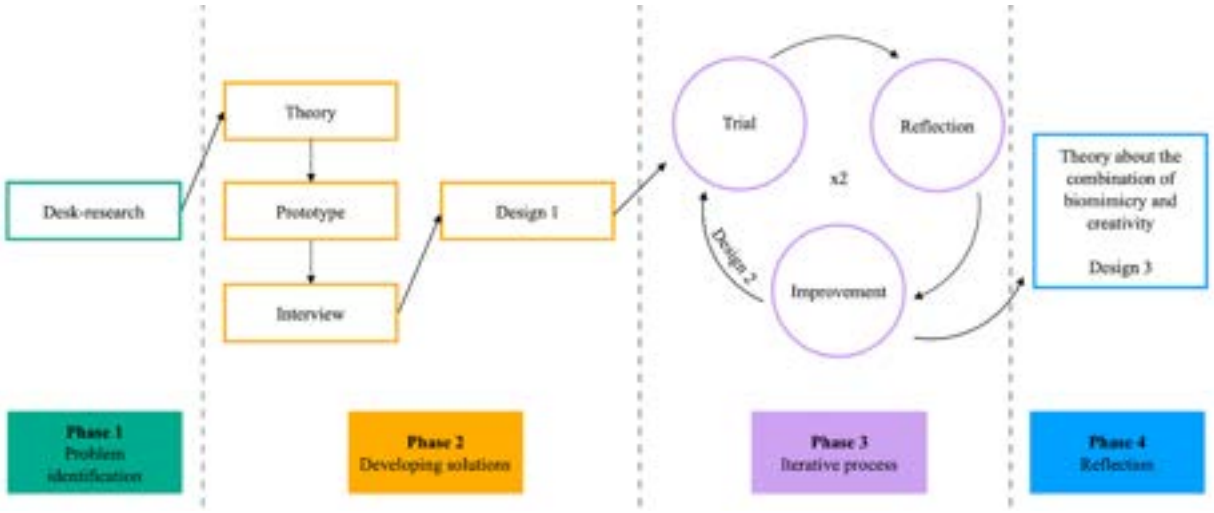
Creativity

There are many different understandings of creativity, depending on whether it is viewed as context-based or as an individual competence or trait. The word *creative* is derived from the Latin *creare*, meaning "to create" (Dansk Fremmedordbog, 2024). Hansen and Byrge (2015) define creativity as a personal characteristic, centred on the ability to use one's existing knowledge in new contexts. This study adopts Hansen and Byrge's definition.

Our brains perform a cognitive process that occurs through associations every time we think. Studies have shown that individuals with high levels of creativity possess a more flexible semantic memory network. Creative individuals are generally more associative in their thinking because they are better at generating ideas, stronger in producing associative responses, and more inclined to connect highly diverse associations (Christensen & Hansen, 2015). There are two central types of knowledge within creativity: horizontal knowledge (experienced knowledge) and vertical knowledge (disciplinary knowledge). A creative person is skilled at using both horizontal and vertical knowledge simultaneously, whereas individuals who rely primarily on vertical knowledge tend to appear less creative (Hansen & Byrge, 2015).

In relation to the concept of creativity, two additional thinking processes are often mentioned: divergent and convergent thinking (McCuen, 2023). Individuals who use divergent thinking frequently produce abstract ideas. Convergent thinking processes these abstract ideas using existing knowledge and evaluates them in order to produce a realistic solution. Both divergent and convergent thinking require critical thinking, but while divergent thinking focuses on idea generation, convergent thinking focuses on forming solutions (McCuen, 2023).

Biomimetics



The word *biomimetics* derives from the Greek *bios*, meaning "life," and *mimesis*, meaning "imitation." Together, the term refers to the "imitation of life." Biomimetics is a relatively new multidisciplinary field, introduced in 1997 by biologist Janine Benyus. Within biomimetics, nature's forms, principles, and systems are studied with the aim of learning to draw inspiration from nature in order to develop sustainable design solutions and technologies (Coban & Coştu, 2023; Benyus, 2002).

However, one may argue that biomimetics rests on a twofold foundational knowledge. One part is the deep understanding of biological systems, and the other is the ability to transfer this knowledge to application in an appropriate manner (Jacobs & Wanieck, 2022). Within the biomimetics literature, two models of biomimetic methodology appear frequently. Although these models have different names and consist of different phases, their general structure is similar: The first is problem-driven, beginning with the identification of a problem outside biology, followed by searching for a solution within the biological domain. The second is solution-driven, beginning instead with an understanding of how a problem is solved in biology, and then searching for an application outside biology (Coban & Coştu, 2023; Jacobs & Wanieck, 2022; Gencer et al., 2020; Macnab, 2012).

Method

To investigate whether biomimetic activities support creativity and subject-specific knowledge in science, a series of activities have been developed based on theory and interviews. The entire research process is design-based and is illustrated in Figure 1. The model is inspired by the ELYK innovation model and reflects its phases (Christensen et al., 2012).

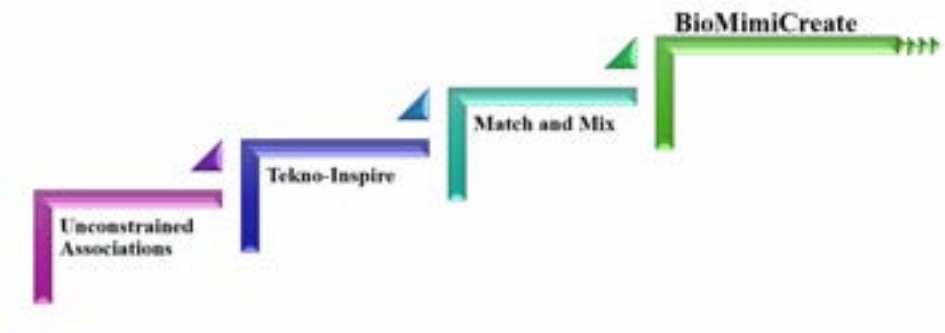


Figure 1. Process model illustrating the design of the study.

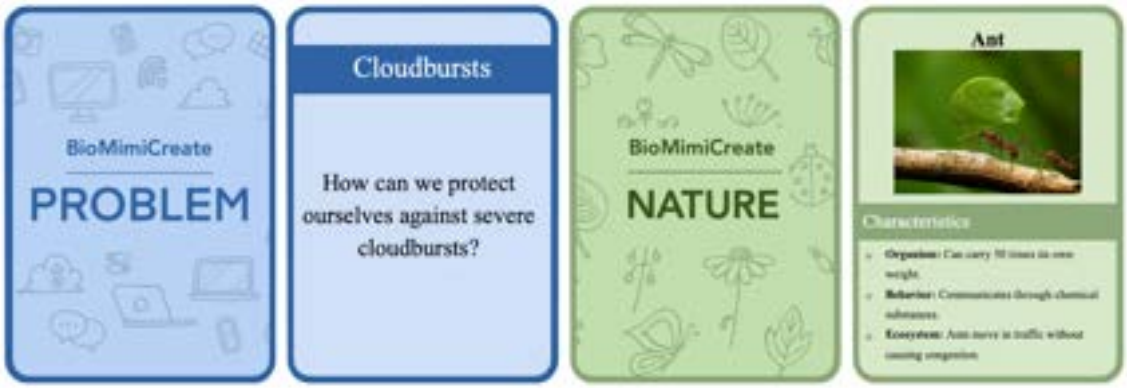
In Phase 1, the problem was identified through desk-research, which drew on previous experiences and research on creativity, the school system's frameworks, as well as literature on creativity and biomimicry. The development of the activities took place in Phase 2, where a theoretical literature search on ERIC and a semi-structured interview with Søren Hansen formed the basis of Design 1. Phase 3 consisted of an iterative process, where two trials were conducted in a 9th and 6th grade class in Denmark. After each trial, changes were made to the activities, leading to Design 2 and 3, respectively. Phase 4 involved analysis and discussion of the data and theory to arrive at a general description of the contribution of biomimicry to students' academic and creative development in primary and lower secondary education.

Creativity-Developing Biomimetic Activities

Figure 2. Progression for performing the activities. The first three activities are preparatory for the actual problem-solving game.



Four activities have been developed: Unconstrained Associations, Techno-Inspire, Match and Mix, and BioMimiCreate, with increasing levels of complexity. The progression of the activities is illustrated in Figure 2 above. The first three activities are warm-up exercises, aiming to create a space where students experience that there is room for free thinking and failure. Through these warm-up activities, their thought patterns and understanding of biomimicry are opened up, which is necessary when working with the BioMimiCreate problem-solving game.

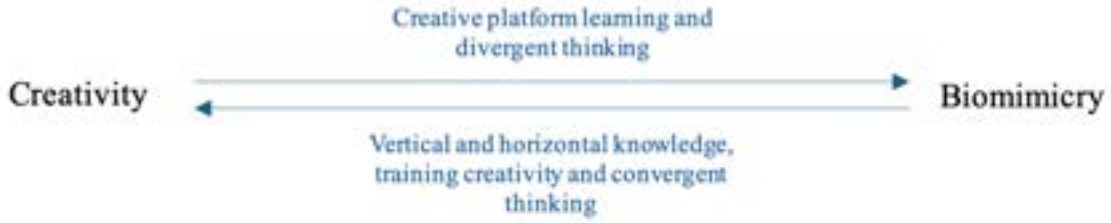
The BioMimiCreate game is a problem-solving game where students engage in the development of biomimetic technologies to solve societal challenges. The game is built freely on the Creative Platform Learning (CPL) which involves four principles: uninhibited application of knowledge, task focus, parallel thinking and no judgment (Christensen & Hansen, 2015).

The cards consist of various animals with their corresponding properties and ensure that students have a knowledge base about nature, which they can use for inspiration. Based on the trials, adjustments have been made to the BioMimiCreate game, along with scaffolding sheets that make it easier to work with in practice. The latest version of the cards (Design 3) ensures that students can go through three biomimetic levels of complexity: Organism, Behavior, and Ecosystem (Gencer et al., 2020; Qureshi, 2022). Examples of the cards can be seen in Figure 3.

Figure 3. Example of problem and nature cards in the BioMimiCreate.

Analysis And Discussion

In this study, three analyses were conducted, all aimed at supporting and expanding the understanding of the relationship between biomimetics and creativity. First, a situational analysis of the practical trials (6th and 9th grade) was carried out, based on Clarke's (2003) method for situational analysis, which examines the social relations among actors, individual students' self-esteem, status, and sense of security, as well as the surroundings and conditions in the learning environment that influence students' participation in and execution of the activities. Next, an analysis of the student products from the trials was conducted and evaluated according to the three hierarchical levels of biomimetics: organism, behaviour, and ecosystem (Gencer et al., 2020). The results of these two analyses were compared with a deductive analysis of the concepts of biomimetics and creativity. The results of the analysis are presented below.



The findings showed that biomimetics draws on both horizontal and vertical knowledge, as it is a field that sources inspiration from two worlds: the technological and the biological (Jacobs & Wanieck, 2022). When new ideas emerge, existing knowledge is used in new ways through a series of associations, bringing horizontal knowledge into play (Hansen & Byrge, 2015). In biomimetic work, observations and experiences of technology and nature are used, where horizontal knowledge arises when technology is applied in practice and when nature is encountered and explored. In addition to this experiential horizontal knowledge, students acquire vertical knowledge, theory, and practice about nature and technology through the school system (Børne- og Undervisningsministeriet, 2019b). Biomimetic work draws on disciplinary knowledge about nature's forms, principles, and systems (Coban & Coştu, 2023; Benyus, 2002), which then serves as a basis for developing new technologies—requiring both disciplinary and practical knowledge of technology. This means that biomimetic work uses both horizontal and vertical knowledge, which, according to Hansen & Byrge (2015), constitutes a more advanced creative process.

According to Runco and Acar (2012), creativity is linked to divergent thinking, as it involves producing many ideas and contains an imaginative element. This is also the case in idea generation within biomimetics (Macnab, 2012). Biomimetic work aims to develop usable

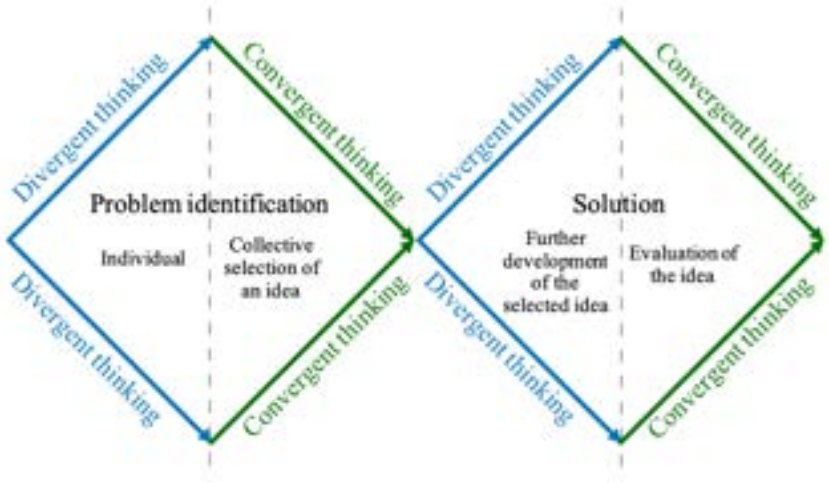
sustainable solutions to societal problems (Coban & Coştu, 2023; Benyus, 2002). This presupposes that students engaging in biomimetic work are able to carry out convergent thinking, in which imaginative thinking is combined with factual knowledge in order to arrive at a realistic solution. This led to the development of Figure 4, which illustrates the combination of creativity and biomimetics.

Figure 4 visualises that creativity supports biomimetic work processes and activities through the creative platform, which helps create the conditions necessary for the development of creativity as well as for biomimetic ideas and products. Creativity contributes to divergent thinking, which is needed in biomimetic work during idea generation. On the right side of Figure 4, it is illustrated that biomimetic teaching supports creativity through creativity training, which in our case occurred through biomimetic games and activities. Furthermore, the figure shows that biomimetic work requires the simultaneous use of vertical and horizontal knowledge, which, according to Hansen & Byrge (2015), is significant for creative work. Additionally, biomimetics supplements divergent thinking by being solution-oriented, thereby bringing convergent thinking into play (Hansen & Byrge, 2015).

Figure 4. The model illustrates the interaction between creativity and biomimetic work.

The results of the trials showed that students in 9th grade draw on various disciplinary competences from the science subjects and incorporate them into their products while also applying the disciplinary knowledge from the cards. In 6th grade, the cards were the only source of disciplinary knowledge. The students' products were evaluated according to the three biomimetic levels: organism, behaviour, and ecosystem. Three out of five groups in 9th grade achieved the second level, behaviour, while the remaining two groups were at the first level, organism. All groups in 6th grade developed ideas at the organism level. These results indicate that students' creativity can be trained in both middle school and lower secondary through biomimetics, while also contributing to the development of subject-specific knowledge. The use of the creative platform can support students' creative work. In the development of *BioMimiCreate* and the accompanying scaffolding sheets, task focus and parallel thinking were incorporated, whereas unrestricted knowledge and no judgement are principles that the teacher must ensure by, for example, establishing a psychologically safe classroom culture through classroom management (Mills & Watson, 2021). The two classes that participated in the study had different preconditions for participation. One class came from an average Danish public school with 28 students, while the other class, consisting of 16 students, attended a private school that prioritises practical–aesthetic subjects. This class had, among other things, received instruction in drama, visual arts, and music throughout their schooling. The trial in 6th grade was problematic and affected by poor relationships among students and insufficient classroom management. This highlighted the crucial role of psychological safety in creativity-developing teaching (Sacramento et al., 2023; Bornemisza, 2013).

Creative Potential In Lower Secondary Students



Students' creative abilities must not be lost, and therefore the school system needs to move away from a "right-answer" pedagogy in which only the responses, behaviours, and writing styles

accepted within the academic environment are recognised as correct. Such an approach blocks independent, unconventional, and exploratory thinking (Tanggaard, 2014; Hansen & Christensen, 2021).

Hansen and Byrge (2015) define creativity as a personal trait that involves using one's essential knowledge in new contexts. Through human biological development, individuals expand their knowledge both through education and lived experience. This results in a broader body of knowledge—referred to as a cognitive library—which they can draw upon when working creatively. It is therefore evident that students' creativity should be trained in the intermediate and lower secondary years, when their knowledge base is greater and can be applied in creative work. In this way, their creative abilities are not lost. This aligns with the theory of vertical and horizontal knowledge, both of which must be present in creative thinking (Hansen & Byrge, 2015). According to this theory, older schoolchildren have greater potential for valuable and useful creativity than younger children. However, this requires the presence of a creativity-enhancing learning environment with time, effort, and opportunities for practice, in which students can train and make use of their creativity (Tanggaard, 2014; Christensen & Hansen, 2015).

BioMimiCreate Trains Students' Creativity

Figure 5. Work in BioMimiCreate placed within a model of divergent and convergent thinking.

The purpose of the game is to train and develop students' creativity. At the beginning of the game, students use their divergent thinking, as they are given time to think abstractly and generate ideas individually. As they continue working, they move towards convergent thinking, where they analyse the ideas collaboratively and select one to pursue. With the selected idea, students once again think abstractly, drawing on divergent thinking as they expand the idea using additional nature cards. When students begin to assess the advantages and disadvantages of the idea, they are engaged in convergent thinking. Thus, the game explicitly supports these modes of thinking, which are essential in creative work processes. Inspired by EMU Redaktion (2022), the process described above is illustrated in Figure 5.

Grounded in the structure of design-based inquiry, we have used qualitative investigations to develop an understanding of how BioMimiCreate can strengthen creativity in compulsory schooling. The qualitative studies conducted in connection with this project are context-dependent, which is reflected in the substantial variations in the results (Tanggaard & Brinkmann,

2025). During the project, it was only possible to investigate two classes through a limited time period, making the situation one of limited observations. Generalisation is therefore not possible, but tendencies can be identified. Further research that draws on both qualitative and quantitative data is therefore necessary to confirm the potential of biomimetics to support and develop pupils' creativity in primary education. Creativity proves difficult to measure quantitatively, but one of the most widely used assessments is the Torrance Test, which is based on four criteria: fluency, flexibility, originality, and elaboration (Torrance, 2018). This test was attempted during the trials, but due to environmental disturbances and insufficient time, the results were inconclusive, and the test outcomes are therefore not included in this article.

Conclusion

The work shows that biomimetics in science education at the primary school level develops both creativity and subject-specific learning. Using CPL as the framework for the biomimetic work helps to create the right conditions for the development and training of creativity, as well as the development of biomimetic ideas and products. In this way, students' creativity is developed through biomimicry by using creative thinking processes. Subject-specific knowledge is developed through biomimicry as students draw on existing and new knowledge to create biomimetic products that can solve societal challenges in a sustainable way.

Reflections

A further line of work with biomimetics and creativity would be to examine their relationship with innovation and the Engineering Design Process (EDP). Both fields involve problem solving, systems thinking, and creativity (Qureshi, 2022; Auener et al., 2022). According to Bemiss (2021), innovation is the ability to adapt an idea through creativity so that it solves a problem and creates value for others. Innovation cannot occur without creativity, whereas creativity can be exercised without necessarily leading to innovation. Creativity enables individuals to use their existing knowledge to see new connections and generate ideas, while innovation builds on these creative ideas by putting them into action, bringing them into the world, and solving problems (Tøttrup, 2023; Designovations Knowledge Articles, 2023; Bemiss, 2021). Bemiss (2021) further argues that innovation should be experienced from early childhood, as children then develop innovative mental schemas that they will draw upon throughout their lives. This is illustrated as follows:

Figure 6. **The figure illustrates the combination of creativity and biomimetic work.**

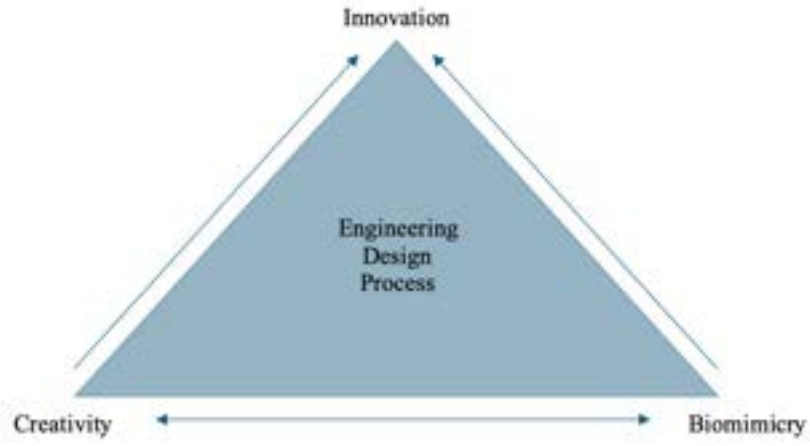


Figure 6 is based on Figure 5, with engineering added as an inner layer of the triangle, functioning as a working method that connects creativity, biomimetics, and innovation.

ESERA 2025 Copenhagen

"Antena Cultural": Podcast As An Educational Tool For Scientific Dissemination Of Amazonian Insect Biodiversity

Letícia Chini de Castro, Marcelo Tadeu Motokane and Dalton de Souza Amorim
University of São Paulo, Brazil

Brazil is the country with the greatest diversity of insects, and much of it is still unknown. Therefore, biodiversity research is important, including for its conservation. One of the projects related to this objective is BioInsecta, which attempts to understand the patterns of vertical distribution of insect biodiversity in the Central Amazon rainforest. In other words, it tries to understand the distribution of the various guilds of insects at different heights in the forest. The project also impacts education beyond science. People's distance from nature has generated a negative perception of insects that must be combated through adequate scientific education. This education must also be culturally contextualized since insects are part of the history and identity of many ethnic groups. Besides, people are rarely sensitized only through science - the favorable feeling comes from this cultural representation. Deconstructing the negative image of these animals must be done inside and outside the classroom, which is why knowledge must be available on digital media and schools must take advantage of these technological tools. In an attempt to reconstruct knowledge about the biodiversity of insects in the Amazon within this cultural context, the Antena Cultural podcast arose as part of the BioInsecta project to connect science and culture educationally. This article describes the creation of the podcast, its central concept, its structure, its products, and its potential for education, while also explaining the next steps of the project.

Keywords: Insect biodiversity, science education, podcast.

Introduction

Insects are part of the largest and most diverse terrestrial multicellular organisms' group on the planet (Lewinsohn *et al*., 2012, p. 1) and Brazil has the highest insect diversity (Rafael *et al*., 2009). Furthermore, the number of existing species is much greater than the species already known, giving great importance to research projects on this biodiversity — and its conservation. One of the projects related to this objective is BioInsecta (https://bioinsecta.org/), which attempts to understand the patterns of vertical distribution of insect biodiversity in the Central Amazon rainforest. In other words, what is the distribution of the various guilds of insects at different heights in the forest: some species live exclusively on the ground, others only in the canopy, and others move at different heights.

This project also impacts education. Rapid urbanization has distanced people from natural environments (Silva & Sammarco, 2015), generating a largely negative perception of insects (Albuquerque *et al*., 2022). This perception, reinforced by the media, common knowledge and even at school, must be restructured through adequate science education (Trindade *et al*., 2012) and culturally contextualized. Although scientific knowledge is fundamental, it hardly generates sensitivity in people towards nature (Fernandes-Pinto, 2017). Insects in different cultures represent part of their history and identity. Education, which also plays a role in conservation through the development of new behaviors towards the world, must incorporate and value this rich part of the culture as much as it exalts textbooks.

Thus, deconstructing prejudices against insects is an essential role of schools, but it is not limited to them. Likewise, schools must use other available tools to make teaching more dynamic. In an attempt to reconstruct knowledge about the biodiversity of insects in the Amazon within this

cultural context, the Antena Cultural podcast (https://open.spotify.com/show/5uTbwtehzLac2YPWCzosuy?si=caa8ab8c604e428f) arose as part of the BioInsecta project to connect science and culture educationally. This article describes the creation of the podcast, its central concept, its structure, its products so far, and its potential for education, while also explaining the next steps of the project.

Methodology

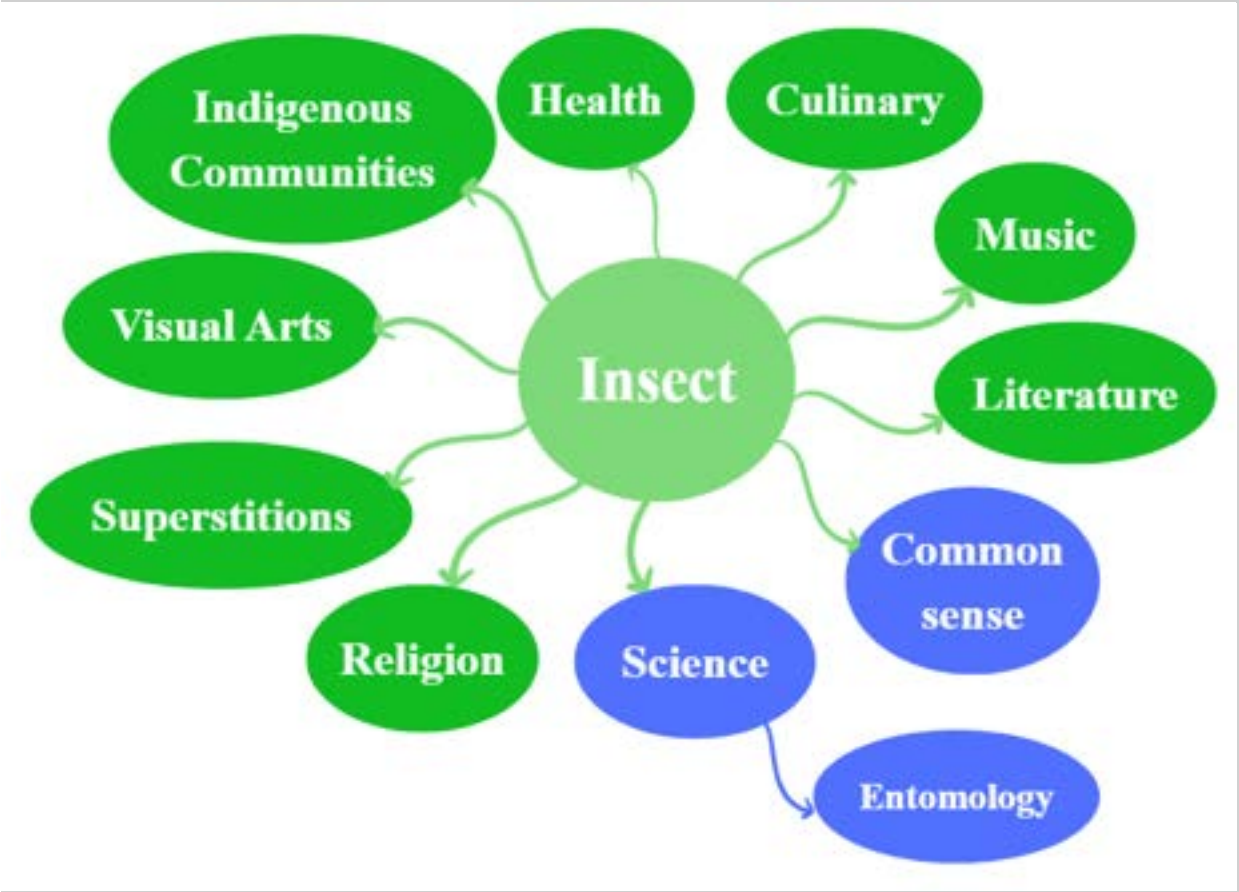
The Antena Cultural concept emerged over six months of weekly meetings and fieldwork during the second half of 2024. Once defined the project's goal (to disclose the scientific advances of BioInsecta and transform the generally negative view that people have of insects), it was necessary to choose the media format, the target audience and the structure of the episodes.

Through fieldwork (interviews with residents of Manaus and Ribeirão Preto) and bibliographical research on the general perceptions of insects, it became clear that, for the project to achieve its objective, it should adopt a flexible, dynamic vehicle of communication with a good audience reach, a relaxed but scientifically accurate language, and a narrative that allowed people to identify with the topics addressed. Podcasts have been seen as a media capable of reaching different audiences, initiating new trends and helping to democratize information (Games, 2021). Not surprisingly, the production and consumption of podcasts have increased, including in Brazil (Games, 2021). Thereupon, it was the chosen vehicle.

Parallelly, the target audience chosen was young adults. The podcast presenters were undergraduate students of Biology and fit into this age group. The podcast, which follows a casual conversational tone, with the students sharing their experiences, adopts the same language used in everyday life. Considering the public, a strictly scientific appeal in the narrative couldn't generate the expected engagement. The theme had to be introduced through emotions and knowledge that could be recognized by the audience. Fear, apprehension or disgust, but sometimes also amazement, admiration and affection, are common feelings for people towards insects, so the narratives should start from this point.

Regarding science, based on people's perceptions, the insects to be covered in the episodes should be contextualized from the point of view of an expert to avoid misunderstandings and the dissemination of distorted information. At the same time, the explanations should not be too complex for the lay public to understand: the expert should communicate effectively. Before being studied by science, insects were already part of the beliefs and history of various ethnic groups. These animals were part of their cuisine, medicine, art, literature, cosmogonies and superstitions. Therefore, the idea was to also bring back these representations, showing that negative feelings towards insects have not always predominated or do not apply to all groups and that these animals also have historical and cultural value. It would allow listeners to come across another logic of the world, reflect on their perceptions and feel more empathy towards this gigantic and diverse group of animals.

Considering all these aspects, it was decided that, once the theme of the episode was chosen, the scripts for the episodes would follow three main lines:



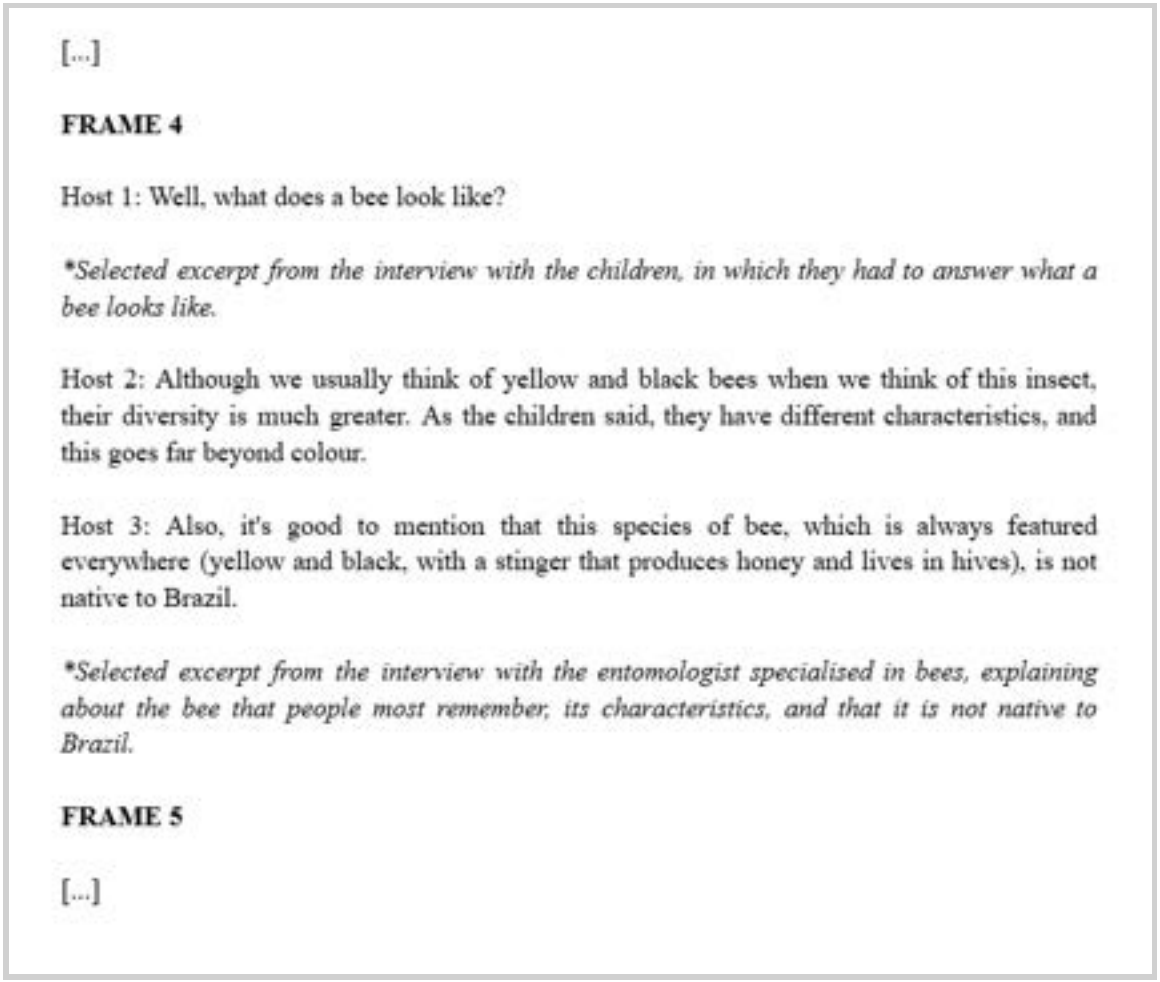
1. Common sense: we would identify how much people know about the insect chosen for each episode, and their feelings and memories towards the animal. The episodes could bring statements from ordinary people obtained through interviews conducted in Ribeirão Preto, Manaus or through some other means of communication;
2. Explanation from an expert: an entomologist, a specialist in the chosen insect, would be invited to provide a brief definition of what the insect is like, its most common

characteristics, and interesting facts related to the animal (according to the episode's theme);

3. Addressing culture: insects would also be remembered as part of the culture through discussions about how important it is for an ethnic group, its relevance to art, cuisine, superstitions or religion, for example. Furthermore, a social issue could be addressed together, such as prejudice towards Brazilian Indigenous culture or gender matters.

For the creation of the episodes, we first defined the theme, conducted all the interviews, analysed them, and then wrote the final script, selecting which parts of each interview would be included in the final audio. The scripts were divided into frames, and each segment featured dialogue from the presenters and interviews with guests (insect experts, artists, the general public, etc.). The script outline, therefore, would be:

Figure 1. Antena Cultural script outline. First, the episode's theme (or insect) is defined, which will be explored from a scientific perspective alongside common sense, and then some sub-themes from the cultural axis are chosen for discussion.



After this phase, the hosts would record the narration, insert the interviews and edit the episodes using tools such as the Audacity program.

Results

The creation of this podcast resulted in 7 episodes so far, and they started to be published in June, 2025. Some episodes aimed to discuss the BioInsecta project specifically, its research members, and introduce Antena Cultural as its scientific outreach hub. Others developed from the choice of a well-known insect. Two episodes chose to focus on important dates in Brazil, such as Children's Day and Christmas.

Figure 2. A part of the script of the fifth episode translated as an example of how it looked. Each episode would follow this structure: 1) define the theme and the subtopics, 2) collect interviews, 3) analyse the interviews, 4) write the final script, always alternating between the hosts' speeches and those of the interviewees in each frame.

[...]

FRAME 4

Host 1: Well, what does a bee look like?

**Selected excerpt from the interview with the children, in which they had to answer what a bee looks like.*

Host 2: Although we usually think of yellow and black bees when we think of this insect, their diversity is much greater. As the children said, they have different characteristics, and this goes far beyond colour.

Host 3: Also, it's good to mention that this species of bee, which is always featured everywhere (yellow and black, with a stinger that produces honey and lives in hives), is not native to Brazil.

**Selected excerpt from the interview with the entomologist specialised in bees, explaining about the bee that people most remember, its characteristics, and that it is not native to Brazil.*

FRAME 5

[...]

Table 1. Antena Cultural released episodes and their respective themes. The titles of the episodes are translated, as the episodes are written and recorded in Portuguese.

Episodes titles	Theme of the episode
Episode 1: Amazon	The first episode was introductory, without focusing on a specific insect. The interviews with the audience showed some Manaus residents' perceptions of insects. The scientists interviewed talked about the project itself and their motivations for enjoying working with science. The last interviewee was an Indigenous nutritionist from the Sateré-Mawé ethnic group, who spoke about the importance that the leaf-cutter ant has for her culture, for example, and about the prejudice of outsiders towards her community's diet.
Episode 2: Ants	The second episode was about ants. The interviewees shared their perception of ants as pests and admiration for their social behavior. The specialist explained what ants are, what differentiates them from other insects, the variety of existing species, and their ecological role. In the last segment, an anthropologist from the Sateré-Mawé ethnic group spoke about eating ants as a social practice and their importance as a symbol of the transition to adulthood. The episode ended with the

	interviewee from episode 1 commenting on the proven nutritional value of leaf-cutter ants according to science.
Episode 3: Butterflies	The third episode begins with the narrative of Iansã, a warrior deity of Candomblé and Umbanda, who can transform into a butterfly. Through this narrative, our own capacity for transformation throughout life was discussed, how changes require patience and reflection, and how we should allow ourselves to feel emotions deeply to become more mature. A parallel was drawn with the metamorphosis of butterflies. An entomologist specialist in these insects explained what butterflies are like, how they change from an egg to a butterfly, why they are so colorful, and their function as pollinators and environmental indicators.
Episode 4: Bioinsecta	The fourth episode is specifically dedicated to better explaining Bioinsecta. It begins with a conversation about the importance of curiosity in biology and develops to discuss what Bioinsecta proposes, its hypotheses, the methodologies used, and how fieldwork and laboratory work are conducted. All interviewees were scientists who are part of the project. Furthermore, the episode also discusses the importance of people and their life experiences in the construction of science, and that practicing it also requires a great deal of love for what is studied.
Episode 5: Bees	The fifth episode was a tribute to Children's Day and included interviews conducted with children at a daycare center located within the University of São Paulo, called Creche Carochinha (https://www.instagram.com/creche_carochinhausp.rp/). The presenters began by sharing stories from their childhoods, what they liked to play with, and introduced the scientists, who commented on what bees are, their colors, their life habits, their evolutionary process, and their ability to play. They explained that there are studies about the ability of these insects to play for pleasure, that bees are quite intelligent and that their play helps in their development. From this, the presenters make a connection to the importance of play for child development, the history of early childhood education in Brazil, and extend an invitation for people, even adults, to engage in play.
Episode 6: Women in Science	The sixth episode was made to honor Brazilian women scientists. It explored the stories of important Brazilian scientists, especially in the field of biology. Interviews were conducted with entomologists who opened up about their stories, their careers, the difficulties of entering and remaining as researchers, the reasons that led them to become scientists, and their future perspectives.
Episode 7: Katydid	The theme of the last episode was hope (in Brazil, katydids are known as "esperança," which means hope in Portuguese). The purpose was to create something inspiring, considering the end-of-year holidays (like Christmas), and at the same time informative, playing with the double meaning of the term "esperança." The episode featured

interviews with people who explained what hope meant to them, what they expect from the future, and why they think the insect is also called "esperança". The researcher interviewed explained about this group of insects, their most common characteristics, and where the name came from.

Discussion And Conclusion

Insects are essential ecologically and economically (Trindade *et al*., 2012) and are part of the culture of many people. Records show a historically peaceful and beneficial coexistence with these animals (Albuquerque *et al*., 2022, p. 119) and they are known in literature, language and music, visual arts, cinema, theatre, cuisine, medicine, religion and recreational processes in different societies — past and contemporary (Costa-Neto, 2002 as cited in Trindade *et al*., 2012, p. 38). There is a long list of reasons for an effort to conserve the enormous biodiversity of insects. Combining science and culture is an effective path.

Raising awareness of the importance of conservation through education is particularly powerful. To overcome prejudice against insects the approach must move away from practices essentially centred on classifications and memorization of scientific terms - a reductionist, fragmented and inefficient view (Amorim *et al*., 1999 as cited in Trindade *et al*., 2012, p. 39). “To be effective, the learning process must, first and foremost, start from an awareness of the times in which we live” (Santos, 2008, as cited in Santos & Santos, 2015, p. 308), so education must take advantage of the technologies used in everyday life. Besides, people seek information in digital media, so they also need to be there! Jesus (2014) says:

> “Education is immersed in culture and not only linked to science, which in modern times were considered the only valid sources of training and capable of offering technologies. It uses processes that construct public and shared meanings, which mediate its way of being in the environment. As this is constantly changing, the Podcast presents educational possibilities and challenges that deserve the attention of educators and researchers” (Jesus, 2014, p. 10).

Podcasts use many journalism techniques and demand research, synthesis and storytelling skills. Furthermore, the structure followed by Antena Cultural is similar to processes described by both Saviani and Vygotsky: both are concerned with not discarding the student's knowledge but rather preparing a class whose objective and methodology resemble the reality of children (Pereira *et al*., 2022). The interviews with the audience in the podcast are precisely the social practice described by Saviani (obtaining prior knowledge from the audience). Each episode ending corresponds to the final social practice (in which the agents involved transform themselves in the learning process) (Pereira *et al*., 2022).

The episodes are rich in science and culture and given their format, they can bring information to a diverse audience, including a class of students (although the target audience is young adults, the episodes can be easily understood by other age groups). Antena Cultural shows how science projects such as BioInsecta can escape the risks of generating decontextualized, boring and dissociated information from culture when sharing their results. The podcast has the potential to be an effective teaching tool; therefore, the objective of this work was to demonstrate its structure and the results of its creation. Considering its recent launch and the context in which it was created (by undergraduate students during a scientific initiation project linked to Bioinsecta), the next steps of the research will be to analyse the podcast's metrics on the platforms where it is available and to use it as teaching material in the classroom (in an inquiry didactic sequence, for example).

Acknowledgement

We thank the University of São Paulo, the Biology Teaching Laboratory and the Laboratory of Morphology and Evolution of Diptera for their support in building the knowledge necessary for this work. We extend our gratitude to BioDossel, Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP), Fundação de Estudos Agrários Luiz de Queiroz (FEALQ), Instituto Nacional de Pesquisas da Amazônia (INPA), Fundação Roberto Marinho, Coordenação de Aperfeiçoamento de Pessoa de Nível Superior (CAPES) and the XPRIZE Foundation. Finally, we thank ESERA for the opportunity to participate in the 2025 Conference and everyone who supported our work in countless ways.

Imagination, creativity, and emotions are essential in science work and have shaped the history and evolution of science. At the same time, they also play a vital role in engaging with, teaching, and learning science. Nevertheless, science is stereotypically still regarded as an objective set of facts and laws, continuing to highlight the divide of the mind over the body and the self. The way science is commonly presented and taught remains fragmented along disciplinary lines and decontextualized from feelings, identities, and imagination. In contrast, the arts embrace emotions and cultures in fictional and non-fictional contexts. Hence, bringing the arts into science education provides an opportunity to create innovative and engaging learning spaces and places. This symposium examines how the art forms of storying, story-(writing, telling, and performing) can be used to provide missing aspects in science education. We investigate how the creation of stories can facilitate the expression and negotiation of meanings and possible selves through fiction and non-fiction worlds. Different modes and story genres are taken into consideration, attending to stories composed in interaction with places, folklore cultures, bodies, and artefacts. The studies shared also offer guidance in developing innovative approaches to science education that make effective use of storying for communicating and negotiating meanings, emotions, and selves.

Keywords: multimodal learning; cultural diversity; equity in education

Introduction

Science is commonly perceived and taught as an objective set of facts and laws, whereas logical and paradigmatic thinking relies on data-driven correlational thinking (Bruner, 1986). On the contrary, the role of imagination and creativity in science has not received enough attention or has even been ignored, regardless of their integral role in the Nature of Science (Hadzigeorgiou, 2016). Moreover, science instruction has mostly followed the divide of the mind from the body, hence connecting knowledge construction to the mind, which appears divorced from the body, the self, and the emotions (Varelas et al., 2022). In response to the need for more informed and holistic representations of science in schools, several researchers have advocated the inclusion of the Arts in science/STEM education. The Arts can provide spaces and places for multimodal representations of ideas, can offer opportunities to share and reflect, and can support choice-making through playful ways (Varelas et al., 2022).

This symposium focuses on the various art forms of storying, such as story-(writing, telling, and performing). We define stories as narrative structures where characters interact in spacetimes with other characters/events/scenes, while the present played out in these interactions is informed

from the past, and influences what may happen in the future. Particularly, the above conceptualization of stories draws upon the use of Bakhtin's notion of chronotopes, i.e. the temporal and spatial relationships, which have been used to examine students' understandings of science and science identities through the analysis of their narratives (Varelas et al., 2012). Not only storying can help researchers gain deep insights about the participants' understandings and identities in science, but it can also help participants make sense of their own teaching and learning as well as their own selves and positionings (Chappell, 2024; Varelas et al., 2022). Furthermore, stories, both in fictional and non-fictional forms, are an effective way to understand the world and communicate understandings (Bruner, 1986) in a more approachable, sustainable, and epideictic manner (Avraamidou & Osborn, 2009).

Considering the above, the three studies included in this symposium aim to explore both theoretically and empirically the potential of storying in science education in a variety of forms and contexts. First, one study examines the use of storying in non-fiction contexts, such as the real-world problem of climate change that challenges our society and our survival, by calling upon teachers to story their understandings, critical views, and experiences. On the other hand, a pair of studies examines storying in fiction worlds, through the analysis of science fiction stories and imaginary fairytales to examine teachers' and instructional designers' use of metaphorical representations in science, sociopolitical inequities in science, and reimagined notions of the future, freed from the confines of reality. Second, the symposium papers investigate storying in diverse contexts: school students, pre-service teachers, and teacher education designers. Hence, the implementation of storying within these distinct communities aims to highlight nuances regarding their applicability and dynamics in each target group.

Third, this symposium examines the use of storying through multimodal ways, including the use of developed textual and/or visual artefacts, folklore cultural assets, and ethnical identities. Particularly, the first study developed a theoretical narrative-based framework to analyse narrative artefacts used in climate change education, as well as to analyse the narratives that school students create while reflecting on the uncertainty involved in climate change from an epistemological point of view. The second study examined the use of fictional storying i.e. fairytales for integrating early childhood curriculum content and teaching strategies such as inquiry-based learning by pre-service preschool teachers. Finally, the third study aimed to critically read and analyse existing Afrofuturistic fiction stories to identify existing normative structures in them, reflect on them, and propose informed and inclusive learning environments for teacher education designers.

An Operative Tool To Unpack The Complexity Of Narratives And Narrative Thinking For Climate Change Education

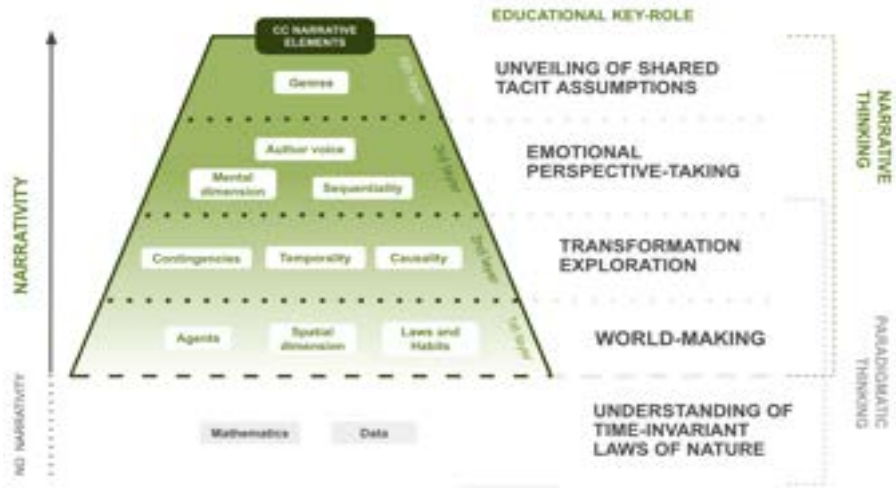
Introduction

In recent years, an increasing number of scholars has shifted attention from narratives as rhetorical or engagement devices to narratives as core cognitive structures that shape how humans understand the world and guide their action (Bruner, 1986; Norris et al., 2005; Fletcher, 2023; Soares et al., 2023). From this perspective, narratives constitute a distinct mode of thought: alongside paradigmatic thinking—characterized by abstraction, generalization, and logical-mathematical reasoning—narrative thinking organizes meaning around action, temporality, and contingency.

Although historically associated with different domains of knowledge, these two modes are not mutually exclusive. Several scientific disciplines operate at their intersection, combining law-like explanations with historically contingent processes. Natural history offers a clear example: as

Gould (2002) argued, narrative explanations are indispensable when outcomes depend on specific sequences of events and initial conditions. In such cases, explanation cannot be reduced to invariant laws alone, but must account for how things could have unfolded differently.

In Climate science, while some scientific practices aim to reduce uncertainty through prediction, climate-related questions often involve irreducible uncertainty, long temporal scales, and complex interactions between physical and social systems. In response, climate science has increasingly adopted narrative approaches—such as storylines and scenarios—to explore uncertainty, risk, and decision-relevant futures (Shepherd et al., 2019; 2021).



Within Climate Change Education (CCE), pairing paradigmatic with narrative thinking could offer a unique avenue for learners to grapple with Climate Change (CC) complexities and uncertainties by moving the focus from prediction to decision-making (Shepherd et al., 2021), making ethical and value-laden dimensions of climate action explicit while maintaining scientific rigor. This study starts the investigation of this issue from the following research question:

RQ) *How can we develop an operational definition of narratives for Climate Change Education purposes that is capable of unpacking narrative complexity as a mode of thought?*

Theoretical Framework and Methodological Approach

Despite their recognized relevance, narratives remain inconsistently defined across disciplines. Educational and communicative frameworks adopt definitions that range from overly broad ones—almost conflating narratives with general beliefs or perspectives—to narrow criteria that exclude scientific narrative artefacts such as scenarios and models (Bruner, 1986; Costantino & Weber, 2021). This study builds on Ryan's concept of narrativity (2005), which distinguishes between "being a narrative" and "possessing narrativity." While the former refers to artefacts explicitly designed as stories, the latter includes any artefact that enables narrative sensemaking, regardless of authorial intent. This distinction is crucial for climate education, where many epistemically relevant artefacts are not stories in a literary sense but nonetheless support narrative reasoning.

Figure 1. CC narrativity pyramid tool for CCE. This figure illustrates the multi-layered tool to analyse the relevance of CC narratives for CCE through the concept of narrativity.

Integrating Ryan's concept with Bruner's dual-mode theory, the study proposes a four-layer narrativity tool that conceptualizes narrative and paradigmatic thinking as a layered spectrum and categorizes climate-related artefacts based on the cognitive practices they afford, rather than on their medium or genre. Methodologically, this study is theoretical and conceptual. Drawing on interdisciplinary literature, it constructs and illustrates the framework called "Narrativity

Pyramid", shown in Figure 1 (D'Orto & Tasquier, 2025).

At the base of the framework are non-narrative, strictly paradigmatic artefacts, such as equations, datasets, and isolated data visualizations. These artefacts privilege abstraction and invariance and are essential for scientific reasoning, yet they offer limited support for temporal or causal sensemaking. The first layer of narrativity introduces world-making processes (Cheng, 2018), where artefacts describe spatial, systemic, or rule-based conditions governing a given reality. Examples include maps, setting descriptions, models, and representations of physical or social law systems in real case scenarios. This layer helps students in contextualizing knowledge. The second narrativity layer incorporates temporality and causality, depicting sequences of events that introduce contingency and the possibility of change. This layer includes chronicles, timelines but also scientific storytelling approaches used in climate science, such as storylines and Shared Socioeconomic Pathways (O'Neill et al., 2017), which support reasoning about alternative futures while remaining grounded in scientific plausibility. The third layer foregrounds subjective experience by introducing perspectives, intentions, and emotional dimensions. Artefacts at this level invite learners to engage with ethical questions and lived experiences, fostering empathy and reflective judgment. The fourth and last layer of narrativity concerns genre conventions, which shape how narratives are structured and interpreted within cultural contexts. Genres like "Climate fiction" and "Solarpunk" exemplify this layer, where narrative forms encode assumptions, values, and visions of social transformation (Ghosh, 2016).

Discussion

The proposed narrativity framework offers a structured approach to integrating narratives into CCE without reducing them to engagement tools. By positioning artefacts along a spectrum of paradigmatic and narrative thinking, the tool's goal is to support educators in selecting and designing materials (or just putting the focus on aspects of them) that are aligned with specific cognitive focus and educational goals. This perspective reframes narratives as cognitive artefacts that foster particular ways of reasoning, rather than as stylistic additions to scientific content.

The key strength of the framework lies in its capacity to balance analytical rigor and meaning-making: while CCE often oscillates between data-driven approaches that risk disengagement and narrative approaches that risk oversimplification, the narrativity pyramid provides a way to integrate these dimensions, ensuring that narratives remain epistemically grounded while supporting agency, ethical reflection, and future-oriented thinking. Its transmedial scope further acknowledges that narrative sensemaking can emerge across diverse formats, from scientific scenarios to literary and visual media.

While this study lays a theoretical foundation, other research has already examined the framework's application in educational settings and its impact on learning outcomes, thereby contributing to a broader understanding of how narrative and paradigmatic modes of thought can be balanced in CCE (D'Orto, 2026).

Inquiry Fairytales: Pre-Service Teachers Integrating Science And Scientific Inquiry In Fairytale-Like Stories For Science Teaching

Introduction

This study focuses on imaginary fairytales as an appropriate and common form of stories for children. Fairytales are defined as "narratives that contain improbable events, scenes, and characters and that often convey a whimsical, satirical, or moralistic theme" (Bayton, 1996). According to Propp (1968), fairytales follow a common structure depicted in a limited list of 31 narrative functions. For example, the plot includes functions such as the hero/ine's absentation, trickery from a villain, hero/ine's struggle, punishment and/or marriage, etc.

The dynamics of fairytales rely upon what Vygotsky called dialectical "relations between fantasy and concrete situations", combining fictional characters, situations, and stories with real-world phenomena (Fleer, 2015). The non-realistic nature of the characters and events allows students to freely cognitively and emotionally connect with them and debate their decisions, either justifying, rejecting, or sympathising with them (Massi & Benvenuto, 2001). However, one of the biggest shortcomings is that stories are mostly implemented through a teacher-led narration with little or no interaction from the students, which we could infer reflects rather traditional pedagogies. Contrastingly, this study proposes incorporating along the story stages of inquiry such as prompting students to make predictions, collect and analyse data, and draw inferences which would significantly affect the evolution of the story and assist the story characters in acting and making decisions. We call this participatory form of stories 'inquiry fairytales', and we hypothesise that this form can benefit and engage students in story-based approaches to science in a similar way that inquiry-based teaching does in traditional science teaching. Another challenge is that fairytales traditionally reflect cultural norms and values which are often criticised as stereotypical and non-inclusive. However, fairytales are remakes of folklore stories that keep coming up generation after generation in an endless loop. Hence, retelling fairytales in new forms has become a recent trend that has the potential to bring inclusive and diverse stories for underrepresented people (Goldman, 2023).

Considering the above, a thorough examination is needed of how appropriate and participatory fairytales can be developed by pre-service teachers. Specifically, inspecting the ways that teachers integrate science and scientific inquiry into the story and the story patterns that they tend to develop would yield insights regarding the dynamics of fairytales for science teaching.

Hence, the research questions are:

RQ1) How do pre-service teachers compose stories in the form of inquiry fairytales for science teaching?

1.1) In which narrative functions do they integrate science, and in what ways?

1.2) To what extent do they integrate stages of inquiry-based teaching, and in what ways?

Methodology

The study was carried out in the context of an undergraduate science education course at the Preschool Education department of the University of Crete. Following six weeks of theoretical lectures including inquiry-based teaching, the participants were called upon to design lesson plans and worksheets on a science topic of their choice. In the ninth week, they were introduced to using story writing for science teaching, including small-group story-writing training activities. Subsequently, each participant was called upon to develop an inquiry fairytale regarding the science topic they had previously chosen, as an optional homework essay. Data collection includes a) teachers' fairytales (n=28), and b) lesson plans and worksheets (n=21). The fairytales were qualitatively analysed concerning a) the stages of inquiry-based teaching that they implemented, b) the narrative functions (Propp, 1968) that they implemented, and c) a qualitative comparison of science topic aspects integrated into the fairytale in comparison to the lesson plans.

Findings

Science Integration In Narrative Functions

The preparatory part was mostly made through *absentation* (n=9 fairytales), *interdiction* (n=7), and *violation* of the interdiction (n=10). Science was not extensively integrated into this part apart from introducing some personifications of natural elements (e.g. droplet, cloud, ice cube) as story characters. Contrastingly, science phenomena were commonly integrated into the story through

the functions of *villainy* or *lack* (n=21). Particularly, instead of using a personified villain, teachers tended to integrate a natural phenomenon or disaster as *villainy/lack* to complicate the plot. Indicative examples are as follows: *He was looking for him [ice-cream] everywhere, and after a long search he finally found his friend who was very sick and had almost melted [T9]. Flames engulfed the kitchen curtain. The fire followed the oil spilt on the floor and reached the exit door, so there was no way out of the house [T7].*

Science was also commonly integrated in the *mediation/connective incident* (n=22). Specifically, this function was frequently actualised by the main character being called, asking help from a character's friend/parent, or seeking advice from an 'expert', who was commonly embodied through a wise owl or the hero/ine's mother. *They decided to visit the Great Tree, where the wise owl was living. She used to know everything concerning atmospheric pressure and weather cycles [T5].* Testing the character through a *struggle/fight* (n=6), *marking the hero/ine* (n=1), *difficult task* (n=5) and its *solution* (n=4) appeared as forms of the climax of the plot in which science came into play. *The Darkie asked his own subjects if they liked living in a state that always has night. All of them answered that they were bored having rest […] She [Earth] decided to spin around herself every 24h while also circling the Sun [T16].* Notably, the functions of an actual fight appeared limited and in milder forms, such as a debate between characters or a reproof. *Lily: Stop, Ben! You don't know how much harm you cause to all of us by cutting the forest trees. [T23]*

Science phenomena were also integrated through the *provision of a magical agent* (n=9), e.g. by obtaining an experimental object (e.g. rock, mirror) to be used for rescue or the evolution of the story. *While they were searching to find something that looked like a boat, suddenly, Vasiliki found a big log [T3].* At the end of the story, almost all stories had a *liquidation* of the misfortune or lack (n=24), while *marriage* appeared limited (n=2), and *punishment* of the villain was absent.

Stages Of Inquiry

A considerable number of teachers (n=13) did not implement any interactive part in their story. Nine teachers implemented inquiry questions through dialogue/questions among the plot characters, without directly engaging the students, which was coded as an implicit way of inquiry. For example, *Katia's mother asked girls "so why did the rock sink and the log floated?" The girls started saying several ideas (T3).* The most common inquiry stage explicitly implemented was the expression of ideas (n=7). *What do you think, kids? How do you say a rainbow is formed?[…]Exactly my long-reigning caliph! The colours are hidden in the white-coloured light! (T15).* Setting up the initial question/problem appeared limited (n=1), and so did the obtaining of conclusions (n=2). Building a model was used in one case by assigning kids to dramatize the motion of the Earth/Moon. Additionally, in three cases, some interaction was implemented, but not related to inquiry, e.g. making a decision about the evolution of the plot, or personal questions.

Discussion

The findings showcase how several narrative functions of fairytales provide opportunities for integrating science instruction. The pre-service teachers extensively used natural phenomena, disasters, or real-world problems to complicate the plot, hence introducing science in an integrated and meaningful way in the story. This supports the literature recommending that non-human 'things' or events can also have agency in science-related stories (Avraamidou & Osborn, 2009). Moreover, fairytales provided space for assisting agents (e.g. a wise owl or a parent) to intervene and provide science instruction in a non-traditional and playful way. Furthermore, findings demonstrate how teachers declined from traditional fairytale patterns by limiting the use of personified villains, wild fights, and romantic themes/marriages, hence educationally appropriating fairytale themes to align with the educational context of preschool children. However, the implementation of stages of inquiry-based teaching appeared limited, and mostly

restricted in expressing ideas. It seems that gathering evidence to make inferences that could affect the plot is demanding; hence, additional guidance and/or scaffolding should be used to transition to more inquiry-based forms of stories. Overall, the findings of this study advocate the affordances of using inquiry-based fairytale-like stories for science teaching.

Pluriversal Emergences: Reading And Living Fractal Possibilities In/Through Afrofuturist Science Fiction

Introduction

We share initial findings from a critical creative inquiry with theoretical, methodological and empirical implications for science education and research. We seek to understand: *how might a collective exploration of Afrofuturist science fiction stories impact our work as a research lab to better support faculty and students in STEMM, in our respective careers, and lives?*

Embracing the era of transition and transformation in science education, The Creativity, Equity and Justice in STEMM (Science, Technology, Engineering, Mathematics, and Medicine/health sciences) research lab, conducts theoretical and pedagogical research, and provides an affinity for Black students at a university in Western Canadian. In Emergent Strategy: Shaping Change, Changing Worlds, brown (2017) describes a mode for working towards just worlds while embracing just practices despite unjust systems for working. Often in academia, what is deemed to be valuable and powerful, such as journal rankings and tenure, does not uphold the values many of us live by, including human dignity and respect (Strong et al., 2016). Aiming to re-imagine existing structures will open up a plurality of space for new, and previously denied ways of being and knowing in STEMM, inclusive of diverse bodyminds (Schalk, 2018) and sociocultural paradigms. brown (2017) laid out six elements to embrace to both unsettle the norms of our workplaces and still thrive professionally and personally: fractal awareness, intentional adaptation, interdependence and decentralization, nonlinear and iterative, resilience and transformative justice, and creating more possibilities.

Theoretical Framework: Afrofuturism And Science Fiction In STEMM

Walidah Imarisha (2015) describes science fiction as "visionary fiction encompass[ing] all of the fantastic, with the arc always bending toward justice" (p. 4). Scholars have theorized how speculative and science fiction, both the reading and creation of, can subvert historical realities and foster revisioning of the normative structures in which we live (Nxumalo & ross, 2019).

Afrofuturism has been uplifted by scholars in STEM education as an innovative, liberatory theoretical approach for Black futurity (Morton et al., 2023). Using “collectivist strategies”, exploratory work with undergraduate Black biology faculty and students, Morton et al. (2023) applied Womack’s (2013) theorization of Afrofuturism, specifically: “1) understanding the multiple truths of the past to ensure a promising, Afrocentric future, 2) an unapologetic centring of and focus on Black culture, Black creativity, Black capabilities, and Black possibilities, and 3) engaging science/speculative fiction, creativity, STEM innovation, and futuristic possibilities within a context that is Black centric” (as cited, p. 9).

Methodology

Engaging through the lens of critical social science theories challenges the conventional norms of who and what is valued in STEMM fields (Strong et al., 2016). Such an approach welcomes imagination for (re)configurations of STEMM and society by infusing radical creativity with critical theory (Bray & Harrington, 2021) to a pluriverse with many co-existing worlds (Leitão, 2022). These methodologies empower participants to identify systems of oppression while collaboratively imagining and constructing new, liberatory frameworks. We shift towards desire-

based frameworks that prioritize community aspirations and collective agency, allowing for transformative possibilities beyond band-aid solutions (Leitão, 2022). Desire is reframed as a destigmatized and generative force, representing the creative impulse and capacity for change. By methodologically framing our critical creative inquiry (Adams, 2018) through our collective desires and desires of Black students, we embrace research activities, like the reading and claiming of science fiction as scholarly work legitimate, and to satiate our desires.

We collectively make methodological decisions around what will become constituted as 'data' in this research, specifically identifying and documenting via fieldnotes and video transcripts of eventful conversations in our meetings which ‘feels like something’ (Stewart, 2020, p. 3). Eventful conversations, as understood here, do not reveal instrumental plans but “rather the possibility of alternative futures, the failures of representations, the contingencies of interventions and the effervescence with which things actually take place” (Vannini, 2015, p. 7). By focusing on data from these eventful conversations, we can learn from reading and discussion to reveal old and new potentialities for collective being, doing and thinking.

Readings with Example Guiding Questions (in sequence)

1. *Introduction in Bodyminds Reimagined: (Dis)ability, Race, and Gender in Black Women's Speculative Fiction* by Sami Schalk (2018)
2. *For I Have Touched the Sky* by Mike Resnick (1989). E.g., How are race, gender, and (dis)ability represented in the story?
3. *The Evening, the Morning and the Night* by Octavia Butler (1991). E.g., How does this reading present medical science, dis/ability, ethics?
4. *Afronauts* written and directed by Nuotama Bodomo (2019).
5. *The Physics of Melanin in The Disordered Cosmos: A Journey into Dark Matter, Spacetime, and Dreams Deferred* by Chanda Prescod-Weinstein (2021).

Findings And Discussion

As brown (2017) was inspired by Octavia Butler, it is unsurprising that we likewise noticed the ways in which Afrofuturist science fiction stories posit nonlinear and iterative strategies. Each week we analysed our experiences of reading to diffract and discern resonant thematic threads across the stories. Themes include:

Leveraging fractal awareness to keep hope alive. Each story sits at the precipice of hope and hopelessness. Ahmed (2013) contends that dominant powers maintain hegemonic relationships via the indoctrination of hopelessness to normalize a sense of changelessness and paralysis of transformative potential. In Resnick’s story, Koriba (the powerful doctor) denies Kamari (a young girl) hope by foretelling the death of a caged bird. Kamari persists to heal the bird in spite of Koriba’s concerns. Solnit (2016) describes hope as an ongoing process of choosing to do something for justice, despite uncertainty. Kamari’s small-scale, hope-filled fractal enactments did not save the bird, yet she still challenged Koriba’s epistemic oppression.

Towards interdependence and decentralization by resisting the young black woman martyr. Central to the stories was a young Black woman martyr (i.e., Matha, Kamari, Lynn). These characters represent resilience, intentional adaptation, moral integrity, curiosity, etc. Take Lynn, who, despite posing harm to herself and others, demonstrated an ironic and powerful resilience when she commits to healing those whose disease causes them to harm. She forfeits a normative independence to embrace a decentralized system that requires interdependence. It goes beyond the utilitarian narrative of for the greater good, as the diseased system she chooses to serve is tabooed. Here lies the creative possibilities for non-linear pluriversal systems (Leitão, 2022).

Forced versus intentional adaptation. Young Black women, in particular, face marginalization

in STEMM (e.g., Strong et al., 2016). In Afronauts, Matha is to be the first person and woman to reach the moon as Zambia enters the space race. As she trains, she becomes an embroiled sacrifice to what an outsider might perceive to be the civilly disobedient intentions of men to colonize space, competing with the colonizer in futility (i.e., the U.S.A, Russia). We see how African nations and peoples, particularly women, are systematically undermined, and how Bodomo uses film to critique how the media stories Black bodies for a colonial audience. Matha's character feels simultaneously coerced and intentional in her sacrifice, suggesting that transformative change can require reconciling things that harm us (in this case, colonization).

By reading Afrofuturist science fiction together we embrace emergent strategies to drive collective and respective professional work in ways that are more human, generative and powerful. We learn from stories' characters how to keep hope alive in the face of injustice (e.g., censoring of equity-language in North America). Through small, fractal moves, we guard against institutionalized hopelessness. Possibilities include heightened attention to daily affirmations both personally and professionally, and group accountability to resist defeatism and despair. Being intentional in our adaptations will mitigate the labour exhaustion, whereby we reject the system working us, and choose to work the system.

Findings will lead to the co-creation of a university course syllabus featuring Afrofuturist speculative fiction through interactive readings and generative dialogues in a salon-style setting. Through a participatory, action-oriented process, learners will be invited not only to make sense of STEMM by describing current issues, but also re-imagine STEMM beyond inequity, seek feedback and iterate, and take action.

With this in mind, we look forward to sharing with researchers and educators how our collective, critical creative inquiry with Afrofuturist science fiction has become a womb of fertile potential and infinite placental transformations, both because of darkness and despite it.

Conclusions

This symposium demonstrates the potential of using storying for science education and provides implications for designing art-based science teacher education settings. Specifically, the aforementioned studies carry out analyses of both existing stories and the stories that participants create in order to explore patterns for a variety of purposes. On the one hand, analysing stories can help researchers examine the integration of content goals, teaching strategies, and epistemological reflections. On the other hand, researchers can gain insights into teachers' emotions and identities, as well as their positionings toward existing social injustices. The findings of the studies showcase the multiple and diverse dynamics of using storying for science teacher preparation and entail implications for curriculum designers in terms of its applicability in several implementation contexts and forms, i.e. both fictional and non-fictional.

The purpose of the exploratory seminar was to explore STEM education activities using conceptual blending by combining the aspects related to embodiment, creativity, and communication needed to produce insightful and lasting learning outcomes. According to the theories of embodied cognition and distributed cognition, cognition is not limited to the manipulation of symbols in an individual's brain. Rather, cognition is anchored in our physical environment, through our perception, manipulatives, and socially dependent on shared culture and communication. Regarding conceptual blending, studies point to the general problem of achieving conceptual stability arguing that material structures act as material anchors for blending. Using examples from empirical research studies in engineering, physics, biology and mathematics education, we first discussed how conceptual blending can be used to design embodied educational experiences. We framed the seminar around the question: How can the conceptual blending theoretical framework be used to model and analyse learning in STEM education, focusing on embodiment, creativity, and communication? After introducing the participants to the theoretical aspects related to conceptual blending, they were asked to work in small groups and apply their own experiences of blending, embodiment, creativity, and communication to phenomena of their choosing. Each group presented results of their activity and a whole group discussion was led by the organizers of the exploratory seminar. Following the conference, we would like to invite all participants to further investigate how conceptual blending can be applied in STEM education.

Keywords: Embodied Cognition, Multimodal Learning, STEM Education

Introduction

Against the background of the focus of Strand 6 of the ESERA 2025 conference on theories and models related to inter/multi/trans-disciplinarity in STEM education, we gave an exploratory seminar on conceptual blending as a theoretical framework in exploring the role of embodiment, creativity, and communication in fostering learning in STEM disciplines.

STEM disciplines are particularly suited to fostering the development of technical and creative skills necessary in an increasingly technological and innovative world. To answer the formidable challenges of globalization and the complexity of life it is necessary to educate on complexity and overcome separations between disciplines (Lensing & Pilous, 2022). But how can we foster learning in this context?

Insightful and sustainable learning is characterized in particular by embodied experiences, problem solving, and multimodal communication (e.g., Clement, 1994; Nathan, 2022; Santos-Trigo, 2024). Embodiment maps sensorial experiences (i.e., audial, tactile, visual, etc.) that ground learners' conceptual understandings on to abstractions (Barsalou, 2008). Problem solving is strictly related to creativity in producing novel features and strategies during solution generation. Multimodal communication is related to expressions of conceptual understandings

depicted and described during reasoning and problem-solving tasks (Grondin et al., 2022).

Lakoff (1987) and Johnson (1987) have been part of developing the field of embodied cognition. They contend that our cognition and language are rooted in embodied experiences, which form fundamental conceptual structures known as image schemas. For instance, through physical interaction with our environment, we develop a container image schema, a foundational structure that allows us to conceptualize objects as being inside or outside a bounded space. This schema can be expressed linguistically using metaphors, as in the sentence, "John is in the kitchen". Lakoff and Núñez (2000) have demonstrated that even mathematics – one of the most abstract areas of human thought – is grounded in embodied experiences; for example, the concept of an equation is built upon a shared balancing image schema. Image schemas are grounded in fundamental experiences but may not be (consciously) formed in the moment of creative problem solving. While image schemas provide grounding, creative problem solving often requires reconfiguring and integrating multiple sources of knowledge in context. This means that something other than experience is needed to produce authentic problem solving that implies the emergence of novel features. Indeed, each authentic problem-solving activity requires a certain kind of novel strategy. This leads us to the importance of creativity in problem solving.

Creativity and communication are key competencies of the 21st century (Ananiadou & Claro, 2009; Pellegrino & Hilton, 2012), necessary to face the exponential growth of innovation in all areas of life associated with technological progress and scientific advancement (Leikin & Sriraman, 2022) and are also essential ingredients in reasoning and problem-solving processes (Haavold & Sriraman, 2022; Leikin & Elgrably, 2022; Schoevers et al., 2022).

But what kind of theoretical framework allows the combination of these three perspectives for insightful learning highlighted above: embodied experiences, problem solving, and multimodal communication? Drawing on our joint experiences from a working group on the theme of conceptual blending (1st Specialist Seminar on Embodied Education, Brixen, Italy, 26-28 September, 2024), we suggest conceptual blending as a promising framework for this combination in STEM education.

Conceptual blending theory

Conceptual blending was developed by cognitive linguists Fauconnier and Turner (2002) to understand human cognition. Understanding and learning about the world combines and recombines multiple mental spaces into a single "blended" space. This new space retains some of the input spaces' characteristics but also includes novel emergent properties and features.

According to Hutchins (1995), conceptual blending also provides a useful framework for considering the joint contributions and mutual constraints of mental and material structure. In this approach, framed by the theory of distributed cognition, cognition is not confined to manipulation of symbols in an individual's mind. Rather, cognition is materially anchored in our physical surroundings, through our perception, technological tools, etc., and socially dependent on shared culture and communication. In relation to conceptual blending, Hutchins (2005) points to the general problem of achieving conceptual stability, in terms of knowing what elements and relations can change and which need to remain unaltered, in particular when combining inputs of very disparate nature. Hutchins argues that material structure – including but not restricted to technical artifacts – may contribute to conceptual stability by acting as material anchors for blending. In this sense, a "material anchor" for the blend is an input space from which material structure is projected into a blend (Hutchins, 2005), emphasizing the embodied nature of cognition.

Conceptual Blending In STEM Education

In recent years, conceptual blending has been adopted as a theoretic and analytic approach in STEM education research.

Research examples from physics education describe how conceptual blending can be used to frame embodied aspects of teaching and learning. Dreyfus et al. (2015) analysed how students' simultaneous use of gestures and speech – representing distinct ontological understandings of energy – can be examined through a conceptual blending perspective. Close and Scherr (2015) showed how participants in a role-play scenario use bodily movements, gesture, and language to enact physical scenarios involving energy transformation. Gregorcic and Haglund (2021) employed a conceptual blending analysis of a computer-supported collaborative learning environment that used interactive whiteboards to teach orbital motion of planets and satellites, in which students experienced that they could throw planets into orbit.

In the context of biology education, students have been found to struggle with understanding plant nutrition (Michelsen et al., 2022). Students' everyday experiences in different source domains, such as human nutrition and human respiration may serve as input spaces for understanding the abstract target domain of plant nutrition. This result is surprising because knowledge of photosynthesis is of central importance for solving climate and environmental problems. However, a scientifically compatible understanding of several aspects of the phenomenon, such as the role of carbon dioxide in the air, has been found to require some element of creative thinking (e.g., a new combination of a source and a target domain) (Michelsen & Groß, 2025) and this aspect seems to be closely related to the unique emergent characteristics that are typical for conceptual blending.

As shown by Gelmi, Garzetti, and Asenova (2024), in mathematics education research, different levels of a kind of creativity which is relevant for educational purposes, named "mini-C" by Beghetto and Kaufmann (2007) and defined as the "novel and personally meaningful interpretation of experiences, actions and events" that is "involved in personal knowledge and understanding" (p. 73) can be framed by different kinds of conceptual blending networks, each of them coped with the emergence of some degree of cognitive flexibility or novelty.

In the context of engineering education, Grondin et al. (2022) explored multimodal communication during a reasoning task. Gesture and speech were used to depict and describe the concepts related to torsion. Results indicated that students invoked conceptually discordant gestures (i.e., misalignment between gesture, speech, and concept) indicative of their emerging conceptualizations presumably generated through conceptual blending. Blends produced during reasoning and problem solving that account for communication, they contend, can institute more valid methods for assessing student learning.

In summary, conceptual blending seems to have the potential to be a suitable theoretical and methodological tool to frame, analyse, and assess the distributed, embodied, creative, and communicative aspects of meaningful learning stemming from reasoning and problem solving in different areas of STEM education.

Exploratory Seminar On Conceptual Blending In STEM Education

The purpose of the exploratory seminar was to explore STEM education activities using conceptual blending by combining aspects of embodiment, creativity, and communication that support insightful and lasting learning outcomes.

Specifically, after introducing the participants to the theoretical aspects related to conceptual blending, they were asked to work in small groups and apply their own experiences of blending, embodiment, creativity, and communication to phenomena of their choosing. Each group

presented the results of their activity and a whole group discussion was led by the organizers of the exploratory seminar.

The aim of the seminar was to bring out different perspectives on the integration of embodiment, creativity, and communication through conceptual blending, thereby supporting the theorization of concept integration in STEM education.

The question we discussed with the participants was: How can the conceptual blending theoretical framework be used to model and analyse learning in STEM education, focusing on embodiment, creativity, and communication? Issues concerning the use of metaphors and analogies in relation to embodiment, distributed cognition, creativity, and communication were raised during the seminar and further explored by the authors in post-seminar discussions. In what follows, we outline this exploration and the theoretical insights gained from it.

Metaphors, Analogies, And Conceptual Blending In STEM Education

During the exploratory seminar, and in continued discussion among the authors and some participants, the role of metaphors and analogies in relation to embodiment, creativity, and communication in STEM education was addressed. Two complementary perspectives emerged. One emphasized structural metaphors grounded in analogical reasoning, in which systematic correspondences are established between a familiar source domain and a target domain, as commonly discussed in mathematics and science education (e.g., Pimm, 1981). The other drew on accounts of cognitive metaphors, grounded in embodied experience and image schemas, as developed within embodied cognition approaches (Johnson, 1987; Lakoff & Núñez, 2000).

In line with Fauconnier & Turner (2002), we suggest that rather than treating these perspectives as incompatible, conceptual blending offers a theoretical perspective in which analogies and metaphors may be interpreted as related forms of conceptual integration. From a conceptual blending viewpoint, both analogies and metaphors involve the selective projection of structure from multiple input spaces into a blended space. Structural metaphors based on analogy can be described as blends in which one input space provides a relatively stable relational structure that organizes elements from another space (e.g., single-scope blends). Cognitive metaphors, by contrast, often involve blends in which embodied experience and abstract conceptual structures jointly constrain meaning (e.g., double-scope blends), potentially giving rise to emergent properties that are not fully reducible to direct structural correspondences.

This distinction is relevant for STEM learning, where metaphors and analogies are frequently introduced as instructional resources to support understanding. During reasoning and problem solving, however, learners may elaborate and transform these resources in ways that go beyond their initial instructional framing. From a conceptual blending perspective, such transformations can be understood as processes in which metaphorical and analogical structures are re-integrated with embodied experience, disciplinary knowledge, and representational practices, occasionally supporting novel and personally meaningful interpretations during learning.

Conceptual blending also draws attention to the role of communication and multimodality in metaphor use. Metaphors are not only cognitive constructions but are enacted and negotiated through language, gesture, diagrams, and material or digital artifacts. Multimodal expressions of metaphor can provide insight into learners' evolving conceptualizations, particularly in situations where different modalities are not yet fully coordinated.

Overall, conceptual blending may provide a useful theoretical lens for relating structural metaphors, cognitive metaphors, and analogical reasoning within a single account of embodied, creative, and communicative aspects of learning in STEM education, while leaving room for

domain-specific differences and further empirical examination.

Conclusion

The reflections on conceptual blending, metaphors, and embodiment presented in the previous section help contextualize the contribution of the exploratory seminar within broader theoretical discussions in STEM education. In this sense, the exploratory seminar contributed to ongoing discussions within ESERA Strand 6 by suggesting that conceptual blending may serve as a boundary framework for relating different theoretical models of metaphor, embodiment, and meaning making across STEM disciplines, rather than as a unifying theory that replaces existing perspectives.

After the conference, participants at the exploratory seminar were invited to virtual meetings in the working group on conceptual blending that was formed at the Specialist Seminar on Embodied Education, with the purpose of further exploring how conceptual blending can be applied in STEM education.

ESERA 2025 Copenhagen

ΘΕΑΝΩ [THEANO] Project: Integrating Drama-Based Pedagogies For STEAM Teacher Preparation

Argyris Nipyrakis and Dimitris Stavrou
University of Crete, Greece

Interdisciplinary teaching approaches have received increasing attention in the science and STEM education literature. Further ambitious approaches aim to integrate arts-based approaches as a creative, entertaining, and effective way to teach science. This project examines the implementation of drama and story writing in the context of preservice teacher education. This poster presentation presents an overview of the planned structure of the project, along with findings from pre-pilot studies using drama and story writing for designing science teaching. Findings revealed that teachers made good use of story writing to represent science concepts and phenomena through imaginary stories, which entailed imaginary plots, events and characters. However, when called upon to dramatize science teaching material, the plots of most of their dramatizations lacked much action and improbable events. Teachers' reflections high valued the implementation of such approaches since they present science in a more understandable and engaging way. The outputs of the study inform the development of arts-based teacher training programmes in terms of the affordances and challenges that such approaches entail.

Keywords: pre-service teacher education; play and science learning; instructional design

Introduction

Contemporary scientific research has been steered to address real-world problems in order to provide solutions to sustainability issues which are complex and interdisciplinary by nature, such as climate change, nanotechnology, energy crisis, and artificial intelligence. Furthermore, contemporary problems are characterised by uncertainties and complexity (Barelli et al., 2022; Levrini et al., 2021; Miani et al., 2025), which signifies the need to teach the transition to post-modern views of science (Levrini, 2025). Consequently, there appears to be a need to educate students in interdisciplinary teaching approaches (EU Commission, 2015; NRC, 2014) and to prepare them in Future-Oriented Science Education competences (Levrini et al., 2021).

In response to these needs, recent science education literature has highlighted the promotion of integrated Science, Technology, Engineering, and Mathematics (STEM) education. STEM by definition entails the integration of several disciplinary areas (Martín-Páez et al., 2019), which appears challenging given that teachers often come into STEM having different disciplinary backgrounds and expertise which affects their views (Nipyrakis, Stavrou, & Avraamidou, 2024) and practices (Nipyrakis, Stavrou, & Avraamidou, 2024b).

This challenge is exacerbated in STEAM approaches that further aim to include art, since art is stereotypically perceived as radically different from science (Hadzigeorgiou, 2016). However, philosophical views of science tend to regard art and science as 'branches of the same tree' (NASEM, 2018), hence as complementary ways that both acquire and interpret knowledge of the world (Hadzigeorgiou, 2016; Jacobson et al., 2016).

Integrating art can impact not only students' cognitive skills in science, but also affective variables such as interest, engagement, and empathy (Odegaard, 2003). The Arts highlights aspects of science which are often neglected, such as imagination, creativity and emotions, while they also embrace several cultural, linguistic, and multi-literacy assets (Nipyrakis & Varelas, 2025; Varelas et al., 2022). Hence, such an approach allows the participants to express, negotiate and develop their identities in science, especially regarding people from historically marginalised

communities in science (Chappell & Varelas, 2019; Chappell, 2024; Varelas et al., 2024). Moreover, the arts activate multimodal ways of teaching and learning (Varelas et al., 2022; Woodard et al., 2023; Woodard et al., 2024); hence, a more holistic development of the students' personality is taken into consideration through arts-based approaches in science.

Specifically, this project focuses on integrating the art forms of theatre and creative story writing. Regarding stories, in the context of primary and preschool education, they can take the form of imaginary fairytales (Nipyrakis et al., 2025; Nipyrakis, Pantagias & Chalkou, 2026). The act of story writing allows the students to realise, express, and negotiate their understandings as well as their identities, hence providing insightful research data (Varelas, et al., 2012). Furthermore, they can help students build cognitive capabilities for scientific thought by activating curiosity, imagination, and creativity (Fleer, 2019).

As concerns drama, it can take various form, such as the form of a structured science-related play (Pantidos et al., 2001) or an improvised theatrical action, e.g. through 'science improv' (Nipyrakis, 2026). Through theatre, science content can be represented in a more favourable and engaging way for students (Pantidos et al., 2001), while it can contribute to students' understanding the content and methodologies of science (Tselfes & Paroussi, 2009). It also allows students to move further from oral communication and develop their multiple literacies including embodiment, gestures, gaze, sound, music, and engagement with artefacts (Chappell, 2024; Varelas et al., 2022). Therefore, training the new generation of teachers in integrating these two art forms appears promising for science education.

In this direction, this project aims to investigate the integration of the art forms of story writing and dramatizing in a pre-service teacher education programme. Particularly, the study examines how pre-service teachers implement these art forms for designing science instruction, and how they perceive this approach regarding its educational value and implementation. The research questions that guide the implementation of the ΘΕΑΝΩ project are as follows.

RQ1) How do pre-service teachers integrate story writing and dramatizing for teaching science?

RQ2) What are the pre-service teachers' views on integrating story writing and dramatizing for teaching science?

The outputs of this project aim to formulate recommendations for STEAM teacher education designers at the Higher Education level. Particularly, it aims to provide guidelines for effectively integrating the arts-based approaches of story-writing and story-performing for science teaching based on empirical findings which value the needs and the views of the pre-service teachers.

Methodology

This study is theoretically framed within arts-based research (Barone & Eisner, 2012) and the model of Educational Reconstruction for Teacher Education (ERTE, Van Dijk & Kattmann, 2007). Particularly, we chose arts-based research in order to investigate aspects that are often ineffable through the limited constraints of discursive communication (Barone & Eisner, 2012). Hence, an arts-based approach may examine multimodal and artful representations that widen the lens of analysis and may shed light to deeper insights regarding teachers' views and practices in science.

As concerns the subject matter to be taught and learnt in such an approach, according to the ERTE model, it should be educationally reconstructed concerning its educational significance and based on students' conceptions of the phenomena. Furthermore, the learning environments designed by teachers dynamically interact with empirical studies on teachers' pedagogical content knowledge and the design of teacher education environments. In the context of this project, arts-based

methods are used to analyse multimodal data such as the participants' dramatizations, written stories/scripts/scenarios, brainstorming discussions and reflections.

Outline Of The Project

This project is carried out in the context of the first author's postdoctoral research at the academic Departments of Primary and Preschool Education at the University of Crete, Greece. The five main phases of the project are described as follows.

a) Literature review on STEAM integration, arts-based approaches to science teaching, drama-based pedagogies and story writing for science teaching. Particularly, examples from empirical studies and prior implementations are examined in order to help design the pre-service teacher education programme and the arts-based methods. In parallel, science content topics are educationally reconstructed, and STEAM activities are developed to be implemented for the teacher education programme. Specific attention is paid to topics related to sustainability and Future-Oriented Education. Implementing insights and recommendations from pre-pilot implementations of STEAM activities in the design of the STEAM activities.

b) First implementation of STEAM activities in pre-service teacher preparation courses related to science education. Data collection and data analysis from the implementation.

c) Revision and redesign of the STEAM activities based on the findings from examining the first implementation.

d) Second implementation of the STEAM activities in their revised form. Data collection and comparative analysis of data coming from the two implementations.

e) Formulation of recommendations and guidelines for teacher education designers and policymakers regarding arts-based STEAM teacher education programmes.

Currently, the project is in its first phase, where STEAM topics to be used for developing the STEAM activities are examined for their educational significance and are educationally reconstructed. In parallel, we carry out a literature review on STEAM integration that will inform the design of the STEAM activities to be implemented for pre-service teacher preparation.

We also draw insights from the findings from pre-pilot implementations of drama-based pedagogies and story writing activities in order to develop the STEAM teacher education programme. These implementations were carried out before the official start of the postdoctoral project and, hence, inform the design of the pre-service teacher education programme.

Data Collection And Analysis

Data collected from pre-pilot implementations of the STEAM activities include a) the science-related stories composed by the pre-service teachers, b) the video recordings of their dramatizations, c) post-interviews, and d) pre- and post- questionnaire responses of teachers' views and experiences in using drama and creative writing for science instruction. The teachers who participated in the study until now have signed consent forms for participating in the study, while the study has been approved by the Research Ethics and Integrity Committee of the University of Crete.

The analysis of multimodal data such as the dramatizations is carried out through multimodal discourse analysis (Kress & Bezemer, 2023), particularly seeking inductive codes and patterns from teachers' discussions, actions and performance. Textual data, such as the scripts and transcripts of the discussions, are analysed through qualitative content analysis (Mayring et al.,

2015). Particularly, the developed dramatizations and stories are analysed concerning their overall structure and the degree to which they engage science, and in what ways i.e. in which part(s) of the story/performance science was integrated, and whether science was meaningfully integrated into the plot. Further aspects examined relate to the extent to which they implement science teaching methodologies such as stages of inquiry-based teaching (Castillo-Hernández et al., 2021).

The interview and questionnaire data are qualitatively analysed based on the potentialities and challenges that teachers identify, the educational value that they see in such approaches, and the teachers' willingness to implement such approaches in their future teaching practice. Particularly, inductive codes are identified in each theme and are further grouped into emerging patterns relevant to the research questions.

Findings

Preliminary findings from the pre-pilot implementations have tested arts-based activities that integrate drama-based pedagogies and story writing in various forms, such as creative essays to be developed as homework, group activities during the classroom time, warm-up exercises in class as well as post-reflections of such approaches. The warm-up and groupwork activities in class were deemed as necessary since most teachers in their pre-questionnaire responses stated that they had limited or no experience in using these artforms for educational purposes.

As regards the activities related to story-writing, the findings revealed that the preservice teachers developed stories in the genre of imaginary fairytales on a variety of topics. Most topics related to the early childhood science curriculum, such as the water cycle and changes of states of matter, weather phenomena and natural disasters, free fall, etc. This reveals that story-writing in the form of fairytales is dynamically appropriate to relate to early childhood science content.

Moreover, the teachers used a variety of models and metaphors to represent science, either through personifying natural objects as characters of the story (e.g. a droplet, ice-cream, the earth, etc.), or through introducing natural phenomena (e.g. disasters, weather phenomena) to complicate the plot. In most cases (n=17 out of 28 stories), science was meaningfully integrated into the plot, i.e. science was integral to the plot. However, there were cases where the story was focused on science and action in the story was limited (n=2) or absent (n=5), while in 3 stories there was a plot and action, but limited relevance to science, or science was not meaningfully integral part of in the story (n=1).

Concerning dramatizations, the teachers were assigned to develop dramatizations in the form of 'science improv' (Nipyrakis, 2026). The analysis of the preservice teachers' dramatizations revealed that most teachers developed dramatizations without complicated action and having few contingencies. Particularly, most teachers chose to present a science phenomenon by adding a group chat with peers about the phenomenon during the video-recorded performance. Character building and unexpected events appeared limited in the dramatized action. The findings support the use of enhanced guidance or scaffolding when it comes to story performing by themselves, contrasting the findings of imaginary fairytales, where teachers seemed to be more comfortable creating more complex plots.

As regards the teachers' views on using story writing and drama for science instruction, teachers regarded using these art forms as interesting, creative, and effective for understanding science. Teachers expressed a high level of willingness to implement such approaches in their future practice in schools. However, some teachers stated that they felt uncomfortable or shy at the beginning of dramatizations, something that was subsequently overcome. Another challenge mentioned was the prerequisite knowledge in science needed in order to be able to dramatize the

science-related story/action effectively.

Discussion

This study presented an overview of the postdoctoral research ΘΕΑΝΩ (Theano), and it also examined the findings from pre-pilot implementations of STEAM activities that integrate drama and story writing for teaching and learning science. The findings inform the development of subsequent STEAM activities for preservice teacher training in the context of the ΘΕΑΝΩ project. Particularly, the findings highlighted the potentialities that drama and story writing offer for science teaching, including the metaphorical representation of science concepts and phenomena, which, according to teachers, was deemed joyful, creative, and contributes to understanding science. Findings confirm the literature that supports the use of models and metaphors in narratives as an interesting and effective way of understanding science (Halkia & Mantzouridis, 2005; Nipyrakis & Varelas, 2025; Pantidos et al., 2014).

On the other hand, further guidance seems necessary when the teachers dramatize themselves science-related stories in order to develop complex plots. It seemed that teachers using their bodies and selves instead of imaginary characters is far more demanding for developing a complex plot. Massi & Benvenuto (2001) supported that imaginary stories can assist participants to freely express their opinions. The findings of this study support that it might become more difficult or demanding when the teachers embody the story characters. We could hypothesise that this is not only due to initial feelings of shame, but also due to the increasing difficulty of improvising and performing stories. Hence, subsequent iterations of implementing the activities plan to provide more scaffolds and assistance in dramatizing science-related plots through extended engagement and workshops.

For the needs of the conference poster presentation, we showcase the implementation of some representative STEAM activities along with examples of developed stories and dramatizations. Hence, we provoke discussions with the audience members in terms of their educational significance and appropriateness for preservice teacher training and co-reflect on the findings in order to redesign the STEAM activities.

Implications of this project relate to designing innovative arts-based pre-service teacher education programmes for science education, specifically through the use of story writing and theatre. The findings aim to develop guidelines and scaffolds for implementing such practices in the science classrooms.

Section: Interdisciplinarity As A Curricular, Professional, And Organisational Challenge

ESERA 2025 Copenhagen

Perspectives And Challenges For Interdisciplinary Teaching Practice In Natural Sciences In Brazil

Cristina Leite[1], Adriana Dickman[2]
[1]University of São Paulo, Brazil
[2]Pontifical Catholic University of Minas Gerais, Brazil

The teaching of natural sciences plays a fundamental role in contemporary education. Despite scientific and technological advances, new challenges and uncertainties are emerging, such as climate crises, highlighting the need for a more integrated approach to science education. However, the traditional emphasis on specific content unrelated to the student's context has made it difficult for them to understand and act in an increasingly complex and interconnected world. It is essential and urgent to incorporate an interdisciplinary and integrated perspective into teacher training. In this context, the Brazilian National Common Core Curriculum (BNCC) proposes the integration of knowledge in the natural sciences, encouraging a more connected view of natural and technological phenomena. This study seeks to analyse the implementation of the National Common Core Curriculum (BNCC) for the area of Natural Sciences in Brazilian secondary schools. The focus is on teachers' perceptions of the challenges and opportunities brought about by the new curriculum structure, which requires contextualized and interdisciplinary teaching. Using questionnaires applied to Biology, Physics and Chemistry teachers, this study identifies significant difficulties related to infrastructure, curriculum integration and professional training, reflecting on the implications of these issues for educational practice and the quality of science education. For the BNCC to become a transformative tool, it is essential to invest in teacher training, the development of appropriate materials and the adaptation of schools to meet the new pedagogical demands.

Keywords: BNCC; Natural Sciences; Secondary Education; Interdisciplinarity; Teacher Training;

Introduction

We are currently living through a period of intense social transformations that have an impact on the relationships between science, technology, nature and humanity (Levrini et al., 2024). Although scientific and technological advances offer new possibilities, they also generate uncertainties and challenges (Pietrocola et al., 2024). Climate crises, for example, reveal the vulnerability of production systems to the complexity of natural phenomena (Magnasson, 2021; Latour, 2020). In this context, curriculum integration becomes an urgent necessity, requiring collaboration and dialogue between different types of knowledge (Leite, 2024).

Researchers and educators have long warned of a crisis of meaning in the teaching of natural sciences. In the past, science education focused on transmitting content that was far removed from the students' reality, but this approach has become obsolete (Fourez, 2003), especially with the spread of the internet and artificial intelligence, which make access to knowledge broader and more immediate. As a consequence, for nearly two decades, there has been a drop in young people's interest in scientific subjects (Sjøberg, 2002a, 2002b).

Studies indicate that young people seek meaning and relevance in their educational experiences and value spaces where their opinions are taken into account. However, the way the natural sciences and maths are taught in schools, often presented as having absolute truths, makes engagement difficult. This epistemological rigidity contributes to the perception that these subjects are poorly connected to personal and social life (Stuckey et al., 2013), demotivating

students even more than in previous periods (Sjøberg, 2001, p. 21).

In Brazil, the implementation of the BNCC has brought a new dynamic to basic education, establishing guidelines for school curricula to integrate fundamental aspects of students' education. The area of knowledge Nature Sciences lists skills and competences to be developed throughout basic education in the thematic axes: *Matter and Energy*, *Life and Evolution* and *Earth and Universe (Brasil, 2018)*. In this way, content that used to be seen in a fragmented way now needs a more integrated look, so that the conceptual and methodological tools of the curricular components allow students to investigate, analyse and debate problem situations that emerge from different socio-cultural contexts, as well as understand and interpret laws, theories and models, applying them to solve various problems of an individual, social and environmental nature, encouraging interdisciplinary approaches (Leite, 2023) that would allow students to have a more integrated view of natural and technological phenomena.

Previous research has shown that interdisciplinary dialogues in Natural Sciences Education are still limited and unevenly distributed across different configurations of knowledge integration, especially in Brazil (Matsuo et al., 2024). Studies mapping interdisciplinary practices indicate a reduced presence of dialogues even at the micro level, that is, among subareas such as Biology, Physics and Chemistry, and an even smaller number of experiences articulating broader curricular areas (Matsuo et. al., 2024). These findings suggest that interdisciplinary integration in Natural Sciences remains an underexplored field in educational research, characterized by punctual and fragmented initiatives.

However, interdisciplinarity is defended by various actors (Silva and Magalhães, 2016; Morin, 2003; Fazenda, 2017), its practical dimension is quite challenging (Mozena and Ostermann, 2016; Leite, 2023; Matsuo et. al., 2024). As such, the proposal demands significant changes in teacher training and in the organisational structure of schools, which need to be prepared to offer adequate support for curriculum integration. Previous research has emphasised that, in order to implement the BNCC, it is crucial to consider the specificities of education networks and the resources available, as well as supporting teachers' pedagogical adaptation to the new curriculum (Gatti, 2022; Brasil, 2018). This study seeks to explore these issues through the perceptions of teachers in the area of Natural Sciences, who are on the front line of implementation, addressing both the advances highlighted and the practical challenges posed.

Methodology

The research used a qualitative methodology (Bodgan; Biklen, 1994) based on the application of online questionnaires addressed to teachers of natural sciences who work in secondary schools. The sample was made up of teachers from various regions, mostly in the states of Minas Gerais and São Paulo, including municipal, state and public schools, in order to capture a comprehensive view of their experiences. The questionnaire, structured in thematic blocks based on the literature on the subject, covered the participants' professional profile, their experiences in implementing the BNCC and their perceptions of the reform's impact on their work. Data analysis was based on Content Analysis (Bardin, 2016), seeking to categorise the main themes emerging from the responses, such as interdisciplinarity, teacher training, the suitability of teaching materials, among others.

Results

The results show that the implementation of the BNCC in the area of Natural Sciences faces substantial challenges, especially in relation to school infrastructure and teacher training. Many teachers reported that their schools' infrastructure is inadequate to support the practical activities and integrated teaching required by the BNCC. In several institutions, there is a lack of

laboratories, up-to-date teaching materials and even classrooms adapted for interdisciplinary methodologies, which jeopardises the application of the new content in an integrated way. In addition, the lack of teaching materials that dialogue directly with the BNCC proposal was mentioned as an obstacle, forcing teachers to develop their own materials.

Chart 1: Challenges and possibilities of the BNCC in Secondary Education from the perspective of Basic Education teachers.

Categories	Challenges	Positive points
Contents	- Excess or lack of specific content considered important. - Lack of clarity in linking content to the BNCC, making it difficult to apply in the classroom.	- Encouragement to connect content with students' daily lives, making learning more meaningful.
Teacher training and Interdisciplinarity	- Challenges in integrating the disciplines of the natural sciences. - Insufficient initial training for the interdisciplinary approach. - Continuing education needs to be improved in order to train teachers in integrated and interdisciplinary practice.	- Encouraging the use of new methodologies, such as active methodologies and interdisciplinary approaches. - Greater interaction between disciplines, promoting a broader and more integrated view of the natural sciences.
Workload	- Reduced workload for subjects such as Physics and Chemistry. - Difficulty in balancing the depth of content with the time available for the area.	- Curricular flexibility to adapt content and meet students' specific needs.
Teaching materials	- Lack of up-to-date teaching materials compatible with the BNCC. - The need for teachers to develop their own resources, adapting existing materials.	- Reinforcing the importance of teaching materials, favoring a more dynamic learning experience.
Student Motivation	- Challenges in engaging students with a new curriculum proposal. - Difficulty in aligning content with student interests, encouraging active participation.	- Stimulating student protagonism, encouraging active participation and the development of socio-emotional skills.
Curricular flexibility	- Difficulty in adapting pedagogical practices to more flexible teaching. - Challenges in maintaining curricular quality and coherence in the face of change.	- Possibility of personalizing learning, allowing students to choose areas of interest and deepen their studies.

The analysis also highlighted that teachers face difficulties with the concept and practice of interdisciplinarity. Although the BNCC document advocates integrated teaching of Biology, Physics and Chemistry, many teachers feel that their initial training did not prepare them for this approach and that the support offered during implementation was insufficient. Only a minority of those interviewed said they had received some kind of continuing training or institutional support to understand and apply the BNCC's interdisciplinary curriculum. The majority, however, reported having learnt about the new curriculum independently, through their own studies and participation in pedagogical meetings, which were often not enough to resolve all of their doubts.

With regard to pedagogical practice, the teachers pointed out that the rigid structure of the curriculum and the limited workload make it difficult to effectively implement interdisciplinary teaching. Many said that the expectations set by the BNCC in terms of integrating subjects are difficult to achieve in today's school environment, where the pressure to cover syllabus content and prepare students for national exams creates an unfavourable environment for innovative methodologies. The introduction of formative itineraries has been viewed with suspicion by teachers, who perceive a lack of clarity in the organisation of the curriculum and the materials to support this approach. In addition, the majority of teachers reported that students are resistant to the new teaching model, as they are used to more traditional methods.

These findings suggest that while the BNCC offers a potentially transformative vision for teaching natural sciences, its implementation lacks more solid support in terms of training and resources. Teachers believe that successful implementation would require a joint effort between schools and government bodies to ensure adequate infrastructure and develop continuing education programmes focused on interdisciplinarity.

Some Considerations

The study indicates that although the BNCC represents, from the teachers' perspective, an advance in the conception of more integrated and contextualised teaching in the natural sciences, the implementation of the proposal has faced important challenges. The main difficulties identified include the lack of specific teaching materials, insufficient teacher training, both initial and continuing, for interdisciplinary practices, and the reduction in the area's workload, making it difficult to delve deeply into the proposed themes. It is suggested that the success of this initiative depends on a reformulation of initial teacher training, incorporating interdisciplinary perspectives and innovative methodologies. Based on the teachers' perceptions, it can be concluded that for the document to materialise as a tool for transformation, it is essential that education systems invest in extensive teacher training and teaching materials.

The study indicates that although the BNCC represents, from the teachers' perspective, an advance in the conception of more integrated and contextualised teaching in the natural sciences, its implementation has faced important structural and institutional challenges. The main difficulties identified include the lack of specific teaching materials, insufficient teacher training for interdisciplinary practices, and the reduction of instructional time allocated to the area, which limits opportunities for pedagogical deepening and collaborative planning.

These findings suggest that the success of the official curriculum document cannot be attributed solely to individual teachers' efforts or to isolated initiatives in teacher education. Rather, it requires consistent public policies capable of articulating curriculum guidelines, teacher training programmes, working conditions and evaluation systems. Without structural investments in time, infrastructure and institutional support, the expectations placed on interdisciplinary teaching tend to remain at the level of discourse, with limited impact on everyday school practices.

In this sense, interdisciplinarity should be understood not as an immediate perspective choice, but as a long-term process that involves negotiation, experimentation and collective construction among teachers, schools and educational systems. The reduced workload, fragmented schedules and frequent curricular reforms reported by participants compromise the continuity of interdisciplinary projects, restricting them to punctual and fragile initiatives. This scenario helps explain why more complex and sustained forms of integration remain scarce in both school practices and academic research.

From a broader social perspective, strengthening interdisciplinary teaching in Natural Sciences is closely related to the role of education in addressing contemporary challenges, such as environmental crises, technological transformations and social inequalities. Therefore, promoting interdisciplinarity implies rethinking educational policies beyond curriculum documents, including investment in stable professional development networks, collaborative school cultures and long-term planning. Only through coordinated and sustained public action will it be possible to transform interdisciplinary discourse into socially relevant and pedagogically meaningful practices.

ESERA 2025 Copenhagen

From Fragmentation To Integration: A Case Study Of Interdisciplinary Teacher Education In Natural Sciences

Jessica Miranda Souza, Wagner Moreira da Silva and Fabiana Guerra da Silva
Faculdade SESI-SP de Educação, Brazil

Teacher education in Natural Sciences has traditionally been organised around disciplinary structures, often reinforcing fragmented approaches to scientific knowledge and teaching. Although interdisciplinarity has been widely advocated in science education research, fewer studies have examined how interdisciplinary principles are concretely conceptualised and operationalised within initial teacher education curricula, particularly in programmes organised by knowledge areas rather than by disciplines. This paper addresses this gap by analysing an area-based initial teacher education programme in Natural Sciences offered by Faculdade SESI-SP de Educação (Brazil). The study adopts a qualitative, theory-informed case study approach based on documentary analysis of the programme's Pedagogical Course Project. The analysis focuses on how interdisciplinarity is embedded in the curricular architecture, the articulation between disciplinary and interdisciplinary knowledge, and the pedagogical strategies designed to support integration throughout the four-year programme. The findings indicate that interdisciplinarity is operationalised through a structured curricular design organised around formative axes that distribute disciplinary depth and interdisciplinary integration across different dimensions of teacher education. Pedagogical strategies such as co-teaching and early engagement in school contexts further support interdisciplinary formation by making visible the relational and negotiated nature of integration. At the same time, the study highlights persistent tensions related to faculty disciplinary backgrounds and the alignment between interdisciplinary teacher education and predominantly discipline-based school curricula. By conceptualising interdisciplinarity as a curricular, pedagogical, and institutional process, this paper contributes to research on science teacher education by offering an analytically grounded account of the possibilities and limits of interdisciplinary approaches in initial teacher education.

Keywords: Science Teacher Education; Interdisciplinarity; Curriculum Integration.

Introduction

Teacher education in Natural Sciences has historically been organised around disciplinary structures, reinforcing fragmented approaches to scientific knowledge and teaching practices. While such organisation has contributed to the development of specialised disciplinary expertise, it has also limited opportunities for future teachers to engage with the complexity of natural phenomena, which often transcend disciplinary boundaries (Morin, 2002; Morin, 2008).

Despite the growing consensus around the importance of interdisciplinarity, research has shown that its implementation in initial teacher education remains challenging. Many programmes endorse interdisciplinary principles at a discursive level, yet struggle to translate them into concrete curricular structures, pedagogical practices, and coherent learning trajectories (Scheie et al., 2025; Klein, 2010). As a result, interdisciplinarity is frequently treated as an aspirational goal rather than as an operational feature of teacher education curricula. This gap between theoretical advocacy and curricular practice highlights the need for studies that examine how interdisciplinary principles are conceptualised and enacted within concrete teacher education contexts.

In the Brazilian context, recent educational reforms and curriculum guidelines have further intensified debates around interdisciplinary teacher education, particularly in programmes organised by knowledge areas rather than by traditional disciplines. Area-based programmes in Natural Sciences aim to articulate Physics, Chemistry, and Biology within integrated curricular

structures, while simultaneously preserving disciplinary depth and epistemic specificity. However, empirical analyses of how such programmes operationalise interdisciplinarity throughout initial teacher education remain scarce in the international literature (Lenoir & Hasni, 2016).

This paper addresses this gap through the analysis of an area-based initial teacher education programme in Natural Sciences offered by Faculdade SESI-SP de Educação, 2024 -Brazil. Rather than presenting the programme as a policy proposal or institutional description, the study examines how interdisciplinarity is conceptualised and curricularised within the programme's pedagogical design. The analysis focuses on the organisation of the curriculum, the articulation between disciplinary and interdisciplinary knowledge, and the pedagogical strategies adopted to support integration across the four-year course.

Guided by these aims, the study seeks to answer the following research question: How is interdisciplinarity conceptualised and operationalised in an area-based initial teacher education programme in Natural Sciences? By addressing this question, the paper contributes to ongoing discussions in science education research regarding the possibilities, tensions, and limits of interdisciplinary approaches in initial teacher education.

Theoretical Framework

The organisation of knowledge into disciplinary structures has historically played a central role in the development of modern science and education. While disciplinary specialisation has enabled significant advances in scientific understanding, it has also contributed to the fragmentation of knowledge, particularly in educational contexts. Fragmentation is not merely a curricular issue, but an epistemological one, as it constrains the comprehension of phenomena whose properties emerge from interactions across multiple levels and domains. From the perspective of complexity, such phenomena cannot be adequately understood through isolated analytical approaches (Morin, 2002; Morin, 2008).

Within this framework, interdisciplinarity emerges as a response to the limitations imposed by fragmented knowledge organisation. Interdisciplinarity is not understood here as the elimination of disciplinary knowledge, but as a relational process that articulates distinct epistemic traditions while preserving their specificities. Rather than dissolving disciplinary boundaries, interdisciplinary work involves coordination, dialogue, and integration among disciplines, allowing for the construction of meanings that cannot be achieved through single-disciplinary perspectives alone (Klein, 2010). This understanding challenges simplified interpretations of interdisciplinarity as fusion or homogenisation, emphasising instead its negotiated and processual character.

In educational settings, interdisciplinarity acquires additional layers of complexity, as it must be operationalised through curricular and pedagogical arrangements. Curriculum integration, in this sense, does not imply the abandonment of disciplinary depth, but its reconfiguration within broader educational purposes. Integrated curricula seek to establish meaningful connections among areas of knowledge while maintaining conceptual rigour and epistemological coherence (Scheie et al., 2025). This perspective is particularly relevant in science education, where the teaching of complex natural phenomena requires the mobilisation of concepts, methods, and explanatory frameworks from multiple scientific disciplines.

Research on interdisciplinarity in school and teacher education contexts highlights both its potential and its challenges. Interdisciplinary approaches have been associated with enhanced relevance, contextualisation, and coherence in learning, yet their implementation often faces institutional constraints, including rigid curricular structures and disciplinary traditions in teacher

education (Lenoir & Hasni, 2016). These challenges are especially pronounced in initial teacher education programmes, where future teachers must simultaneously develop disciplinary expertise and the capacity to integrate knowledge across domains.

Taken together, these perspectives suggest that interdisciplinarity in teacher education cannot be understood solely as a pedagogical choice but must be examined as a curricular and epistemological configuration. They provide the analytical lenses through which the present study examines how interdisciplinarity is conceptualised and operationalised within an area-based initial teacher education programme in Natural Sciences. By grounding the analysis in theories of complexity, curriculum integration, and interdisciplinary knowledge organisation, this framework supports a critical examination of the possibilities and limits of interdisciplinary teacher education.

Methodology

This study adopts a qualitative, theory-informed case study approach, focusing on the analysis of an area-based initial teacher education programme in Natural Sciences. Case studies are particularly suitable for examining complex educational phenomena situated within specific institutional and curricular contexts, allowing for an in-depth analysis of how theoretical principles are translated into concrete educational practices.

The empirical corpus consists of institutional documents related to the Natural Sciences Teacher Education Programme at Faculdade SESI-SP de Educação (2024), with particular emphasis on the Pedagogical Course Project (PPC) implemented for the incoming cohort of 2025. These documents include the official curriculum structure, descriptions of formative axes, and pedagogical guidelines that inform the organisation and implementation of the programme. The PPC was treated not as a normative policy text, but as an analytical object through which curricular and pedagogical assumptions about interdisciplinarity could be examined.

Data analysis was conducted through a qualitative documentary analysis, guided by theoretical perspectives on interdisciplinarity, curriculum integration, and complexity in science education. The analysis focused on identifying how interdisciplinarity is articulated across different dimensions of the programme, considering: (a) the curricular organisation by formative axes; (b) the relationship between disciplinary knowledge (Physics, Chemistry, and Biology) and interdisciplinary curricular components; and (c) pedagogical strategies designed to promote integration, such as co-teaching practices and the Educational Residency Programme.

Rather than evaluating learning outcomes or pre-service teachers' perceptions, the scope of the study is limited to the analysis of curricular and pedagogical structures that support interdisciplinary teacher education. This analytical focus allows for a systematic examination of how interdisciplinarity is embedded in the programme's design, while also acknowledging the limitations of the study regarding empirical data on student experiences. These limitations are addressed in the discussion section, where implications for future research are outlined.

Analysis And Results

The analysis is organised around three analytical dimensions that emerged from the documentary examination of the Pedagogical Course Project (PPC): (a) interdisciplinarity as a structuring curricular principle; (b) the role of formative axes as devices for integrating disciplinary and interdisciplinary knowledge; and (c) pedagogical strategies designed to support curricular integration throughout the programme.

Interdisciplinarity As A Structuring Curricular Principle

Interdisciplinarity in the Natural Sciences Teacher Education Programme is not presented as an auxiliary or complementary element, but as a structuring principle that informs the overall curricular design. Rather than replacing disciplinary knowledge, the programme explicitly seeks to articulate Physics, Chemistry, and Biology through curricular arrangements that promote relational understanding while preserving epistemic specificities.

The PPC conceptualises interdisciplinarity as a process of articulation among disciplines, grounded in the recognition that complex natural phenomena cannot be adequately understood through isolated disciplinary lenses. This conceptualisation aligns with theoretical perspectives that emphasise integration without epistemic dilution, positioning interdisciplinarity as a relational practice rather than as the fusion or homogenisation of disciplinary knowledge.

Importantly, the programme distinguishes between disciplinary depth and interdisciplinary articulation. Disciplinary knowledge is treated as foundational and non-negotiable, particularly in curricular components dedicated to specific scientific domains. Interdisciplinary integration, in turn, is operationalised through curricular structures that create opportunities for dialogue among disciplines, rather than through the elimination of disciplinary boundaries. This distinction directly addresses concerns regarding the potential superficiality of interdisciplinary programmes, highlighting that integration is pursued through coordination and articulation rather than through compression of disciplinary content.

Formative Axes As Devices For Curricular Integration

The organisation of the curriculum around four formative axes constitutes the primary mechanism through which interdisciplinarity is operationalised. Each axis plays a distinct role in balancing disciplinary specificity and interdisciplinary integration, collectively structuring the learning trajectory across the four-year programme.

The axis Specific Knowledge in Natural Sciences is primarily responsible for developing foundational disciplinary knowledge in Physics, Chemistry, and Biology. Within this axis, curricular units are organised to ensure conceptual depth and epistemological coherence within each discipline. Although these units are predominantly disciplinary, their positioning within the broader curriculum allows for subsequent articulation with interdisciplinary components.

In contrast, the axis Interdisciplinary Knowledge in Natural Sciences explicitly targets the integration of disciplinary perspectives. This axis encompasses three complementary orientations: (a) traditionally interdisciplinary fields, such as Environmental Education and Materials Science, where disciplinary boundaries are inherently porous; (b) thematic articulations across Physics, Chemistry, and Biology, designed to overcome fragmentation characteristic of higher education curricula; and (c) reflection on the language, nature, and epistemology of scientific knowledge, framing Natural Sciences as an integrated field of inquiry. Through these orientations, interdisciplinarity becomes a curricular object of study rather than a mere pedagogical aspiration.

The axis Didactics in Natural Sciences operates at the intersection of content and pedagogy, focusing on how scientific knowledge is transformed for teaching. Interdisciplinarity within this axis emerges through the analysis of teaching practices that require the mobilisation of concepts from multiple disciplines, particularly in the context of science education in Basic Education. This axis reinforces the connection between interdisciplinary content knowledge and pedagogical decision-making.

Finally, the axis Education and Teacher Professionalisation situates interdisciplinary formation within broader educational, social, and institutional contexts. Through engagement with educational theory, school practices, and non-formal education experiences, this axis supports

reflective integration across disciplinary and pedagogical domains. The Educational Residency Programme, embedded within this axis, plays a key role in linking curricular integration to real teaching contexts.

Together, the four formative axes create a curricular architecture that distributes interdisciplinary integration across different dimensions of teacher education, rather than concentrating it within isolated curricular units. This distribution addresses concerns regarding the feasibility of integrating scientific and educational knowledge within a four-year programme by structuring interdisciplinarity as a progressive and cumulative process.

This organisation enables interdisciplinarity to function as a longitudinal curricular process, rather than as an episodic instructional feature.

Pedagogical Strategies Supporting Integration: Co-Teaching And Educational Residency

Beyond curricular organisation, the programme adopts specific pedagogical strategies to support interdisciplinary integration, particularly co-teaching practices and the Educational Residency Programme. These strategies function as mediating mechanisms between curricular intentions and pedagogical enactment.

Co-teaching is implemented in selected curricular units, involving instructors from different disciplinary backgrounds. This arrangement is designed to model interdisciplinary dialogue for pre-service teachers, making explicit the negotiation of perspectives, concepts, and methodological approaches across disciplines. Rather than presenting integrated knowledge as a finished product, co-teaching exposes the processes through which interdisciplinary understanding is constructed, including tensions and divergences among disciplinary viewpoints.

The Educational Residency Programme further reinforces integration by situating pre-service teachers in authentic school contexts from the beginning of their training. Residency experiences require students to mobilise disciplinary and interdisciplinary knowledge in response to concrete pedagogical challenges, fostering connections between curricular learning and professional practice. In this sense, residency operates as a contextual anchor for interdisciplinary formation, grounding abstract curricular principles in lived teaching experiences.

While these strategies enhance the visibility and enactment of interdisciplinarity, the analysis also reveals persistent challenges. Co-teaching demands significant coordination among instructors, many of whom were themselves trained in highly disciplinary contexts. Similarly, residency experiences may expose tensions between interdisciplinary training and school curricula that remain largely discipline based. These tensions are not treated as failures of the programme, but as constitutive challenges inherent to interdisciplinary teacher education.

Discussion

The analysis of the Natural Sciences Teacher Education Programme at Faculdade SESI-SP de Educação highlights both the possibilities and the inherent tensions of implementing interdisciplinarity within initial teacher education. Rather than presenting interdisciplinarity as an unproblematic solution to the limitations of disciplinary curricula, the findings suggest that interdisciplinary teacher education is best understood as a structured yet dynamic process, shaped by curricular design, pedagogical strategies, and institutional conditions.

One of the central contributions of this study lies in demonstrating that interdisciplinarity can be operationalised through curricular architecture, rather than being confined to isolated pedagogical initiatives. The organisation of the curriculum into formative axes distributes disciplinary and interdisciplinary learning across different dimensions of teacher education, allowing for the preservation of disciplinary depth while creating systematic opportunities for integration. This

finding resonates with research that emphasises the importance of curriculum-level coherence in supporting interdisciplinary learning, particularly in teacher education programmes that aim to move beyond fragmented approaches.

At the same time, the analysis reveals that interdisciplinarity in this programme is not achieved through the dissolution of disciplinary boundaries, but through their deliberate articulation. Disciplinary knowledge in Physics, Chemistry, and Biology remains a foundational component of the curriculum, especially within the axis dedicated to specific knowledge. Interdisciplinary integration emerges through thematic articulation, epistemological reflection, and pedagogical transformation of content, rather than through curricular compression. This distinction is particularly relevant in addressing concerns frequently raised in the literature regarding the risk of superficiality in interdisciplinary programmes, suggesting that integration and depth need not be mutually exclusive.

The role of pedagogical strategies, such as co-teaching and the Educational Residency Programme, further underscores the complexity of interdisciplinary formation. Co-teaching practices make visible the dialogical and negotiated nature of interdisciplinary work, exposing pre-service teachers to the epistemic and methodological tensions that arise when different disciplinary perspectives intersect. Similarly, early and sustained engagement in school contexts through residency experiences situates interdisciplinary learning within authentic professional challenges. These strategies highlight that interdisciplinarity is not solely a curricular attribute, but also a pedagogical and relational process that unfolds through interactions among educators, students, and institutional contexts.

However, the findings also point to persistent challenges that must be acknowledged. Faculty members' prior disciplinary training may limit their familiarity with interdisciplinary pedagogical approaches, requiring sustained professional development and institutional support. Additionally, the alignment between interdisciplinary teacher education and predominantly discipline-based school curricula remains a source of tension, particularly during residency experiences. These challenges are not unique to the programme analysed but reflect broader structural conditions that shape teacher education systems internationally.

Importantly, this study does not claim to evaluate the effectiveness of the programme in terms of student learning outcomes or professional identity development. The absence of empirical data on pre-service teachers' perceptions and experiences constitutes a limitation of the study but also delineates a clear agenda for future research. Longitudinal studies examining how graduates of area-based programmes navigate disciplinary and interdisciplinary demands in their professional practice would significantly enrich current debates in science education research.

By conceptualising interdisciplinarity as a curricular, pedagogical, and institutional process, this study contributes to the literature on science teacher education by offering an analytically grounded account of how interdisciplinary principles can be embedded within initial teacher education programmes. Rather than positioning interdisciplinarity as a normative ideal, the findings highlight its operational conditions, constraints, and transformative potential, providing insights for researchers, teacher educators, and policymakers engaged in rethinking the organisation of science teacher education in contemporary educational contexts.

Implications For Science Teacher Education

The findings of this study offer several implications for science teacher education, particularly for programmes seeking to move beyond fragmented disciplinary models toward more integrated curricular approaches. By analysing how interdisciplinarity is conceptualised and operationalised within an area-based initial teacher education programme, this paper contributes empirically and

theoretically to ongoing debates on curriculum design, pedagogical strategies, and institutional conditions in science teacher education.

First, the study underscores the importance of treating interdisciplinarity as a curricular principle rather than as an isolated pedagogical innovation. The organisation of the programme into formative axes illustrates how interdisciplinary integration can be distributed across different dimensions of teacher education, enabling a balance between disciplinary depth and integrative learning. For teacher education programmes, this suggests that interdisciplinarity should be embedded in the overall curricular architecture, rather than confined to specific courses or short-term projects.

Second, the analysis highlights the role of pedagogical strategies—such as co-teaching and early engagement in school contexts—in supporting interdisciplinary formation. These strategies make explicit the relational and negotiated nature of interdisciplinary work, helping pre-service teachers to understand integration as an ongoing professional practice rather than as a predefined instructional outcome. For science teacher educators, this finding points to the need for collaborative teaching arrangements and sustained partnerships with schools as key conditions for interdisciplinary teacher education.

Third, the study draws attention to the institutional and professional challenges associated with interdisciplinary programmes. Faculty members' disciplinary backgrounds and the predominance of discipline-based curricula in schools shape the possibilities and limits of interdisciplinary enactment. Recognising these constraints is essential for avoiding idealised conceptions of interdisciplinarity and for designing support structures, such as professional development initiatives and collaborative planning time, that enable educators to engage meaningfully with interdisciplinary approaches.

Finally, this study suggests directions for future research in science teacher education. Empirical investigations that incorporate pre-service teachers' perspectives, longitudinal analyses of graduates' professional trajectories, and comparative studies across different national and institutional contexts would deepen understanding of how interdisciplinary teacher education influences teaching practices and professional identity formation. Such research would complement the curricular analysis presented here and contribute to a more comprehensive understanding of interdisciplinarity in science teacher education.

Taken together, these implications suggest that interdisciplinary teacher education is not a singular pedagogical solution, but a complex and context-dependent process that requires coherent curricular design, pedagogical intentionality, and institutional commitment. By foregrounding these dimensions, this study offers insights that may inform the development and analysis of interdisciplinary teacher education programmes in diverse educational settings.

Preparing Teachers For Integrative STEM Education In An Era Of Transition And Transformation: An Innovative M.Ed. Program

Noa Ragonis, Osnat Dagan amd Daphne Goldman
Beit Berl College, Israel

The integration of science, technology, engineering, and mathematics (STEM) is critical in preparing students for an increasingly complex, uncertain and interdisciplinary world. Effective interdisciplinary STEM education requires educators capable of bridging disciplinary divides, fostering critical thinking, and implementing innovative teaching practices. This paper presents an innovative M.Ed. program in integrative STEM education, designed to address these challenges. Grounded in interdisciplinary and constructivist principles, the program prioritizes project-based learning (PBL) to promote active knowledge construction, collaboration, and problem-solving. Two courses particularly anchor these within the program, guiding the participants in designing authentic STEM projects and interdisciplinary teaching units that apply PBL principles and methodologies in real-world contexts. Analysis of the students' reflections reveals the program's effectiveness in equipping educators with 21st-century skills. Participants highlighted the challenges, and their professional development associated with identifying problems, developing assessment criteria, and managing iterative processes, as well as demonstrating enhanced self-regulation and productive collaboration. The program produces graduates well prepared to lead interdisciplinary STEM initiatives, and drive innovation within their educational settings. This paper underscores the transformative potential of well-designed professional development programs in STEM education. It provides a model for empowering educators to drive change, ensuring that graduates of the education system are equipped with the interdisciplinary skills required for success in an unpredictable, technology-driven and environmentally unsustainable world. From a future-oriented perspective, this program aims to create a community of educators committed to continuous improvement and cross-disciplinary collaboration, setting a benchmark for global STEM education reform.

Keywords: STEM Curriculum development, STEM Professional Development, Project-based Learning, Integrative STEM education

Introduction: The Need

STEM education, which emerged in the 1990s, integrates science, technology, engineering, and mathematics to prepare students for an evolving, interdisciplinary world. Historically, STEM has been largely associated with science and mathematics, addressing these in an isolated approach and with limited focus on technology and engineering (Dugger, 2010). Literature highlights the importance of integrating all disciplines to develop students' ability to solve real-world problems, consequently, different STEM curricula and initiatives have been developed to address these gaps (Bybee, 2013; Cagle et al., 2018; Yurchenko et al. 2022).

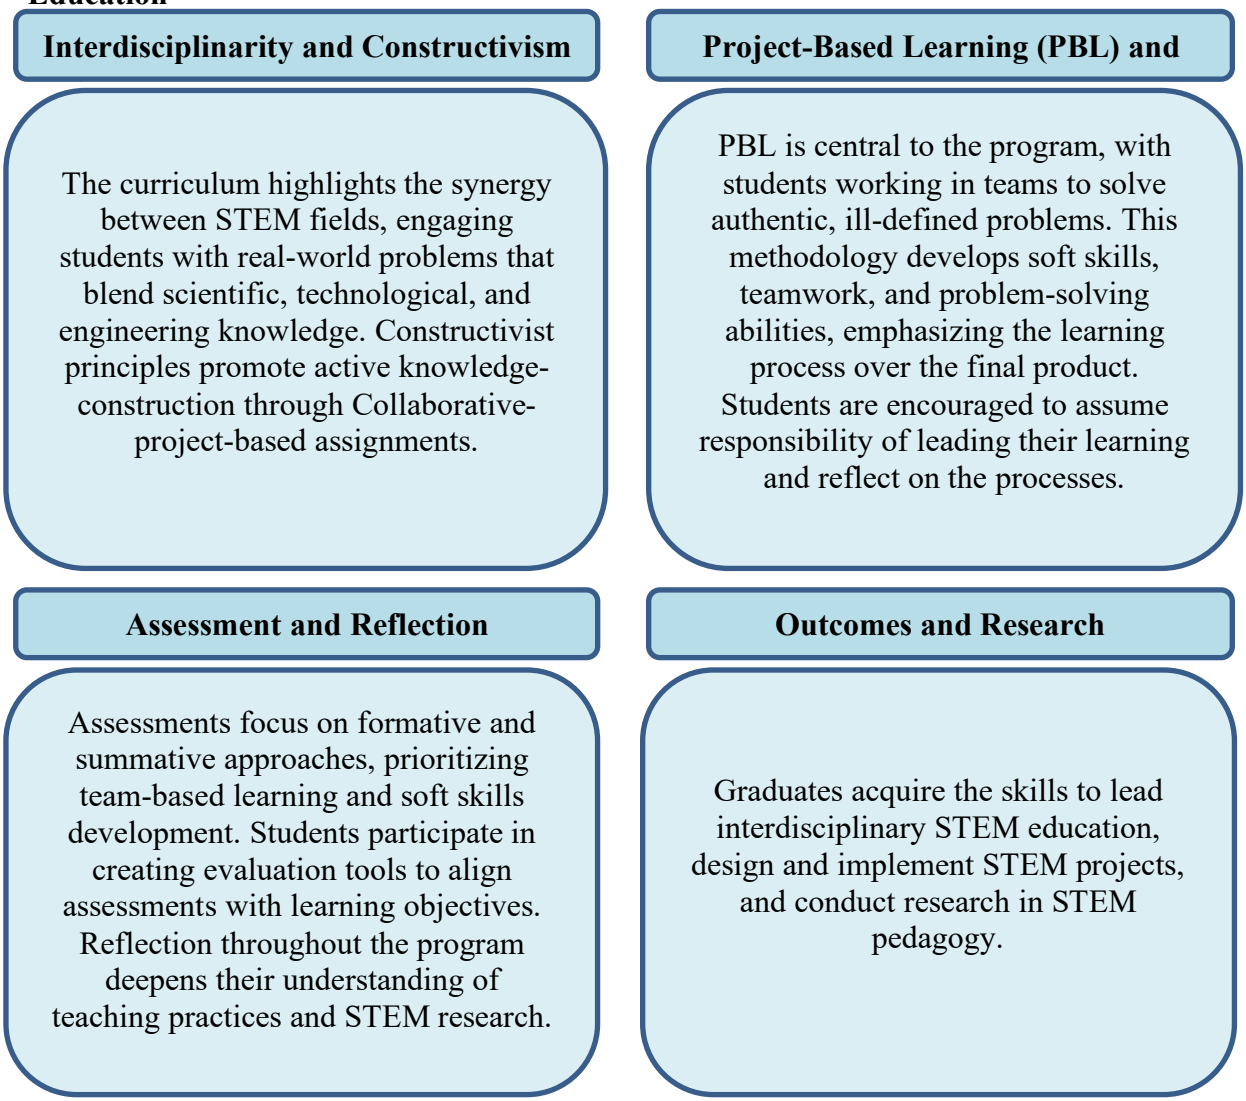
The need for effective STEM education is increasingly acknowledged as schools are required to equip students with essential 21st century skills. These include teamwork, problem-solving, critical thinking, and the ability to innovate and adapt in a rapidly changing world (Bybee, 2013; Doppelt & Barak, 2021). Unfortunately, many teachers lack the training necessary to integrate STEM disciplines effectively, as they often specialize in a single subject area and lack experience in cross- and interdisciplinary collaboration (Joyce & Dzoga, 2013). In response, the Israeli Council for Higher Education approved the development of an integrative STEM master's program to address these challenges (Dagan et al., 2019). This paper presents principles of this innovative academic program and its impact on the participants.

Ultimately, STEM education aims to prepare students for an unpredictable future. Effective STEM curricula can enhance higher-order cognitive skills and promote deep understanding through collaborative hands-on learning (Bybee, 2013). This will also prepare graduates of education systems with strong motivation and curiosity, ensuring they are well-equipped for higher education and careers in STEM fields.

The Program's Design Principles And Structure

The M.Ed. program 'Integrative STEM Education' equips educators with the skills to lead change in formal and informal educational settings. Drawing from literature, educational policy, and expert consultations, the program focuses on integrating STEM disciplines. It emphasizes interdisciplinary understanding, pedagogical content knowledge (PCK), and leadership, enabling educators to tackle real-world challenges and foster cross-disciplinary collaboration. The program aims to create educators with an interdisciplinary mindset, capable of bridging the unique and shared aspects of STEM fields who can facilitate their students in transferring knowledge and problem-solving approaches across disciplines. Active learning, teamwork, problem-solving, and research methodologies are central. These are achieved through the following objectives:

1. Enhancing understanding of STEM subjects in interdisciplinary contexts supporting the development of critical thinking skills.
2. Developing PCK and TPACK for effective teaching, emphasizing Project-Based Learning (PBL) and active learning environments.
3. Building leadership skills for initiating and leading STEM projects in educational frameworks.
4. Promoting the "teacher as researcher" approach through action research in STEM education.



The pedagogical principles and practices of the program are detailed in Figure 1.

The two-year M.Ed. program translates its design principles into a cohesive structure reflecting a progressive developmental process (Figure 2). Infrastructure courses provide the foundational interdisciplinary knowledge and skills that will be employed in the advanced project-oriented courses. Interdisciplinary science-oriented courses such as *Biomimicry* and *Biosphere Research*, together with education-oriented courses like *Education for Values in Science and Technology* and *Computational Thinking*, are key components of the program. The seminars focus on *Reforms in Scientific and Technological Education* and *Action Research on STEM Project Implementation* (Dagan et al., 2023). Two core project-based courses, the focus of this paper, specifically reflect PBL: *Developing an Integrative STEM Project*; *Developing and Implementing an Integrative PBL-based STEM Educational Project*.

From Design To Practice

To demonstrate how the program's design "comes to life", we showcase how its objectives and key pedagogical principles and practices are embodied in the two main project courses. We then highlight student outcomes in these courses and share their reflections on the overall learning experience in this program. As shown in Figure 1. These courses are based on previous infrastructure courses that build a deep understanding of the essence of the interdisciplinary STEM approach, how PBL provides a model for profound problem-solving, and leverage key skills to enhance the interdisciplinary project-based approach. In both courses, students work in multidisciplinary teams in which each member specializes in a different STEM discipline. Beyond peer learning, the aim is to build on the different perspectives towards developing an integrative project. The courses are delivered via co-teaching, implementing the pedagogy of facilitator - serving as guides and advisors through the process.

Figure 1: Pedagogical principles and practices of the M.Ed. program 'Integrative STEM Education'

Development Of STEM Project Via PBL Approach

In this course, students identify an authentic problem with societal relevance and address it employing the PBL framework, with emphasis on the engineering design process. The course culminates in a solution-oriented product and comprehensive documentation of the entire process. This course aims to provide students with hands-on experience in developing a STEM project, engaging in a comprehensive, long-term process (two semesters), which includes navigating challenges, managing frustrations, and celebrating successes. Experiencing this challenging and significant journey first-hand is essential for equipping the students with the competencies to implement such a learning process in their educational contexts. For further details, see Dagan et al. (2023).

Examples of students' products:

- *Umbrecoola*

  The problem: In an era of climate change, how can the body be cooled when outside in increasingly warming environments?

  The solution: A cooling umbrella ("Umbrecoola"). Under the umbrellcoola's canopy, a rechargeable water-based cooler is installed, providing a combination of shading and efficient personal cooling when outside.

- *Walking-Phone*

The problem: How can we assist elderly people who use walking canes in using a mobile phone while walking?

The solution: An adjustable connector attached to the walking cane, allowing a mobile phone to be securely mounted.

Figure 2: Program structure.

Development And Implementation Of An Integrative PBL-Based STEM Educational Project

In this course, students develop a teaching unit that applies interdisciplinary STEM learning through the PBL process and implement it in their educational settings. The implementation is evaluated in an accompanying action research seminar (not detailed here). This course builds on the concepts developed during the previous project. The learning-unit design process begins with selecting a driving question that is meaningful and addresses value-related challenges in the students' educational settings and defining the unit's learning goals. The learning unit incorporates inquiry-based and scientific practices, emphasizes creating a tangible, measurable artifact, and includes formative assessment and reflection. Importantly, the students engage in learning through the PBL process, the learning-unit they design must embody PBL principles, ensuring that their pupils learn through PBL methodologies. For further details, see Ragonis et al. (2024).

Examples of learning units:

- *Ethical gambling – is there such a thing?*

  Driving questions: How are gambling machines programmed in terms of players' luck? What is considered fair gambling? Can fairness be calculated mathematically – How?

- *What did I inherit (genetically) from my parents*?

  Driving questions: Is it okay to select/determine my children's traits? What [inheritable] traits will our children inherit from my partner? What is the probability regarding each trait.

- *Renovating the local safari*

  Driving questions: As the designer of this renovation, what are the central considerations, challenges and solutions in designing an optimal habitat for a selected animal in the safari?

Students' Reflections

Students reflected on their experiences and learning process using a structured protocol addressing seven PBL characteristics (Dagan, 2023). Content analysis of their responses revealed that active engagement in PBL helped them identify its key characteristics and understand their significance for learning. The students faced several challenges inherent in the PBL process, which they addressed and overcame through various strategies. Students acknowledged valuable insights gained about teaching and learning in STEM PBL environments and expressed intentions to apply this in their educational fields:

Identifying the Problem. Defining a motivating yet feasible, multi-disciplinary problem suited to their knowledge, capabilities, and timeframe was challenging. The students viewed STEM knowledge gaps they encountered as opportunities for learning, collaborating with teammates, faculty, and external experts.

Assessment. Developing their own assessment criteria was challenging. However, students recognized its importance for understanding the design process and the skills required for each project component, as it required them to delve into the components' significance to the learning process.

Timetable. Managing the project's schedule proved difficult due to the iterative nature of PBL, often creating frustration. Nevertheless, students appreciated the importance of planning while acknowledging the need for flexibility, as changes are inherent to PBL.

Students reflected that they overcome these challenges by leveraging teamwork, self-regulation, narrowing problem scope, and seeking professional guidance. These strategies reflect essential 21st-century skills, which they aim to instill in their own students. Through this process, students demonstrated their growth and readiness to implement STEM PBL principles in their classrooms, underscoring the program's success in fostering professional and pedagogical development.

Some supportive quotes from students' reflective reports:

> It allows me as a teacher to know where the points of failure are, to know what should be more or less structured, how to assist learners in the process, and above all, how to really implement a PBL project in the best way for all partners in the process." (ES)
>
> "To understand that the main goal of the PBL process is to develop personal abilities along with empathy, which will increase the chances that he/she will grow up to be a person engaged in improving the world." (YN)
>
> "Encountering real-life projects deepened the understanding that to be ready for the future world, students need to learn in an integrative way, to establish broad knowledge in many areas, to understand the connections among these areas and know how to make new connections that will lead to new original developments. (TS)

These students' responses support the idea that in the process of developing the STEM projects, this M.Ed. program, and particularly the above-described PBL-based courses, met the core objectives.

Conclusion - A Future-Oriented Vision

Our vision is to see our graduates applying the approaches and strategies they have learned

throughout the program in their own classrooms. We aim for them to be change-agents within their educational settings, driving progress and innovation. This vision extends to transforming the perception of schools, where the integration of STEM education and project-based learning is seen complementary to existing curricula, rather than conflicting. Ultimately, we hope this program will attract diverse students, creating a sustainable impact on education by fostering a community of educators committed to continuous improvement and cross-disciplinary collaboration, necessary in a constantly changing world.

Nature Of Engineering For School Science: Insights From Experts

Tamar Ginzburg[1]and Miri Barak[1,2]
[1]Technion – Israel Institute of Technology, Israel
[2]University of Oxford, UK

In today's rapidly evolving world, early engineering literacy is essential for navigating digital and environmental transitions. Science education must adapt to foster interdisciplinary understanding, problem-solving, and ethical reasoning. A comprehensive, unified perspective of the nature of engineering (NOE) is essential for guiding these efforts and fostering informed and engaged citizenship. However, the conceptualization of NOE is complex, and there is no consensus on what should be included in school curricula. Hence, the study aimed to examine experts' views on the aspects of engineering that should be explicitly taught in school science. The study utilized the thematic analysis approach to analyse data collected via semi-structured interviews among engineering education experts. The findings revealed three themes in experts' views: engineering practices, engineering-society concepts, and engineering core ideas. The themes highlight 'what engineers do', 'how engineers think', and 'what engineers know' while addressing societal needs. Each identified theme corresponds with one of the three dimensions of the Next Generation Science Standards (NGSS), as well as with cognitive-epistemic and social-institutional Family Resemblance Approach (FRA) categories. The study underlines the need to identify and classify sets of engineering-specific core ideas that could establish a foundational vocabulary. Addressing this gap could enhance FRA-informed NOE and engineering literacy as part of the school science curriculum. In turn, this would help equip students with the knowledge and skills needed to navigate the societal transformations of our era.

Keywords: STEM Education, STEM Curriculum, Science Education

Introduction

For more than two decades, educators and policymakers have called for promoting engineering literacy from an early stage. This approach aims to deepen the understanding of scientific principles by applying engineering concepts in authentic contexts, thereby fostering an interdisciplinary grasp of the technology-driven world (Antink-Meyer & Brown, 2019; Cunningham et al., 2020). The growing interdisciplinarity of scientific fields stresses the importance of this integration of engineering concepts into the science curriculum (Antink-Meyer & Arias, 2022; Barak et al., 2024; NASEM, 2020; NGSS Lead States, 2013), equipping students for the challenges of the 21st century. But what ideas about engineering should be taught in schools?

There is general agreement that, in order to foster socially aware, innovative, active citizens who are ready to contribute to an equitable, inclusive, and sustainable future, students need to know something about the nature of engineering (NOE). As stated by NGSS, strengthening the engineering aspects will clarify for students the relevance of STEM to everyday life. Specifically, with the growing dominance of STEM in our day-to-day lives, understanding the NOE and its social implications becomes increasingly important. This understanding may foster informed citizenship, equipping individuals to address the challenges of an evolving technological society. In fact, contemporary pluralistic democratic societies strive to cultivate citizens capable of actively participating in meaningful decision-making. To that end, teaching the NOE from an early age is crucial.

However, the conceptualization of NOE is complex, and there is no consensus on the content or the view that should be included in school science curricula to address this complexity (Barak et al., 2024; Pleasants & Olson, 2019; Parrish et al., 2024; Deniz et al., 2020). This is further complicated by the fact that engineering is a multifaceted field that necessitates advanced scientific knowledge and high-level mathematical skills and, therefore, presents notable challenges for both teachers and students (Barak & Usher, 2022; Pleasants & Olson, 2019). Literature on engineering literacy has attempted to create a list of concepts and aspects that should be taught as an integral part of the science curriculum by elucidating learners' NOE understanding (Karataş et al., 2015), conducting Delphi studies (Hartman & Bell, 2017), building upon NOS literature (Deniz et al., 2020; Barak et al., 2024), synthesizing engineering studies from various perspectives (Pleasants & Olson, 2019), and by surveying state standards (Carr et al., 2012). However, there is no agreed-upon set of key aspects that define the NOE.

Teaching engineering concepts in a way that provides students with a comprehensive understanding of their nature necessitates an interdisciplinary, holistic view. This approach involves making connections across domains to foster a nuanced understanding of the engineering practice, along with its complexities and interconnections. NOS researchers have shown that it is naïve to expect students to understand science's nature implicitly simply by engaging in scientific practice (Abd-el-Khalik & Lederman, 2000). It is rather a considerable collective and reflective endeavour, like the images of science that historians, philosophers, and sociologists of science have been constructing. The Family Resemblance Approach (FRA) has been recently borrowed from NOS studies (Erduran et al., 2019) and utilized for framing the NOE as a two-dimensional system. Emerging research suggests that the FRA offers a promising framework to cultivate an inclusive understanding of both the cognitive-epistemic and social-institutional dimensions of NOE (Barak et al., 2024).

Hence, the study's goal was to examine experts' views on the aspects that should be explicitly taught in school science.

Method

The study participants included seventeen leading and acknowledged experts in engineering education, including engineering professors, science and engineering curriculum designers, teachers with an engineering background, and practicing engineers with teaching experience. They were recruited through a purposeful sampling process (Creswell, 2018), starting with distinguished engineering professors, who then recommended other qualified experts from their network. They were specifically targeted to provide educational and pedagogical points of view for the essential aspects that should be taught about engineering in pre-college education. Data from experts were collected through semi-structured interviews with questions pertaining to the conceptualization of NOE. For example: *in your opinion and from your experience, what is important for the average 21st-century citizen to understand about engineering? What are the important aspects of engineering?*

The responses of the engineering education experts were analysed by two educational researchers according to the thematic analysis approach (Braun & Clarke, 2021; Creswell, 2018). The analysis included the following steps: the participants' answers were compiled into a distinct, coherent document; the document was rigorously read, and relevant text segments on what a 21st-century citizen should understand about engineering were marked. The analysis applied an inductive orientation to the data, and coding and theme development were driven by the data content (Braun & Clarke, 2021).

Findings

Experts pointed to the importance of fostering engineering literacy through the development of a nuanced perspective that goes beyond technical problem-solving. They emphasized deliberately engaging students in discussions focused on three themes: engineering practices, engineering-society concepts, and engineering core ideas. The first theme, **engineering practices**, referred to 'what engineers do' to design and build systems, solve interdisciplinary problems, and address real-world challenges. Experts focused on the process of defining human-related problems, developing and using engineering models, and designing solutions. These practices require key competencies, including social behaviors "*such as the ability to work in a team and brainstorm ideas*" (A.A., engineering curriculum designer); or "i*nterdisciplinary communication and collaboration are key… as engineers work, for example, with policymakers to design public infrastructure*" (A.B., engineering professor and curriculum designer). They also referred to cognitive behaviors, including "*one needs to be a lifelong learner and think creatively*" (A.A., engineering curriculum designer) in order "*to use systems thinking to define and solve problems*" (H.F., engineering curriculum designer). Additionally, they pointed out cognitive practices such as "*students need to understand complex trade-offs in engineering decisions*" (R.L., engineering curriculum designer). "*Trade-offs and constraints, like budget and environmental impact, should be introduced as part of the design process*" (M.W., science teacher with an engineering background).

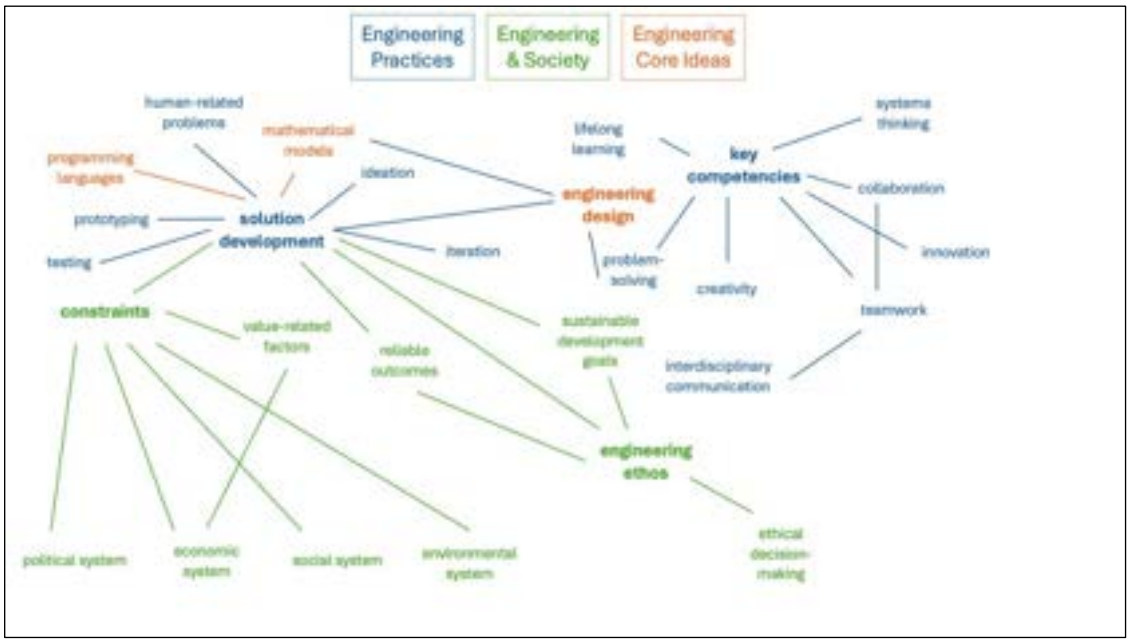
The second theme, **engineering-society** concepts, referred to 'how engineers think', considering ethical, social, and global perspectives while addressing challenges and developing solutions. Experts provided insights into the interplay between engineering and societal contexts and focused on the dynamic, interrelated relationship between engineering and the social, cultural, economic, political, and environmental systems. Experts stressed that:

"When designing an engineering solution, the engineer must consider value-related factors, such as whether the development and the resulting improvement in quality of life align with sustainable development goals, like those established by the UN" (D.B., engineering curriculum designer).

Building on this idea, participants highlighted seeking reliable outcomes, mentioning that:

"Engineers must create environmentally sustainable solutions while also addressing any potential ethical concerns. They need to perform a life cycle assessment and look beyond the solution itself… For example, an electric car – what are the environmental implications of this development? Or transportation as a system - where do you position the bus or train within physical space, and how does this placement impact human behavior?" (A.B., engineering professor).

It was noted that responsibilities regarding the safety of users, equity, and long-term impacts are an important aspect of engineering: *"Engineering solutions impact various aspects of life, like how transportation systems affect urban development"* (A.B., engineering professor); or *"digital technologies and their societal implications on labor markets and daily life"* (D.M., engineering education professor), and "*bias and privacy concerns in AI technologies*" (I.L., engineering education professor).



The third theme, **engineering core ideas**, received comparatively less emphasis from experts. This theme encompasses 'what engineers know' - foundational knowledge and disciplinary concepts critical to understanding and applying engineering principles. A recurring theme in the responses was that "*the focus needs to be on programming languages*" (A.A., engineering curriculum designer), "*Scratch programming, for example, is an easy way to teach complex ideas*" (D.C., engineering education professor). Experts also underscored the importance of science and mathematics knowledge as the foundations for understanding engineering:

"…to calibrate a sensor, mathematics is essential. It involves taking two measurements under extreme conditions, deriving a linear equation, and applying a conversion function to translate the signal output into the corresponding physical value being measured" (D.C., engineering education professor).

"For engineering, one must have a solid scientific knowledge foundation, including chemistry, organic chemistry… heat transfer, energy and matter flows, materials, and the principles of acids and bases. Generally speaking, physics, chemistry, and biology are the foundations of mechanical engineering, while mathematics is the backbone for fields such as information systems, data science, and biotechnology engineering" (H.F., engineering curriculum designer).

Figure 1 shows a conceptual map of the various engineering aspects that the participants suggest teaching in schools as part of the science curriculum. It presents the three emerging themes and the links between the concepts, with the top-rated elements highlighted.

Figure 1. Conceptual map of participants' ideas and identified links.

Discussion And Conclusion

This study delves into the engineering dimension of STEM education by bringing the expert community's views on the NOE aspects that should be explicitly taught in school science. Based on the findings, the study suggests conceptualizing NOE as an FRA-informed engineering-specific framework. The FRA's focus on characterization rather than definition of disciplines positions it as a powerful model for balancing disciplinary identities and interdisciplinarity (Satanassi et al., 2023). Each emerging theme corresponds with one of the three dimensions of the NGSS model (NGSS Lead States, 2013), as well as with cognitive-epistemic and social-institutional FRA categories (Barak et al., 2024). The suggested conceptual framework integrates engineering practices, engineering-society crosscutting concepts, and engineering core ideas, similar to NGSS 3-dimensional learning. The responses highlight what engineers do to design and build systems (engineering practices and the FRA cognitive-epistemic dimension), and the connections across fields that drive innovation and address societal needs (engineering-society crosscutting concepts, and the FRA social-institutional dimension).

However, unique foundational ideas that span multiple engineering disciplines (engineering core ideas, or the engineering knowledge FRA category from the cognitive-epistemic dimension) have limited presence in experts' conceptualizations. The model of science learning outlined by NGSS includes the Engineering, Technology, and Applications of Science (ETS) domain as one of its

four DCI domains. This domain consists of two subcategories: ETS1 - engineering design - which emphasizes defining problems, developing solutions, and optimizing designs; and ETS2 – links among engineering, technology, science, and society – which emphasizes the interdependence of these fields and their impact on society and the environment. However, this framework emphasizes science core ideas (like matter and its interactions in physical sciences, or ecosystems in life sciences) and their applications in engineering, without mentioning core ideas that are distinct to engineering. This prompts a deeper examination and possibly an additional subcategory of the core ideas that should form the foundational vocabulary of engineering literacy, ensuring that 21st-century citizens are equipped to navigate technological and societal challenges.

Future research would benefit from strengthening the not-yet-agreed-upon set of core ideas in engineering by defining key ideas central to the field. These ideas may be represented as engineering knowledge under the cognitive-epistemic FRA dimension, relating to scientific and mathematical theories, laws, and models. These core ideas should be broadly applicable across multiple engineering fields, serve as essential tools for problem-solving, resonate with students' interests, address significant societal concerns, and be designed for incremental teaching and learning over time (NGSS Lead States, 2013). These may include systemic core ideas, for example, sustainability is central to structural engineering in the planning and construction of energy-efficient buildings; similarly, safety and reliability play a crucial role in materials engineering in the development and testing of materials for aerospace applications. Alternatively, these ideas may include fundamental core ideas, for example, elasticity is central in materials engineering in analysing and predicting the behavior of materials under mechanical forces; likewise, Reynolds Number is foundational in predicting flow behavior for designing pumps and turbines in machinery engineering or bridges and water distribution systems in structural engineering.

The study's theoretical contribution is in identifying key NOE aspects to be incorporated into school curricula, expanding both the NGSS 3-dimensional model and the FRA. This warrants careful consideration, particularly when balancing competing priorities, navigating complexity, gaining stakeholder support, and addressing practical constraints in curriculum design. The next step is to deepen science teachers' understanding of NOE concepts and provide them with effective heuristics for teaching these ideas.

ESERA 2025 Copenhagen

Shaping STEM Educators: The Evolution Of Student Teachers' Perceived Importance And Self-efficacy In Integrated STEM

Fien Burm and Hanne Deprez
Faculty of Engineering Science & LESEC, KU Leuven, Belgium

In recent years, integrated STEM (iSTEM) education has received increasing attention, with research exploring a wide range of factors that influence its effectiveness. Literature seems to incline toward five central principles for high-quality integrated STEM education: "integration", "real-world problem context", "design", "inquiry" and "teamwork". The question why a great variability in effects of integrated STEM education exists, can partly be explained by a variety of instructional practices employed by teachers. Moreover, it has been shown that teachers' attitudes are strongly related to these instructional practices. Despite their importance, little is known about the effect of teacher training in iSTEM on (student-)teachers' attitudes. Therefore, this work-in-progress research longitudinally investigates the evolution of student-teachers' attitudes during their teacher training. Using a slightly adapted validated questionnaire, a cognitive dimension (perceived relevance) and a perceived control dimension (self-efficacy) were distinguished in a survey. Initial descriptive statistical analyses show a V-like trend in the importance student-teachers attribute to the iSTEM principles before, during and after an integrated STEM teaching course. This indicates that students devalue the five iSTEM principles during the course, in contrast to the initial situation, but regain importance by its end. On the other hand, student-teacher self-efficacy rises consistently during the course, especially during the first part. Although further qualitative and quantitative data are needed to confirm and explain these findings, this first-of-its-kind study about the longitudinal changes in (student-) teachers' attitudes towards iSTEM, already provides valuable results for teacher education in integrated STEM.

Keywords: iSTEM education, teacher training, attitudes

Introduction

Integrated STEM (iSTEM) education, which aims to educate STEM specialists and STEM-literate citizens by fostering transitions across STEM subjects, has grown significantly in recent years. Despite diverse perspectives on iSTEM education (e.g. Fan et al., 2021; Kelley & Knowles, 2016; Roehrig et al., 2021), literature seems to converge on five central principles for high-quality integrated STEM education: "integration", "real-world problem context", "design", "inquiry" and "teamwork" (Portillo-Blanco et al., 2024; Thibaut, Ceuppens, et al., 2018).

The objectives of iSTEM education are diverse. Gao et al. (2020) provide a matrix that categorizes intended learning objectives along two dimensions. The first dimension distinguishes objectives related to individual disciplines (monodisciplinary, e.g., calculating a derivative), connections between disciplines (interdisciplinary transitions between STEM-subjects, e.g., using an integral to calculate work), and those that transcend disciplinary boundaries (transdisciplinary transitions between STEM concepts and the real-world or transversal skills, e.g., fostering creativity). The second dimension considers objectives in terms of knowledge, skills, practice (e.g., engaging in scientific investigation), and the affective domain. Numerous studies have illustrated positive effects of integrated STEM approaches on one or more of these objectives (Ali Al-Mutawah et al., 2021; Chang et al., 2022; De Loof et al., 2023; De Loof, Boeve-de Pauw, et al., 2022; De Loof, Boeve-De Pauw, et al., 2022; Le et al., 2023; Mustafa et al., 2016). However, studies also reported neutral or negative effects (Becker & Park, 2011; De

Loof, Boeve-de Pauw, et al., 2022; Le et al., 2023).

The observed variability in outcomes may partly be related to the diversity of targeted objectives and the relative emphasis they receive during teaching, but it is also likely influenced by a diversity of instructional practices used in the classroom. Implemented iSTEM instructional practices significantly affect students' ability to apply knowledge (Thibaut, 2018). Moreover, teachers' attitudes influence the implementation of new educational approaches (Pintó 2005; Roehrig, Kruse, and Kern 2007). For iSTEM, teachers' attitudes are significantly related to their instructional practices (Shahali & Halim, 2024), including the five principles mentioned above (Thibaut, Knipprath, et al., 2018b).

These results imply that teacher training, aimed at fostering positive attitudes towards the iSTEM principles, is crucial for achieving the desired effects. However, in- and pre-service teachers often lack prior experience with iSTEM principles as secondary school pupils, yet they are expected to implement them. Teacher training initiatives therefore face the challenge of familiarizing (student-)teachers with iSTEM while preparing them for actual classroom practice. Given the important impact of teachers' attitudes on their instructional practices, teacher training initiatives should evaluate their effects on (student-)teachers' attitudes.

While previous studies have cross-sectionally investigated the relations between school context, personal factors and/or teachers' knowledge to teachers' attitudes towards iSTEM (Shidiq & Faikhamta, 2020; Sokha, 2024; Thibaut, Knipprath, et al., 2018a), to our knowledge, longitudinal research studying the evolution of (student-) teachers' attitudes during training is lacking. This work-in-progress study therefore aims to address the research question "How do student teachers' attitudes towards iSTEM change during their teacher training program?".

Methods

Participants And Teacher Training Program

This research involved students enrolled in KU Leuven's Master of Teaching in Sciences and Technology. During this teacher training, students, often already holding a disciplinary Master's degree, take pedagogical courses, subject-specific teaching courses and corresponding internship(s), and an integrated STEM course and internship 'Interdisciplinary Education: iSTEM and Natural Sciences'. Depending on their prior Bachelor or Master, students can specialise in the school subjects Biology, Chemistry, Computer Science, Earth Sciences, Engineering & Technology, Physics, and Mathematics. Given the importance of cross-disciplinary linking for conceptual understanding, the integrated STEM course is obligatory for all student teachers. The course (6 ECTS) consists of two parts: (1) iSTEM didactics, where students learn about the iSTEM principles and design their own iSTEM project collaboratively in a multidisciplinary team, and (2) an internship, where student teachers implement the designed project with upper secondary school pupils.

Measures

In line with previous research, we defined "attitude" as the overall evaluation of an object on several dimensions (Ajzen, 2005; Maio and Haddock, 2009; Thibaut et al., 2018a). A conceptual framework for teachers' attitudes towards science was proposed by van Aalderen-Smeets and van der Molen (2015) and build upon for iSTEM by Thibaut et al. (2019). Thibaut's questionnaire included a cognitive dimension (perceived relevance), an affective dimension (anxiety) and a perceived control dimension (self-efficacy). This questionnaire served as the basis for our study, but was slightly adjusted to better reflect the meaning of each iSTEM principle for student-teachers, e.g. the item "How important do you think it is that students find an answer to their own questions?" was split up in "... that students formulate their own research questions?" and "... that

students learn to search for an answer for their own questions based on scientific arguments?". Furthermore, to keep the questionnaire length manageable, the affective dimension was dropped. Four-point Likert-type scales were used. All student teachers enrolled in the iSTEM course in 2023-2024 were asked to fill in the online questionnaire at three-time instants: (1) before the iSTEM course (n=77), (2) after the first (design) part of the course (n=76), and (3) after the second (internship) part of the course (n=74). Pseudonymized responses were collected, in line with the ethics committee approval (G-2021-3888-R3).

Analysis

All analyses were executed in R v.4.2.3. (R Core Team 2023). Due to the limited sample size, construct validity was not yet established but will be assessed in the future when more data become available. Cronbach's alpha reliability scores were computed for each of the 10 expected factors, i.e. perceived importance and self-efficacy for each iSTEM principle. Per expected factor, mean factor scores were calculated, for which the median (and IQR) over participants were determined. Friedman tests were used to evaluate main effects of the test moment on each expected factor, and three post-hoc tests (Wilcoxon signed rank) were executed between time instants 1-2, 1-3 and 2-3. In order to maintain a significance level of 0.05, p-values were compared to a Bonferroni corrected cut-off value of 0.05/3=0.017.

Results

Results presented in Figure 1 and Table 1 indicate that there is a consistent V-like trend in the importance student-teachers attribute to the iSTEM principles before, during and after the iSTEM course. For most principles, self-efficacy increases during the course, with the largest increase during the first part of the iSTEM course.

Figure 1: Median scores over participants for perceived importance (IMP) and self-efficacy (SE). Error bars indicate interquartile ranges. INT = integration, PCL = real-world problems, IBL = inquiry, DBL = design, COO = teamwork.

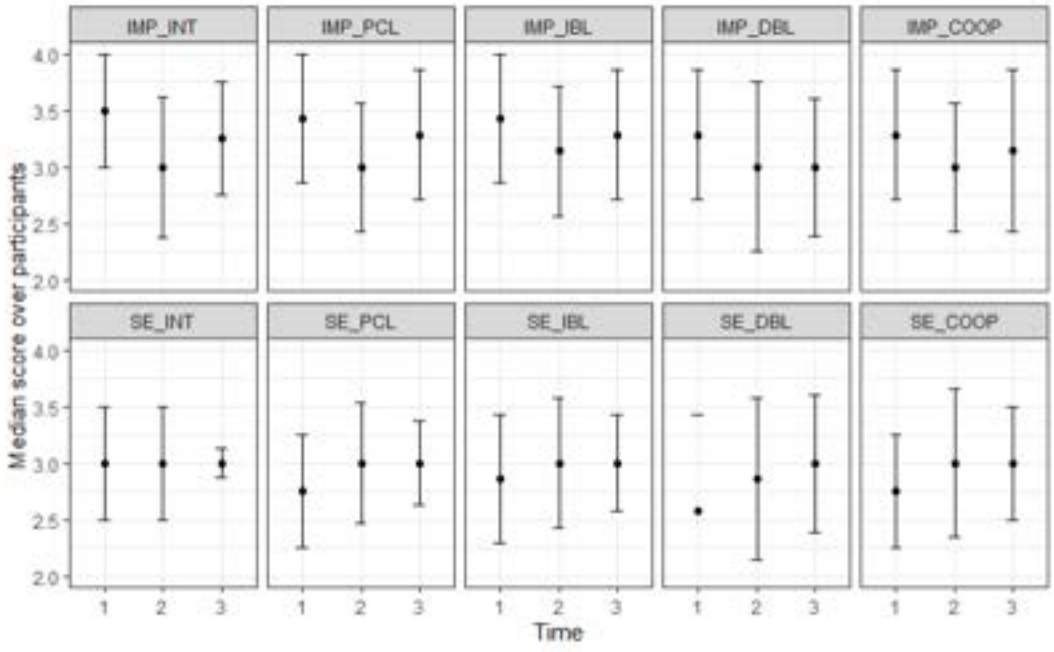

Table 1: Significant differences indicated in bold-face. INT = integration, PCL = real-world problems, IBL = inquiry, DBL = design, COO = team work.

	Perceived importance						Self-efficacy					
	Median			p-value between test moments			Median			p-value between test moments		
	1	2	3	1-2	1-3	2-3	1	2	3	1-2	1-3	2-3
INT	3.5	3.0	3.3	**<0.001**	0.573	**<0.001**	3.0	3.0	3.0	**0.005**	**<0.001**	0.113
PCL	3.4	3.0	3.3	**<0.001**	**0.002**	0.022	2.8	3.0	3.0	**<0.001**	**<0.001**	0.701

COO	3.3	3.0	3.1	**<0.001**	0.138	**0.006**	2.8	3.0	3.0	**<0.001**	**<0.001**	0.461

Discussion and conclusion

In this work-in-progress study researching student-teachers' attitudes, we tracked evolutions in students' perceived importance and self-efficacy towards five iSTEM principles, aiming to facilitate learners' transitions between STEM-subjects and beyond: integration, use of real-world problems, inquiry, design and teamwork. Preliminary results indicate that students attribute less importance to the five principles during an iSTEM course, than at the beginning, but that this effect disappears towards the end. We will collect qualitative data, via student interviews, attempting to explain this observation. Furthermore, students' self-efficacy towards each of the five principles seems to increase towards the teacher training program, with the most pronounced increase at the start of the iSTEM course. Although this study has limitations, such as the lack of control group and limited sample size, this is the first study investigating longitudinal changes in (student-)teachers' attitudes towards iSTEM. We will collect more data in the future and use this to assess construct validity of the adjusted (validated) questionnaire, confirm or refute the observed evolutions, and further investigate factors (prior experience, group composition, …) explaining (evolutions in) (student-)teachers' attitudes.

Transition From Secondary To University Level Education; Students' Skills Development For Math Education And Beyond

Georgia Kittou
Univeristy of Twente, Netherlands on behalf of Community of Learners Twente

This paper highlights the discussions from the first workshop of the Community of Learners Twente (C.O.L.T), emphasizing the importance of students' skills development to foster a smoother transition from high school to university, and academic success in STEM education. The findings and discussions focus on aligning educators observations and expectations from shared experiences.

Keywords: STEM, Transition, Community

Introduction

The Transition From K12 To Tertiary Education

The importance of discussions that focus on students' transition from high school to university cannot be overstated. Even though initiatives do exist addressing the topic, these remain isolated between high schools and universities. Research on this transition has been ongoing for over 20 years (Krause, 2005). Despite various initiatives to bridge the gap, studies (Y.Y. Hong, 2009) reveal that students often feel underprepared, and may experience a significant reality shock as they enter their first semesters. This mismatch between preparation and expectations can lead to declining academic standards or higher retention rates, as many students struggle to adjust during their first year (Brinkworth, 2009).

To begin with, the teaching methodologies in high school typically emphasize structured lesson plans, teacher-led instruction, and standardized assessments that often prioritize memorization and regurgitation of information. In contrast, university education frequently employs more diverse teaching approaches. Lectures may delve deeper into complex concepts and often emphasize the application of theoretical knowledge. This transition requires students to adapt quickly and develop strategies to engage actively with course material beyond passive absorption.

Moreover, university education places a premium on independent learning and self-directed study. Unlike the structured schedule of high school where classes are typically held daily and assignments are more predictable, university timetables may offer fewer face-to-face contact hours, leaving students with greater responsibility for managing their time effectively and sustaining motivation. The expectation to engage with supplementary readings, undertake independent research, and pursue personal academic interests demands strong self-regulation and organizational skills—areas where some students may initially struggle.

To continue with, the academic demands in university escalate significantly compared to high school. While high school curricula lay foundational knowledge across a broad spectrum of subjects, university courses delve deeper into specialized areas, demanding higher levels of analytical thinking, synthesis of information, and original thought. Additionally, the shift to university involves a cultural change in academic expectations. Students are expected to participate actively in class discussions, contribute to group projects, and seek out academic support resources proactively. This transition challenges students to develop interpersonal skills, collaborate effectively with peers, and navigate diverse learning environments where individual contributions significantly shape the collective learning experience.

Community Of Learners And C.O.L.T

In educational literature, the concept of a "community of learners" was first introduced in the 1980s and 1990s by Brown and Campione (Brown, 1994), and emphasizes on collaborative learning, where each member is actively engaging in constructing knowledge through interactions with peers and the environment. It set the foundations in shifting from traditional, teacher-centred education to a more social-constructivist approach, fostering a more interactive, and student-centred learning experience.

Under the principles of collaborative learning (Barton, 2010), where community members bring diverse experiences, expertise, and share best practices, the Community of Learners Twente (C.O.L.T) was established in 2024 to address the gaps identified between high school and university education. Initially, the community consisted mostly of math educators, but it soon expanded to include other disciplines such as physics and social sciences. This expansion transformed C.O.L.T into a comprehensive learning environment where STEM education is actively discussed and improved. It's a mutually beneficial scenario where high school teachers gain insights into the skills and knowledge students need for success in higher education, while university instructors benefit from valuable perspectives on strengthening foundational concepts and fostering critical thinking. Moreover, this collaborative community not only seeks to address immediate challenges but also aims to cultivate a supportive environment where educators can collaborate, learn from each other, and advocate for meaningful changes in STEM education. By doing so, we can better equip students with the skills, knowledge, and confidence needed to excel throughout their academic journeys and beyond. Ultimately, by fostering a culture of continuous improvement and innovation within this community, educators can collectively develop and refine approaches to mathematics education. This includes designing transition programs, integrating real-world applications into curriculum, and implementing assessment strategies that better reflect the expectations of university education.

This paper focuses on sharing discussions that took place during the first workshop of the community in October 2024.

Community Workshop 1

Bridging Gaps: From High School To University; Aligning Expectations And Observations For Student Success

The first workshop of the community took place in October 2024 at the University of Twente, with the participation of 4 high schools from the region of Twente. Both high school teachers and university instructors from diverse disciplines, including mathematics, physics and social sciences, came together to exchange ideas and insights.

Workshop Objectives

The purpose of the workshop was to investigate the transition from high school to university, with a focus on aligning educators' expectations with their observations of students' preparedness.

Workshop Design and Participants

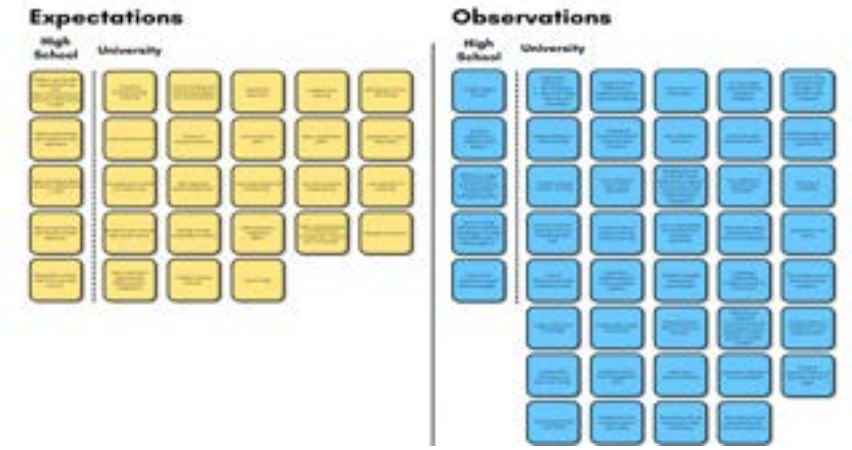
To meet the outlined objectives, activities were carefully designed to encourage a collaborative and cross educational reflection, foster an active dialogue between educators at both levels, and identify key areas for student development.

The workshop tool placed in October 2024 for one and a half hours in a dynamic hybrid environment and involved high school teachers (2 present and 2 online due to teaching responsibilities), university educators (8), a guest PhD student, a session chair, and student research assistants (2).

Data Collection

Data was collected through a two-part question-and-answer activity, using sticky notes to collect teachers' input. The following questions were shared among the participants:

Question 1: What skills or knowledge do you expect students to have when transitioning from high school to university (both academically and behaviorally)?



Clarification A: High school teachers were to describe their expectations for students upon graduation, while university teachers outline what they expect from incoming students.

Question 2: What do you observe about students' preparedness when they move from high school to university?

Clarification B: High school teachers were to share their perceptions of students' readiness at the end of high school, and university teachers to describe their observations of students' strengths and gaps when they first entered university.

Participants provided their responses on sticky notes, which were color-coded: yellow for "Expectations" and blue for "Observations." These responses were then placed in designated columns on a whiteboard (see Figure 1). The use of sticky notes enabled short and dynamic responses, fostering an open exchange of ideas. After the teachers completed their answers, two groups were formed (Yellow Team-Expectations, Blue Team-Observations) to discuss the findings before sharing them with the whole team.

Figure 1: Shared Expectations and Observations among educators.

Data Analysis

Once all responses were collected, it was asked by both groups to identify patterns in their provided answers. Through this process, three key themes were identified:

I. Skills

II. Foundational and Transferable Knowledge

III. Mindset and Attitude

The Venn diagram below summarizes the group findings.

Findings and Discussion

Finding a common ground between educators' expectations and observations was the goal of the comparison and discussion of the selected themes. The conclusions from the discussions are summarized below.

Figure 2: A Venn diagram comparing expectational and observational themes for students' skills, fundamental and transferable knowledge, and mindset and attitudes (Note: In green are the themes found in both).

Key Theme I: Skills

Students are expected to develop a range of skills as they transition from high school to university. These include information and media literacy, which involves searching, reading, and analysing literature, as well as tackling misinformation. Critical thinking and problem-solving skills, including logical reasoning, basic problem-solving for mathematics, and the ability to critically evaluate solutions and outcomes are also crucial. Furthermore, it is anticipated that students would acquire organizational skills, interpersonal (soft) skills, and teamwork and social skills, which include systematic approaches, effective communication, collaborative learning, and basic cooperation skills.

It is observed that students transitioning from high school to university often struggle with higher-order cognitive skills, critical thinking, problem-solving, and creativity. They experience a different, often faster pace at university, which requires adaptability. Additionally, students lack effective planning and time management skills, which are essential for balancing academic and personal responsibilities.

Key Theme II: Foundational And Transferable Knowledge

A solid foundation in mathematics and science concepts is essential for university success. Students are expected to have basic math skills, including polynomials, differentiation, and integration, although these concepts may not yet be well connected. The ability to apply these

concepts to broader areas is also important, highlighting the need for transferable knowledge. This foundational knowledge in mathematics and science forms the basis for further academic development and the ability to tackle more complex problems.

Shared observations among the teachers indicate that there is significant variation in students' foundational knowledge, particularly in basic math skills, which are essential for advanced studies. Students often struggle to apply learned concepts to real-world problems, highlighting the need for strong analytical and application skills. They also face challenges synthesizing multiple sources of information and transitioning from concrete to abstract mathematical reasoning.

Key Theme III: Mindset And Attitude

A proactive mindset and positive attitude towards learning are critical for students' success at university. This includes taking responsibility for their education, managing anxiety (especially in mathematics), and being able to plan and set up their study routines. Students are expected to be resilient, managing uncertainty effectively, and open-minded, showing a willingness to learn new things. Having confidence in themselves, engaging in their studies, and being able to ask for help from the right person are also important.

It is evident among observations that students often have a passive attitude towards learning and lack confidence in their abilities. They struggle with self-regulation, setting learning goals, and taking responsibility for their own education. Additionally, students have difficulty maintaining focus, are easily distracted, and often jump to conclusions without fully understanding problems. Building resilience and emotion regulation skills is also a challenge, as students struggle with dealing with failure and have a fear of mathematics.

Conclusion And Future Work

These series of workshops aim to establish a safe space where educators can share their best practices and discuss possible ways to address challenges that students face, especially on the transition from high school to university.

During the first workshop, the teachers from both levels shared their expectations, as well as their observations for the students ‘performance, behaviour and attitude towards learning. Group discussions revealed that many experiences overlap, emphasizing the importance of community and collaboration. These insights will be critical for the development of the upcoming workshops, ensuring valid and effective preparedness in promoting student success.

An important action point will be to ask students the same questions from both educational levels. This will ensure that the strategies developed reflect students' viewpoints as well.

As part of future workshops, the community will focus on developing strategies that promote a culture of respect for the learning process, and the educational environment. The goal is to help students recognize the value of owning their learning both for academic and personal growth as well. Furthermore, we aim to delve into discussions about student motivation, engagement, and self-regulation, student learning differences, inclusivity, and diversity. We aim to expand our community, host more voices, and foster a prosperous learning environment for students and educators.

Acknowledgement

The author gratefully acknowledges the contributions of the high school and university teachers of Twente region in the Netherlands, students, and invited guests who participated in the first community workshop, from which the results presented in this work were derived. Their active

engagement, constructive discussions, and collaborative efforts were essential to the successful implementation of this initial workshop and to the outcomes reported herein.

We also extend our sincere appreciation to all participants whose dedication and commitment supported the objectives of the first workshop series, which aims to promote scientific knowledge, community involvement, and educational collaboration. The continued support of educators, students, and community members is fundamental to the success of this ongoing initiative.

PBL In STEM Across The Education Continuum In Denmark

Lykke Brogaard Bertel[1], Mette Møller Jeppesen[1], Martin Niss[2] Dorte Moeskær Larse[3] and Connie Svabo[3]
[1]Aalborg University, Denmark
[2]Roskilde University, Denmark
[3]University of Southern Denmark, Denmark

This paper outlines the principles and characteristics of problem-oriented and project-based learning (PBL) across educational levels in Denmark, focusing on authentic problems as a catalyst for reimagining pedagogical approaches in STEM education. The study examines PBL models in STEM from primary through higher education, highlighting the importance of easing transitions and fostering critical thinking, creative problem-solving, and collaborative competencies.

PBL, a student-centred instructional approach, engages students in interdisciplinary, experiential learning by addressing real-world problems. Originating in the 1960s in medical education, PBL was later adopted in engineering education in some universities, as well as technical high schools, evolving into various tailored versions. This paper compares PBL implementations in primary schools (Engineering in School), general and technical high schools (STX and HTX), and higher education engineering programs at Aalborg University (AAU), Roskilde University (RUC) and University of Southern Denmark (SDU).

Key findings emphasize the role of authenticity and student agency in problem-based STEM teaching. While primary and secondary education often present predefined problems to some degree, higher education engineering gradually introduces complex, ill-defined problems, emphasizing problem analysis and scientific evaluation of proposed solutions to enhance critical thinking. The paper highlights the need for integrated approaches and authentic assessment in STEM to enhance student motivation and learning outcomes, and it suggests directions for future research into the impact of cross-institutional collaboration on students' experiences of transition in STEM PBL practices.

Keywords: problem-based learning, educational transitions, STEM education

Introduction

Across educational levels, there is a growing emphasis on active, student-centred learning approaches such as problem-based and project-based, and inquiry-based learning aimed at enhancing student motivation, participation, and learning, particularly in STEM fields, often through authentic problem-solving. This article explores the characteristics of problem- and project-based learning (PBL) in STEM and examines similarities and variations in PBL models across the education continuum in Denmark. It emphasises the importance of articulating differences to support students' awareness and reflection on their diverse learning experiences and the progression in problem-oriented project work throughout the education system. Based on this analysis, the article provides recommendations for researchers, teachers, and educational institutions seeking to integrate more PBL into their teaching practices.

What Is PBL And Why Is It Relevant In STEM?

PBL is a student-centred instructional approach wherein students engage in interdisciplinary, experiential, and collaborative learning by addressing authentic problems. The concept of PBL emerged in the 1960s as a novel, application-oriented approach in medical education, aiming to better prepare students for practice (Hmelo-Silver, 2015). Denmark pioneered the field of PBL

within higher education outside medical education, with Roskilde University (RUC) in 1972 and Aalborg University (AAU) in 1974, particularly focusing on project-based PBL (Servant-Miklos & Spliid, 2017; Andersen & Kjeldsen, 2015). From the 1980s, PBL was also implemented in the newly established technical high school (HTX) in Technology and Engineering subjects, inspired by models from AAU and RUC (Jeppesen, 2021). Since then, more higher education institutions such as University of Southern Denmark (SDU) have implemented their own tailored versions of problem-oriented project work, particularly within engineering education, e.g. through case-based learning and semester projects centred around authentic problems (Giacalone, 2016). Recently, general high schools (STX) and primary education also increasingly focus on incorporating problems into teaching, for instance, in previous General Study Preparation ('Almen studieforberedelse') and later multi-disciplinary projects ('flerfaglige forløb') (EVA, 2021), along with initiatives like 'Engineering i Skolen' (Engineering in School, EiS, https://engineerthefuture.dk/undervisning/engineering-i-skolen/) and the 'Learning and Engagement through Authentic Projects focusing on Science' (LEAPS) schools (https://leapsskoler.dk/).

Various perspectives exist on what constitutes PBL, yet some consistent characteristics and principles include the following (Hmelo-Silver, 2004; Savery, 2015; Savin-Baden, 2007; Thomasson & Stentoft, 2020):

- A focus on complex, authentic, and exemplary (practice-oriented) problems with no single "correct" solution
- Students work in groups
- Students construct new knowledge through self-directed learning
- Teachers serve as facilitators

Authenticity And Agency In Problem-Based STEM Teaching

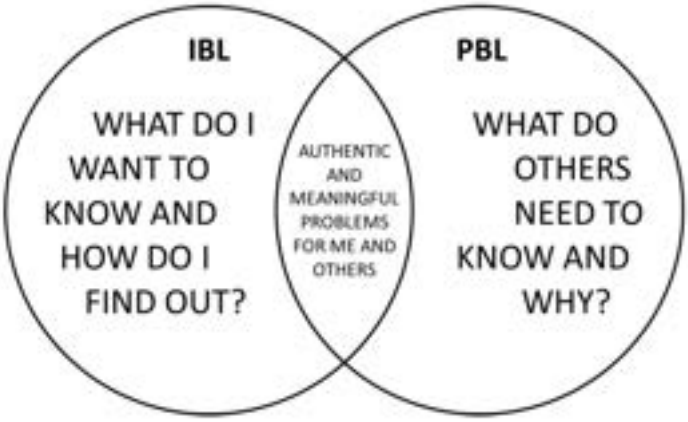
While PBL effectively incorporates current societal challenges, socio-scientific issues (SSI) in STEM (Ratcliffe & Grace, 2003), inquiry-based learning (IBL) emphasizes students' curiosity and connection to their local context and lived experience, fostering motivation and meaningful learning. Combining these approaches in STEM PBL is essential, as focusing solely on large-scale and 'wicked' problems such as the SDGs without actionable solutions can discourage students and contribute to climate anxiety (Darling, 2023). Therefore, we suggest combining the two in STEM (Figure 1) to ensure not only the authenticity and urgency of a given complex problem (e.g. reducing microplastics in the oceans), but also its perceived relevance, i.e. the connection to a student's individual curiosity, local community and personal science capital (e.g. reducing/recycling plastics in 'my own' household) (Nomikou, Archer & King, 2017).

This also highlights another important aspect: STEM PBL should encompass more than solely problem-solving. Solving complex problems requires significant creative, analytical, critical, and systems thinking, all competencies related to the ability to understand problems, namely, to identify, delimit, and formulate problems, rather than just solving them (Møller, 2022; Lavi & Bertel, 2024; Svabo et al., 2025).

PBL In STEM Across The Education Continuum

Below, comparable STEM PBL in primary school (Engineering in School - EiS), general (STX) and technical high school (HTX) and higher education (HE) engineering programs at AAU, RUC and SDU were used as basis for comparison (Figure 2) to illustrate different models, phases, and focus areas, and their emphasis at different levels in the education continuum.

Figure 1. Formulating authentic and meaningful problems in STEM.



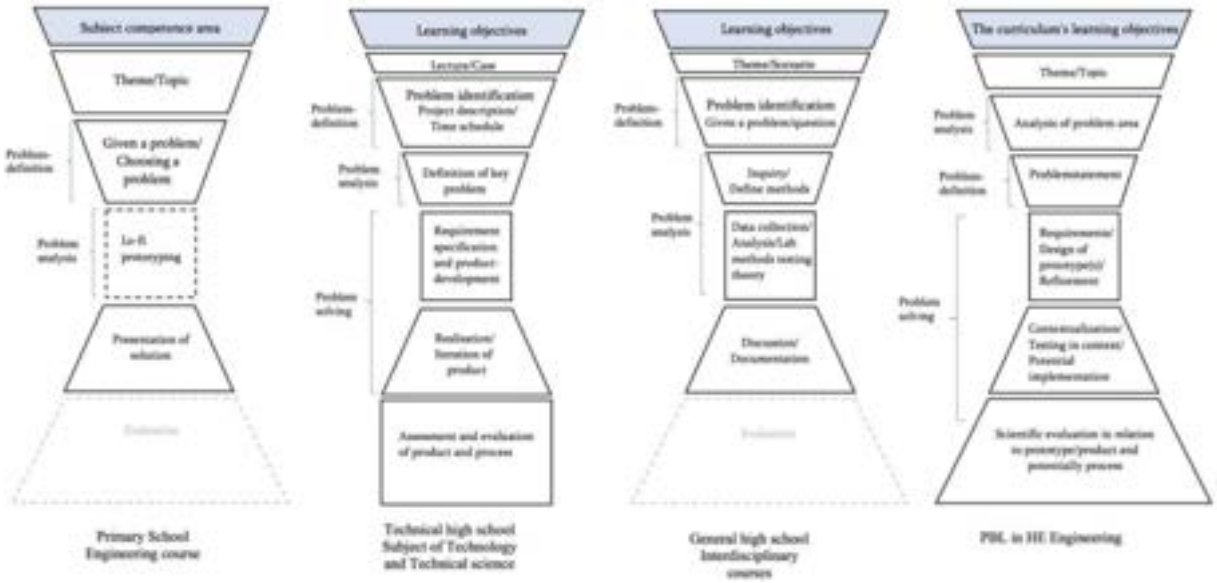


Figure 2. PBL variations across STEM education levels.

Problem Identification And Authenticity

The starting point for inquiry is often a theme or a delimited case. In EiS, HTX, and STX, problems are usually presented alongside the subject theme, with limited student involvement in defining them, although increasing attention is paid to students' problem identification skills in K12 (Møller, 2022; Jensen et al., 2025). In higher education (HE) engineering, student autonomy in defining problems varies, with problems becoming more complex at undergraduate and graduate levels. Authenticity motivates students across all levels, but the involvement of external stakeholders in problem identification and solution implementation increases in HE, especially at the master's level. While HE often struggles to integrate interdisciplinary collaboration in project work, even when the nature and complexity of a problem call for it (Bertel et al., 2022), primary and high schools have managed to formally integrate interdisciplinary learning (across science subjects) into their curricula to some extent.

Problem Analysis And Problem-Solving

While problem analysis and solving dominate in HTX and HE engineering, problem-solving is more limited in EiS and STX, where the focus is on designing lo-fi prototypes, research designs, or lab experiments to explore subject-specific knowledge and methods, rather than design processes and product development. HTX and HE engineering both emphasize problem-solving, but in HE, it is often part of problem analysis, with products serving as prototypes for rigorous

scientific evaluation. This evaluation, rather than the feasibility of the prototype, is the focus of summative assessment, although extracurricular entrepreneurship programs increasingly encourage students to explore product development as well.

Evaluation And Assessment

The evaluation of designs, solutions and learning processes varies across educational levels and between institutions. In EiS and STX, STEM PBL projects are generally short-term and often not formally assessed, though individual assessments of science-integrated projects are newly implemented in primary education. In HTX and HE engineering, STEM PBL projects are generally semester-long and assessed through group exams where students collaboratively elaborate on and defend their work. Knowledge-sharing and formative assessments, such as exhibitions, (public) pitch presentations and peer feedback in PBL schools like LEAPS, could potentially inspire STX, HTX, and HE engineering to involve stakeholders in authentic and contextual assessments of ideas and solutions.

Discussion And Future Work

This paper highlights the diverse implementations of problem-based learning (PBL) in STEM education across different educational levels in Denmark. By examining variations in STEM PBL approaches from primary school through higher education, we emphasize the importance of authentic, interdisciplinary, and student-centred learning experiences. Integrating real-world problems or socio-scientific issues (SSI) with students' personal curiosity and local context is crucial for creating authentic cases/scenarios, meaningful problems and actionable solutions, to foster motivation and increase student agency.

The role of students in defining and analysing problems varies across educational levels. While primary and secondary education often present predefined problems, higher education encourages engagement with more complex and ill-defined problems, essential for developing critical thinking and problem-solving skills. Interdisciplinary collaboration is more formally integrated into the curriculum at primary and secondary levels compared to higher education. However, HE institutions increasingly recognize the value of interdisciplinary approaches, particularly for addressing complex, real-world and ‘wicked’ problems.

Future work should include longitudinal studies to track the impact of PBL on student outcomes across and in transition between different educational levels. This will provide valuable insights into how PBL influences academic performance, motivation, and career readiness over time. Professional development opportunities and cross-institutional collaboration, such as those of the LabSTEM projects, should be encouraged to enhance a shared understanding of PBL, authentic assessment, and integrated STEM approaches and to support seamless transitions and progression in PBL practices through the education system. Policy changes and curriculum development supporting the widespread adoption of PBL in STEM education are also necessary. With the rapid developments in generative AI disrupting many disciplines, traditional assessments focusing on recalling factual knowledge are inadequate for assessing genuine skills and competencies. Therefore, guidelines and resources for facilitating interdisciplinary learning, authentic and formative forms of assessments (Dolin & Evans, 2017) are needed to better reflect the experiential, collaborative, and self-directed nature of PBL.

In conclusion, by addressing variations in STEM PBL, this paper calls for a continued focus on authentic, interdisciplinary, and student-centred learning experiences as well as ongoing dialogue and cross-institutional collaboration to improve STEM education and better prepare students for the challenges, transitions and transformations of the future.

Acknowledgement

This analysis was conducted in the context of the LabSTEM North project at Aalborg University (AAU) funded by the North Denmark Region. This project, together with LabSTEM East at Roskilde University (RUC) funded by Region Zealand, is part of the networked research- and development project LabSTEM initiated by University of Southern Denmark (SDU) funded by the Novo Nordisk foundation and the Region of Southern Denmark.

ESERA 2025 Copenhagen

Bottom-Linked LabSTEM Learning Laboratories Across Denmark

Dorte Moeskær Larsen[1], Maiken Svendsen[1], Connie Svabo[1], Lykke Brogaard Bertel[2] and Martin Niss[3]
[1]University of Southern Denmark, Denmark,
[2]Aalborg University, Denmark,
[3]Roskilde University, Denmark

This article examines the application of the Laboratory Model within the LabSTEM projects in Denmark, exploring its role as a bottom-linked approach to research and development in STEM education. The Laboratory Model, a framework designed to integrate practice, education, and research, supports iterative collaboration between teachers and researchers. This dynamic methodology fosters competence development and innovative solutions to address transitions between STEM disciplines.
The study analyses three regional LabSTEM projects—South, North, and East—each tailored to local contexts and priorities. LabSTEM South emphasizes real-world orientation and integration of STEM disciplines through teacher-researcher collaboration. LabSTEM North focuses on "STEMification" via cross-institutional collaboration, emphasizing problem-based learning. LabSTEM East targets cross-level transitions, fostering problem-based and mathematical modeling learning to address subject integration challenges.
Findings highlight the Laboratory Model's adaptability and its capacity to empower teachers as agents of change, while generating practice-informed research insights. Collaborative learning emerged as a key theme across all three projects, enabling creativity, problem-solving, and sustainable teacher development. The study concludes that the Laboratory Model bridges the gap between research and practice by ensuring innovations are context-sensitive, widely applicable, and capable of transforming STEM education. These insights will inform future initiatives to enhance STEM education in Denmark and beyond, preparing students for future challenges and opportunities.

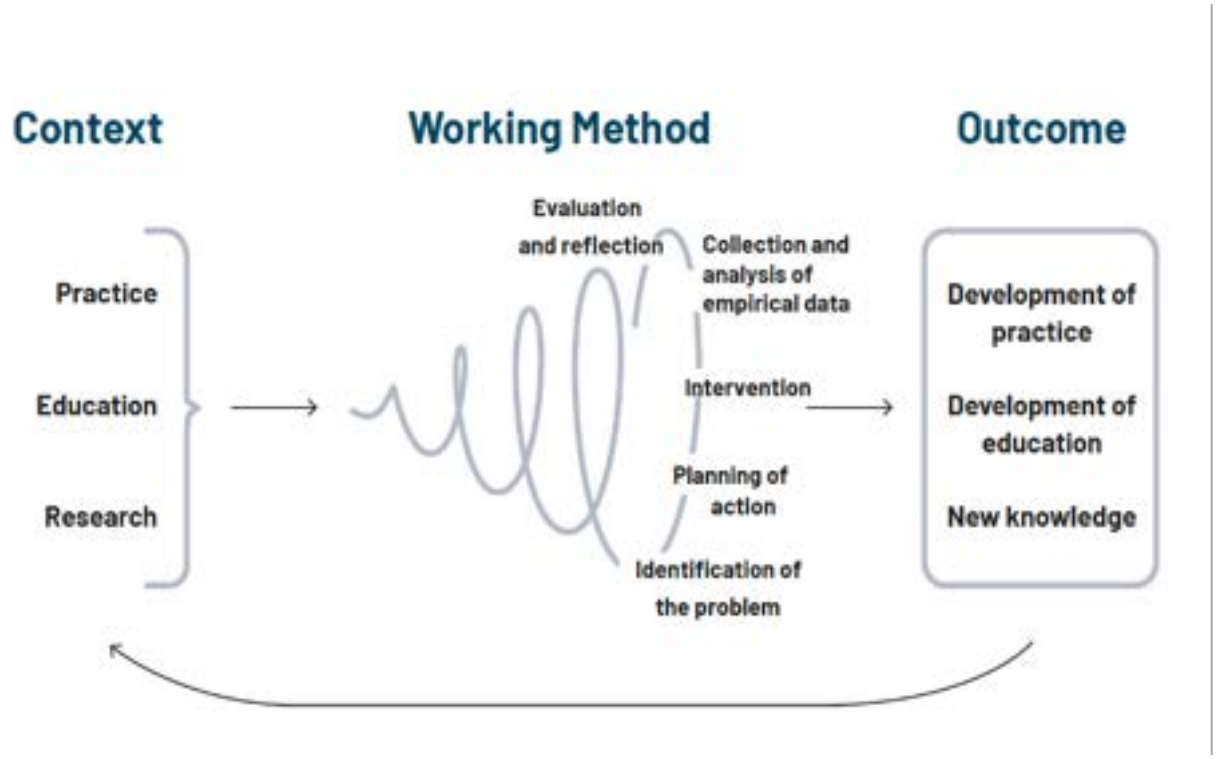
Keywords: STEM-teaching, laboratory-model, development

Introduction

In education, bridging the gap between research and practice remains a challenge, as educational innovations often struggle to be effectively integrated in classrooms (Coburn & Penuel, 2016). A key challenge in practice is developing integrated STEM education that facilitates transitions between disciplines while combining both conceptual understanding and practical application (Nadelson & Seifert, 2017). Transitions in STEM education involve teachers and students moving between disciplines, while ensuring a coherent learning experience (Kristensen et al., 2024). Given the increasing complexity of this challenge, there is a need for a development- and research model that is not only flexible but also capable of offering a range of possibilities to meet diverse educational needs. Research that integrates practice as both a site of inquiry and a source of learning might have the potential to address this gap. More recently, scholars have introduced the concept of bottom-linked research as a way to integrate the benefits of bottom-up and top-down approaches (Balslev, 2021). Bottom-up research starts from local practices and focuses on addressing practical challenges faced by practitioners, often prioritizing context-specific solutions over generalizability. In contrast, top-down research begins with broader theoretical frameworks or policy-driven agendas, which are then applied to practice, sometimes with limited sensitivity to local contexts. Bottom-linked research aims to bridge these approaches by

grounding inquiry in the realities of practice while also connecting findings to larger theoretical or strategic frameworks (Nielsen & Ryberg, 2011). This dynamic interaction ensures that research is both deeply relevant to practitioners and contributes to the broader knowledge base, addressing the limitations of purely bottom-up or top-down methodologies.

This article examines the 'Laboratory Model' (Svabo et al., 2024) in the LabSTEM projects as a bottom-linked approach that fosters inclusive, collaborative innovation.



We address the question: *How is the Laboratory Model used in the research and development process to support transitions in the LabSTEM projects across Denmark, and what insights can be gained from its regional adaptations?*

The Laboratory Model

The Laboratory Model is a framework developed to enhance competence development in educational practices, particularly with a focus on transforming practice within schools and other educational settings. It was primarily developed by Claus Michelsen (Petersen et al., 2017) but further developed in (Svabo et al., 2024). The model is designed to foster collaborative research practices by integrating theoretical insights with practical application in a bottom-linked research approach. It emphasizes the role of both the teachers and the researchers as active participants in both the research and reform processes, allowing them to experiment, reflect, and refine their practices in real-world settings. The Laboratory Model supports an ongoing dialogue between theory and practice, thereby enabling continuous professional development through participation in transformative projects that target specific educational challenges.

The Laboratory Model connects three contexts: practice, education, and research, with the intended outcomes of practice development, educational development, and the creation of new knowledge (Figure 1).

Figure 1. The laboratory-model (Svabo et al., 2024).

The laboratory-model follows a circular and iterative change process: Starting at the bottom, the method consists of processes of 1) Identifying a problem, 2) Planning actions, 3) Intervening, 4) Producing data, and 5) Reflecting and evaluating.

Methods And Context - Three LabSTEM Projects

The LabSTEM projects, comprising three different initiatives across Denmark (South, North, and East), share a common goal of enhancing transition between the STEM-subjects in education. Central to these three projects is the Laboratory Model, which has been adapted to suit regional educational needs, local contexts, and the diverse backgrounds of participating teachers and researchers. By examining the different ways, the model has been employed in each region, we can gain insights into the adaptability of the Laboratory Model and its effectiveness in different educational settings.

The three LabSTEM projects, with LabSTEM South and North still ongoing, primarily target secondary school teachers.

In the following analysis, the three project leaders (who are also authors of this article) have described the application of the Laboratory Model across the different projects. This insider perspective provides a unique insight into the use and adaptation of the laboratory approach within various educational contexts.

LabSTEM South

LabSTEM South (2020–2025) focuses on developing and implementing STEM teaching based on core didactic principles. These principles are 1) a real-world orientation, 2) the integration of at least two STEM disciplines, 3) adopting a participant-centred teaching approach and 4) aligning with the subject-specific learning goals from the curriculum. In total, 250+ educators have been involved in the project's development activities.

In the circular and iterative change process of the Laboratory Model, the problem is defined (1) based on these principles and taken into account by the teachers. Planning the actions (2) takes place in established laboratories situated within the individual schools, where science and mathematics teachers collaborate with STEM-didactics researchers, often specializing in both mathematics and science education, to co-develop STEM teaching activities. In the collaborative process, researchers impose certain requirements which are based on STEM didactic principles. Reciprocally, teachers provide insights into practical context, including content preferences and pedagogical approaches tailored to their students' needs. This interplay fosters a rich exchange, integrating project-defined strategies with experiential knowledge, ultimately enhancing educational practices.

Teachers carry out the developed activities in their classes (3), while researchers observe and collect empirical data from these applications (4). This is followed by a collective reflection on the outcomes (5). The process culminates in a LabSTEM-conference that facilitates knowledge transition across laboratories, institutions, and educational levels. This dynamic supports both practice development and new research. LabSTEM South exemplifies the integration of practice and research, enhancing STEM teaching while deepening understanding of subject transitions.

LabSTEM North

LabSTEM North (2021-2025), focuses on developing a 'STEMification' framework, integrating principles and practices from problem-based learning (PBL), inquiry-based science education (IBSE), and creative platform learning (CPL) to foster students' curiosity and competences in STEM. The project adapts the Laboratory Model to emphasize cross-institutional collaboration in 'STEM Labs', where teachers from various subjects and/or educational levels work to co-create and STEMify their teaching, supporting transitions both between subjects and across educational levels in STEM. Initially, due to the covid-19 lockdowns, these STEM Labs were facilitated as online communities, through which teachers collaborated across disciplines and

institutions to co-create teaching materials and designs. However, initial results identified challenges with the online format, particularly due to external pressure and fatigue from emergency remote teaching at the time. Based on these experiences, the project transitioned to a blended model in 2022, combining online resources and face-to-face meetings which successfully enhanced participation and motivation.

In total, the project has engaged 90+ teachers from lower and upper secondary education, high school, vocational education, and higher education institutions in Northern Denmark, who work iteratively and collaboratively with integrating student-identified questions and authentic problems as points of departure for inquiry and problem-solving. Data is collected through observations and follow-up interviews to inform subsequent iterations. A yearly conference facilitates collective reflection and feedback sessions, along with workshops focusing on specific aspects of PBL and STEM to ensure continuous improvement and adaptation of local teaching practices.

LabSTEM East

LabSTEM East (2023-2024), concentrated on the development and application of teaching sequences within STEM education following certain core principles. Some of these are shared with LabSTEM South, including having a real-world orientation, the integration of at least two STEM disciplines, adopting a participant-centred teaching approach and aligning with the subject-specific learning goals from curriculum (in this case, the development of modelling competence). In addition, LabSTEM East adhered to a principle of problem-based learning, so teaching sequences focused on solving problems rather than, say, the exploration of a theme.

Two labs were established where teachers and researchers collaborated in ways quite similar to the labs of LabSTEM South where teachers and researchers were collaborating to co-develop teaching sequences based on the teachers' practical experiences and the researchers' didactical insights. One notable difference was the shorter duration of LabSTEM EAST due to the funding conditions, which meant that the labs in this project iterated the teaching sequences fewer times. One significant feature of LabSTEM East is that the labs brought together teachers from different educational levels focusing on the transition from lower secondary to upper secondary; when evaluating the labs, the teachers noted that this feature was highly beneficial. It allowed them to interact and inspire one another in developing their teaching sequences across levels.

Common Themes And Regional Adaptions - Analyses And Discussion

The Laboratory Model exemplifies a bottom-linked strategy by integrating the practical, context-sensitive strengths of bottom-up approaches with the broader, theoretical aspirations of top-down research. It fosters a dynamic interplay between practitioners and researchers, enabling co-creation and iterative refinement of STEM education practices. By grounding its methodology in real-world educational contexts and connecting these insights to larger frameworks, the Laboratory Model ensures that innovations are both deeply relevant and widely applicable. This approach empowers teachers as agents of change while providing researchers with a robust, practice-informed foundation for advancing STEM education theory and practice.

While the approaches in LabSTEM South, North, and East have been shaped by local contexts and priorities, several common themes have emerged across all three regions. One of the most significant of these is the emphasis on collaborative learning. Collaboration has been a cornerstone of the Laboratory Model. This collaborative environment has fostered creativity and problem-solving, allowing researchers and teachers to learn from each other and develop new ideas and solutions.

Each laboratory adapted to its research environment and school practices. The Northern and Eastern labs emphasized problem-based learning, reflecting their university's philosophy, while the Southern labs took a more open-ended approach with a focus on mathematics in STEM.

Adaptation to local context is an advantage of the Laboratory Model: it helps teachers become more independent over time. They build the skills needed to run their own "labs" in the future, even without researcher involvement. This aligns with the bottom-linked strategy by empowering teachers to take ownership and continue the work sustainably. Teachers who participated in previous years report continuing to use the project's developed activities.

Conclusion - Outcomes And Impact: The Laboratory Model As A Bottom-Linked Strategy

The Laboratory Model exemplifies a bottom-linked strategy by integrating the practical, context-sensitive strengths of bottom-up approaches with the broader, theoretical aspirations of top-down research. It fosters a collaboration between practitioners and researchers, refining STEM education practices. By grounding its methods in real-world contexts, it ensures innovations are relevant and applicable, empowering teachers as change agents and providing researchers with a solid foundation for advancing STEM education.

The Laboratory Model used across the LabSTEM projects has significantly impacted both researchers and participating teachers. For teachers, it provided opportunities to develop their ability to address transitions between subjects, while researchers gained valuable insights and produced research on these transitions. The regional variations in LabSTEM South, North, and East highlight the model's adaptability to diverse educational contexts and priorities. By fostering collaboration, inclusivity, and real-world connections, the laboratory model demonstrates its potential to transform STEM education, making it more relevant, engaging, and accessible to all learners. The learning from these projects will inform future STEM education initiatives and help prepare students to navigate and contribute to the challenges and opportunities of the future.

Section: Views Of And Experience With Interdisciplinarity

ESERA 2025 Copenhagen

Self-efficacy Of Pre-service Teachers And In-service Teachers Towards Integrated Science And STEM

Lukas Rokos[1], Helena Koldova[2] and Zuzana Nedvedova[1]
[1] University of South Bohemia in České Budějovice, Faculty of Education, Department of Biology, Czechia
[2] University of South Bohemia in České Budějovice, Faculty of Education, Department of Mathematics, Czechia

The study focuses on comparing the levels of self-efficacy among pre-service teachers and in-service teachers in relation to integrated science and STEM education. The study is framed by an ongoing curricular reform in the authors' home country, which provides increased opportunities to emphasize the integration of educational content. The paper presents findings from a quantitative survey conducted through a structured questionnaire (N = 680). The results show that in-service teachers report substantially higher levels of self-efficacy than pre-service teachers, particularly in pedagogical content knowledge and in managing instructional activities. The biggest differences in content-related self-efficacy appear in mathematics and in the ability to explain natural phenomena. Both groups demonstrate comparatively low self-efficacy in the practical implementation of STEM integration and in adapting integrated content to diverse age groups. Based on these findings, the study identifies priority areas for strengthening support in pre-service teacher education and outlines strategies to enhance competency development among both practicing teachers and teacher education students.

Keywords: self-efficacy, STEM education, science education

Theoretical background

In the Czech Republic, national curricular documents are currently undergoing revision, with increasing attention to opportunities for integrating educational content and fostering cross-curricular connections. In the fields of science and mathematics education, integration is frequently discussed through the lens of science education (as Biology, Physics, and Chemistry are traditionally taught as separate subjects in the Czech Republic) and through the STEM approach (see Sanders, 2009; Siekmann & Korbel, 2016). Both forms of integration aim to respond to the needs of a globalized world, emerging economic challenges, issues of sustainability, and the overarching emphasis on competencies for the 21st century (UNESCO, 2019).

Although the previous curriculum framework allowed schools to integrate subject areas (Hejnová, 2011), only a small number of schools took advantage of this opportunity. The newly designed curriculum provides schools with model school framework programmes in which integration has already been implemented, offering school leaders and teachers a more accessible source of inspiration. Every school has to design own school framework programme but they can decide if the follow traditional subject-related model, integrated model or thematic model. The subject Příroda a já ("Nature and Me"; designed by a team that included authors of this contribution) is the example from integrated model school framework programme (NPI ČR, 2025). This subject integrates content from Biology, Physics, and Chemistry at ISCED 2 level, thus corresponding to international conceptions of integrated 'science'

Implementing a high-quality integrated approach requires teachers to possess a sufficient level of self-efficacy and pedagogical beliefs (Chen et al., 2020). Teachers must not only be confident in their content-matter knowledge but also capable of carrying out appropriate pedagogical

transformations to ensure that tasks and instructional content are aligned with the abilities and developmental characteristics of learners (An, 2017). Both Czech studies (e.g., Koldová, Rokos, & Hašková, 2022; Patoková et al., 2024) and international research (e.g., Yang, Wu, & Li, 2023; Margot & Kettler, 2019) highlight that teachers often lack methodological support during pre-service preparation as well as in their in-service practice, whether in the form of professional development courses or examples of effective instructional practice. As a result, their self-efficacy for implementing STEM in classroom settings tends to be low.

The concept of self-efficacy is grounded in Bandura's (1997) theoretical work, which stresses that individuals' beliefs in their capability to successfully perform a task substantially influence their actual performance. In the educational context, teachers with higher levels of self-efficacy tend to feel more competent to adopt innovative methods and technologies, leading to improved instructional effectiveness (Tschannen-Moran & Hoy, 2001; Klassen & Chiu, 2011; Zakariya, 2020). Within STEM education, teacher self-efficacy – together with content knowledge and pedagogical content knowledge across integrated domains – constitutes a critical factor in realizing effective integrated instruction (Yang et al., 2023; Geng et al., 2019; Gunning & Mensah, 2011; Smetáčková & Páchová, 2025; Zakariya, 2020).

A variety of studies address teacher self-efficacy within individual STEM disciplines (e.g., Nipyrakis, Stavrou, & Avraamidou, 2024; Chen et al., 2020; Çiftçi et al., 2020; Park et al., 2017; Simoncini & Lasen, 2018), yet comprehensive investigations in the Czech educational context remain limited. This research study builds on and adapts existing validated instruments for assessing self-efficacy among in-service teachers and pre-service teachers, thus enabling international comparability while simultaneously addressing a significant research gap within Czech education.

Existing evidence on the most common barriers and opportunities for implementing integrated instructional approaches in educational practice (Rokos & Koldová, 2024; Patoková et al., 2024) suggests that strengthening the self-efficacy of both in-service teachers and pre-service teachers for STEM-based instruction will require a combination of complementary approaches and strategies targeting their pedagogical, disciplinary, and methodological skills. At the same time, it will be essential to prepare pre-service teachers in ways that equip them with the necessary competencies and a sufficient level of self-efficacy for integrated instruction, while also providing in-service teachers with robust professional, methodological, and didactic support (Koldová, Rokos, & Hašková, 2022; Rokos & Koldová, 2024).

Methodology

The paper presents the initial phase of a broader research project examining the self-efficacy of pre-service teachers and in-service teachers. The results reported in this contribution are based on a quantitative survey conducted using a structured questionnaire and are complemented by selected insights from the subsequent qualitative phase of the study. The aim of the quantitative investigation was to address the following research questions: (1) What is the level of self-efficacy among pre-service teachers and in-service teachers in relation to integrated science instruction and the STEM approach? (2) To what extent do perceptions of self-efficacy differ between these two groups? and (3) What forms of support for enhancing self-efficacy would the respondents prefer?

Research Instrument

The research instrument was adapted from several established tools, specifically the STEM Teaching Efficacy Belief Instrument (STEBI; Riggs & Enochs, 1990; Deehan, 2017), the T-STEM Science Scale (Unfried et al., 2022), the Teachers' Sense of Efficacy Scale (TSES;

Tschannen-Moran & Hoy, 2001), and the STEM Teaching Self-Efficacy Scale (STSS; Yang et al., 2023). To ensure validity and reliability, several steps were undertaken: forward–backward translation and cultural adaptation, assessment of content validity, split-half reliability testing (80/20), and calculation of Cronbach's α, which exceeded 0.7 for all items.

In total, the instrument comprised 49 items divided into five sections:

1) Demographic data: information about respondents (four multiple-choice items and three open-ended questions);
2) Integrated science teaching: one open-ended question and ten statements;
3) Integrated STEM teaching: one open-ended question and ten statements;
4) Self-efficacy related to integrated pedagogical content knowledge: ten statements;
5) Self-confidence and motivation to implement integrated teaching: ten statements.

All statement items were rated on a five-point Likert scale (1–5), where 1 corresponded to option 'strongly agree'.

Characteristics Of The Research Sample

The first group of respondents consisted of pre-service teachers from the Faculty of Education, University of South Bohemia in České Budějovice. In total, 100 responses were collected, including 84 female and 16 male participants. All respondents were master's degree students who had completed at least two courses in subject didactics and were studying at least one specialization within the STEM disciplines. Data collection for the pre-service teacher group took place between 2023 and 2024.

The second group consisted of in-service teachers, with 580 participants in total (458 women, 122 men). Among these respondents, 403 were biology teachers, 147 chemistry teachers, 61 physics teachers, 139 mathematics teachers, 25 informatics teachers, and 90 geography teachers. (Note: In the Czech Republic, teachers are typically trained in two-subject combinations; therefore, the sum of subject specializations exceeds the total number of respondents, as some teachers qualified in combinations such as biology–mathematics.)

Regarding teaching experience, the sample included novice teachers with fewer than four years of practice (33.96%), experienced teachers with four to twenty years of practice (44.66%), and highly experienced teachers with more than twenty years of practice (21.38%).

Focus Groups

Responses to the third research question were obtained primarily from the qualitative phase of the study, which involved semi-structured interviews with selected respondents and discussions conducted in focus groups. The interviews focused on interpreting the results of the quantitative survey and, in particular, on participants' personal perceptions of their own self-efficacy. Their purpose was to extend and deepen the findings emerging from the quantitative phase.

In addition, the interviews explored examples of situations in which respondents felt confident or uncertain with regard to the integration of educational content, key challenges they encountered, strategies they used to manage uncertainty, approaches and methods they believed would support their practice, and the perceived implications for their professional development. Four focus group sessions were conducted in total – two with pre-service teachers and two with in-service teachers. Each focus group involved 20 voluntary participants. All sessions followed a pre-defined discussion protocol and were facilitated by the same member of the research team. The discussions were audio-recorded to allow for subsequent transcription.

Data Analysis

For the quantitative dataset, an aggregation metric was applied in which positively valenced responses (strongly agree and agree) were combined, as were negatively valenced responses (strongly disagree and disagree). Subsequently, item-level comparisons between the two respondent groups were conducted using a two-tailed z-test for the difference between proportions (normal approximation without continuity correction). All calculations were based on the actual number of agreement responses in each group. p-values were rounded to four decimal places, and statistical significance was set at $p < 0.05$.

For the focus groups, transcripts of each session were analysed using thematic coding (Kusnir, 2025). Two researchers independently coded the data, and their outputs were compared. The analysis was conducted using Atlas.ti software. In cases where discrepancies between coders were identified, the coding was repeated by a third independent researcher.

Results

Given the unequal sample sizes across the two respondent groups, all results are presented in relative frequencies.

Integrated Science

Pre-service teachers reported the highest level of agreement in relation to confidence in their biology content knowledge (70% agreement; 17% neutral; 13% disagreement), whereas the lowest confidence was observed in physics content knowledge (13% agreement; 16% neutral; 71% disagreement). In-service teachers showed the highest agreement for the statement "I am constantly looking for better ways to teach science topics" (89.7% agreement; 6.4% neutral; 4.0% disagreement), alongside a similarly high level of confidence in their biology content knowledge (75.3%). Their lowest agreement also appeared in relation to physics content knowledge (29.8%).

When comparing the two groups' confidence across the content areas integrated within the science approach (biology, physics, chemistry), in-service teachers were markedly more confident than pre-service teachers (46.0% vs. 24.0% agreement). Among pre-service teachers, disagreement prevailed (49.0%) on items relating to content knowledge. Both groups felt confident in biology (75.3% vs. 70.0% agreement). In physics, confidence remained low for both groups (29.8% vs. 13.0% agreement), although in-service teachers showed a 16.8 percentage-point (p.p.) higher agreement than pre-service teachers.

Unsurprisingly, the largest differences favouring in-service teachers were found in self-efficacy related to pedagogical content knowledge and didactic skills, including classroom interaction, reflection, and the ability to clearly explain scientific concepts. For example, the statement "When teaching science, I feel confident welcoming students' questions" yielded 63.4% agreement among in-service teachers compared to 24.0% among pre-service teachers (+39.4 p.p.). For the statement "I can clearly and comprehensibly explain natural laws and phenomena", agreement was 71.9% vs. 39.0% (+32.9 p.p.). These items were subsequently identified in the item-level analysis as those showing the largest differences between the two respondent groups (see Table 2 below).

Integrated STEM

In the context of integrated STEM, the differences between the two respondent groups are even more pronounced. Pre-service teachers reported very low confidence on both items related to mathematics content knowledge: mathematics content knowledge: 7.0% agreement; 20.0% neutral; 73.0% disagreement; application of mathematical principles: 7.0% agreement; 25.0% neutral; 68.0% disagreement. In-service teachers expressed substantially higher confidence on the same items: mathematics content knowledge: 46.7% agreement (20.0% neutral; 33.3%

disagreement); application of mathematical principles: 44.7% agreement (20.2% neutral; 35.2% disagreement). These differences amount to +39.7 and +37.7 percentage points, respectively, in favour of in-service teachers.

Among in-service teachers, the highest level of agreement was recorded for the statement "I am confident in my science-related knowledge" (62.1%). Conversely, agreement was extremely low for "I have sufficient knowledge across all STEM disciplines" (12.6%). Pre-service teachers likewise showed low agreement on this item (10.0%), indicating a general lack of confidence in relation to the cross-disciplinary breadth of STEM.

Interestingly, the pattern reverses for the statement "I have sufficient knowledge of technologies used in STEM education": pre-service teachers reported 39.0% agreement, compared with only 14.1% among in-service teachers (−24.9 p.p., in favour of pre-service teachers). However, in-service teachers showed slightly higher agreement on "I am confident in the field of technical education" (25.9% vs. 15.0%), although overall confidence in this domain was low in both groups, with disagreement or neutrality prevailing.

For the statement "I am able to prepare lessons that integrate STEM content", agreement was low and nearly identical in both groups (21.0% among pre-service teachers and 20.0% among in-service teachers; −1.0 p.p.). A similar pattern was observed for "I am able to adapt STEM content for students of different age groups while respecting the school's curriculum framework" (27.0% vs. 25.3%; −1.7 p.p.). These results suggest that practical integration and differentiation of STEM content remain challenging areas across both respondent groups.

Welcoming students' questions in the STEM context again showed higher agreement among in-service teachers (17.4% vs. 9.0%). However, the absolute levels of agreement were low in both groups and accompanied by high neutrality or disagreement, which aligns with the patterns observed in the integrated science results.

Findings From The Focus Groups

To address the identification of preferred forms of support for enhancing self-efficacy (see Research Question 3: Which forms of support would respondents prefer?), four focus groups were conducted – two with pre-service teachers (N = 40) and two with in-service teachers (N = 40). Pre-service teachers expressed a preference for structured mentoring (that means collaboration with an assigned mentor during their induction into school practice), continued opportunities for cooperation with colleagues teaching other science subjects, and receiving feedback from more experienced teachers (e.g., through peer observations).

In-service teachers most frequently selected professional learning communities, sharing of good practice, and the possibility of consulting colleagues who teach the same subjects. Both groups agreed on the importance of accessible professional development courses that would explain not only the principles of integration but, crucially, also present concrete examples of good practice and actionable teaching activities.

When related to Bandura's theory of self-efficacy sources (see Bandura, 1977; Palmer, 2006; Evans, 2015), it is evident that pre-service teachers most strongly value vicarious experiences, whereas in-service teachers prefer mastery experiences as the most effective source of building their confidence. In-service teachers described vicarious experiences primarily as stimuli or motivation for designing and implementing their own teaching activities, which would then allow them to strengthen their self-efficacy through personal mastery. Only a small number of respondents in both groups identified social persuasion (e.g., encouragement from school leadership or colleagues) as a significant source of their self-efficacy.

Overall Summary

The aggregated overview of agreement, neutral responses, and disagreement across items indicates that in-service teachers report substantially higher levels of alignment with statements related to science teaching; their disagreement rates are less than half those observed among the pre-service teacher group (Table 1). This pattern is consistent across all items examined. In the STEM context, overall confidence and the self-reported ability to integrate content are lower than in the integrated science context, although in-service teachers again achieve higher values than pre-service teachers.

Table 1. Aggregated comparison of agreement, neutrality, and disagreement across research areas for both respondent groups.

Area	Pre-service			In-service		
	agreement	neutral	disagreement	agreement	neutral	disagreement
Science	36.6%	22.8%	40.6%	60.3%	21.7%	18.0%
STEM	19.7%	21.4%	58.9%	31.3%	29.1%	39.6%

Within the item-level analysis, it was possible to identify statements showing the largest differences between the two respondent groups. Table 2 (next page) summarizes the five largest differences in favour of in-service teachers within the integrated science domain (items labelled Sci) and the five largest differences within the integrated STEM domain (items labelled STEM). The overall ordering in the table is sorted in descending order according to the magnitude of the percentage-point difference.

Discussion, Limitations, And Implications

The data show that while content knowledge is strongest in biology and most challenging in physics for both respondent groups, this pattern is consistent with international findings highlighting uneven teacher confidence across STEM disciplines (Margot & Kettler, 2019; Yang, Wu & Li, 2023). The relatively positive results in biology-related self-efficacy are strongly influenced by the fact that biology was the most frequently represented specialization in both groups (pre-service teachers: 88.0%; in-service teachers: 69.5%). Thus, a higher degree of confidence in biology content knowledge is expected, confirming the role of disciplinary preparation in shaping domain-specific self-efficacy (Klassen & Chiu, 2011).

In the STEM domain, in-service teachers demonstrate relatively stronger confidence in mathematics and basic mathematical principles, whereas integrated STEM and the technological dimension represent more problematic areas. Interestingly, pre-service teachers report higher confidence specifically in technologies, yet this does not translate into confidence in integrated didactic application – as reflected in the consistently low agreement for items on preparing integrated STEM lessons and adapting STEM content. This pattern suggests that while pre-service teachers are exposed to modern technologies during their training, they do not feel sufficiently confident to implement them effectively in practice (An, 2017). In contrast, in-service teachers often develop their use of technologies gradually through teaching experience or through consultation with more technologically advanced colleagues. Overall, they also show relatively lower confidence unless they hold formal qualifications in informatics, physics, or technical education.

Pedagogical self-efficacy (e.g., classroom interaction, explaining phenomena, supporting conceptual understanding, fostering student interest) consistently shows higher values among in-service teachers, aligning with self-efficacy theory (Bandura, 1997) and extensive empirical

evidence (Tschannen-Moran & Hoy, 2001; Zakariya, 2020). These differences are logical, given that teachers develop key competencies predominantly through practical experience, whereas pre-service teachers have limited opportunities to cultivate them (Çiftçi et al., 2020).

Table 2. Item-level analysis – largest differences between responses of pre-service and in-service teachers.

Item	Agreement (%)		Difference (p.p.)	z	p
	pre-service	in-service			
STEM4: Confidence in mathematics	7.0	46.7	+39.7	7.46	$p < 10^{-5}$
Sci7: Welcoming students' questions	24.0	63.4	+39.4	7.37	$p < 10^{-5}$
STEM9: Application of basic mathematical principles	7.0	44.7	+37.7	7.13	$p < 10^{-5}$
Sci10: Seeking better ways to teach science	55.0	89.7	+34.7	8.86	$p < 10^{-5}$
Sci5: Clear explanation of natural laws and phenomena	39.0	71.9	+32.9	6.46	$p < 10^{-5}$
STEM1: Confidence in science-related knowledge	30.0	62.1	+32.1	5.99	$p < 10^{-5}$
Sci8: Helping students who do not understand a concept	32.0	62.9	+30.9	5.80	$p < 10^{-5}$
Sci9: Increasing students' interest in science	41.0	65.7	+24.7	4.70	$p < 10^{-5}$
STEM2: Confidence in using technologies in teaching	32.0	44.5	+12.5	2.33	0.0198
STEM3: Confidence in technical education	15.0	25.9	+10.9	2.34	0.0193

Legend: Full wording of statement items: **STEM4**: I am confident in my knowledge of mathematics.; **Sci7**: When teaching science, I feel confident welcoming students' questions.; **STEM9**: I understand basic mathematical principles and can apply them in teaching in alignment with the school curriculum.; **Sci10**: I continually strive to find better ways to teach science topics.; **Sci5**: I can clearly and comprehensibly explain natural laws and phenomena.; **STEM1**: I am confident in my science related knowledge.; **Sci8**: When a student struggles to understand a scientific concept, I feel confident that I know how to help them better understand it.; **Sci9**: I know what to do to increase students' interest in science.; **STEM2**: I am confident in my knowledge of using technologies in teaching and introducing them to students.; **STEM3**: I am confident in my knowledge of technical education.

These findings are further confirmed by the results from the focus groups, where the groups identified the relevant sources of self-efficacy (see Bandura, 1997; Palmer, 2006; Evans, 2015). Pre-service teachers demonstrated a strong need to gain confidence and practical experience through support from experienced educators and by observing successful integrated instruction. This preference reflects their lower professional autonomy and their reliance on vicarious experiences. Conversely, in-service teachers prioritized professional communities and peer consultation, appreciating opportunities to share concrete experiences and solve issues emerging from everyday practice, reflecting their emphasis on mastery experiences. These conclusions are consistent with selected international studies (e.g., Palmer, 2006; Rice & Roychoudhury, 2003).

Based on the data, several practical recommendations and directions for further investigation can be formulated. It is evident that in the context of integrated STEM, the mathematical component requires targeted support, particularly for pre-service teachers. One possible approach is the inclusion of didactically structured activities that explicitly link mathematical content with science subjects, accompanied by formative assessment focusing on mathematical reasoning and the identification of analogies (Samková, Rokos & Vízek, 2025).

There is also a need to place greater emphasis on the development of interactive teaching skills within the science context, such as preparing for effective classroom discussion, facilitating student questions, and explaining scientific phenomena with a focus on conceptual understanding of integrated content. In everyday practice, in-service teachers possess considerable tacit knowledge and classroom-based expertise that could be more systematically incorporated into

pre-service teacher preparation.

Regarding technology, for pre-service teachers it is important to transform technological confidence into competence in integrated instruction – for instance, through the design of lessons requiring connections across S-T-E-M components, rather than relying solely on isolated uses of ICT (see also Unfried et al., 2022). Insights from the focus groups indicate that both pre-service and in-service teachers would welcome a broader range of professional development courses introducing effective approaches to integration and offering concrete examples of good practice.

The influence of the sample composition – particularly the high proportion of respondents specializing in biology – could be addressed by conducting a follow-up substudy comparing only respondents with a biology background. Such a comparison would also be appropriate given the almost identical sample sizes of pre-service and in-service teachers within this specialization.

Conclusion

The results confirm that in-service teachers consistently report higher self-efficacy than pre-service teachers, particularly in the areas of pedagogical skills and science content knowledge. The most substantial differences relate to confidence in mathematics and the ability to apply mathematical principles, which represents a critical challenge for pre-service teacher preparation. Both groups exhibit low levels of confidence in the practical integration and differentiation of STEM content, indicating a clear need for targeted methodological support. Pre-service teacher education should therefore be strengthened through didactically structured activities that link mathematics with science subjects, an emphasis on the integrated context of science education, and the presentation of examples of good practice from schools where integrated science or STEM instruction has already been implemented. It is also essential to foreground pedagogical strategies for making disciplinary content accessible and to provide both pre-service and in-service teachers with opportunities to build stronger confidence in understanding STEM-related disciplinary content – particularly for those who have not formally studied these subjects. Such support should prioritise knowledge directly relevant to the primary and lower-secondary curriculum.

ESERA 2025 Copenhagen

Teachers' Experiences With STEAM Outdoor Education Training: Challenges And Opportunities

Marisa Correia[1,2] and Teresa Ribeirinha[1,2]
[1]School of Education, Santarém Polytechnic University, Portugal
[2]Life Quality Research Center, Portugal

Despite recognition of outdoor learning's potential to enrich STEAM education, its sustained implementation in schools remains limited by teacher training gaps, resource constraints, and cultural resistance. This study explores in-service teachers' experiences following completion of a postgraduate STEAM Education programme featuring a dedicated STEAM Outdoor Education module. Thematic analysis using Braun and Clarke's (2006) six-phase framework was applied to semi-structured interviews with seven Portuguese primary and secondary teachers. Eight themes emerged: (1) professional identity building around STEAM outdoor; (2) training quality; (3) transformation toward outdoor-integrated practices; (4) student impacts; (5) institutional barriers (time, self-funding); (6) peer collaboration versus resistance; (7) families and community role; and (8) need for ongoing professional support. Findings reveal training's efficacy in building confidence and interdisciplinary skills, tempered by school-level sustainability challenges. Implications include redesigned primary-focused programmes with formalized mentoring and institutional partnerships to scale adoption.

Keywords: Outdoor Learning, STEAM Education, Teacher Professional Development

Introduction

Across the globe, we are facing rapid changes and transformations that demand professionals to continually update their knowledge in order to address a range of pressing issues, including environmental, food, energy, and healthcare challenges (Kelley & Knowles, 2016). In response to this, there has been a growing interest in an educational approach that fosters the integration of multiple disciplines—Science, Technology, Engineering, Arts/Humanities, and Mathematics (STEAM)—which has proven to be highly beneficial for the learning and development of children and young people (Dejarnette, 2012; Thibaut et al., 2018). This approach is viewed as crucial in nurturing students' interest and engagement in various subject areas from an early age (Haas et al., 2021; Khwaengmek et al., 2021; Jamali et al., 2022; Molina-Ascanio et al., 2023). However, achieving this requires adopting an integrative STEM (Science, Technology, Engineering, and Mathematics) perspective, which emphasizes an interdisciplinary approach to content, and encourages problem-solving, inquiry-based learning, design thinking, and collaborative learning (Thibaut et al., 2018).

STEM education first emerged in the United States in the 1990s, initially coined as SMET (Science, Mathematics, Engineering, and Technology). Its evolution into STEAM reflects a broader understanding of the educational process, recognizing the value of the arts, social sciences, and humanities in fostering creativity and offering a more holistic view of the world (English, 2016; Sanders, 2009). Numerous studies have highlighted the advantages of STEAM education. Conradty and Bogner (2018) emphasize the importance of its interdisciplinary approach in fostering social and emotional skills, while Stephenson et al. (2022) underscore the value of connecting theory with practice as a key benefit of this model. Providing students with a solid grounding in STEAM subjects is essential not only for preparing them for future careers but also for equipping them with the tools to apply scientific knowledge in their everyday lives, thus honing their critical thinking and problem-solving abilities (Metz, 2014). STEAM activities

are particularly effective in stimulating creativity and collaboration due to their practical, hands-on, and exploratory nature (Malecha, 2020), which is why they are widely recommended at all educational levels (Campbell & Speldewinde, 2022; Correia & Martins, 2023).

Outdoor education, as a pedagogical method, acknowledges the potential of natural spaces—such as gardens, parks, and schoolyards—as ideal environments for meaningful learning. Through active engagement with nature, students have the opportunity to develop motor, cognitive, and emotional skills in a holistic manner (Molina & Tasiopoulou, 2023). Numerous studies highlight the benefits of outdoor learning, including increased motivation to learn, the development of interpersonal skills, and improved academic performance (Browning & Rigolon, 2019; Waite et al., 2016). Has also been gaining prominence, particularly with growing concerns over obesity and sedentary lifestyles among young people (WHO, 2016), as well as evidence that connecting with nature enhances students' physical and mental well-being by reducing stress and promoting physical activity (Louv, 2005; Reese, 2018). Considering that outdoor learning in environments where children can engage with nature plays a crucial role in fostering exploration, investigation, observation, debate, hands-on activities, and sensory reconnection with nature (Molina & Tasiopoulou, 2023; Van Dijk-Wesselius et al., 2020), it serves as a valuable resource that can complement the STEAM approach effectively.

Despite widespread recognition of the potential of outdoor learning by many educators (Erdem, 2018), this approach remains underutilized in schools (Feille & Nettles, 2019; van Dijk-Wesselius et al., 2020). In comparison to other educational settings, schoolyards are used less frequently for pedagogical purposes (Larsson & Rönnlund, 2021). Several studies have highlighted barriers that hinder the adoption of outdoor learning, including teachers' lack of knowledge and confidence, safety concerns, curricular constraints, and organizational pressures within schools (Bentsen et al., 2013; Dring et al., 2020; Dyment, 2005; Ernst, 2007; Fang et al., 2022; van Dijk-Wesselius et al., 2020). In this context, teacher training plays a pivotal role (Caballero-Blanco & Lasaga-Rodriguez, 2021; Dyment, 2005; Larrea et al., 2022; Pitiporntapin et al., 2023; Tan & Atecio, 2016; Tuuling et al., 2019).

Given the significant potential of outdoor learning to connect STEAM content with real-world experiences—enhancing both the meaningfulness of learning and the holistic development of children and young people—an exploratory study was conducted to address the lack of concrete data on teachers' perceptions and training needs regarding the pedagogical use of outdoor spaces (Correia et al., 2024). This study aimed to assess how kindergarten and primary school teachers (1st and 2nd cycles) from a group of schools in Portugal perceive the educational value of outdoor spaces and to identify the competencies and training they consider essential for implementing a STEAM outdoor approach. Findings from the questionnaire indicate that teachers recognize outdoor spaces as valuable for STEAM education, with play, expression, and well-being emerging as the most emphasized dimensions. However, interdisciplinary activities integrating multiple STEAM subjects were infrequent, primarily due to the rigidity and time constraints of the curriculum, as reported by participants. Teachers highlighted the need for professional development in outdoor pedagogy, curriculum integration, and interdisciplinary teaching. While most educators reported having no formal training in outdoor education, they expressed a strong willingness to participate in training programmes (Correia et al., 2024). To fully leverage the pedagogical potential of outdoor learning within the STEAM framework, it is essential to provide targeted training opportunities that equip teachers with the skills and strategies necessary to integrate outdoor spaces effectively into their teaching practices.

Previous research highlighted the critical need to equip in-service teachers with the knowledge, skills, and opportunities required to implement outdoor teaching in a dynamic and

interdisciplinary manner, maximizing the potential of outdoor education (Correia et al., 2024). To build on these findings, further research and discussion are necessary to better understand the knowledge, experience, and training in-service teachers need to effectively integrate STEAM education into outdoor settings. Building on this prior research, some in-service teachers who had previously completed a postgraduate programme in STEAM education were interviewed. The objective is to gather their perceptions and feedback on the strengths and areas for improvement within their experience, particularly concerning STEAM outdoor education.

Methodology

Data was collected through a semi-structured interview conducted with seven in-service teachers—one each from Biology, Physics, Mathematics, and ICT, plus three from primary school—who attended the Outdoor STEAM Education module as part of the Postgraduate Programme in STEAM Education at the Santarém Polytechnic University during the 2023–2024 academic year.

A thematic analysis was conducted on the qualitative data set. In particular, a deductive thematic analysis was undertaken, with the researcher's preconceptions and ideas, developed through the literature review, informing the coding process. The interview protocol was structured around three primary dimensions: (1) participants' perceptions of pedagogical outdoor space utilization; (2) their experiences and outputs from the postgraduate programme; and (3) the translation of acquired skills and knowledge into classroom practices. Nevertheless, any codes or themes that were not aligned with the preconceived concepts were employed to guarantee that the data collection process was adaptable to the teacher's voice.

The Braun and Clarke (2006) six-phase framework was employed for thematic analysis. In the initial stages of data analysis, transcripts were produced from the interviews. The coding process was conducted in a systematic manner, with the transcripts being highlighted and assigned their initial codes. Subsequently, the data were categorized based on their collective meaning. The coded data were then rearranged into more refined themes. Subsequently, the resulting themes were subjected to a process of reflection and review by two researchers, with the objective of ensuring accuracy and relevance.

Findings

The interviews cover professional background, motivations for enrolling in the STEAM Education postgraduate programme, experiences during training (curriculum structure, methodologies, delivery mode), contributions of the STEAM Outdoor Education module, examples of implemented activities, school contextual conditions, teacher collaboration, and suggestions for training improvement. Excerpts reveal rich narratives with concrete practice descriptions (e.g., ecotrail, biocube, schoolyard paths, pedagogical gardens, insect hotels, local pedestrian routes) and reflections on impacts for students, teachers, schools, and communities.

The presentation of results is organized according to the eight themes derived from the thematic analysis of the interviews, following Braun and Clarke's (2006) six-phase framework.

Professional identity building around STEAM Outdoor. This theme captures how in-service teachers from diverse backgrounds (e.g., primary, languages, sciences, ICT) view the postgraduate as a pivotal affirmation of their innovative identities, validating prior paths in active/digital methodologies while fuelling further development like master's pursuits. Participants describe it as "pedagogical path validation" and "right path confirmation," bridging autodidactic experiences (e.g., robotics, field trips) with structured STEAM expertise, fostering confidence to lead as change agents in schools.

Training Quality. Participants overwhelmingly portray the postgraduate programme as offering a well-structured, coherent curriculum with a strong practical emphasis, grounded in active methodologies and, in particular, in STEAM outdoors's hands-on field trips and effective theory-practice integration, which many describe as transformative. This excerpt demonstrates this positive perception of training in the words of one of the participants:

> We diversified learning spaces, and I learned that in this postgraduate programme too. (...) We created outdoor learning scenarios ourselves, meaning we didn't just talk about academic terms in the classroom, we actually went on field trips, and I think that part was very important.

Participants highlight peer sharing, contributions from guest experts (e.g., 3D printing), and Saturday face-to-face sessions as key moments for building professional networks and enriching learning. The hybrid format is generally viewed as appropriate and flexible, although participants consistently call for additional in-person, "hands-on" sessions to deepen engagement. Reported weaknesses focus mainly on the Arts component, which some perceive as insufficiently engaging or not well integrated with the varied disciplinary profiles of the participants.

The positive experience of attending this training programme motivated two participants to enroll in a master's degree, as one of them explains: "I liked the training immensely and that's what motivated me to continue and enrol in a master's... The methodology used in the postgraduate was very motivating".

Transformation toward outdoor-integrated practices. It reflects how the training equips in-service teachers with tools to shift from classroom-bound to outdoor-integrated STEAM practices, enabling them to confidently design and implement authentic activities such as ecotrails (using Actionbound® with QR codes), biocubes, pedagogical gardens, and insect hotels within schoolyards. This training fosters essential sequencing skills, constraint anticipation, and interdisciplinary adaptation across diverse contexts and subjects—including languages—transforming participants who were novices in outdoor structuring into assured implementers who readily share resources and lead collaborative projects within their schools. One of the participants demonstrates the confidence and knowledge that this training has given him to change his practices:

> We can also encourage our students to develop activities and learning scenarios in spaces that do not have to be closed classroom spaces. And that was also a bit of a search for that kind of dynamic and also for knowledge in that area, and it made perfect sense to me, because I feel much more confident now, also here, carrying out the activities.

Student Impacts. In-service teachers consider that STEAM outdoor education fosters student autonomy, confidence, motivation, and critical reflection, with eagerly requesting activity repetition, demonstrating "better self-regulation", expanding vocabulary (e.g., in language classes). As one of the participants points out: "Kids are more autonomous, confident... (…) more willing to ask doubts/intervene. They highlight sustained engagement and clear behavioral shifts from passive recipients to active interveners, supported by student productions and assignments, consistently emphasizing outdoor STEAM's effectiveness for real-world relevance and transversal competencies.

Institutional Barriers. Participants highlight key barriers including lack of planning time, self-funded materials, and municipal disparities in outdoor investments. They contrasted supportive leadership with entrenched transmissive school cultures that prioritize immediate academic results over long-term transversal skills development.

> I feel I lack the time allocated by management for these activities. I handle everything during my personal, non-teaching hours, receiving no institutional time investment despite the effort required to manage implementation under real-world conditions. The available time proves insufficient for quality execution on the ground... It's genuinely challenging!

Peer Collaboration versus Resistance. Participants described supportive peer networks—including WhatsApp groups for resource sharing and collaborative teaching within science clubs—coexisting with resistance from fatigued and individualistically oriented colleagues who remained entrenched in established practices and perceived outdoor STEAM initiatives as additional workload without immediate academic returns. They underscored the efficacy of "change agents" who modelled these activities directly in classrooms, facilitating gradual acceptance and highlighting the necessity of patience to effect fundamental shifts in professional mindsets.

Families and Community Role. Families emerge as “ultimate allies”, who enhanced the legitimacy of STEAM outdoor initiatives through the dissemination of student successes at home (e.g., awards, science fairs, international trips), particularly within primary education contexts. Municipal authorities and parish councils facilitated programmatic extensions such as field trips and community projects. This external involvement effectively helped overcome obstacles, sustained teacher motivation, and extended educational impacts beyond the school environment.

Need for Ongoing Professional Support. Post-training support via virtual communities, dedicated laboratories, and regular mentoring sessions—to maintain implementation momentum, address implementation uncertainties, and counteract post-training demotivation, particularly among initially reticent colleagues. One teacher emphasized that: “virtual communities: maintain thread, support network, share experiences, keep focus active.

Overall, the participants have a highly positive evaluation of the postgraduate programme and highlight several key strengths of the programme. The training was regarded as a valuable opportunity for professional development, with participants reporting that it effectively grounded and validated their knowledge, thereby enhancing their innovative teaching practices. The emphasis on hands-on, practical activities, such as field trips and real-world applications, was particularly praised. Collaborative work also emerged as a key strength, with teachers highlighting the value of sharing experiences and strategies with colleagues. The programme successfully demonstrated how to integrate various disciplines, a crucial aspect of STEAM outdoor education. Participants also appreciated the ongoing support from trainers, who were available for follow-up and to address any questions. Ultimately, participants noted a positive impact on students, observing increased confidence, autonomy, and participation during outdoor activities.

Regarding the less successful aspects of the training and the difficulties they experienced, participants highlighted several challenges. Some secondary school in-service teachers felt the content was primarily tailored to primary education, lacking adaptation for different educational levels. Participants also faced difficulties managing the demanding workload, as balancing training with teaching responsibilities proved challenging. Additionally, some were uncertain about independently implementing STEAM Outdoor methodologies. Many students, unfamiliar with group work or outdoor activities, made practical application more difficult. Finally, there was limited exploration of the artistic component within the STEAM framework, which could have been more engaging and integrated across the curriculum.

Participants highlighted several opportunities for improving the programme. They emphasized

the importance of post-training follow-up through mentoring programmes and ongoing sharing groups to support the practical application of the activities. Additionally, they stressed the need for greater institutional involvement, advocating for increased awareness among school boards and local authorities regarding the value of STEAM outdoor education, alongside efforts to secure more logistical and financial support. Teachers also suggested the development of structured materials and guides to aid in preparing and implementing outdoor activities. Furthermore, they recommended adapting the training to better address the needs of secondary education and expanding the integration of other subjects, including art education, to strengthen the STEAM approach.

Several challenges were identified that could hinder the successful implementation of STEAM outdoor methodologies. Participants reported encountering resistance from colleagues and institutions, making it difficult to engage others in adopting these innovative approaches. The demanding workload and bureaucratic tasks were also seen as significant obstacles, as they limited the time available for integrating outdoor activities into teaching practices. Furthermore, not all schools are equipped with the necessary resources, such as appropriate spaces and materials, to support STEAM outdoor education effectively. A traditional focus on academic results, coupled with a reluctance to change established teaching practices, also emerged as a barrier. Additionally, the lack of autonomy to invest in the development of outdoor spaces, particularly in schools dependent on municipal funding, was cited as a further limitation.

Conclusions

Drawing from the findings of this study, we aim to develop a conceptual framework for a training programme specifically focused on the STEAM outdoor educational approach. The results indicate that in-service teachers feel unsupported within their schools and face challenges in engaging their colleagues in the development and implementation of activities, which is consistent with prior studies (Bentsen et al., 2013; van Dijk-Wesselius et al., 2020). Also, in the study by Pitiporntapin et al. (2023), participants emphasized the need for training opportunities that involve collaboration in the development of interdisciplinary activities. Furthermore, it was found that offering a post-graduation in STEAM Education to in-service teachers across all educational levels (from pre-school to secondary school) led to difficulties in adapting content and activities to the specific teaching contexts and interests of each participant.

In response, a partnership is being established with a local school network to enable the participation of a broader range of in-service teachers, fostering a collaborative environment by bringing together educators who work within the same context. Additionally, the focus of the post-graduation programme will be narrowed to target a single educational level, specifically primary school teachers, in order to ensure more contextually relevant content and activities. Efforts will also be made to strengthen the integration of the arts component within the curriculum, further enriching the STEAM approach.

ESERA 2025 Copenhagen

Secondary Students' Perceptions Of STEM Subjects In Interdisciplinary Education In The Context Of Education For Sustainable Development

Anna Kellinghusen[1], Sandra Sprenger[1], Catharina Zieriacks[1], Anna Orschulik[1], Katrin Vorhölter[2] and Sandra Schulz[1]
[1]University of Hamburg, Germany,
[2]TU Braunschweig, Germany

Interdisciplinary STEM education offers the advantage of addressing complex issues such as climate change through the integration of multiple subjects. By merging these subjects, topics and methodologies can be attributed not solely to one subject but often to multiple subjects, such as diagram analysis or problem-solving. It is therefore essential to understand how students perceive each subject in interdisciplinary STEM education to determine whether the working methods and content of each subject can be applied accordingly, and which working methods and content have connections and differences between the subjects. In this way, points of connections and barriers for teachers and science in the learning process can be made visible. This study investigates students' perceptions of interdisciplinary STEM lessons in geography, mathematics, and computer science. Data were collected through an open digital questionnaire distributed to two ninth-grade classes in a secondary school in Hamburg, Germany (n = 45). Qualitative content analysis of the responses revealed that students perceived diagram analysis in both mathematics and geography; that calculation is part of mathematics, computer science and geography; and that students perceived media with particular subjects, for example, maps to geography and the calculator to mathematics.

Keywords: Qualitative research, Secondary education, STEM education

Introduction

Complex societal issues cannot be addressed solely through the knowledge of individual disciplines within Science, Technology, Engineering, and Mathematics (STEM) (Siller, Vorhölter & Just, 2024). As STEM subjects are taught separately in many parts of Germany, it is essential to integrate knowledge and methodologies from various fields in order to address societal problems holistically (Fensham, 2012). Common methods shared by all STEM disciplines, such as modeling and problem-solving, can be examined in conjunction and facilitate the avoidance of overlaps while promoting meaningful connections between the disciplines (Bacon, 2018). The categorization and perception of subjects in interdisciplinary instruction, from the perspective of students, allows educators to gain a clear understanding of students' perception regarding the subjects in STEM education, which can serve as an indicator of educational success. When these perceptions are made visible, points of connection and potential barriers to learning can be identified and addressed (Hopwood, 2007). A common perception that arises in this context is the reduction of mathematics to numbers and calculations, geography to map work and the memorizing cities and rivers, or computer science to just the computer lab (Beck et al., 2024). Such reductive perceptions offer valuable entry points for uncovering advanced learning content among students. By recognizing students' perceptions of the subjects, it is also possible to highlight barriers between pedagogical research and the actual experiences within the classroom.

The aim of this study is to identify students' perceptions of the subjects of geography, mathematics, and computer science within interdisciplinary STEM education in the context of Education for Sustainable Development (ESD).

The central research question is: What are secondary students' perceptions of geography, mathematics, and computer science in interdisciplinary teaching?

Theoretical Framework

Relevance Of Interdisciplinary STEM Education In ESD

In recent years, there has been an increasing focus on integrated approaches in STEM education, as they contribute to improved student learning outcomes (Jong et al., 2020) while simultaneously promoting the essential competencies of the 21st century (Bybee, 2010; Dare et al., 2022). The integrated teaching of STEM subjects is crucial not only for acquiring specific skills but also for development knowledge necessary to solve real-world problems (Siller, Günster & Geiger, 2024). ESD and STEM education share overlapping areas in educational discourse, as both fields address themes such as climate change and utilize interdisciplinary learning methodologies (Smith & Watson, 2019). According to a systematic review by Kellinghusen et al. (2025a), ESD and integrated teaching in geography, mathematics, and other (STEM-related) subjects complement each other particularly well, as both approaches promote interdisciplinary and context-based learning. Consequently, STEM education presents an opportunity to engage with topics articulated within the context of ESD, thereby contributing to the Sustainable Development Goals (Siller, Vorhölter & Just, 2024). This could enable learners to make informed decisions and take an active role in creating a sustainable society (Vorhölter et al., 2025).

Students' Perceptions Of STEM Subjects

In educational research, students' perceptions of subjects are central, as they often differ from those of subject experts and researchers (Lam & Lai, 2003). Although such differences should not be seen simply as inadequacies or misconceptions on the part of the students, they do reflect students' learning experiences and provide insights for improving curriculum and instructional design (Lam & Lai, 2003). Students' perceptions of a subject are additionally shaped by their motivation to learn, their academic performance, and the teacher (Wong et al., 2002).

There are various terms used in the literature to describe the perception of a subject, which are often used synonymously. The most common terms are 'ideas', 'attitudes', 'beliefs', 'conceptions' and 'perceptions' (Lam & Lai 2003). As there is no consensus on the use of the various terms, the authors have opted for the neutral term 'perception' in this study.

Methods

Sample

To address the research question, an open-ended digital questionnaire was administered to two ninth-grade classes in a secondary school in Hamburg, Germany (n = 45). Ninth grade (14/15-year-old students) was chosen because it represents a transition point before upper secondary education, reflecting accumulated experiences from geography, mathematics, and computer science lessons. At the time, computer science was not yet compulsory, meaning some student may not have received instruction in that subject.

Data Collection

Date were collected with a digital questionnaire in early December 2023 as part of the project "Nachhaltig handeln – MINT4all", which translates in English as "Sustainable action – STEM4all"[1]. The questionnaire included various materials, such as worksheets and slides, which were discussed in the interdisciplinary teaching unit focused on sustainable consumption and climate change. A real-world problem was addressed: whether a locally produced apple is more

[1] This research was funded by Bundesministerium für Bildung und Forschung, grant number 16MF1017.

sustainable in terms of greenhouse gas emissions and water than an apple imported from overseas.

After completing the teaching unit, students were asked to explain in writing, which subjects they perceive in the materials and to explain their reasoning in an open response format. Three material examples and corresponding student perceptions are discussed in this paper.

- The first material (M1) consisted of a worksheet designed for students to compare various apple cultivation regions, focusing on climatic zones, climate data, and seasonal calendars.
- In addition, the second material presented a pie chart illustrating the demand for apples in Germany, which required students to conduct an analysis of the data depicted in the diagram.
- Lastly, the third material (M3) comprised another worksheet where students were tasked with representing the storage of an apple in a cold storage facility over the course of the calendar year using the software GeoGebra.

The teaching materials are available in German at Vorhölter et al. (2025).

Data Analysis

The students' responses were analysed using the qualitative content analysis method according to Kuckartz & Rädiker (2023). Two researchers developed a category system describing students' perceptions of the subjects and their justifications within the interdisciplinary instruction, following a deductive-inductive approach. For the formulation of the deductive categories, the German educational curriculum for geography, mathematics, and computer science was selected (Brinda et al., 2008; German Geographical Society, 2014; Kultusministerkonferenz, 2022). This curriculum outlines the knowledge, methods, and competencies that students are expected to possess by the end of their educational journey in the respective subjects. The subjects, along with the associated content, methods, and competencies articulated in the educational curriculum, partially align with the experiences of the students, as educators utilize this framework for their instructional design, thereby influencing students' conceptions of each subject. To ensure inter-rater reliability in the coding process, a consensual coding approach was employed.

Key Results

Depending on the material, students give different reasons for their perception of a subject in interdisciplinary STEM education in the context of ESD. Selected examples are summarized below, reflecting findings reported in Kellinghusen et al. (2025b).

Calculation As Part Of Mathematics, Computer Science, And Geography

For students, calculation is central not only to mathematics and computer science, but also to geography. One student articulates this aptly: "We calculate how many apples we would be missing without the imported apples. The subject's mathematics and geography play a role in this" (M2_student_11). In another quote, both mathematics and computer science are mentioned in relation to calculation: "Math is used by calculating data just like computer science" (M2_student_43).

Analysing Diagrams As An Interdisciplinary Discipline Of Mathematics And Geography

For the students, analysing diagrams is anchored in both mathematics and geography. This is supported by this statement from one student: "We assessed the material by looking at it. I think it belongs a bit to mathematics (...) and a bit to geography" (M2_student_38).

(Digital) Media Assigned To Specific Subjects

The perceptions of subjects among students indicate that certain media can be specifically attributed to particular subjects. In this context, the use of atlases, maps, and climate diagrams plays a central role in geography. An example of the attribution to geography is: "In order to complete the content of the task sheets, we had to work with climate diagrams, tables, and climate maps from the atlas" (M1_student_38). In contrast, calculators can be assigned to mathematics for students: "That was math, because you had to calculate with a calculator. (M1_student_35)" and the digital program GeoGebra are significant for mathematics and computer science: "GeoGebra from the mathematics class (M3_student_24)" and " using GeoGebra [is] also computer science (M3_student_7)".

Discussion

Our key results highlight the students' perceptions of geography, mathematics, and computer science within the context of interdisciplinary teaching. First, students demonstrated a clear understanding that calculation serves as a fundamental element connecting mathematics, computer science, and geography. They articulated that calculations are not only central to mathematics and computer science but also play a significant role in geography. Second, the analysis of diagrams emerged as a crucial interdisciplinary skill that students associate with both mathematics and geography. Third, students' perceptions emphasized the use of different media linked to specific subjects, such as atlases, climate diagrams, and maps for geography; calculators for mathematics; and the online tool GeoGebra for mathematics and computer science. Lam & Lai (2003) confirm that the perception of the subject as limited to media is not incorrect, but it does not capture the complex understanding of the subject by the respective didactics and academics and provides information on how the curriculum and teaching in schools could be improved.

One limitation of the study is that the personality of the teacher, the teaching methods chosen and the subjects taught in the study have an influence on the results (Wong et al., 2002). Additionally, German educational standards shape students' perceptions of each subject; in another country, different standards might yield different results. Despite these limitations, the results suggest that students perceive that the subjects are not lost in integrated STEM teaching, and that connections among the subjects are, to a certain extent, promoted. These findings support the further implementation of integrated STEM education at the secondary level, as certain students recognize the connections among subjects and perceive subject-specific content. Especially in terms of ESD, it is becoming increasingly important that students are able to make these connections between subjects in order to develop sustainable solutions and better understand complex interrelationships.

Conclusion

In summary, this study highlights that students perceive connections and duplications of categories among geography, mathematics, and computer science in interdisciplinary STEM lessons within the context of ESD. By making these perceived connections visible, educators can gain an understanding of how students perceive the subjects of geography, mathematics and computer science in an interdisciplinary STEM teaching context. These findings require educators to further promote these connections within their curricula and ensure that students not only acquire subject-specific knowledge, but also develop necessary skills to collaboratively tackle and solve complex real-world problems.

Part 7 / Strand 7 Discourse And Argumentation In Science Education

Understanding, supporting, and promoting the use of evidence and argumentation discourse in science education. Includes scientific practices related to knowledge evaluation and communication, supporting the development of critical thinking, discourse analysis, talking and writing science in the classroom, and meaning making in science classrooms.

Sub-themes:

1) Analysis of Argumentation and Student Discourse in Science Education
2) Developing Critical Thinking through Science Argumentation
3) The Role of Talking and Writing in Science Knowledge Construction
4) Tools and Techniques for Enhancing Scientific Discourse
5) Meaning-making in Science Classrooms

Strand 7: Discourse And Argumentation In Science Education

Metin Şardağ[1] and Andri Christodoulou[2]

[2] University of Southampton, UK

Argumentation and discourse studies in science education can be defined as a broad research field that focuses on how individuals evaluate, justify, explain, discuss, and meaningfully use knowledge in scientific and social contexts on the basis of evidence (Kelly, Brown & Jiménez-Aleixandre, 2023). This field examines how scientific knowledge is spoken about, written, represented, defended, and questioned. Therefore, research on argumentation and discourse constitutes a strong area of intersection among scientific literacy, critical thinking, media literacy, science communication, and socio-scientific issues.

One of the main reasons why this field has become more visible today is that information circulates through media and digital environments at an irresistible speed and reaches large audiences within a short period of time. Misinformation, distorted scientific claims, sources of uncertain reliability, and anti-science discourses spreading through social media make it necessary to question the source of information, its evidence base, the context in which it is produced, and the way it is presented (Osborne & Pimentel, 2023).

The studies included in this section make this need visible through different age groups, subject areas, and methodological approaches. Kelles et al. (2026) examine students' relationships with media content and information sources in biology lessons and reveal the importance of teacher questions in questioning the origin, reliability, and possible conflicts of interest of sources. Matsuyama et al. (2026), through the Argu-made 2.0 system developed in the context of the bioaccumulation of pufferfish toxins, support sixth-grade students' processes of selecting appropriate evidence and constructing claim-evidence-reasoning structures. Dachauer and Lembens (2026) demonstrate that the Toulmin Argumentation Model can be used to improve the structural quality of high school students' scientific arguments in the context of ocean acidification. Santos Coutinho and Sasseron (2026), in a writing activity on climate change using the En-ROADS Climate Solutions simulator, show that students partially activated their critical thinking skills; however, they also needed further pedagogical support for strong justification and the evaluation of alternative perspectives. These studies indicate that selecting evidence, constructing reasoning, and questioning the reliability of information are learning processes that need to be explicitly designed and taught in science lessons.

The discourse dimension of the section includes studies on how teacher-student interactions shape learning opportunities. Cortés Morales and Marzabal (2026) analyse teachers' discursive moves in modeling-oriented instruction that make students' ideas visible, prompt them to question these ideas, and guide them toward a shared scientific model. Loidl et al. (2026), by positioning students who produce podcasts on electromagnetic radiation as science communicators, emphasize that content knowledge alone is not sufficient for producing high-quality explanations; explanation and communication skills also need to be explicitly supported. Kang and Adofo (2026), by combining automatic speech recognition and social network analysis, show that participation in science group work should be understood not only in terms of the amount of talk, but also together with variables such as students' relational positions, gender, science identity, and extraversion. Thus, the section addresses discourse both in terms of teachers' moment-to-moment pedagogical decisions and students' practices of explanation, participation, and

meaning-making.

The main trends in these studies appear to concentrate on argumentation, source evaluation, teacher discourse, the production of scientific explanations, learning supported by digital tools, and equitable participation. Another noteworthy trend is that students are positioned as active meaning-makers who construct arguments, write explanations, produce podcasts, use simulators, question sources, and participate in group interactions.

From a methodological perspective, these studies indicate that classroom interactions should be examined not only through outcome indicators but also through process data. Video recordings, students' written products, simulator outputs, podcasts, automatic speech recognition data, and social network structures show that research on argumentation and discourse relies on multilayered, multi-modal data sources. In this way, the field opens up both the effects of pedagogical interventions and students' positioning in classroom interactions to more detailed discussion.

The themes of sustainability and digital developments also strengthen the contemporary importance of this field. Climate change, ocean acidification, global warming news, food safety, and sustainability-themed group work enable students to relate scientific knowledge to social and environmental responsibilities. Digital argumentation systems, simulators, podcasts, automatic speech recognition, and social network analysis both support students' thinking and communication processes and provide researchers with opportunities to examine classroom discourse in a more detailed and scalable way.

Sources Of Information And Media In Biology Lessons: Relationships In A First-Grade High School Classroom

Ludmila Kelles[1], Blanca Puig[2] and Luiz Franco[1]
[1]Universidade Federal de Minas Gerais, Brazil
[2]Universidade de Santiago de Compostela, Spain

In this paper, we present an ethnographic study in which we observed Biology lessons over an academic year in a Brazilian 1st-year High School classroom. Based on video records of the lessons, we select events in which misinformation was a central part of discussions. These events were described in event maps and transcribed into message units. Analyses were guided by notions of reflection/refraction of language (Bakhtin circle) in order to answer two questions: i) For these students, how does the media reflect and/or refract science when disseminating diverse socioscientific issues? ii) How teachers' questions influenced students' evaluation of information sources throughout the year? As results, the students showed two roles that media could assume: as refracting scientific information, by: i) deceiving; ii) hiding; iii) distorting; iv) using retracted research data; v) using outdated information or manipulating news; or as reflecting scientific information, when: i) being used as checking tools; ii) recognizing mistakes and correcting itself. The teacher's questions were relevant in bringing about changes in students' evaluation of information sources throughout the year. His questions challenged arguments based on authority and gave visibility to key aspects of source analysis, such as explaining a source's origin, assessing the credibility of cited sources and considering possible conflicts of interest. These results bring empirical evidence that pedagogical activities articulated with the aim of promoting autonomous and well-informed positioning can generate learning opportunities beyond superficial criticality.

Keywords: Media literacy, Sources of information, Biology lessons.

Context And Relevance To Science Education

In this study we investigate how High School students discursively constructed relationships between science and media over Biology lessons in a public school in Brazil. Allchin (2022) argues that the role of the media is not secondary in science education. Students should have opportunities to understand how science is mediated, how it is communicated to society and what are the science images disseminated for different media.

Such demands are linked to discussions on how post-truth scenarios has affected schooling and, more specifically, science education in the contemporary world (Allchin, Bergstrom & Osborne, 2024). The media (traditional and new media) are one of the main foci of such issues. Traditional media lose support and trust (Chinn; Barzilai & Duncan, 2021), while new media produce echo chambers and increase the dissemination of fake news (Barzilai & Chinn, 2020).

The role of science education in this scenario goes beyond to promote critical thinking for distinguish between what is "true" and "false", to take critical action (Martínez Pena et al., 2024), what is coherent with the "criticality" notion presented by Davies and Barnett (2015). Other discussions have been demanded at school, such as: who invests in misinformation, what are the interests in propagating it, what is behind false information, what mechanisms are linked to beliefs in misinformation, what is the role of sources (e.g., Barzilai & Chinn, 2020). We seek to contribute to these discussions through a perspective of social interactions in the classroom as linguistic processes in which critical thinking can emerge and take action.

Theoretical Framework And Research Questions

People, through discourse, continually negotiate the meanings of texts, events and contexts in the

flow of their social life. In the post-truth era a very large part of critical thinking is evaluating the truth – or at least plausibility – of the premises (Lyons & Ward, 2024) or claims that are spread by social media.

Thus, meanings of certain textual and contextual elements of language can reflect or refract other texts, events and contexts (Bloome et al., 2022). This conception is particularly relevant to our study. When analysing how students relate media and science, it is important to consider that the meanings, interpretations and relationships proposed by them are intrinsically related to how these students reflect and/or refract histories, cultures, references, knowledge, values and norms.

The notions of reflection and refraction used in this paper are based on scholars from the so called Bakhtin circle. Language can be used to reflect or refract aspects of a culture, a context, a history. When language reflects something, it is maintaining certain historical, social and cultural meanings, without changes or questions, that is, it reproduces what is communicated. When language refracts something, in turn, it is being used to modify the original, historical meanings, considered standard for that particular culture, resulting in changes in meanings (Bakhtin, 1981).

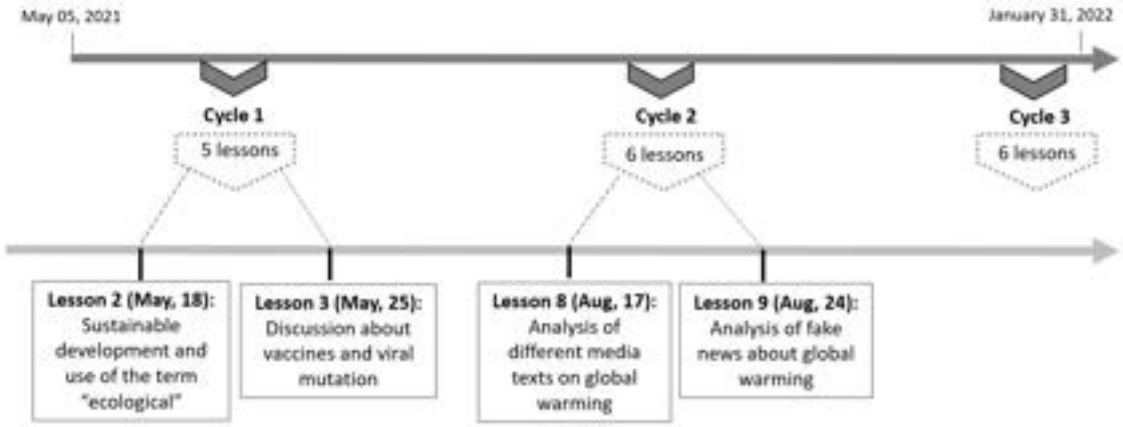
To contribute to discussions in science education field, we investigated discursive interactions in a 1st year high school classroom (15-year-old students in Brazil) over the course of an academic year. The following questions guided the study: i) For these students, how does the media reflect and/or refract science when disseminating diverse socioscientific issues? ii) How teachers' questions influenced students' evaluation of information sources throughout the year?

Research Method And Design

The study took place in a public school in a big city in Brazil. Our research team conducted participant observation and recorded written field notes (Spradley, 1980). Data were gathered from videotaped records of Biology lessons and students' artifacts to better understand forms of participation in the classroom (e.g., Castanheira et al., 2001).

We followed a 1st year high school classroom (9 boys and 24 girls) over the course of the academic year in 2021. As a result of the COVID-19 pandemic, the school adopted an emergency remote teaching system, in which teachers used platforms such as Google Classroom® to communicate with the class. For online synchronous lessons, Google Meet® was used.

The lessons were organized in three cycles of activities (Figure 1) in which students participated in scientific inquiry units (e.g., Pedaste et al., 2015) and activities guided by the use of socio-scientific issues (e.g., Sadler, 2009).



We adopted elements of an ethnographic perspective on education to develop our analysis. We built macroscopic representations, as charts of lessons and event maps (Castanheira et al., 2001) that allowed a broader view of the history of the group in different levels of detail. These representations made it possible to establish whole-part relationships, situating events in the group's history. From this panoramic view, we selected four lessons for analysis of interactions (Figure 1).

When analysing the 17 lessons of the year, we selected 4: lessons 2, 3, 8 and 9. The selected events were chosen because misinformation was a central part of each SSIs discussion in these lessons, thus opportunities for critical evaluation. The events were transcribed word by word and the analysis was guided by proposals on reflection/refraction of language (Bahktin, 1981).

In lesson 2, students analyse three media that use the word "ecological" in different situations: 1) ecological leather for clothing production; 2) water reuse in towel washing; 3) ecological bags produced from organic matter. In lesson 3, the teacher showed a map with the distribution of dengue cases around the world. Then, the students discussed possible relationships between the

development of a dengue vaccine and the ecological data on the map. In lesson 8, students analyse three reposts about global warming. Each repost addressed different aspects of the phenomenon, including false information. Finally, in lesson 9, the teacher showed fake news about global warming that has become common in WhatsApp® groups. The students discussed how they would react to that information if they received it in a group of their families.

Figure 1. Biology lessons selected for analysis in this paper.

Findings

Throughout the selected lessons (Lessons 2, 3, 8 and 9), we identified different relationships between media and science constructed by the students. We also observed changes over the lessons regarding the role of sources. As the complete discursive interactions are too long for this paper, we opted for showing excerpts from the participants' discourse in order to illustrate the analyses (Figure 2).

Regarding our first research question, the analysis indicates different interpretations by students about the relationship between media and science. We found events in which the media was interpreted as an agent capable of refracting scientific information, when it acted by: i) deceiving the reader (Lesson 2 and 9); ii) hiding data (Lessons 8 and 9); iii) distorting them (Lessons 3 and 8); iv) using retracted research data (Lesson 8); v) using outdated information (Lesson 8); or manipulating news (Lessons 2, 8 and 9).

Despite this, the students also indicated the media as an agent capable of reflecting scientific information. For example, when the media: i) consistently uses scientific knowledge (Lessons, 2, 3 and 8); ii) disseminates actions corresponding to scientific practice (Lesson 2); iii) promotes actions aligned with science official discourse (Lesson 2); iv) recognizes mistakes and corrects itself (Lesson 9). In addition, the students indicated that the media could also act in this way by functioning as a tool for checking information (Lessons 2 and 8).

Regarding our second research question, we mapped teacher issues onto student performances when evaluating information sources. Table 1 shows some of these questions.

In the first lessons of the school year, the students started from more restricted analyses, relying on arguments from authority. The teacher's questions challenged authority arguments, which appeared, for example, in the speeches of Gleice and Gisele (Lesson 2). In addition, the questions gave visibility to relevant aspects of source analysis, such as the need to explain the origin of the source and, even, to send them to colleagues, as seen, when discussing with Isabel (Lesson 3). In lessons 8 and 9, we observed more complex verifications that included assessing the credibility of the cited sources and considering possible conflicts of interest (e.g., Gisele's remarks in Lesson 8 and Lúcia's in Lesson 9). Questions made by the teacher were also important in this process.

Figure 2. Illustrative excerpts from the analyses. All excerpts are student speeches over the lessons.

	Lesson 2	Lesson 3	Lesson 8	Lesson 9
How does the media refract scientific information?	"it was a lot of marketing by these companies to put the word ecological" "all three are useless, because it doesn't help those who consume think they are leaving of consuming animal leather since it is not true" "it's more of an excuse to say you did something"	"I confused some data, it's been more than three months that I had been watched"	"in this text, he used the fallacy of authority a lot" "not to mention that the research is from 1958 and his text is from 2017, and notions of global warming have already changed a lot" "in the text itself, he uses very complicated words and graphics to try to somehow fit the research done" "He also uses information in a distorted way to convince people"	"Many of his studies have montages in the images. He makes a mistake and that's why his information was wrong" "Teacher, what you said is true that there is manipulation of the news even from important newspapers" "Of course, this newspaper will stop criticizing climate change. Not necessarily spreading misinformation but choosing what they're going to talk about."
How does the media reflect scientific information?	"there was a survey there in the United States that even made a documentary in which the result was that even if everyone reduced the water bill by forty percent, it would not be enough to not run out of water in the near future why the problem it's the industries" "I logged into the hotel's Instagram while we were discussing and I didn't see anything about tree planting"	"I saw a video from a YouTube channel. It's something like that. They brought the data and then the vast majority of people got dengue haemorrhagic fever. They brought the research data" "I saw reports talking about studies of two new viruses that cause symptoms similar to those of dengue or Zika that were being researched, but it is not yet known if these are dengue virus"		
How do students deal with sources of information?	"it is a biologist who creates, because I think it conveys more credibility" "the last one was the only one that we thought the term ecological fits and also the only one [media] that has the real intention of helping the environment so much so that he was a biologist, right?"	"The information is from a biomedical". "Googling more, I just found an infectologist talking about the 5 dengue viruses".	"NASA only posts on its website, the research it uses as a basis" "The sources he uses are unreliable and he uses this political scope a lot"	"the sources he uses are not very reliable" "he also uses an author a lot in this report. A man called Nils-Axel Mörner, who was a former president of the IPCC. When we went to research, we saw that he is not a source that has credibility"

We identified some challenges over this process. Even in the lessons we observed more complex analysis of sources, students still gave authority to some figures without going into detail (e.g. the authority that Izabel gave to the teacher and the researcher who had written the text analysed in classroom 8). So, the changes in analysing sources of information did not happen linearly but happened throughout the events in a variable way and correlated to teacher's questions over the discussions.

Table 1. Excerpts of the teacher's questions over the lessons and students' reactions.

Lesson	Teacher questions	Student	Excerpts from students' performances in evaluating sources
2 2	So, I wanted to put a reflection here for you to think about. Is there a biologist who does bad things for the environment?	Gleice	(…) the third one is interesting (..) that says is a biologist who creates, because, yes, I think it gives more credibility.
	Does every biologist have this environmental concern because he is a biologist? So, for you to think about (…)	Gisele	Yes, the real intention of helping the environment so much so that he was a biologist, right?
3 3	Based on what are you saying this? On a report you saw in a newspaper?	Izabel	I saw a video from (…) from a YouTube channel (…) they show the data from research.
	Because when we make a statement like that, it's good to bring the source, the data that we are relying on (…) Can you send it to us?	Izabel	Yes, I'll send it (…) I'll send it.
8 8	You commented on partisan political use of information, remember?	Gisele	(…) the text (…) it is radical to one side. The side that does not consider what (…) what the human being affects.
	But you have to doubt and even criticise what I say (…) Got it? You must be critical of your own teacher	Izabel	Wow teacher (…) I said (…) he is making fun of us (…) seriously, he didn't (…) he didn't put this here (…) for real
9	You should check what's in the source, who is that source (…) Who's talking about this?	Lúcia	There is manipulation of news (…) this newspaper not necessarily (…) will spread misinformation but choose what they will say.

Conclusions

The results of this research bring empirical evidence that pedagogical activities articulated with the aim of promoting autonomous and well-informed positioning can generate learning opportunities beyond a shallow criticality. We align ourselves with the proposals of Barzilai and Chinn (2020), when they suggest that science education should go beyond just identifying deficiencies in people's knowledge and skills to critically deal with information. Science teaching must be able to deal with cognitive biases, assessing disagreements about "how to know", recognizing and coordinating multiple epistemologies.

The analyses indicate challenges in this process. Naive views about science and difficulties in engaging in argumentative practices are examples of such challenges (Nehring, 2020) and were identified in our data. In this context, the teacher has a role in the organization and conduction of didactic processes. Our analyses reinforce the importance of the school as a fundamental institution in social organization, as well as the need to value actions and curricula for autonomous and critical students.

Exploring High School Students' Mobilization Of Critical Thinking Skills Through Argumentation About Climate Change

João Pedro Santos Coutinho[1], Lúcia Helena Sasseron[2]
[1]Interunit Graduate Program in Science Teaching of the University of São Paulo, Brazil
[2]School of Education of the University of São Paulo, Brazil

The purpose of this study was to investigate how Brazilian high school students mobilized critical thinking through a writing activity in the Chemistry class in which the students had to investigate and analyse a simulator related to the impact of anthropogenic variables on climate change, entitled En-ROADS Climate Solutions Simulator. The activity was developed with 57 first-year high school students at a Brazilian public school in the state of São Paulo. In order to analyse the information collected, we used the Critical Thinking Analytic Rubric (CTAR), composed of 6 categories (interpretation, analysis, evaluation, inference, explanation and disposition) evaluated with scores from 1 to 6. The results showed that students mobilized half of what would be expected to be the ideal level of high cognitive demand skills related to critical thinking, since most of the scores were at the midway point. This highlights the need to promote more activities in science teaching that help students develop critical thinking, but it also reveals limitations both in the wording of the activity questions analysed in this study and in the ability of the rubrics to assess actions related to critical thinking. Therefore, it is interesting that further research on the topic is conducted in order to address these issues.

Keywords: Critical Thinking. Scientific Argumentation. Classroom Research.

Introduction

In recent years, the spread of misinformation and disinformation involving scientific topics through digital means has reached alarming proportions and, even though young people are usually expected to have skills necessary to use today's technology effectively, studies show their struggle with evaluating information (Osborne et al., 2022). Considering this, it is a Science Education priority to promote classroom research and practices that foster students' higher order thinking skills development by understanding the social practices of science, evaluating information, and developing a consensus that help justify trust in scientific knowledge.

Therefore, critical thinking (CT) development, which is associated with higher order thinking skills such as the ones described above (Saxton et al., 2012), is essential to promote the development of critical subjects who can identify incorrect scientific information, hopefully reducing its spread. Based on that, this study's objective is to answer the following research question: "*How do high school students mobilize critical thinking skills in the Chemistry class through a writing activity aligned with a global climate simulator analysis?*"

Conceptual Rationale

The development of CT is considered a consensual objective of education by scholars (Jiménez-Aleixandre & Puig, 2022; Kuhn, 1999; Kuhn, 2019). Despite this, its understanding and definition are not homogeneously disseminated, that is, there are different perspectives regarding the characterization of CT, involving its meaning, components and how to develop them (Jiménez-Aleixandre & Puig, 2022).

One of the first and most influential definitions was proposed by Ennis (1985), who defined CT as "reasonable, reflective thinking that is focused on deciding what to believe and do" (p. 45). Later, the American Philosophical Association (APA) held a Delphi panel with various CT

experts, including Ennis, aiming to propose a consensual definition of CT. This panel considered that CT include both cognitive and dispositional dimensions, defining it as "purposeful, self-regulatory judgment which results in interpretation, analysis, evaluation, and inference, as well as explanation of the evidential, conceptual, methodological, criteriological, or contextual considerations upon which that judgment is based" (Facione, 1990, p. 2).

Years later, Davies and Barnett (2015) discussed some shortcomings of the APA definition, such as its rooting in only one kind of CT, related to argumentation and judgment formation. For this reason, they proposed changing this perspective to one in which CT consisted of "criticality," a perspective including action. Even though both movements considered that the development of skills and dispositions related to CT are important, the criticality movement differed from the traditional CT movement because it defended that the skills and dispositions by themselves weren't enough and they should be guided by ethical values and result in critical action.

Similarly, Jiménez-Aleixandre and Puig (2022) reviewed and proposed a holistic characterization of CT aiming to explicitly integrate both perspectives. This proposal considers that CT is characterized by two sets each one comprised of two components, the first set marked by purposeful judgment, aligned with the APA definition, with the components cognitive and epistemic skills and critical character; and the other set marked by civic participation and social justice, aligned with criticality, with the components independent opinion and critical action.

Regarding CT assessment, it is commonly derived from multiple choice tests, such as Critical Thinking Assessment Test (CAT) (Stein & Haynes, 2011) and Watson-Glaser Critical Thinking Appraisal (Watson & Glaser, 1964), which arguably do not measure the higher order skills associated with CT, since they are not designed nor have the purpose of formative feedback (Reynders et al., 2020; Saxton et al., 2012). Given this, instead of using tests to assess CT, rubrics could be used, as they provide more detail regarding the scores, what is being measured and what should be included in the data interpretation (Saxton et al., 2012).

Considering this, Saxton et al. (2012) proposed and experimentally studied the Critical Thinking Analytic Rubric (CTAR), heavily influenced by the APA definition, stating that it can be used by raters to score student work samples in a consistent manner. Since they adopted the APA definition as the construct for the instrument, it focuses on the cognitive and epistemic skills and critical character, assessing "five cognitive skills (interpretation, analysis, evaluation, inference, and explanation) and the disposition towards thinking critically" (Saxton et al., 2012, p. 254), rating these categories in scores of 1 to 6.

The categories are briefly defined as follows: *Interpretation* is concerned with understanding and accurately communicating the meaning of information; *Analysis* involves examining and comparing different sources of information; *Evaluation* involves identifying arguments and judging the credibility of sources; *Inference* involves making realistic predictions and forming rational and logical conclusions; *Explanation* is related to the use of evidence and reasoning to support an argument or perspective; *Disposition* towards CT is an affective dimension of CT, highlighting the need for the person to be motivated to mobilize their higher order thinking skills (Saxton et al., 2012).

Methodology And Research Design

This study uses a qualitative approach (Erickson, 2012) and involves the analysis of an activity carried out at a public school in São Paulo (Brazil) in the Chemistry subject by 57 first year high school students (14–16 years old) from different social classes and ethnicities in two classes, divided in 6 groups of up to 5 students per class, totaling 12 groups, anonymized as G1 to G12. The students received tablet computers with internet connection and they had to answer a question

while exploring the En-ROADS Climate Solutions Simulator (Climate Interactive & MIT Sloan, 2023), which is a simulation model that allows the exploration of scenarios focused on how changes in taxes, subsidies, carbon prices, and other factors can alter global carbon emissions and the global temperature in the following years. After the activity was completed, we collected the written responses and digitized them following the ethical procedures of informed consent, transparency and confidentiality.

We provided the students with a worksheet that introduced the simulator, explaining it was developed by Climate Interactive and the MIT Sloan Sustainability Initiative. The worksheet also had a summary of a special report of the Intergovernmental Panel on Climate Change (IPCC, 2022) that stated the goal of limiting global warming to around 1.5°C (2.7°F) by 2100. The question was as follows: "*Point out two variables present in the En-ROADS Climate Solutions simulator that you consider most important to be changed to achieve the target proposed by the IPCC. Explain how changing these variables can influence global temperature.*"

In order to analyse the students' responses, we used the CTAR instrument (Saxton et al., 2012) adapted to the question the students had to answer, as presented in Table 1. Both authors scored the responses individually and then compared the scores, discussing and reaching consensus regarding the divergent scores.

Table 1. Overview of the Critical Thinking Analytic Rubric. Adapted from Saxton, Belanger and Becker (2012).

Rubric categories	Scores					
	1	2	3	4	5	6
Interpretation	Demonstrates no ability to work with the key concepts	Demonstrates an extremely limited ability to work with the key concepts	Demonstrates an uneven or shaky ability to work with the key concepts	Demonstrates a clear ability to work with the key concepts	Demonstrates a strong ability to work with the key concepts	Demonstrates confident ability to work with the key concepts and terminology
Analysis	Does not identify patterns in the evidence	Incorrectly identifies patterns in the evidence	Superficially identifies patterns in the evidence	Identifies patterns in the evidence	Accurately identifies patterns in the evidence	Accurately identifies important patterns in the evidence
Evaluation	Ignores all alternative perspectives	Ignores obvious alternative perspectives	Superficially evaluates obvious alternative perspectives	Evaluates all alternative perspectives	Evaluates most perspectives	Thoughtfully evaluates all perspectives

(Table Continues)

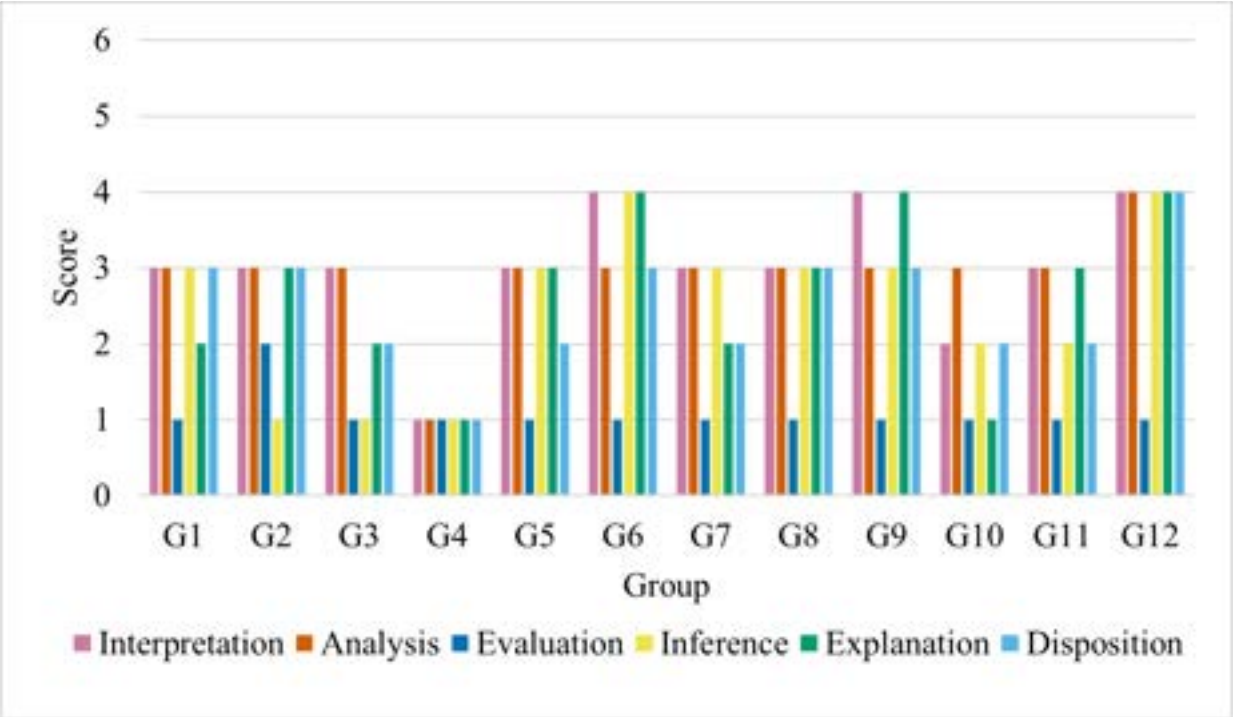

Table 1. Continued.

Rubric categories	Scores					
	1	2	3	4	5	6
Inference	Cannot extend key concepts or make predictions	Inadequately extends key concepts or make predictions	Shakely extends key concepts or predictions	Adequately extends key concepts	Clearly extends key concepts to make predictions	Confidently extends key concepts to make predictions and analyse implications
Explanation	Uses fallacious or irrelevant reasons	Conclusions lack support	Conclusions are weakly supported	Conclusions appear reasonable through use of support	Strong, warranted conclusions	Judicious, persuasive conclusions
Disposition	Close-minded, hostile to reason	Defends only with a single perspective, ignores others	Follows evidence but ignores context	Fair-mindedly follows evidence, addresses context	Fair-mindedly follows evidence, considering context	Objectively considers context and evidence

Findings

The results of the CTAR scores for the response of each group can be seen in Figure 1.

Figure 1. CTAR scores' results for the students' responses.

Although we analysed all the responses, for the purposes of this study, we present, as examples, the analysis of G10's and G12's responses. They presented, for the most part, the lowest and highest scores, respectively, among those with at least *Disposition* score 2, considering that a *Disposition* score 1 means that the response didn't present any justification, which was the situation of G4, whose response only pointed out the variables but did not justify the choice. It is important to note that the student's responses were written in Portuguese and were translated to English for this paper.

G10's response was as follows: "*The increase in the carbon price and the decrease in methane gas emissions. With the increase in the carbon price, we would use less forms and objects that emit gas, and the decrease in methane gas emissions increases the greenhouse effect on Earth.*"

Regarding *Interpretation*, G10's response showed a limited ability to work with the key concepts, considering that they stated that the decrease in methane gas increases the greenhouse effect when it's the opposite, hence score 2. As for *Analysis*, both variables listed were related to the decrease of the global temperature, but this relation is presented superficially, therefore score 3. In regard to the *Evaluation* category, the response did not present any alternative perspective, so score 1. Considering *Inference*, as they incorrectly relate the methane to the greenhouse effect and don't provide much detail about the increase in the carbon price, the category's score was 1. In the matter of the *Explanation* category, the reasons used to warrant the claim are incorrect, hence score 1. Finally, as regards the *Disposition* category, the response only defended one perspective and didn't discuss the context that prevents those variables from being changed, so score 2.

G12's response was as follows: "*The main variables that need to be changed to limit the temperature to 1.5°C by 2100 are: coal, the oil market, and the carbon price, as these are issues that directly impact climate change. Another variable would be the economic development of Third World countries that would reduce the burning of fossil fuels as an energy source and replace it with the use of clean and renewable energy.*"

From this response, we realized that, in relation to *Interpretation*, G12 not only identified both variables, but also perceived the nuance of the relation between the economic situation of a country and its access to sustainable energy, therefore, score 4. Regarding *Analysis*, they identified correctly the patterns in the evidence, thus score 4. As for *Evaluation*, we noticed that they only explained the positive sides of changing each variable, ignoring other points of view and hurdles needed to be overcome in order to change those variables, therefore, score 1. Since they adequately extended the key concepts, especially the relation between economic development and renewable energy sources, *Inference*'s score was 4. Furthermore, as they did not raise any negative side, *Explanation* seems reasonable rather than fully justified, hence score 4. Finally, regarding *Disposition*, we considered that G12 followed the evidence provided by the simulation and addressed the socioeconomic context, therefore, score 4.

Conclusion

In this study, we sought to investigate how high school students mobilize CT skills by structuring their arguments after analysing anthropogenic variables that contribute to the worsening of climate change with the help of an online simulator. Through the data presented, we noticed that most of the categories presented scores equal to 3, stating that in general the students mobilized half of what would be expected to be high cognitive demand skills related to CT.

Interpretation was the skill they managed to mobilize the best, considering most of the groups, except for G4, achieved a score of 3 or higher. This is evidence that the students, in the context of the Chemistry class, are more comfortable with working and applying the key concepts related to the subject.

The poor result in the *Evaluation* category may come from the wording of the question, which did not explicitly ask for alternative points of view. The only group that achieved a score higher than 1 was G2, that pointed out the variable of nuclear energy and briefly talked about its risks, while defending it to be clean and safe due to containment systems.

In future research, we should create the questions considering the opportunity to talk about different perspectives so that the students can better mobilize the *Evaluation* category. The new

questions should be created in a way that the students are motivated to mobilize high cognitive demand skills, so that the questions can't be answered with low score mobilizations.

The CTAR, as previously mentioned, is heavily tied to the APA definition of CT (Facione, 1990). So, it doesn't assess critical action and critical virtue defended by the criticality movement (Davies & Barnett, 2015). Considering this, it is important to state that only assessing students' essays and activity responses does not provide the full picture of CT mobilization, as it can be mobilized through actions and dialogue (Jiménez-Aleixandre & Puig, 2022; Kuhn, 2019).

Finally, this study's findings indicate both the urgency of implementing practices that mobilize CT in Science classes, since students don't seem to be used to mobilizing all the CT skills, as well as the need for academic research in Science Education regarding CT development, such as the assessment of students' criticality, as rubrics are limited to assess actions.

Deep Dive: Evaluating Students' Use Of Toulmin's Argumentation Pattern In Chemistry Classrooms For Constructing Scientific Arguments About Ocean Acidification

Jennifer Dachauer and Anja Lembens
University of Vienna, Austria

Science education plays a key role in helping students to become responsible citizens, capable of making appropriate decisions based on scientific information, participating in discussions on socio-scientific issues (SSIs), and taking action in the context of climate change. Thus, achieving scientific literacy in general and practising scientific argumentation skills – as part of scientific literacy – in particular, are essential. Therefore, the pilot study presented here focusses on improving upper secondary students' (ISCED 3) scientific argumentation skills by implementing Toulmin's Argumentation Pattern (TAP) in the chemistry classroom. We focus on chemistry education to better understand subject-specific argumentation in chemistry classrooms. This pilot study is part of an interventional study that aims to implement TAP as a construction mechanism to improve students' scientific argumentation skills. Our study is embedded in the SSI of human-induced ocean acidification. In order to gain insight into students' scientific argumentation patterns and develop adequate teaching materials, we asked 29 upper secondary students to write well-founded arguments to confirm a claim about calcification of coral skeletons made in a newspaper headline. Students' arguments were constructed prior to and following the provision of support material based on TAP. These arguments were analysed with regards to their formal quality using qualitative content analysis. Our findings indicate that TAP aligned well with our participants' intuitive arguments. We discuss our findings and propose how using TAP can contribute to teaching and learning chemistry-specific argumentation skills.

Keywords: Scientific Argumentation, Scientific Literacy, Classroom Research

The Need To Improve Scientific Argumentation Skills In Chemistry Education

At present, society is confronted with numerous challenges regarding climate change (IPCC, 2023). To address these challenges, science education plays a key role in helping students to become responsible citizens, capable of taking action in order to protect our environment (Bianchi et al., 2022). In this context, there is a relevant association with scientific literacy as "the ability to engage with science-related issues, and with the ideas of science as a reflective citizen" (OECD, 2019, p. 100). Being scientifically literate is fundamentally tied to using scientific information, i.e., to making appropriate decisions and participating in public discussions about socio-scientific issues (SSIs) (Lederman et al., 2024). Subsequently, on the one hand, students should be able to re-construct already existing scientific arguments and, on the other hand, construct their own ones (Cavagnetto, 2010; Christodoulou & Grace, 2019; Osborne, 2002). At the same time, students' lack of scientific literacy in general (Lederman et al., 2024), and argumentation skills in particular (Osborne, 2002), is problematic. Osborne and colleagues (2016) demonstrate the validity of an overarching instrument for assessing argumentation skills. We adopt one of their major implications here, proposing that "[e]xercises that asked students to distinguish claims, warrants and data would provide a foundation for more demanding exercises which asked students to construct their own arguments" (p. 841). As Toulmin (2003) distinguishes between claims, warrants and data explicitly, we use Toulmin's Argumentation Pattern (TAP) in this study to understand upper secondary students' (ISCED 3) intuitive scientific argumentation in the chemistry classroom.

TAP In Chemistry Education

Following Toulmin (2003), arguments follow a structure based on up to six elements: data, warrants, backing of warrants, modal qualifiers, rebuttals, and the claim itself. TAP is widely used (Henderson et al., 2018) and has proved suitable for analysis of scientific arguments (Erduran et al., 2004; Lieber & Graulich, 2022). Although the idea of implementing TAP (e.g. Erduran et al., 2004; Lazarou & Erduran, 2021) or an adapted version (e.g. McNeill et al., 2006) in the classroom is not new in science education, studies are required that help to delineate a chemistry-specific approach at the secondary level (Christodoulou & Grace, 2019).

Above and beyond subject matters, SSIs are excellent vehicles to practise scientific argumentation (Christodoulou & Grace, 2019). Tackling SSIs via argumentation enables students to become responsible citizens capable of facing global challenges (Sadler, 2004). Argumentation, in terms of formally connecting premises to conclusions, is generisable. Yet, making an argument within SSIs requires domain-specific knowledge (Tricot, 2018). Therefore, our study uses the chemical side of human-induced ocean acidification, which is highly relevant when discussing climate change (IPCC, 2023).

Research Question

This contribution gives insights into a pilot study that poses the following research question, focussing on upper secondary students in chemistry education: How can the implicit implementation of TAP in a chemistry lesson support students in applying this pattern to improve the structural quality of their scientific arguments? In this case, ‘implicit’ refers to the introduction of TAP elements through scaffolds without explicitly naming or defining these elements, allowing students to engage with them intuitively.

Research Method And Design

The present study was designed as a pilot study that aimed to evaluate whether implementing TAP in the chemistry classroom can improve students’ scientific argumentation skills in the context of human-induced ocean acidification. Prior to an actual intervention, we evaluated how students re-constructed preset scientific arguments. 29 students with prior declarative knowledge about human-induced ocean acidification from 11th and 12th grade from a general high school in Austria participated in this study, taking place in a 50-minutes chemistry lesson. At first, a picture of a fictional newspaper headline claiming ‘calcification of coral skeletons is impaired’ was presented to the students.

Phase I: Students were first asked to individually formulate a well-founded written argument supporting the headline, based on their current knowledge about human-induced ocean acidification from the perspective of a climate activist.

Phase II: Afterwards, students were prepared with ‘argumentation cards’. These cards contained part of an argument, each corresponding to an element (e.g. data, warrants) of TAP, and enabled various thematic lines of reasoning (e.g., lime-carbonic acid cycle, pH, solubility of calcium carbonate in solutions of varying pH, solubility of carbon dioxide gas in water). Technically, these cards could be used to form up to seven different arguments to confirm the claim. Cards corresponding to the same element were coloured the same, helping students to recognise patterns between these elements. Apart from this structuring aid, no further information about these elements was given to students. The sole instruction provided to students was that the utilisation of these cards could be in any combination deemed suitable, including the use of more than one card of the same colour, or omitting the entire cards of one colour. In this phase, students worked in pairs discussing which cards were suitable to support their claim but did not formulate a written

argument.

Phase III: Subsequently, students individually composed another written argument – this time using the previously selected argumentation cards – to support the headline regarding the impairment of coral skeletons calcification.

Phase IV: In a final phase, students were asked to formulate an additional written argument without any support materials, analogous to Phase I. However, due to time constraints, only a few students reached this phase.

Throughout all phases, students were provided with additional supporting material containing information about basic chemical concepts (e.g. chemical equilibrium, pH) relevant in this context. We chose this strategy to even out individual variance due to prior knowledge, allowing the students to focus on the argumentation process itself.

Analysis And Findings

Students' written arguments from phases I, III and IV were analysed regarding their structural quality through structural qualitative content analysis (Mayring, 2022). Content accuracy was not addressed in this contribution, as it was evaluated in a separate study (Dachauer & Lembens, in press). For the structural analysis, a deductive category system initially based on TAP was used. Due to challenges in assigning sequences of students' arguments to the categories *warrants* or *backing of warrants*, which required intense communicative validation (Steinke, 2004) between the raters - and even then, in some cases more than one categorisation would have been applicable – these two categories were merged into a single one labelled reasoning. This approach aligns with McNeill et al. (2006). As rebuttals were neither incorporated into the construction of the support materials nor observed in students' arguments, they were not included in the category system underlying the structural analysis. Based on the analysis of students' arguments and existing literature (McNeill et al., 2006; Toulmin, 2003), the coding system was further developed and serves as the foundation for a deductive coding approach in the planned follow-up study. This category systems comprises the following categories and their respective definitions:

- *Claim* refers to the statement whose content must be demonstrated and whose validity must be determined.
- *Data* refers to data and/or facts that serve as the basis for the argument and supports the claim.
- *Reasoning* refers to justifications, explanations, or elaborations that provide a basis for the claim in relation to the data. 'Reasoning' functions as a kind of bridge between the claim and the data. It can also reinforce the claim.
- The *Modal qualifier* provides information about the degree of certainty or binding force of the reasoning used to support the confirmation of the claim.
- *Other* refers to a sequence that cannot be assigned to any of the established categories.

During the process of assessing intercoder reliability, distinguishing between *data* and *reasoning* was occasionally challenging. This was due to the fact that some sequences were introduced with linking words such as *due to* or *because*, which could give the impression of aligning with *reasoning*. However, detailed content analysis revealed that these sequences often served as the foundation of an argument and should therefore be categorised as *data*. Two examples are given in Figure 1. Both examples demonstrate that the underlined linking words can introduce either *reasoning* or *data*, depending on the specific content they accompany.

During the communicative validation process between the two raters (Steinke, 2004), aimed at better defining and distinguishing between *data* and *reasoning*, the concept of the *'conceptual*

bridge' emerged as a visual representation to illustrate the connection between *claim*, *data* and *reasoning*.

Figure 1. Distinction between data and reasoning in students' arguments (students' arguments from phase I, Pos. 5-6 and phase III, Pos. 78, translated from German).

The calcification of coral skeletons is impaired because, due to the intense exchange of CO_2 caused, for example, by the combustion of fossil fuels, carbon dioxide dissolves in seawater and reacts to carbonic acid. From this hydrogencarbonate and oxonium ions are produced in the water. Due to the increased concentration of H_3O^+ ions, the pH of the seawater increases. Although the pH remains in the basic range, it nevertheless harms the calcification of coral skeletons.

Because the pH in the ocean decreases and the CO_2 concentration in the water increases, the calcification of coral skeletons is impaired. This occurs because coral skeletons require solid $CaCO_3$ to form lime, and the decrease in pH increases the solubility of solid $CaCO_3$ in water.

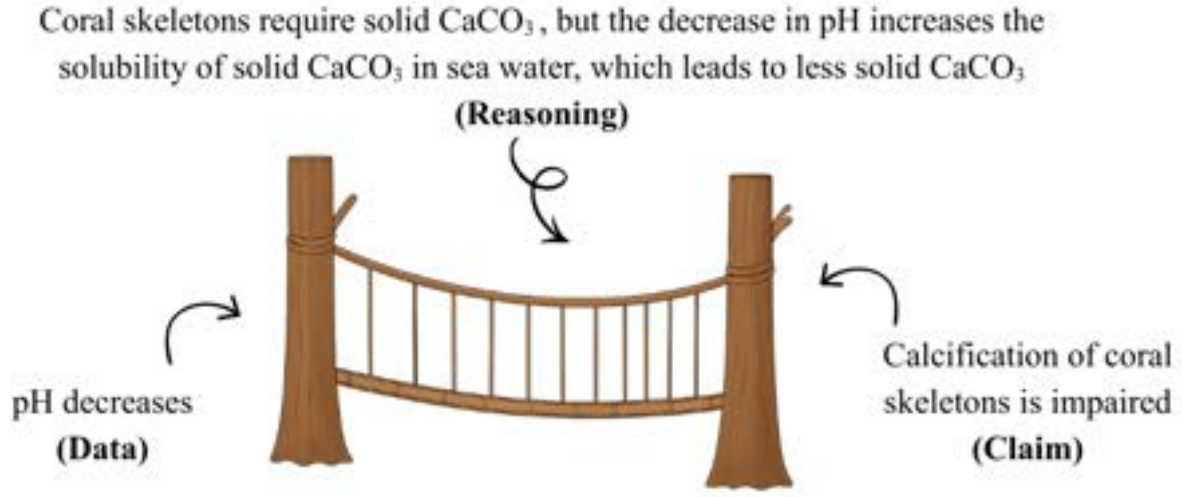
Legend: data – reasoning

This *conceptual bridge* breaks down students' arguments into distinct components, focusing exclusively on *data*, *reasoning* and *claim*, while disregarding *modal qualifiers* and the category *other*. The student argument presented in Figure 2 serves as an example to illustrate the concept of the *conceptual bridge* in Figure 3. As demonstrated in Figure 2, the student's argument includes more than just the elements *data*, *reasoning* and *claim* – in this case, it also contains a modal qualifier. However, this modal qualifier is not relevant to the conceptual bridge.

Figure 2. Example of a student argument (Student argument from Phase III, Pos. 3-4, translated from German).

The pH decreases, as a result, it is certain that the calcification of coral skeletons is hindered. Coral skeletons require solid $CaCO_3$, but the decrease in pH increases the solubility of solid $CaCO_3$ in sea water, which leads to less solid $CaCO_3$.

Legend: data – modal qualifier – claim - reasoning



In order to determine whether a sequence of a student's argument serves as either *data*, *reasoning* or *claim*, the *conceptual bridge* can be used as a tool for discussion between raters. Furthermore, it may also serve as an instructional instrument to help students actively distinguish between these elements in their own arguments. As illustrated in Figure 3, *data* and *claim* are visualised as bridge pillars, literally forming the foundation of the bridge – and, figuratively speaking, the foundation of the argument. *Reasoning* functions as the bridge itself, connecting the two pillars and enabling movement from one to the other. This visualisation emphasises the essential link between *claim* and *data* within the structure of scientific argumentation.

A total of three iterative coding cycles took place, each followed by communicative validation between the two raters. Table 1 illustrates the development of intercoder reliability across these three coding cycles.

To assess intercoder reliability, we began by coding students' arguments from phases III and IV – written after the intervention – under the assumption that these arguments would be easier to categorise. We used them to refine the definitions of each category and to add anchor examples to the coding system. Consequently, the category *other* did not exist during the first coding cycle for students' arguments in phases III and IV. This category was introduced during the first communicative validation and is therefore not referenced in the coding of students' arguments

from phases III and IV coded in the first cycle.

Figure 3. Conceptual Bridge (Students' arguments from Phase III, Pos. 3-4, translated from German; Bridge generated with ChatGPT).

In addition, intercoder reliability increased significantly across all coding cycles of phase III. Between the first and second cycle, the visualisation of the *conceptual bridge* was created and initially discussed between the two raters. Between the second and third cycle, this visualisation was incorporated into the coding system, along with an anchor example. However, assessing intercoder reliability for students' arguments of phase I remained challenging, even with the visualisation of the *conceptual bridge*. During this process, intense communicative validation took place between the two raters, with each arguing for their own coding strategy, using the *conceptual bridge* visualisation. No agreement on coding modal qualifiers was reached during the first coding cycle of students' arguments of phase I. This can be attributed to the absence of relevant anchor examples needed to define this category. While one rater coded sequences such as *so*, *decisive* or *therefore*, the other only coded sequences only where the degree of certainty was explicitly stated, such as *therefore, it follows with certainty* or *presumably follows*. Consequently, more diverse anchor examples were added to the coding system, resulting in higher reliability in the subsequent coding cycles. Also, intercoder reliability increased significantly between the first and the second coding cycle of phase I, whereas this was not the case during the final intercoder cycle.

Table 1. Development of the intercoder reliability over three iterative cycles.

		Claim	Data	Reasoning	Modal qualifier	Other	κ
Phase I	1st	38.46 %	47.06 %	34.78 %	0 %	22.22 %	**0.22**
	2nd	83.64 %	90.57 %	67.61 %	68.97 %	100 %	**0.74**
	3rd	91.23 %	96.30 %	73.24 %	91.43 %	100 %	**0.84**
Phase III &	1st	89.66 %	45.71 %	23.33 %	66.67 %	-	**0.43**
	2nd	92.96 %	78.87 %	78.26 %	88.89 %	0 %	**0.80**
	3rd	98.59 %	91.43 %	82.86 %	98.18 %	100 %	**0.91**
Total		**95.31 %**	**93.55 %**	**78.01 %**	**95.56 %**	**100 %**	**0.88**

Our analysis of students' approaches to structuring their arguments revealed a broad use of TAP across all phases. However, the significance of these elements was generally low in students' arguments from phase I. While modal qualifiers appeared in all phases, their use became more nuanced after the intervention – for example, shifting from phrases like *so* or *this leads to* to *this*

probably leads to or *this could lead to*. This enhancement is likely attributable to the provision of the pre-structured argumentation cards. Furthermore, the different elements in students' arguments were not seamlessly linked during phase I. After the intervention, however, the majority of students demonstrated more coherent argumentation. In particular, *data* and *claims* were more effectively connected through deeper reasoning. This progress also likely resulted from the use of pre-structured argumentation cards.

Conclusion And Outlook

We conclude that implementing TAP implicitly through teaching materials such as argumentation cards may lead to an intuitively appropriate use of these tools, thereby laying the foundation for a more explicit implementation of TAP later on. This scaffolded intervention could lead to "[e]xercises that asked students to distinguish [between] claims, warrants and data", thereby to re-construct existing arguments, and thus providing a "foundation for more demanding exercises which asked students to construct their own arguments" (Osborne et al., 2016, p. 841).

Based on our findings, implementing TAP already shows promise in improving students' scientific argumentation skills – even within our short-term intervention, despite limitations such as time constraints, a small number of participants, and a generally high socio-economic status. Therefore, we are going to scale up our follow-up study with a larger, more diverse group of students. To this end, teaching materials will first be developed through design-based research (Bakker, 2018), in close collaboration with both students and teachers to iteratively refine the materials. This will be followed by a two-phase intervention study ($n \approx 150$). From a structural point of view, phase one will implement a simplified version of TAP, focussing on Claim, Data and Reasoning (based on the CER model of McNeill et al., 2006), first implicitly, then explicitly. From a content point of view, phase one focuses on chemistry specific content knowledge. An interactive learning video introduces the topic of human-induced ocean acidification and its effects on coral skeletons. Following this, students are asked to formulate written arguments – later extending to other calcifying organisms as well. Phase two will deepen TAP instruction by extending the CER model to include modal qualifiers and rebuttals. The SSI of human-induced ocean acidification will serve as the central content. Through structured discussions, students strengthen their argumentation skills, reflecting on their actions, and formulating personal courses of action – also considering the broader relevance for humans and ecosystems beyond coastal regions. Given the need for more chemistry-specific research on scientific argumentation in SSI-related subjects at the secondary level (Christodoulou & Grace, 2019), we anticipate that this contribution will offer valuable insights and stimulate further work in this research area.

Acknowledgement

We thank the students and the school for their participation and support.

ESERA 2025 Copenhagen

Explaining Facts About Electromagnetic Radiation In Podcasts: Students As Science Communicators

Hannah Loidl[1,2], Christoph Kulgemeyer[2] and Thomas Plotz[1]
[1]KPH Vienna/Lower Austria, Vienna, Austria
[2]University of Bremen, Bremen, Germany

Although students often construct explanations in class, they receive limited instruction in communication skills needed to articulate them effectively. In this project secondary school students (N=130-140, age 12-13) were put into the role of science communicators to produce science podcasts on topics of their choosing in electromagnetic radiation (EMR). Two test groups received different introductions prior to the production of podcasts: one on EMR content knowledge (CK) and the other on principles of good explanations. Assessing the depth and type of explanations revealed that students predominantly provide superficial and descriptive explanations. Interestingly, elevated CK did not result in higher-quality explanations. As numerous non-physics explanations were found, we analysed the contexts of the explanations in more detail. Two distinct genres of podcasts emerged: Nature of Science (NOS) podcasts (N=12), which embedded phenomena in a broader scientific context, and science podcasts (N=22), which provided science-based explanations of a phenomenon. We conclude that developing explanatory competence requires explicit instruction in communication skills rather than content knowledge alone. Podcasts offer a promising medium for fostering science communication competence and deepening students' engagement with NOS concepts.

Keywords: Science Communication Competence, Explaining, Podcast

Science Communication And Science Education

Fostering positive attitudes towards science as well as the construction of scientific knowledge are primary goals of both science communication research and science education research. However, the disciplines developed in separate directions. Thus, some scholars advocated for the rapprochement of the two disciplines (e.g., Baram-Tsabari & Osborne, 2015). Kohen and Dori (2019) therefore conducted a literature review to identify similarities and disparities between these "sister disciplines" (p. 526). A key finding concerns the different orientations of the two communities: "the science communication community mostly considers the process of communicating science to the public, whereas the science education community by and large focuses on the product—the knowledge and understanding of science that students gain as a result of learning and engaging with science" (Kohen & Dori, 2019, p. 545). By *process*, the authors refer to the way science content is communicated to the target audience, i.e., through various communication channels. While science communicators prioritize engagement and outreach, science educators (bound to formal settings and regulations) prioritize conceptual understanding and knowledge about science.

Our project seeks to bridge this gap by designing an intervention that targets both objectives: fostering *science engagement* through active participation in authentic communication practices while simultaneously developing students' *scientific knowledge* and *explanatory competence*. Specifically, we implement this approach through a workshop where students are put into the role of science communicators and create podcasts focused on Electromagnetic Radiation (EMR). In the next section, we briefly discuss the relevance of communication competence for science education and present the theoretical framework for the evaluation of the students' explanations.

The Role Of Communication Competence In Science Education

Through communication we make sense of the world, both through passive communication when i.e. obtaining information from written text or listening to explanations from others and through active communication when constructing our own explanations of observed phenomena. Furthermore, the relevance of communication competence becomes clear when examining key science education frameworks. For instance, communication competence is a core element of PISA, as scientifically literate students should be able to "explain phenomena scientifically", and "research, evaluate and use scientific information for decision making and action" (OECD, 2023, p. 9). Similarly, *constructing explanations* and *communicating information* are two out of the seven science practices included in the Next Generation Science Standards (NGSS, 2013). Moreover, explanatory and communication competencies are embedded in several school curricula worldwide, including those of Austria and Germany.

As a result, Kulgemeyer and Schecker (2013b) developed a constructivist model of communication competence. In this model, they distinguish between the subject adequacy and the addressee adequacy of a communication product. Communication between addressee and communicator is considered successful if the communication product is both addressee-adequate and subject-adequate. An addressee-adequate explanation considers the addressee's prior knowledge and interests, whereas subject adequacy refers to the correctness of the communicated information.

To analyse the subject adequacy of the students' explanations in this study, we examine the explanatory type and the explanatory depth. The explanatory type is linked to philosophical accounts of explanation described in detail by Braaten and Windschitl (2011). For this study, we adopted and slightly adapted their three levels of explanation: a) *descriptive explanations* which answer questions about the what of a phenomenon and describe it on the basis of patterns and surface features, b) *process-oriented explanations*, which answer questions about the how of a phenomena by invoking causes and simple if-then relationships, and c) *justifying explanations*, which answer questions about the why of a phenomenon by embedding it within the larger framework and drawing on theoretical concepts and laws. Because these three explanatory types do not capture the factual correctness of an explanation, we additionally examined its explanatory depth.

Research Gap And Research Question

Although the construction of explanations is crucial for the development of students' scientific literacy, the research field is still emerging. There are few existing studies, i.e., Helms (2017) developed a method to improve students' explanations to teach their peers, de Andrade et al. (2019) analysed students' written explanations in the context of chemistry, Alameh et al. (2023) compared explanations of students, teachers and experts and Kulgemeyer and Schecker (2013a) filmed students while explaining physics contents during a roleplay. They analysed the filmed explanations through a qualitative content analysis, focusing on the addressee-adequateness. The more beneficial categories an explanation counted, the better its quality. In this study, we aim to look deeper into the subject-adequacy of students' explanations to answer to what extent the CK affects the subject-adequacy of students' explanations.

In previous studies, students had to explain a certain phenomenon in a fixed setting. It remains unknown how students construct science explanations when put in the role of science communicators and choosing their own topics. We further aim to discover how the students' Content Knowledge (CK) and Communication Competence (CC)[1] affect the subject-adequacy of

[1] This influence of the CC on the explanations is not presented in this paper as the analysis is still in process.

the students' explanations and what contexts students choose for their podcasts as science communicators. The following questions guide our analysis:

RQ 1: Does elevated content knowledge result in increased levels of subject-adequacy of the students' explanations?

RQ 2: What contexts do students choose to communicate their physics knowledge in podcasts and how does the context affect the level of subject-adequacy of the students' explanations?

Research Design

The presented study is embedded in the bigger project *We talk about Science*. In this project, students are put into the role of science communicators and are tasked with the creation of science communication products. The products are presented during science communication events for the school community. To measure influences of the CK and the CC, we used two test groups and one control group. One test group received a communication training (CT group) comprising two school lessons in advance. The training consisted of theoretical knowledge on good explanations and various tasks to practise explaining. The other test group received four physics lessons on EMR prior to the Science Communication Workshops. In this article, we present the results of the produced podcasts with a focus of the students' CK and the podcasts' contexts. The study took place in the summer semesters of 2024 and 2025.

The Science Communication Workshops

The workshops in the second cycle in 2025 consisted of two days each comprising of three school lessons (each 50'). On the first day, students were briefly introduced to the goals of science communication (i.e., inform, entertain) and most important aspects to be considered when producing science communication products (i.e., choosing the right medium, tailoring the product to the target group). Afterwards, we presented the subject EMR to the students. This topic was chosen as we knew that the participating students had not received any training on EMR prior the intervention. Additionally, a teaching concept has been developed recently and evaluated for secondary school students by Zloklikovits (2022) in Vienna. Based on this concept, we introduced the students to some key ideas guided by a prepared power point presentation and interrupted by experiments (i.e., feeling versus seeing IR-radiation, observing the effect of UV-radiation on UV-sensible beads). Afterwards, we asked students how the new acquired knowledge should be explained to their peers. We introduced them to an explanation cycle (see Malotki et al., 2026) that was developed for the communication training. Subsequently, the students performed a paper pencil test (~20') to inquire about their CC and CK on EMR. The first day ended with the students choosing a topic in the field of EMR for their podcasts. We supported the selection process with a collection of links to information texts on the browser-based application *taskcards*. On a pinboard, we arranged the links according to the type of radiation discussed in the texts. The texts ranged from science communication texts from popular German speaking journals (i.e., *Spektrum der Wissenschaft*) to information texts from the *German Federal Office for Radiation Protection*, and physics texts especially for students (i.e., *www.leifiphysik.de*). In groups, the students planned their podcasts with the help of printed storyboards. On the storyboards, they focused on three to five main research questions, chose the genre of their podcast (i.e., interview or discussion format), and planned their explanations. The next day started with the students writing scripts on printed worksheets (~ 50'). In the next 50 minutes, students recorded their podcasts with their mobile phones or tablets using the App C*apCut* (free version). In the last 50 minutes, students edited and handed in their products. The workshop ended with listening and appreciating the students' podcasts. Also, the products were uploaded to our project website. This way, students and teachers could share the podcasts with the school community, family and friends.

In contrast to cycle II as described above, cycle I in 2024 provided maximum freedom for the students. The first day, we briefly introduced the students to the five key ideas of EMR based on the work of Plotz (2017, p. 5). Afterwards, the students posed three questions concerning EMR on their own and then chose one question in groups of three. The students did research on the internet to answer their chosen question. Using a storyboard and worksheets for preparing their scripts (similar to cycle II), they planned their science communication products in their preferred format: podcast, video or Instagram post. On the second day, students created their products. There was no exact timeline for each step of the production process and the teacher as well as the project team only assisted when help was required. The podcasts from cycle I will be examined together as one group (Z1).

Participants

In this study secondary students from the age of 12 to 13 participated (N = 130-140 students from six different classes). We chose middle school classes, as this is the most representative student population in Austria. One of the participating schools is located in Vienna and two in rural areas of Austria (Styria and Lower Austria). In contrast to the two schools in Styria and Lower Austria, the school in Vienna is a private school with a greater percentage of students with migration background. Next to the middle school in Upper Austria, there is a gymnasium–high achieving students are therefore more likely to attend the gymnasium next to the middle school. This information is important, as the location and separation of high-achieving and low-achieving students probably influenced the quality of the learning products.

Research Method

For this study we chose a mixed-methods design to analyse the quality of the students' podcasts and influences of the students' CK and CC. The students' podcasts were analysed by applying a structural thematic content analysis according to Kuckartz and Rädiker (2022). All podcasts (N = 34; duration: approx. one to five minutes) were transcribed and then uploaded to MAXQDA 2024. After transcribing the podcasts, each text was read and structured in explanation sequences. One explanation sequence (usually) equals the proposition of one student. Next, the type of each explanation sequence was determined using the deductive subcodes: descriptive, process-oriented, and justifying explanations. Subsequently, the depth of each student explanation was examined. We distinguished the four subcategories non-physics, insufficient, superficial and concept-oriented explanations. As this distinction resulted in a large number of non-physics explanations, we examined the context of each explanation in more detail and categorised them as dealing with physics, astronomy, history of physics, biology/medicine or Nature of Science (NOS). To have a better impression of the students' associations with science, we analysed NOS aspects that students addressed in their explanations. For this purpose, we used the already existing category system of Sattelkau (2021). She derived the NOS categories from diverse NOS concepts (i.e., Family Resemblance Approach, Whole Science) and reflections on science communication. In our analysis of the explanatory context of each explanation sequence and the number of NOS dimensions, three types of podcasts emerged: Physics Podcast, Biological Podcast and NOS Podcast.

To compare the different groups (CK group, CT group, Control group, and Z1 group) and the different types of podcasts, we calculated scores of the explanatory depth and explanatory type. Each proposition was assigned with one to three points, according to Table 1. The scores were calculated by dividing the sum of the points in depth and type through the number of explanation sequences in the podcast. For example, a podcast containing 4 propositions with three descriptive explanations and one justifying explanation results in six points divided by four, achieving a Type Score of 1.5. Similarly, the depth score of each podcast was calculated. To compare the groups,

we used quantitative tests such as ANOVA and Kruskal-Wallis-Tests. Furthermore, we compared the explanatory type and depth of the different podcast types using the Kruskal-Wallis-Test. Finally, the CK test on EMR was evaluated to compare the content knowledge of the three participating groups in the second cycle by running an ANOVA. To measure influences of the students' CK on the explanatory type and depth, we calculated correlations.

Table 1. Distribution of points according to the applied code.

	0 points	**1 point**	**2 points**	**3 points**
Explanatory Depth	Non-physics	Insufficient	Superficial	Concept-oriented
Explanatory Type	-	Descriptive	Process-oriented	Justifying

Results

Analysis Of The Explanations' Subject-Adequacy

We measured the level of the subject-adequacy by examining the type and depth of each explanation in the podcasts. As one can see in Table 2, most assertions were coded as descriptive explanations (n = 128). Those assertions deliver facts or describe observable phenomena, usually answering questions about the "what of a phenomenon". To a lesser extent, assertions were coded as process-oriented (n = 31) or justifying (n = 32). Process-oriented explanations answer questions to the "how of a phenomenon" and include i.e. if-then-clauses, showing simple relations between descriptions ("what") and their trigger ("how"). Justifying explanations answer questions of the "why of a phenomenon" and include causes, theoretical concepts and laws, usually signalled by the word "because". To compare the podcasts of the different groups, a type score of each podcast was calculated as described in the methods section. Running a Kruskal-Wallis Test, no difference was found between the four groups. Neither the communication training nor additional lessons on the concept of EMR seem to influence the explanatory type score.

For determining the depth of explanations, the inclusion of physic concepts, theory and laws as well as the correctness of the assertations was considered. At level zero, there are *non-physics explanations*, which address a physics phenomenon but do not provide a physics-based explanation (i.e., the history of the microwave oven and biological, medical subjects). At the next level are i*nsufficient explanations*, which present a physics perspective but are based on incorrect facts. The next level comprises *superficial explanations*, which include mostly correct facts but do not connect them to underlying physics concepts. In contrast, *concept-oriented* explanations contain physics concepts, draw conclusions, and rely on correct information only. In Table 2, one can find the distribution of codes concerning the explanatory depth. Calculating the depth score and comparing the measures of the groups did not show any differences when computing the Kruskal-Wallis Test, $\chi^2(3) = 3.764$, $p < .288$, $\varepsilon^2 = .114$. However, the CK group shows a slightly higher mean depth score when compared to the other groups. Especially when looking at Dunn's post hoc comparisons, the highest difference was found between the CK and Z1 group (p = .060). This might indicate that the additional lessons on EMR before the workshops had some effect on the explanatory depth. Moreover, the Z1 group that received the least information on EMR and the least guidance during the workshop achieved the lowest mean depth score of all groups, however we found no significant differences.

Influences Of The Students' Content Knowledge On The Explanations' Subject-Adequacy

In cycle II, the students took a brief paper-pencil test on EMR to measure influences of their CK on the explanation quality in their podcasts. After verifying the assumptions, we conducted an

ANOVA which revealed significant differences between the groups in their CK ($F(2, 68) = 10.02$, $p < .001$, $\eta^2 = .23$). Post hoc comparisons using Tukey's test showed that the CK group did not differ from the control group, $t(68) = .677$, $p = .777$, $d = .198$. However, we found significant

Table 2. Distribution of subcodes in the categories type and depth of explanations.

Type of Explanations

	Z1	C	CK	CT	Total
Descriptive	45	33	29	21	128
Process-oriented	8	6	8	9	31
Justifying	13	6	6	7	32
SUM	66	45	43	37	191
N = Documents	12	8	7	7	34

Depth of Explanations

	Z1	C	CK	CT	Total
Non-physics	30	17	9	9	65
Insufficient	7	0	7	9	23
Superficial	22	23	24	16	85
Concept-oriented	7	5	3	3	18
SUM	66	45	43	37	191
N = Documents	12	8	7	7	34

differences between the CK and CT group, $t(68) = 4.181$, $p < .001$, $d = 1.207$ and the control and CT group, $t(68) = 3.458$, $p < .003$, $d = 1.009$. Although the mean test score of the CK and control group was significantly higher than the test score of the CT group, comparing the depth scores in the section above, those groups did not present explanations in more depth. This is also evident when examining the correlations between one group's content knowledge and their explanatory type score, as we found no correlation between students' mean test scores and explanatory type or depth.

Context Of The Explanations

During the analysis of the explanations' depth, many non-physics explanations emerged. Nevertheless, the podcasts clearly referred to the field of science. Therefore, we added the main category NOS dimensions to explore which aspects of science the students discussed. As a first step, we decided for each proposition if a phenomenon was explained from a physics, astronomy, history of physics or biological/medical perspective. Explanations that did not fit into any of those categories were coded as NOS. Next, we analysed all explanations regarding NOS dimensions using the coding manual of Sattelkau (2021). An overview of found NOS dimensions in the podcasts and their adapted and summarized descriptions can be found in The Explanations' Subject-Adequacy In The Different Genres Of Podcasts

Given the non-normal distribution of the data, a Kruskal–Wallis test was used to compare the depth scores and type scores of the different genres of podcasts. The test showed that the three genres differed significantly in terms of the explanatory depth $\chi 2(2) = 14.333$, $p < .001$, $\varepsilon 2 = .434$. In Dunn's post hoc comparisons, Physics Podcasts achieved significantly higher depth scores than NOS Podcasts ($p < .001$, $rrb = .850$) and Biology/Medicine Podcasts ($p = .002$, $rrb = .800$). As expected, there were no significant differences comparing the types of explanations between the three genres, $\chi 2(2) = 1.971$, $p = .373$, $\varepsilon 2 = .060$. However, this result is not surprising, as NOS Podcasts and Biology/Medicine Podcasts count a higher number of non-physics explanations which are scored with zero points.

Table 3.

By comparing the number of applied codes in each podcast two main genres of podcasts emerged: Science Podcast (n = 22) and NOS Podcast (n = 12). Podcasts coded as Science Podcasts mainly focus on scientific explanations, either from a physics or biological/medical perspective on selected phenomena of EMR. Therefore, we distinguished between two subgenres depending on the referred science discipline: Physics Podcasts (n = 10) or Biology/Medicine Podcasts (n = 12). Physics Podcasts not only included science explanations but also the two dimensions NOS

Products and NOS *Production*. For instance, one group described how the sunlight can be used for energy production through *solar panels* (= subcode *Applications* in the dimension NOS *Products*). In Biology/Medicine Podcasts, we only discovered the NOS dimension *Products* with two subcodes *Applications* and *Risks and Benefits*. Several Biology/Medicine Podcasts presented the application of X-ray imaging, highlighting its benefits for medical examinations, as well as its risks. In contrast, NOS Podcasts displayed a variety of NOS dimensions, for example, they name different nationalities of scientists, describe collaborations and typical tasks of scientists (NOS *Actors*) and name different institutions around the world (NOS *Players*). In the main NOS Podcasts category, we discovered the subgenre History of Physics Podcasts. For instance, one group described the *coincidental* invention of the microwave oven, while another podcast tells the story of the *discovery* of infrared light in 1800 (NOS *Production*). Furthermore, we found evidence in the NOS Podcasts that, alongside the development of *Applications,* one goal of science is the acquisition of *Knowledge* (NOS *Products*).

The Explanations' Subject-Adequacy In The Different Genres Of Podcasts

Given the non-normal distribution of the data, a Kruskal–Wallis test was used to compare the depth scores and type scores of the different genres of podcasts. The test showed that the three genres differed significantly in terms of the explanatory depth $\chi^2(2) = 14.333$, $p < .001$, $\varepsilon^2 = .434$. In Dunn's post hoc comparisons, Physics Podcasts achieved significantly higher depth scores than NOS Podcasts ($p < .001$, $r_{rb} = .850$) and Biology/Medicine Podcasts ($p = .002$, $r_{rb} = .800$). As expected, there were no significant differences comparing the types of explanations between the three genres, $\chi^2(2) = 1.971$, $p = .373$, $\varepsilon^2 = .060$. However, this result is not surprising, as NOS Podcasts and Biology/Medicine Podcasts count a higher number of non-physics explanations which are scored with zero points.

Table 3. Short descriptions of the NOS dimensions, adopted and adapted according to Sattelkau (2021). Specific examples found in the products are given in brackets.

NOS Dimensions	Products (n=71)	Knowledge (n=6)	One intention is the generation of knowledge, differentiation between models, theories and laws (i.e., finding out the origin of the universe)
		Applications (n=65)	Specific applications or technologies, optimization of applications and visions of future applications; Risks and benefits for humans and the environment (i.e., risks of x-ray imaging)
	Players (n=31)	Politics (n=1)	Diverse political actors, Scientific findings inform political decisions, politics can influence the direction of scientific research, i.e. through financing (i.e., Federal Office for Radiation Protection)
		Society (n=10)	Influences of society's needs, development through science, science communication, trust and mistrust (i.e., what radiation types are dangerous, radiation protection)
		Science (n=19)	Institutions, Disciplines, Financing of Science and Lobbying (i.e., scientific facilities around the world, collaborations in large science projects)
		Industry and Economy (n=1)	Influences of industry and economy on scientific projects, input and output of science for industry (i.e., invention of the microwave in the laboratory of an armaments industry)
	Actors (n=40)	Personnel Diversity (n=19)	Scientists have various cultural, religious, gender backgrounds and nationalities, different professions (i.e., physicists)
		Activities (n=15)	Scientists produce knowledge through observing, examining, measuring, … name substances, planets etc.
		Characteristics (n=2)	Scientists have different personalities, typical and atypical characters (i.e., curiosity), they experience success and failure, have vast expertise
		Social Interactions (n=4)	Scientists work together, discuss findings in (inter-)national conferences, use peer reviews, award prizes for outstanding work or name i.e. methods after scientists (i.e., Planck Telescope)
	Production (n=24)	Methods, mechanisms and practices (n=18)	Nature of scientific inquiry, different scientific methods, empirical evidence, formulation and testing of hypotheses (i.e., drawing on empirical evidences, presenting different scientific methods)
		Development and Time (n=6)	Scientific findings take time, there are highs and lows, errors and irregularities (i.e., coincidental invention of microwave oven, year dates)

Discussion

Students Mostly Provided Descriptive And Superficial Explanations

Although children are usually interested in more detailed information when confronted with explanations (*Why is that so?*), they did not show the same inquisitiveness about their own explanations in the analysed podcasts. Students mostly offered *descriptive explanations* and rarely provided *justifying* or *process-oriented explanations*. However, in the second cycle, we explained that in science, a claim is always followed by justifications. This was also one of the points highlighted in the communication training. Nevertheless, the CT group did not provide more justifications than the other groups. We do not know whether students are satisfied with the quality of their explanations or if they simply were overwhelmed by all the steps they had to take in our workshop. It is also possible that students lacked detailed knowledge of the phenomenon to be explained. Note that students did not show signs of time pressure during the research phase.

Furthermore, all groups tended to provide predominantly *superficial explanations*. We anticipated that the CK group might provide explanations in more depth, since they could rely on key ideas and experiences from the lessons on EMR before the workshop. However, the CK group did not provide a higher number of *concept-oriented explanations* than the other groups. This might indicate that students need some kind of guidance to connect prior knowledge to new information gathered from research. Additionally, Schecker and Höttecke (2021) report that in students' explanations claims often lack the connection to physics principles. To guide students in this process, Tschentscher and Berger (2016, as cited in Schecker & Höttecke, 2021, p. 500) developed the methodological tool "Explanatory Chain" (Erklärkette) to support students in formulating subject-adequate explanations.

Interestingly, only about 12 % (n = 23) of the propositions were coded as insufficient, which means that explanations based on wrong facts (i.e., humans cannot see but feel UV radiation, or gamma radiation is radioactive) were not predominant in the student-created podcasts. Nevertheless, we found a large number of explanations that were not physics related. This raises the question of whether students avoid intensive engagement with physics topics, preferring to talk about related sciences (i.e., biology or medicine) rather than explain phenomena from a physics perspective.

Influences Of The Content Knowledge On The Quality Of Explanations

In this study, we did not find statistical evidence that higher levels of CK resulted in higher quality of explanations. This was measured by evaluating the subject-adequacy in terms of the type and depth of explanations. The mean scores of the groups on the CK-test neither influenced the depth score nor the type score. This might indicate that it does not suffice to provide students with information about a certain topic to provide high quality explanations. This is in line with previous studies on CK and its influences on students' communication skills (Kulgemeyer & Schecker, 2013b). Similar results were found for teachers, needing a certain level of pedagogical content knowledge (PCK) to use their CK for delivering high-quality explanations (Kulgemeyer & Riese, 2018). Perhaps students too must develop communication competence skills in science education in order to provide high-quality explanations. Interestingly, students are usually tasked with the formulation of explanations during science lessons or in exams without being prepared with explanatory skills. As part of this study, we therefore developed and evaluated a communication training that focused on the addressee-adequacy of explanations. So far, the CK group has not shown better results in terms of the subject-adequacy of explanations. However, the results regarding the influences of the CC on the subject-adequacy as well as influences of the communication training on the addressee-adequacy are still being processed.

A deeper analysis of propositions coded with the subcategory non-physics opened a new perspective on the student-produced podcasts. We found two main genres of podcasts, Science Podcasts with the focus of explaining phenomena scientifically (at an age-adequate level) and NOS Podcasts that embed a topic in the field of EMR in a broader picture and address various aspects of science. In this category, we found the subgroup History of Science Podcasts. This is especially interesting, as one propagated way of teaching NOS is through the History of Science approach. Regarding the distribution of genres in the different groups, most NOS Podcasts were found in cycle II (n = 10) in the control group (n = 5). This might be influenced by the fact that we offered them a diverse range of topics concerning EMR on *taskcards*. However, in the end the students chose the topic by themselves. Furthermore, ten out of twelve Physics Podcasts were also created in cycle II. One might anticipate that most of the Physics Podcasts were produced by the CK group, however, in each group of cycle II we found three or four Physics Podcasts. Interestingly, eight out of twelve Biology/Medical Podcasts were created in cycle I. Apparently, students avoid deeper engagement with a chosen topic from a physics perspective, especially if they are not confronted with pre-selected topics/texts.

Limitations

Please consider that there are several limitations in this study:

- The correlations between the CK and the explanation quality in the first cycle is based on a small number of students (N = 71). The analysis of the explanatory type and depth score is based on both cycles with a sum of n = 34 podcasts. However, this is an exploratory study with a focus on the development of teaching materials.
- The findings reported are preliminary, as this is part of the ongoing dissertation project of the first author. Intercoder agreement on the coded data is planned for summer 2026.
- The groups included are not easily comparable, as the students have different socioeconomic backgrounds. Additionally, two of the participating middle schools are located next to a gymnasium. Consequently, high-achieving students are more likely to attend the gymnasium. In contrast, there is no gymnasium near to the third middle school (control group). This may explain why the control group performed better in the CK test. The choice of different schools was made due to the project's focus on science communication and the goal of greater outreach.
- As the podcasts are created in groups, it was not possible to compute correlations between individual CK scores and their skills in providing subject-adequate explanations.
- The used CK test on EMR is based on previous work of Zloklikovits (2024). The adapted and used items were not evaluated in advance. Also, the test only consisted of four items due to time restrictions.

Conclusion

Although we established considerable high standards for the students, they delivered commendable products in a short period of time and demonstrated strong engagement during the podcast production on the second day of the workshops. Incorporating science communication practices, particularly divers communication channels and attention to *communication processes*, appear to be effective approaches to engage students with science. While approximately a third of the created podcasts focused on physics explanations to present a chosen topic in the field of EMR another third of the podcasts focused on facts *about* science. This might indicate that the production of podcasts might be a beneficial way to teach NOS, especially when addressing NOS

explicitly. However, aiming at the production of Physics Podcasts, students need more guidance in obtaining information and translating gathered information into valuable science explanations. Formulating subject-adequate explanations is a skill that must be learned. One way of supporting this process is through the explanatory chain developed by Helms (2017). The analysis of the explanations' addressee-adequacy and influences of the developed communication training on the students' explanations are still ongoing. So far, this article presented a useful way of analysing the subject-adequacy in terms of type and depth of explanations. Those categories along with characteristics of the addressee-adequacy will be part of a diagnostics tool for analysing students' explanations. To conclude, we think that next to a certain level of CK, students should be prepared with explanatory skills in science education as are teachers with PCK. By strengthening students' communication skills, we enable them to express and share their knowledge effectively.

ESERA 2025 Copenhagen

Argument Construction System 'Argu-Made 2.0' To Support The Examination Of Evidence And Scientific Judgement Regarding The Bioaccumulation Of Pufferfish Toxins

Yuka Matsuyama[1], Keita Muratsu[2], Shinichi Kamiyama[3], Hideo Funaoi[4], Tomokazu Yamamoto[1]

[1]The Joint Graduate School in Science of School Education Hyogo University of Teacher Education, Japan

[2]Osaka Shin-Ai Gakuin University, Japan

[3]Osaka University of Health and Sport Sciences, Japan

[4]Soka University, Japan

Japanese primary school education is required to develop the ability to make scientific judgements about food safety and prevent food poisoning. For example, the consumption of pufferfish requires a scientific understanding and judgement of the bioaccumulation of pufferfish toxins. An argument consisting of 'claim – evidence – reasoning' is effective in using scientific understanding, and, in particular, the appropriate use of evidence is considered important. Therefore, this study developed an argument construction support system 'Argu-made 2.0', and conducted a class using this system and simulators by Matsuyama et al. (2023) promoting understanding of the bioaccumulation of pufferfish toxin, and the effectiveness of Argu-made 2.0 was evaluated. This class was conducted for sixth-grade food-chain studies. Students learned about the bioaccumulation of pufferfish toxins using simulators and constructed arguments while examining the evidence in Argu-made 2.0. The effectiveness of Argu-made 2.0 was evaluated from two perspectives: 'examination of evidence' and 'achievement of scientific judgement'. In 'examination of evidence', the process of using evidence appropriately in Argu-made 2.0 was analysed, while in 'achievement of scientific judgement,' the content of the students' arguments was analysed. The results showed that 48 [87%] students selected appropriate evidence, and 42 [76%] constructed arguments by correctly constructing all elements. These results indicate that Argu-made 2.0 was effective in supporting sixth-grade students in considering appropriate evidence and in making scientific judgements about the presence or absence of pufferfish toxins.

Keywords: Argument, Primary school, Argu-made 2.0

Introduction

Japanese primary school education is necessary to make effective scientific judgements about food behaviours, which is crucial for food safety especially preventing food poisoning. However, not only in Japan, recent studies have indicated that many consumers make incorrect judgements about food safety due to limited knowledge and awareness (e.g., Sharif & Al-Malki, 2010). There is a growing need for teaching methods that enable primary school students to learn to handle food safely and make informed judgements using this knowledge.

One example of scientific judgement regarding food safety is food poisoning by pufferfish toxins. In this case, a scientific understanding of the bioaccumulation of pufferfish toxins and a scientific judgement regarding the safety of consuming pufferfish by applying this understanding are necessary (e.g., Malloggi et al., 2023). Students must understand how the concentration process works to gain a scientific understanding of pufferfish toxin bioaccumulation. The simulator developed by Matsuyama et al. (2023) to understand the bioaccumulation of pufferfish toxins was effective in promoting this process. Developing the ability to form scientifically valid ideas (claims) is key to making scientific judgements. Arguments structured as 'claim (answer to a question) - evidence (experimental results) - reasoning (scientific principle)' have proven effective (e.g., Kamiyama et al, 2015; Iordanou et al, 2019). In particular, since the use of

appropriate evidence provides higher scientific credibility and validity to one's claims, it is important to consider the appropriateness of evidence in terms of it being obtained for proper purposes and methods and it being linked to one's claims while being based on theoretical support (scientific conventions) (Duncan et al., 2018).

Matsuyama et al. (2024a) developed an argument construction support system, 'Argu-made', to help users share, compare, and examine evidence online to promote the appropriate use of evidence. Matsuyama et al. (2024b) developed and evaluated a teaching method to encourage scientific judgement on the subject of bioaccumulation of pufferfish toxins, using a simulator developed by Matsuyama et al. (2023) in combination with arguments consisting of 'claim-evidence-reasoning'. The results showed that some students did not appropriately use their knowledge of the mechanism of bioaccumulation in their scientific judgements, indicating the need for improved instruction on the structure of evidence and reasoning.

Therefore, this study focused on examining this evidence, which was one of the challenges identified by Matsuyama et al. (2024b). To improve evidence examination, support is needed to allow opinions on the appropriateness of evidence to be shared and compared online and reconsidered from multiple perspectives. Therefore, we improved Argu-made by Matsuyama et al. (2024a) and developed an argument construction support system called 'Argu-made 2.0' that has the functions to realise these improvements. Unlike traditional paper media, this system enables asynchronous commenting based on individual progress, improving learner participation. Another feature is that past opinions can be confirmed and revised based on the comment history. This study aimed to develop and implement an instructional method using the simulator by Matsuyama et al. (2023) and Argu-made 2.0, and to analyse the effectiveness of this method by focusing on the process of examination of evidence by students and the achievement level of scientific judgement.

Research Question

This study verified the effectiveness of Argu-made 2.0. The two research questions are as follows:

Did Argu-made 2.0 support the evidence for bioaccumulation of pufferfish toxin?

Was Argu-made 2.0 effective in achieving scientific judgement?

Argument Construction Support System 'Argu-made 2.0'

Argu-made 2.0—a system developed using the no-code application development tool 'Adalo'—supports the construction of an argument consisting of 'claim (answer to a question) - evidence (experimental results) - reasoning (scientific principle)'. Figure 1 shows the home screen of Argu-made 2.0. Using the 'Decision of Claim (①)' function, users decide on the claim (the answer to the question) and make a plan for the construction of the argument, such as considering the characteristics of evidence to enhance its scientific reliability and validity (hereinafter referred to as 'appropriate evidence'). Using the 'Examination of the Evidence (②)' function, they can compare evidence and discuss the appropriateness of each evidence while considering the evidence to be used in the argument. The 'Examination of the Reasoning (③)' function allows them to construct reasoning that strongly supports the scientific credibility of their claims (hereafter referred to as 'appropriate reasoning'), just as when considering the selection of evidence.

Figure 1. Home screen.

Selecting 'Examination of the Evidence (②)' takes the users to the screen shown in Figure 2. Several pieces of evidence are submitted and shared here. They can extract appropriate evidence with a good mark (②-2) using the characteristics of the appropriate evidence noted in ②-1 as a hint. Furthermore, by selecting the comment mark (②-3) on each piece of evidence, they can move to the screen shown in Figure 3 to examine the appropriateness of the specified evidence. They can share their opinions, such as reasons, with others using the comment-sending function (②-4), and check the contents in the list (②-5).

Figure.2 Screen for submitting and sharing evidence

Figure.3 Screen for discussing the appropriateness of evidence

Overview Of The Class

A four hour long class was conducted by the second author in the science course 'Connections among living creatures' for 55 sixth-grade students (11–12 years old). Students had already studied the food-chain on land and in rice paddies. At the beginning of this class, they also knew that pufferfish toxin is not produced endogenously but by marine bacteria. They were asked the following learning question: 'If only marine bacteria were not eaten, would pufferfish be poisonous?' They made scientific judgements about the presence or absence of pufferfish toxins in the following two scenarios.

In Scenario 1, using the simulator and the knowledge of the content of the previous class, the students were asked to organise the food-chain with the five creatures (pufferfish, crabs, starfish, clams, and marine bacteria) and understand the basic mechanism of bioaccumulation: All the toxin in the prey is absorbed into the predator's body. In Scenario 2, through simulations, they confirmed the mechanism of bioaccumulation: The amount of toxin accumulated depends on what and how much a predator preys on, and more toxin is accumulated as it gets closer to the top of the food-chain. Subsequently, they constructed arguments using Argu-made 2.0. First, the students were given the prospect of constructing the argument by deciding their claim with the function of 'Decision of Claim (① in Figure 1)'. Next, they submitted and shared their evidence using the function of 'Examination of the Evidence (② in Figure 1)', and extracted the evidence they considered appropriate with a good mark (②-2 in Figure 2). Only one appropriate piece of evidence was selected when discussing the appropriateness of each piece of evidence with comments (②-4, 5 in Figure 3). Finally, the function of 'Examination of the Reasoning (③ in Figure 1)' was used to construct the appropriate reasoning just as when considering the selection of evidence.

Analysis

The class was evaluated from two perspectives: 'examination of evidence' and 'achievement of scientific judgement'. In the 'examination of evidence', the extraction of evidence with good marks (②-2 in Figure 2) from students' activity history in Argu-made 2.0 in scenario 2 was analysed by classifying the students into four types (Table 1).

For the 'achievement of scientific judgement', the content of the students' arguments in scenario 2 were analysed by scoring them, and their judgements about the presence or absence of pufferfish toxins were evaluated. We scored the claims, evidence, and reasoning independently on a 1-point scale, with the sum of the scores on a 3-point scale, based on a rubric. Concerning claim, one point was awarded if the student was able to write 'poisonous' in response to the question: If only marine bacteria were not eaten, would pufferfish be poisonous? Concerning evidence, one point was awarded if the student was able to select the experimental result: the pufferfish fed on zero marine bacteria and at least one other creature of one or more species. For reasoning, one point was awarded for correctly describing the basic explanation of how bioaccumulation works: All the toxins in the prey are absorbed into the body of the predator.

Results

From the 'examination of evidence' section, Table 1 shows the status of evidence extracted with good-mark. Of the students who selected appropriate evidence, Type A (42 [76%]) extracted only appropriate evidence with good marks. Type B (6 [11%]) selected appropriate evidence at the end, although they extracted appropriate and inappropriate evidence with good marks.

Among the students who ultimately failed to select appropriate evidence, Type C (2 [4%]) extracted appropriate and inappropriate evidence with good marks. Type D (4 [7%]) extracted all

inappropriate evidence with good marks. Type E (1 [2%]) did not select anything at the extraction or selection stage.

In the 'achieving scientific judgement' section, 54 out of 55 [98%] students received a score of 1 for the claim, 48 [87%] for the evidence, and 47 [85%] for the reasoning in each component. In addition, 42 students [76 %] correctly constructed all the elements (students who scored a perfect score of 3). Most students used the food-chain and bioaccumulation mechanisms to make scientific judgements regarding the presence or absence of pufferfish toxins while providing evidence of appropriate simulation results.

Table 1. Extraction of evidence with the good-mark to its adoption into the argument

Type	Number of students [The ratio]
A: All evidence given a good mark is appropriate, and the appropriate evidence is ultimately selected.	42 [76 %]
B: The evidence given a good mark is a mixture of appropriate and inappropriate evidence, but the appropriate evidence is ultimately selected.	6 [11 %]
C: The evidence given a good mark is a mixture of appropriate and inappropriate evidence, and the inappropriate evidence is ultimately selected.	2 [4 %]
D: All evidence given a good mark is inappropriate, and the inappropriate evidence is ultimately selected.	4 [7 %]
E: None of the evidence was given a good mark, or no evidence was ultimately selected.	1 [2 %]

Discussion

Argu-made 2.0 developed in this study was able to support the examination of evidence regarding the bioaccumulation of pufferfish toxins. Based on the status of the extraction of evidence with good marks, Argu-made 2.0 effectively helped sixth-grade students examine appropriate evidence. This effectiveness was attributed to Argu-made 2.0 encouraging the step-by-step selection of evidence using the good-mark function and supporting discussion its appropriateness during the selection process.

Furthermore, Argu-made 2.0 was effective in achieving scientific judgements. Most students used food-chain and bioaccumulation mechanisms to make scientific judgements about the presence or absence of pufferfish toxins while providing appropriate evidence. This success was likely because the selected evidence could be uploaded immediately to the argument, reducing the workload for the students and allowing them to focus on constructing arguments without interruptions. Additionally, since Argu-made 2.0 allows repeated modifications after uploading, this feature likely encouraged the students to re-examine the appropriateness of their evidence.

Future studies should investigate these factors in greater detail through questionnaires and follow-up interviews.

Gender Differences In Science Groupwork Participation: Exploring Students' Voices Using Automatic Speech Recognition And Social Network Analysis

Jingoo Kang and Stephen Adofo
Univeristy of Eastern Finland, Finland

This study explores gendered participation patterns in secondary school science group work by integrating Automatic Speech Recognition (ASR) and Social Network Analysis (SNA) in authentic classroom settings. Audio data were collected during science activities involving 16 students in a Finnish secondary school, using individual microphones with separate-channel recording to capture student speech. ASR was applied to generate time-stamped transcriptions and speaker labels, and interaction networks were subsequently constructed using SNA to identify participation patterns and student roles. Student speech was also manually coded into functional categories to examine discourse roles over time. The results demonstrate that ASR, when combined with individual microphone systems, can accurately differentiate speakers and capture student interactions in natural classroom environments. SNA effectively identified central and peripheral participation roles, while discourse analyses revealed how gender, science identity, and extroversion intersect to shape students' participation patterns. Although exploratory, this study highlights the methodological potential of combining ASR and SNA for fine-grained and scalable analyses of equitable participation in science classrooms.

Keywords: gender difference, automatic speech recognition, social network analysis

Introduction

Gendered Participation In School Science Group Work

Over the last decade, in many countries including Finland, female students have outperformed male students in school science subjects (OECD, 2016; 2023). In addition, previous studies indicate that female students tend to report stronger preferences for collaboration (Li et al., 2021) and higher levels of extroversion than their male peers (Weisberg et al., 2011). Taken together, these characteristics—higher academic performance, greater cooperativeness, and stronger extroversion—would suggest that female students are likely to participate actively in science group work.

Contrary to this expectation, participation in science group work often follows gendered patterns. Research consistently shows that boys tend to dominate group interactions and assume leadership roles, whereas girls are more frequently positioned at the periphery of group activities (Wieselmann et al., 2020). One potential explanation for this pattern lies in differences in science identity. Boys, on average, report higher levels of science identity, encompassing recognition, confidence, interest, and perceived competence, compared to girls (Williams & George-Jackson, 2014).

However, science identity alone does not fully explain observed participation dynamics. Empirical evidence suggests that some girls with high levels of science identity still participate passively in group work, while some boys with relatively low science identity engage actively (Kang, 2023). Moreover, it remains underexplored why girls' reported extroversion and collaborative preferences are not consistently manifested in their observable participation during science group activities. These inconsistencies point to a need for more nuanced analyses that consider the intersection of gender, science identity, and personal characteristics in shaping participation patterns.

To date, however, most studies investigating gendered participation in science group work have relied on small samples and labor-intensive manual observation or coding. While such approaches have provided important insights into classroom interaction, they offer limited temporal resolution and constrain the ability to examine participation patterns systematically across groups and contexts. There is therefore a clear need for methodological approaches that enable scalable, fine-grained analyses of student participation in authentic classroom settings, making it possible to link individual dispositions with observable interactional roles and participation trajectories.

Emerging Technologies For Capturing Participation Patterns

Traditionally, participation patterns during group work have been examined through direct classroom observation or video-based coding schemes, both of which are time-intensive and limited in scalability (e.g., Wieselmann et al., 2020). While these approaches allow for rich qualitative interpretation, they pose challenges for capturing fine-grained interactional dynamics across larger samples and multiple classroom contexts.

Recent advances in educational data science have introduced computational approaches that offer new possibilities for analysing classroom interactions in more systematic and scalable ways. One such approach is Automatic Speech Recognition (ASR), which enables the automated transcription of spoken interactions and the quantification of verbal participation (Jensen et al., 2021; Pugh et al., 2021). In classroom research, ASR has primarily been applied to teacher talk, as it is logistically easier to equip a single teacher with a high-quality microphone than to provide individual recording devices for students (Jensen et al., 2021). Only a small number of studies have applied ASR to student speech. For instance, Pugh et al. (2021) examined collaborative dialogue among students aged 12–15 using headset microphones; however, their data were collected outside natural classroom environments, with students interacting in pairs over Zoom. Consequently, the potential of ASR to capture student participation in authentic, face-to-face science group work remains underexplored.

While ASR enables the identification of who speaks and how much, it provides limited insight into the relational structure of interactions within a group. To address this limitation, Social Network Analysis (SNA) has increasingly been adopted in educational research as a powerful analytical framework for examining interactional patterns among learners (Saqr et al., 2020). SNA conceptualizes classroom interactions as networks, where students are represented as nodes and communicative exchanges as ties. This approach makes it possible to identify participation structures, such as central or peripheral roles, leadership, and dominance, that may not be readily visible through frequency-based measures alone.

In the context of group work, SNA has been used to examine collaboration quality, knowledge construction, and social positioning within learning groups (Saqr et al., 2018; 2020). Importantly, SNA offers a theoretically grounded way to operationalize participation as a relational phenomenon rather than an individual attribute, making it particularly well suited for investigating gendered participation patterns.

Integrating ASR with SNA offers a promising methodological advancement. ASR can provide automated, fine-grained data on verbal interactions, while SNA can model these interactions as dynamic networks that reveal students' participation patterns and roles within group work. Despite this potential, empirical studies that combine ASR and SNA to analyse student participation in natural classroom settings remain scarce. This study seeks to address this gap by leveraging the complementary strengths of ASR and SNA to examine gendered participation patterns in science group work.

Research Aim And Questions

Addressing these gaps, the present study aims to examine students' participation patterns during science group activities conducted in natural classroom settings. Specifically, it investigates how gender, science identity, and personality characteristics—particularly extroversion—are associated with students' participation patterns and roles within group work. Methodologically, this study explores the integration of ASR and SNA as complementary tools for identifying participation structures and interactional roles in an automated and scalable manner.

The study is guided by the following research questions:

RQ1. Can ASR capture and differentiate students' speech during science group activities in natural classroom settings?

RQ2. Can SNA effectively identify participation patterns and student roles within science group work?

RQ3. How are gender, science identity, and personality traits (extroversion) related to students' participation patterns and roles in science group activities?

Methods

Sample, Data Collection, And Measures

The study was conducted with high school students participating in a mandatory two-day science project on sustainability in Finland. A total of 28 students took part in the project, of whom 16 volunteered to have their voices recorded during the first two-hour brainstorming session. These 16 students were organized into four groups, each consisting of four members. Three groups comprised two female and two male students, while one group consisted of one female and three male students.

To capture individual student speech during group work, each participating student was provided with a wireless microphone. Audio signals were recorded on separate channels using an LR20 mixer to ensure high-quality speech input suitable for ASR processing. After recording, the audio channels were grouped according to team membership and merged into four final audio files—one per group—while preserving channel-level information for speaker identification.

In addition to audio data, students completed questionnaire measures assessing science identity and personality characteristics, including extroversion. These self-report measures were used to contextualize participation patterns identified through ASR and SNA and to explore potential associations between individual characteristics and participation roles.

Data Analysis

ASR processing generated time-stamped transcriptions and speaker labels, which served as the basis for constructing interaction networks for SNA. To address RQ1, the quality of ASR outputs was evaluated using two complementary metrics: Word Error Rate (WER) and Diarization Error Rate (DER). WER quantifies the proportion of incorrectly recognized words relative to a human reference transcript, with lower values indicating greater transcription accuracy. In speech recognition research, lower WER values (e.g., below approximately 20–30% in noisy multi-speaker environments) have been considered acceptable for interaction-level analysis rather than for perfect lexical accuracy alone (Attia et al., 2023).

On the other hand, DER measures the proportion of total recording time that is incorrectly attributed to speakers, combining false alarms, missed speech segments, and speaker confusions into a single error metric. DER is the most widely used metric for evaluating speaker diarization systems, especially in multi-speaker contexts where correctly identifying "who spoke when" is

critical for interaction analysis. In natural, spontaneous speech environments such as classroom group discussions, DER values up to mid-30% range have been reported in recent diarization research as indicative of a feasible diarization system for exploratory interaction analysis (Wang et al., 2024).

The outputs of ASR (time-stamped transcriptions and speaker attributions) were used to construct participation networks for SNA. In these networks, students were represented as nodes, and ties were defined based on temporal co-occurrence of speech segments and turn-taking interactions. SNA indicators (e.g., degree and eigenvector centrality) were then used to distinguish between more central and more peripheral participants within each group, addressing RQ2.

Survey data on science identity and personality traits were integrated with ASR- and SNA-derived indicators to explore associations between individual characteristics (gender, science identity, extroversion) and participation patterns, addressing RQ3. Given the pilot nature of the study and the small sample size, these analyses were exploratory and aimed at identifying preliminary trends rather than testing causal relationships.

To complement the automated analyses, a manual content analysis of student speech was conducted. Each utterance was coded into one of six functional categories: directing, elaborating, questioning, sharing, disagreeing, or agreeing. This coding provided (a) richer interpretive insight into participation patterns beyond structural measures, and (b) a labelled dataset for future development of machine learning models for automated speech function classification. In the present pilot study, the manually coded speech functions were incorporated into the participation analysis to capture both quantitative interaction structures and qualitative discourse roles.

Results

RQ1. Can ASR Capture And Differentiate Students' Speech During Science Group Activities In Natural Classroom Settings?

Audio data were collected from four student groups in a secondary school science classroom. To address RQ1, an initial performance evaluation was conducted using the audio data from the first group to compare several commercially available ASR systems, including Whisper, Google Cloud Speech-to-Text, AWS Transcribe, and AssemblyAI. The comparison focused primarily on the systems' ability to accurately differentiate between individual speakers in a natural classroom environment. Based on this evaluation, AssemblyAI was selected for subsequent analyses, as it demonstrated the highest speaker differentiation accuracy.

For the first group, ASR performance was quantitatively evaluated using WER and DER. The word-level comparison between ASR output and human transcripts yielded a WER of approximately 2.1% (63 word errors out of 3001 reference words), indicating very high lexical accuracy. At the utterance level, comparison of human and ASR speaker labels resulted in a confusion-based DER of approximately 19.5%, corresponding to a speaker attribution accuracy of about 80.5%. These values substantially exceed typical feasibility thresholds reported for classroom-based, multi-speaker ASR applications, where considerably higher error rates are often considered acceptable for participation-level analysis. Following this initial evaluation, AssemblyAI was applied to the remaining three groups.

Despite the overall high accuracy, minor errors were observed in both word recognition and speaker identification. For example, as shown in Table 1, in Occurrence 1, the utterance "I don't have any ideas" was incorrectly transcribed as "I do have any ideas," representing a word-level recognition error. In Occurrence 298, an utterance was incorrectly attributed to a group member when it originated from a brief interruption by a neighboring group, resulting in a speaker

attribution error. Such cases were rare and did not meaningfully affect the identification of speaker turns or overall participation patterns.

As illustrated in Table 1, the ASR system detected approximately 300 speech occurrences among the four members of the first group, providing detailed information on speech duration and speaker identity. Each entry includes an occurrence number, timestamps marking the start and end of speech, an assigned speaker label (A, B, C, or D), and the corresponding transcription.

Overall, the results demonstrate that ASR can capture and differentiate students' speech with high accuracy during science group activities in natural classroom settings. The high level of performance observed in the initial evaluation, together with consistent outputs across all groups, supports the feasibility of using ASR for analysing student participation patterns, addressing RQ1.

Table 1. Sample conversation excerpt from ASR output.

Occurrence	Duration	Speaker: Statement
1	00:00:01,439 --> 00:00:03,020	Speaker A: I do have any ideas.
2	00:00:06,879 --> 00:00:10,259	Speaker B: What kind of inequality do you want to focus on?
3	00:00:12,480 --> 00:00:15,660	Speaker A: Unfortunately, I haven't experienced any inequality.
4	00:00:20,239 --> 00:00:24,300	Speaker C: Last year they did the accessibility.
5	00:00:24,719 --> 00:00:50,466	Speaker D: The first thing that pops into my mind is like, you know, language inequalities, you know, like if you don't speak Finnish, like, how much that sets you back. Like in general, living in XXX or in Finland, of course it like depends on the area. Like in XXX, like, there might be more English translations and stuff, but like, think about how hard it is to participate in everything.
….	….	….
298	00:46:16,420 --> 00:46:57,019	Speaker D: How are you guys doing? What is it? What is it? That is interesting. That is such a good idea. I know. Great.
299	00:46:59,159 --> 00:47:13,619	Speaker A: Yeah. We're doing about nutrition in relation of malnutrition to poverty and reinforcing this free school food with nutrients which are, like, less common in the poorer.

RQ2. Can SNA Effectively Identify Participation Patterns And Student Roles Within Science Group Work?

Following ASR-based transcription and speaker identification, Social Network Analysis (SNA) was conducted to examine interaction patterns within student groups. Due to space limitations, the results presented here focus on a single 45-minute recording from Group 1, consisting of two male and two female students. The speakers' characteristics were as follows: Speaker A (Male 1, high science identity, extroverted), Speaker B (Female 1, low science identity, introverted), Speaker C (Male 2, average science identity, extroverted), and Speaker D (Female 2, average science identity, extroverted).

Frequency Of Speech Transitions And Speaking Duration

A total of 299 speech transitions were identified and ranked by frequency (Table 2). The most frequent transitions occurred between Speaker A and Speaker C (A→C: 70; C→A: 66), indicating that a substantial portion of the discussion was concentrated between the two male students. The next most frequent transitions were between Speaker C and Speaker D (C→D: 50; D→C: 45), suggesting that Speaker C actively engaged with multiple group members. In contrast, transitions involving Speaker B were rare, with only three transitions observed between Speaker C and Speaker B and between Speaker B and Speaker A, indicating limited participation and a

peripheral role in the discussion.

Analysis of speaking duration further supported these patterns. Speaker C had the longest total speaking time (751.52 seconds), followed by Speaker D (571.53 seconds) and Speaker A (564.83 seconds), whereas Speaker B spoke substantially less (119.76 seconds). Together, the high frequency of transitions and extended speaking duration position Speaker C as the most central participant in the group, while Speaker B appears comparatively marginalized.

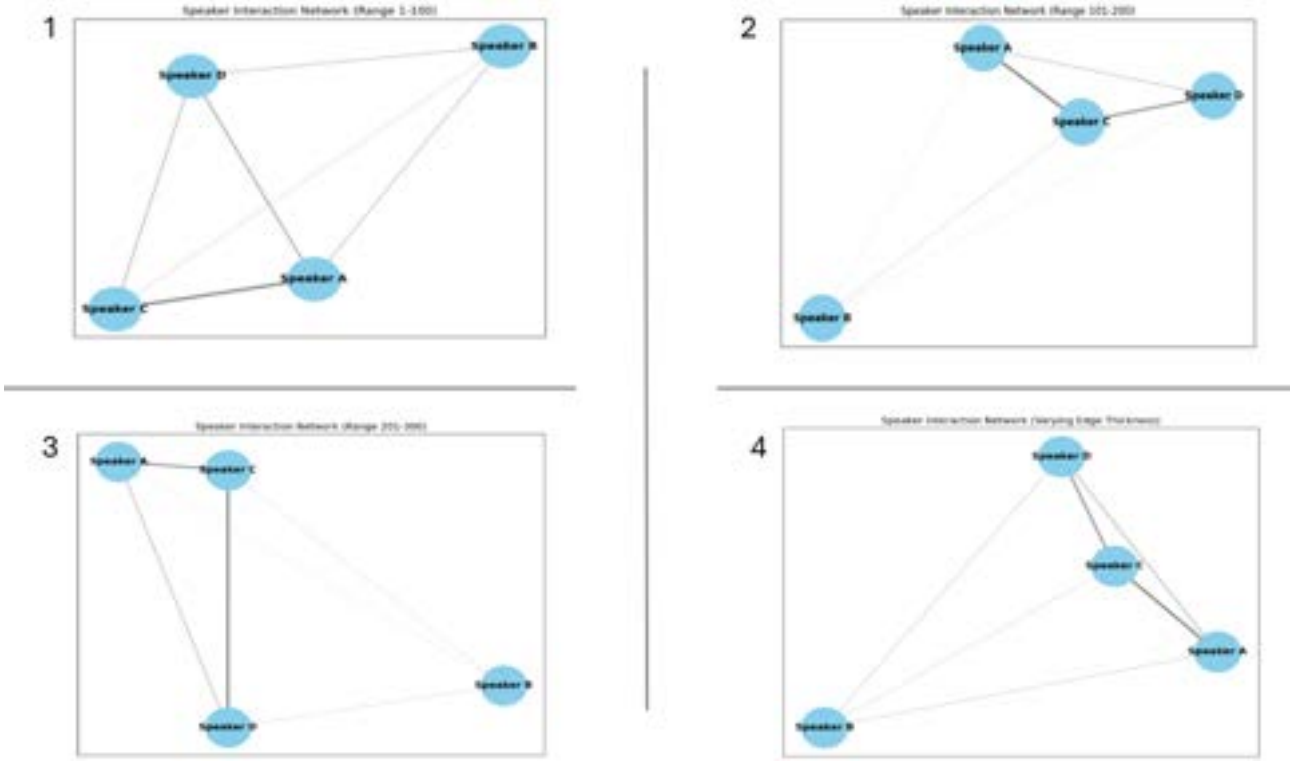

Table 2. Speech transition occurrences between group members.

Rank	Speaking direction	Frequency	Rank	Speaking direction	Frequency
1	'Speaker A' → 'Speaker C'	70	7	'Speaker A' → 'Speaker B'	8
2	'Speaker C' → 'Speaker A'	66	8	'Speaker B' → 'Speaker D'	8
3	'Speaker C' → 'Speaker D'	50	9	'Speaker D' → 'Speaker B'	5
4	'Speaker D' → 'Speaker C'	45	10	'Speaker B' → 'Speaker C'	5
5	'Speaker D' → 'Speaker A'	22	11	'Speaker B' → 'Speaker A'	3
6	'Speaker A' → 'Speaker D'	14	12	'Speaker C' → 'Speaker B'	3

Network Structure And Temporal Dynamics

Figure 1 illustrates interaction networks derived from SNA, where node proximity reflects interaction strength and edge thickness represents transition frequency. To examine temporal changes in participation patterns, the interaction data were segmented into three consecutive phases of 100 speech occurrences, followed by an aggregated network representing all 300 transitions.

Figure 1. Temporal changes in interaction patterns among four participants based on SNA results.

During the first phase, interactions were relatively balanced, although Speakers A and C were already more strongly connected than other pairs. In the second phase, Speaker C became increasingly central in the network, while Speaker B engaged less frequently and moved farther from the core interaction structure. This pattern intensified in the third phase, with Speakers C and A forming even stronger ties. The aggregated network highlights Speaker C's dominant role in the discussion and Speaker B's consistently peripheral position.

Overall, these results demonstrate that SNA effectively captures participation patterns and reveals

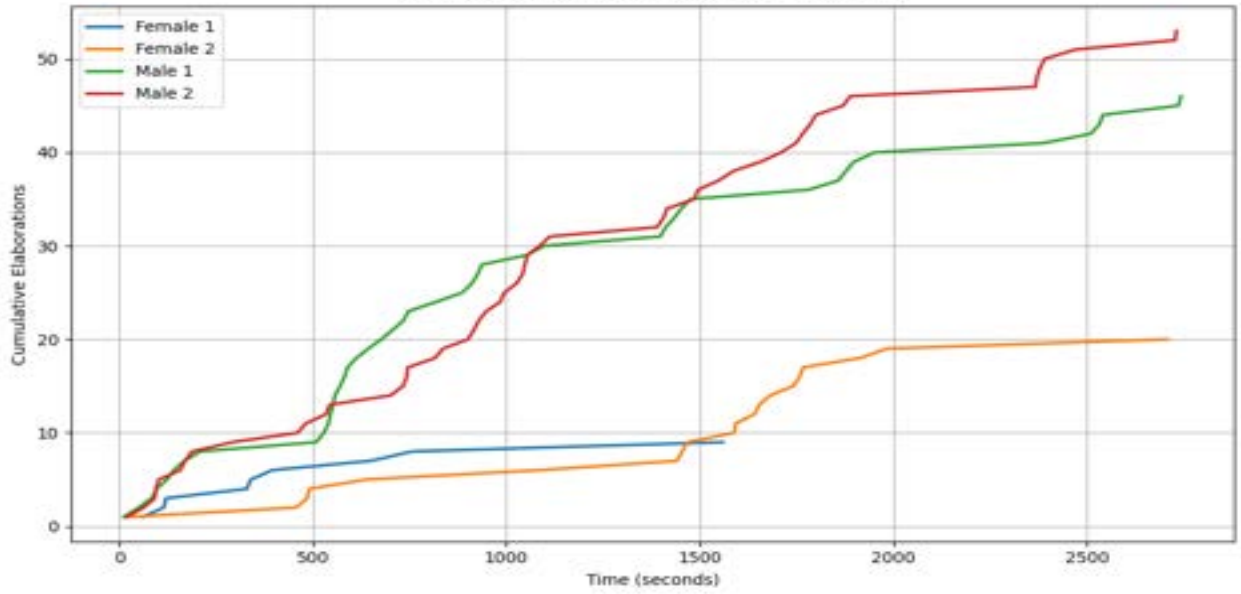
distinct student roles within science group work. By integrating transition frequency, speaking duration, and network structure over time, SNA enabled the identification of central and peripheral participants, providing clear evidence in support of RQ2.

RQ3. How Are Gender, Science Identity, And Personality Traits (Extroversion) Related To Students' Participation Patterns And Roles In Science Group Activities?

To further explore how individual characteristics relate to participation patterns and roles, each speech occurrence was manually coded into one of six functional categories. This analysis complemented the SNA results by examining not only how much students participated, but also how they contributed to the ongoing discussion.

Among the six categories, cumulative elaboration statements were first examined to trace how participants contributed to advancing the discussion over time. As shown in Figure 2, the two male students exhibited a crossing pattern in cumulative elaboration, indicating that they alternated in taking the lead during the conversation. In contrast, Speaker B (Female 1, low science identity, introverted) contributed to elaboration primarily during the early phase of the session but gradually withdrew from active participation around the midpoint. Speaker D (Female 2, average science identity, extroverted) showed a gradual increase in elaboration contributions over time; however, her participation followed a different trajectory from that of the male students and did not converge with the dominant interaction pattern.

Figure 2. Cumulative elaboration statements over time.



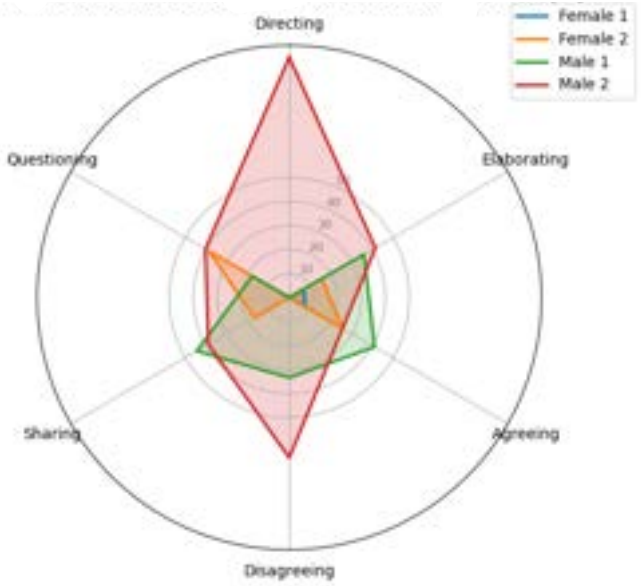


Figure 3 presents the proportion of speech functions attributed to each speaker. Speaker C (Male 2, average science identity, extroverted) dominated across multiple conversational functions, including directing, elaborating, and disagreeing, indicating a central and influential role in shaping the discussion. Speaker A (Male 1, high science identity, extroverted) contributed primarily through elaboration, suggesting a supportive but still central role. In contrast, Speaker B (Female 1, low science identity, introverted) accounted for a substantially smaller proportion of all speech categories, reflecting a marginalized participation role. Speaker D (Female 2, average science identity, extroverted) contributed across several categories but was less involved in directing or disagreeing, functioning primarily as an active follower within the group interaction.

Taken together, these findings suggest that participation patterns and roles in science group work are shaped by an interplay of gender, science identity, and personality traits. In this group, male students—regardless of differences in science identity—occupied more central and directive

roles, while female students displayed more varied participation trajectories that were sensitive to both science identity and extroversion. Although exploratory in nature, these results provide initial evidence that individual characteristics are meaningfully related to how students participate and position themselves within science group activities, addressing RQ3.

Figure 3. Proportion of each category attributed to speakers (%).

Discussion

Building on the results addressing RQ1, the ASR system demonstrated performance that exceeded commonly reported feasibility thresholds for classroom-based, multi-speaker environments (Wang et al., 2024; Attia et al., 2024). This high level of performance can be attributed not only to recent advances in ASR technology but also to the use of individual microphones with separate-channel recording, which substantially improved speaker separation and audio quality. Together, these results provide empirical evidence that ASR, when supported by individual microphone systems, can be successfully applied to investigate student interactions in authentic, co-located classroom activities involving more than 16 students.

In addition, whereas previous studies have primarily focused on online learning contexts (Saqr et al., 2018; 2020), the integration of SNA in the present study proved effective for identifying participation patterns and distinguishing central and peripheral roles within authentic, face-to-face science group work (RQ2). By modelling interaction structures over time, SNA made visible participation dynamics that are difficult to capture through traditional observational approaches alone. When combined with functional analyses of student talk, the results further revealed how participation roles are shaped by a complex interplay of gender, science identity, and personality traits such as extroversion (RQ3). These findings underscore the importance of considering individual characteristics when examining collaborative learning processes in science education.

While the present study is exploratory in nature and based on a limited number of groups, it demonstrates the methodological promise of combining ASR and SNA for scalable and fine-grained analyses of classroom interaction. Accordingly, future work should further validate the use of ASR and SNA in educational research and deepen understanding of equitable participation and inclusion in science classrooms with larger student populations.

Unpacking Science Teachers' Discursive Practices In Instructional Modelling.

Alba Cortés Morales and Ainoa Marzabal
Pontificia Universidad Católica de Chile, Chile

This study explores the discursive practices of science teachers in modelling-oriented teaching contexts, particularly emphasising dialogic classroom decision-making and its impact on students' learning opportunities. Teachers' speech turns are analysed when implementing a task with modelling potential to visualise these discursive processes. This is achieved through a discourse analysis of the productive conversation, including the breakdown of the dialogue into modelling phases (familiarisation, discussion, and consensus) and the classification of interaction types such as validation, information, clarification, challenge, and consolidation. The unpacking of these modelling-oriented talk moves highlights how teachers perceive and respond to student responses and how their discourse can facilitate or hinder the modelling process. The results suggest that the talk moves teachers use to enable the development of a productive conversation in which students' cognitive engagement in modelling processes is promoted.

Keywords: Instructional Modelling, Talk Moves, Teachers' Discursive Practices

Theoretical Framework

In accordance with the needs of the learning process in science education is critical for teachers to promote interactive talk in the classroom, as questioning students increases students' motivation to learn, supports productive classroom discussion, and fosters knowledge construction (Tiffany et al., 2023; Tytler & Aranda, 2015). Questioning is a process of collaborative learning that requires active, reciprocal participation that promotes a tension between students' need to express their ideas and teachers' need to mediate their reasoning in terms of scientific knowledge (Hamnell-Pamment, 2023). In modelling-based instruction, this tension is palpable in the mediation process teachers enact to facilitate students' mental model-building. As a teaching approach, modelling instruction requires teachers to promote an instructional task sequence that allows students to engage in modelling practices (Garrido & Couso, 2024). This performance is associated with a student-centred discourse, where teachers encourage students to express their ideas and promote divergence and convergence to help them gradually revise and refine their initial models.

Promoting the performance of modelling practices through dialogic teaching involves spaces to listen to other ideas, reasoning with others, and negotiating new ideas (Vergara et al., 2025b). So far, the study of the dialogic opportunities given in science instruction has been focused in the count of instances in which discursive strategies are used (Christodoulou & Osborne, 2014), the comparison of the distribution of linguistic movements in the dialogue (Balyan et al., 2022), the presentation of dialogue in a particular episode (Cui & Teo, 2023), the time spent on the stages of a task (Newman, 2017), flow diagrams (Larusso et al., 2023), and the use of discursive categories over time (Tytler & Aranda, 2015). In science modelling processes, visualisations have focused on the flow of the chain of discursive strategies (Vergara-Sandoval et al., 2025a) and graphs of discourse variation in different episodes (Garrido Espeja, 2016). However, to understand how teachers promote modelling practices, a deeper analysis of their dialogical decisions is required.

Exploring productive conversations between teachers and students through conversation analysis can shed light on teachers' discursive strategies to facilitate model construction (Hamnell-

Pamment, 2023). While embedded within the intricate, in-the-moment decision-making processes of teaching, these strategies can be identified and visualised. To achieve this, it is essential to analyse teachers' talk moves in terms of their specific purposes. This approach also highlights the importance of examining the balance between allowing students to articulate their reasoning and the teacher's role in guiding instructional modelling (Hamnell-Pamment, 2023).

Analysing teacher discourse in dialogical science classrooms can reveal patterns and strategies that contribute to refining students' ideas as they develop a school scientific model (SSM). However, the learning opportunities available depend significantly on how tasks are implemented (Krist et al., 2023). Given that task implementation can often diminish a task's modelling potential, it becomes crucial to integrate an analysis of teachers' discursive practices that foster students' intellectual engagement (Tekkumru-Kisa et al., 2023). Although efforts have been made to enhance students' epistemic agency (Krist et al., 2023), the role of teachers' discursive decisions in shaping discussions within the specific context of task implementation has not been extensively explored.

Therefore, it is important to identify how talk moves within a modelling process mediates students' learning (Tytler & Aranda, 2015), particularly when considering how these moves are shaped by teachers' noticing, interpretation, and responses during task implementation and student interactions. This research aims to examine visualisations of classroom interactions between teachers and students by analysing modelling-oriented talk moves and their patterns, with a focus on decisions that support students' modelling processes. By characterising these talk moves, the study seeks to illustrate the learning opportunities created by science teachers through their modelling-oriented discourse.

Research Question

In characterising classroom interactions between teachers and their students in which dialogic decision-making affects learning opportunities in a task with modelling potential, we seek to respond to the following research question:

> RQ: What discursive decisions do science teachers make to facilitate modelling processes in their students?

Methods & Context

To achieve the study's objective, a qualitative research approach with discourse analysis was employed. The study involved 3 Chilean chemistry teachers, Chris, Marina, and Caroline, who constitute the participants of this research. The data collection included the audiovisual recording of one lesson for each secondary education teacher.

Context Of The Study

The teachers in this study are part of a learning community in model-based teaching. The learning community lasted a year and a half, during which they revised their ideas about models and modelling, discussed their experiences, and received feedback on the tasks with modelling potential that they enacted in their classrooms. In this context, in the last months of the learning community, the teachers co-designed a modelling-oriented teaching and learning sequence (TLS) that follows the criteria for a modelling-oriented task proposed by Cortés-Morales & Marzabal (2025a) and the design principles for a modelling-oriented TLS proposed by Tena & Couso (2023).

To recognise teachers' discursive practices and establish possible talk move patterns in the modelling conversations, the implementation of task 5 was selected for its characterisation: "Represent and describe the final state of the reaction". This task is part of an experiment that

compares the reaction between copper sulphate and iron shavings in a TLS about ponderal laws.

By presenting a scientific phenomenological context associated with low cognitive demand in an open-ended question, it can be established that the tasks have low modelling potential (Cortés-Morales & Marzabal, 2025a). This low potential is related to a selected context that is distant from the students' experiences and knowledge, so an extensive familiarisation process may be required to enable students to relate what they know about the phenomenon.

Strategies For Data Collection And Analysis

The video recordings were made following the analytical strategy proposed by Lehesvuori et al. (2018) to analyse teaching processes. This meant using a camera positioned at the back of the classroom to record the teacher's interactions with the whole group and a mobile camera to record the teacher's interactions with the small groups. This meant that a camera and microphone followed the teacher to record the conversations.

A coding scheme was developed to examine the talk moves used by science teachers to support their students' modelling; the analysis required arranging the codes to visualize the discourse. Previous work on modelling conversations made by Tytler & Aranda (2015) and Vergara-Sandoval et al. (2025a) led the researchers to make adaptations in their proposals in order to consider how the nature of the talk move could change the purpose of the discourse action taken by the teachers. Consequently, this tool for characterising conversations considers the purpose of the talk move and its nature depending on how the move is framed. In this sense, a distinction was made between the cognitive demand imposed by the teacher and whether that demand entails a process of requesting or providing ideas for constructing an SSM (Table 1).

The dialogue between teacher and students during a task with modelling potential was coded according to the following aspects of discourse:

a) Communicative act. The identification of turns of speech, differentiating between student and teacher turns, and communicative intentions to differentiate one turn among several together (Hennessy et al., 2016)

b) Typology: The distinction between productive conversation and general classroom conversation (Soysal, 2019)

c) Organisation: The organisational difference between students in conversation, i.e., interaction with the teacher in a small or large group (Alexander, 2018).

d) Identification of the phase of the modelling cycle that teachers promote with their discourse: familiarisation, discussion, and consensus (Garrido & Couso, 2024).

e) Characterisation of the type of interactions in Table 1 (next page).

This qualitative research proposes analysing data to visualise the discourse led by teachers through their turns of speech (Category A), which are framed by the organisation of the students with whom they interact (Category C) in a phase of the modelling cycle (Category D). These turns are differentiated by the type of conversation (Category B) and the type of interaction the teacher promotes (Category E).

For this, in the first instance, how teachers interact with their students during the same task was characterised and presented in the visualisations by their location on the axis. In a second instance, the purpose of the interactions was characterised by the sub-code indicated in the turn-of-speech box (P: Provide; R: Request). The discourse display is a chronological map of the teacher's talk moves as they implement a common task.

Table 1. Talk moves for modelling conversation (Cortés-Morales et al., 2026).

Talk move	Teacher request…	Teacher provides…
Acknowledge		A word or phrase to signify the value of the student's contribution, to validate or acknowledge a point of view, or time for students to think about what they have expressed. *i.e., ok, very good, right*
Inform	Information to get a first appreciation of the students' ideas *i.e., How are we doing? What happened? What were you able to observe?*	
Clarify	Students to expand on their ideas with a more robust response or to explain what they meant. *i.e., You say it's an oxidation, what was oxidized? And that, to what equate? Ok, we would see particles, particles of what?*	A thought-provoking idea by providing information or an analogy for the revision of an idea about the phenomenon. *i.e., But if it were to dye it blue and we don't see it blue, then maybe the change doesn't go hand in hand with dying it*
